1.9.5 Configuring to Send Broadcast RIPv2 Packets on an Interface

1. Overview

This function can be configured if the neighbor device does not support receiving of multicast RIPv2 packets.

2. Restrictions and Guidelines

- The default behavior depends on the configuration of the **version-num** command.
- The configuration result of this command can overwrite the default configuration of the **version-num** command.
- This command affects the behavior of sending RIP packets on the current interface, and the interface is allowed to send RIPv1 and RIPv2 packets simultaneously.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure to send broadcast RIPv2 packets on an interface.

ip rip version2-broadcast

By default, RIPv2 packets are multicast on an interface.

1.9.6 Configuring to Allow an Interface to Receive RIP Packets

1. Overview

If you want to prevent an interface from receiving RIP packets, you can enable this function.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the VXLAN routed interface configuration mode.

  interface overlayrouter *interface-number*

(4) Configure to allow an interface to receive RIP packets.

ip rip packet-receive enable

By default, an interface can receive RIP packets normally.

1.9.7 Configuring to Allow an Interface to Send RIP Packets

1. Overview

If you want to prevent an interface from sending RIP packets, you can disable this function.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the VXLAN routed interface configuration mode.

  interface overlayrouter *interface-number*

(4) Configure to allow an interface to send RIP packets.

ip rip packet-send enable

By default, the RIP packet sending function is enabled on an interface.

1.9.8 Configuring to Allow an Interface to Send RIP Packets of a Specified Version

1. Overview

To be compatible with the RIP version running on the peer device, use this function to change the version of RIP packets sent by the interface.

2. Restrictions and Guidelines

- The default behavior depends on the configuration of the **version-num** command.
- The configuration result of this command can overwrite the default configuration of the **version-num** command.
- This command affects the behavior of sending RIP packets on the current interface, and the interface is allowed

to send RIPv1 and RIPv2 packets simultaneously. If this command does not contain any parameter, the behavior of receiving RIP packets depends on the configuration of the **version-num** command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the VXLAN routed interface configuration mode.

  interface overlayrouter *interface-number*

(4) Configure to allow an interface to send RIP packets of a specified version.

ip rip packet-send version-num [**1** | **2**] *

By default, the default behavior depends on the configuration of the **version-num** command.

1.9.9 Configuring to Allow an Interface to Receive RIP Packets of a Specified Version

1. Overview

To be compatible with the RIP version running on the peer device, use this function to change the version of RIP packets that can be received by the interface.

2. Restrictions and Guidelines

- The default behavior depends on the configuration of the **version-num** command.

- The configuration result of this command can overwrite the default configuration of the **version-num** command.
- This command affects the behavior of receiving RIP packets on the current interface, and the interface is allowed to receive RIPv1 and RIPv2 packets simultaneously. If this command does not contain any parameter, the behavior of receiving RIP packets depends on the configuration of the **version-num** command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the VXLAN routed interface configuration mode.

  interface overlayrouter *interface-number*

(4) Configure to allow an interface to receive RIP packets of a specified version.

ip rip packet-receive version-num [**1**] [**2**]

By default, the default behavior depends on the configuration of the **version-num** command.

1.10 Configuring to Enable RIPv2 Authentication

1.10.1 Overview

This function prevents learning unauthenticated and invalid routes and advertising valid routes to unauthenticated devices, ensuring stability of the routing system, and protecting the system against intrusions.

1.10.2 Restrictions and Guidelines

- The basic functions of RIP must be configured.
- Only RIPv2 supports authentication of RIP packets, and RIPv1 does not.

1.10.3 Configuration Tasks

The configuration for enabling RIPv2 authentication includes the following tasks:

(1) Configuring RIP Authentication Mode

(2) Configuring a Key Chain for Authentication

(3) Configuring a Key Chain for RIP Plain Text Authentication

1.10.4 Configuring RIP Authentication Mode

1. Overview

RIPv2 supports plain text authentication and cipher text authentication, and ensures secure transmission of RIP packets.

2. Restrictions and Guidelines

- For all devices that need to directly exchange the RIP routing information, the RIP authentication mode of these devices must be the same.
- Cipher text authentication is recommended because the plain text password is saved in the configuration file and the security is low.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the VXLAN routed interface configuration mode.

  interface overlayrouter *interface-number*

(4) Enable the RIP authentication mode.

ip rip enable-auth mode { **text** | **md5** }

Plain text authentication mode is used by default.

1.10.5 Configuring a Key Chain for Authentication

1. Overview

A key chain can be used to change the key dynamically to improve the security.

2. Restrictions and Guidelines

- The specified key chain must be defined using the **key chain** command in global configuration mode in advance.
- If this command and the **ip rip enable-auth mode md5** command are configured, MD5 mode authentication is adopted. If the **ip rip enable-auth mode** command is not configured, authentication is performed according to the authentication mode specified by the configured **key chain**. MD5 authentication and SM3 authentication are supported at present.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the VXLAN routed interface configuration mode.

  interface overlayrouter *interface-number*

(4) Configure a key chain for authentication.

ip rip enable-auth keychain *name-of-keychain*

No key chain is set by default.

1.10.6 Configuring a Key Chain for RIP Plain Text Authentication

1. Overview

This function uses a string to implement plain text encryption and improve the security of RIP packet transmission.

2. Restrictions and Guidelines

- This function takes effect only in plain text authentication mode.
- Encrypted strings can be displayed in plain text or cipher text. Cipher text is recommended.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the VXLAN routed interface configuration mode.

  interface overlayrouter *interface-number*

(4) Enable RIP plain text authentication and configure a key chain.

ip rip enable-auth text-password [**0** | **7**] *password-string*

No character string of plain text authentication is set by default.

1.11 Configuring BFD Correlation with RIP

1.11.1 Overview

Once a link fails, RIP can quickly detect the failure of the route. This function helps shorten the traffic interruption time.

1.11.2 Restrictions and Guidelines

- The basic functions of RIP must be configured.
- The BFD correlation configured in interface configuration mode takes precedence over the global configuration.

1.11.3 Configuration Tasks

The configuration for enabling BFD correlation with RIP includes the following tasks:

- Configuring BFD Correlation with RIP Globally
- Configuring BFD Correlation with RIP on an Interface

1.11.4 Configuring BFD Correlation with RIP Globally

1. Overview

This function enables BFD correlation with RIP globally. Once a link fails, RIP can quickly detect the failure of the route, which helps shorten the traffic interruption time.

After BFD is enabled on RIP, a BFD session will be set up for the RIP routing information source (that is, the source address of RIP route update packets). Once the BFD neighbor fails, the corresponding RIP route directly enters the invalid state and is not forwarded.

2. Restrictions and Guidelines

The BFD configured on an interface takes precedence over that configured in process configuration mode.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the RIP routing configuration mode.

router-protocol rip

(4) (Optional) Enter the IPv4 VRF address family configuration mode.

address-family-mode ipv4 vrf *vrf-name*

(5) Configure to enable BFD correlation with RIP globally.

bfd whole-interfaces

The BFD function is disabled by default.

1.11.5 Configuring BFD Correlation with RIP on an Interface

1. Overview

This function enables BFD correlation with RIP on an interface. Once an interface link fails, RIP can quickly detect the failure of the route, which helps shorten the traffic interruption time.

2. Restrictions and Guidelines

- By default, the BFD configuration is subject to that configured in RIP process configuration mode.
- This configuration must be performed if you need to enable or disable BFD correlation on a specified interface.
- The BFD configured on an interface takes precedence over that configured in RIP process configuration mode.
- According to the actual environment, you can select to enable BFD on the specified interface, or enable BFD globally in RIP process, or disable BFD on the specified interface.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the VXLAN routed interface configuration mode.

  interface overlayrouter *interface-number*

(4) Configure BFD correlation with RIP on an interface.

ip rip bfd [**disable**]

By default, BFD link detection on an interface is disabled by default.

1.12 Configuring to Enable RIP Fast Reroute

1.12.1 Overview

Once RIP detects a route failure, the router immediately switches to the second-best route. This configuration helps shorten the traffic interruption time.

1.12.2 Restrictions and Guidelines

- The basic functions of RIP must be configured.
- The route map and the backup next hop must be configured.
- To accelerate convergence, set **carrier-delay** of the interface to **0** and enable BFD correlation with RIP.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a routing policy.

route-map *route-map-name* [{ **permit** | **deny** } *sequence*]

(4) Run this command to configure the interface-based matching rule.

filter interface { *interface-type interface-number* }&<1-n>

No interface-based matching rule is configured by default.

(5) Return to the global configuration mode.

exit

(6) Enter the RIP routing configuration mode.

router-protocol rip

(7) (Optional) Enter the IPv4 VRF address family configuration mode.

address-family-mode ipv4 vrf *vrf-name*

(8) Enable fast reroute.

frr route-map *route-map-name*

The fast reroute function is disabled by default.

1.13 Enabling GR

1.13.1 Overview

The GR period is the maximum time from restart of the RIP process to completion of the restart. During this period, RIP performs route recovery and the forwarding table remains unchanged. After the restart period expires, RIP exits the GR state and performs common RIP operations.

1.13.2 Restrictions and Guidelines

- The basic functions of RIP must be configured.
- The GR period is at least twice the RIP route update period.

1.13.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the RIP routing configuration mode.

router-protocol rip

(4) (Optional) Enter the IPv4 VRF address family configuration mode.

address-family-mode ipv4 vrf *vrf-name*

(5) Enable GR.

gr [**grace-period** *grace-period*]

The GR function is enabled by default.

1.14 Configuring to Enable RIP Supernetting Routes

1.14.1 Overview

This function is used to allow RIP to send RIP supernetting routes on a specified interface. The concept of supernetting is similar to that of subnet. Subnet means dividing a large network segment into several small network segments, while supernetting means aggregating some small network segments into a large network segment. The number of network address bits allowed by supernetting is larger than that allowed by a classful network.

1.14.2 Restrictions and Guidelines

The basic functions of RIP must be configured.

1.14.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the VXLAN routed interface configuration mode.

  interface overlayrouter *interface-number*

(4) Enable supernetting routes.

ip rip packet-send supernet-routes

By default, the supernetting route sending function is enabled on an interface.

1.15 Configuring MIB Binding

1.15.1 Overview

Since RIP MIB does not have RIP instances, you can only operate on the unique instance when operating RIP instances through SNMP. With this function, you can bind the MIB to the RIP instance of the specified VRF, and operate the RIP instance of the specified VRF through the SNMP protocol.

1.15.2 Restrictions and Guidelines

The RIP basic functions (with VRF parameters) must be configured.

1. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the RIP routing configuration mode.

router-protocol rip

(4) (Optional) Enter the IPv4 VRF address family configuration mode.

address-family-mode ipv4 vrf *vrf-name*

(5) Configure binding the MIB of RIP to the specified VRF instance.

enable mib-binding

By default, the MIB is bound to the RIP instance of the default VRF.

1.16 Configuring a Super VLAN to Enable RIP

Note

This function is not supported by the S6980-64QC, S6580-48CQ8QC, or S6580-24DC8QC.

1.16.1 Overview

This function is used to run RIP on a super VLAN. A super VLAN is also called VLAN aggregation. Multiple sub VLANs are associated with one super VLAN. All sub VLANs share the SVI interface of the super VLAN and use it as the gateway of Layer-3 communication to save IP resources.

In normal cases, a super VLAN contains multiple sub VLANs. Multicast packets of a super VLAN are also sent to its sub VLANs. In this case, when RIP multicast packets are sent over a super VLAN containing multiple sub VLANs, the RIP multicast packets are replicated multiple times, and the device processing capability is insufficient. As a result, a large number of packets are discarded, causing protocol flapping.

In most scenarios, the RIP function does not need to be enabled on a super VLAN, and it is disabled by default. However, in some scenarios, the RIP function must be run on the super VLAN, but packets need to be sent to only one sub VLAN. In this case, you can decide to send multicast packets to a certain sub VLAN or to all sub VLANs as actually needed. You can run this command to specify a particular sub VLAN. You must be cautious when configuring packet transmission to all sub VLANs, as the large number of sub VLANs may cause a device processing bottleneck, which will lead to the neighbor flapping.

1.16.2 Restrictions and Guidelines

- The basic functions of RIP must be configured.
- The designated sub VLAN must be connected to neighbors.

1.16.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the SVI interface configuration mode.

interface vlan *interface-number*

(4) Enable RIP on a Super VLAN.

ip rip subvlan { **all |** *vlan-id* }

By default, RIP is disabled on a super VLAN.

1.17 Enabling Source Address Verification

1.17.1 Overview

You can run the command to validate the source address of a RIP route update packet. The purpose is to ensure that the RIP routing process receives only the route update packets coming from the same IP subnet neighbor.

1.17.2 Restrictions and Guidelines

- The basic functions of RIP must be configured.
- After split horizon is disabled on an interface, the RIP routing process will perform source address validation on the update packet no matter whether the **verify-update-source** command is executed in routing process configuration mode.
- For an interface not configured with an IP address, the RIP routing process does not perform source address validation for the update packet no matter whether the **verify-update-source** command is executed in routing process configuration mode.

1.17.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the RIP routing configuration mode.

router-protocol rip

(4) (Optional) Enter the IPv4 VRF address family configuration mode.

address-family-mode ipv4 vrf *vrf-name*

(5) Enables source address verification.

verify-update-source

The source address validation function for update packets is enabled by default.

1.18 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

⚠ Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

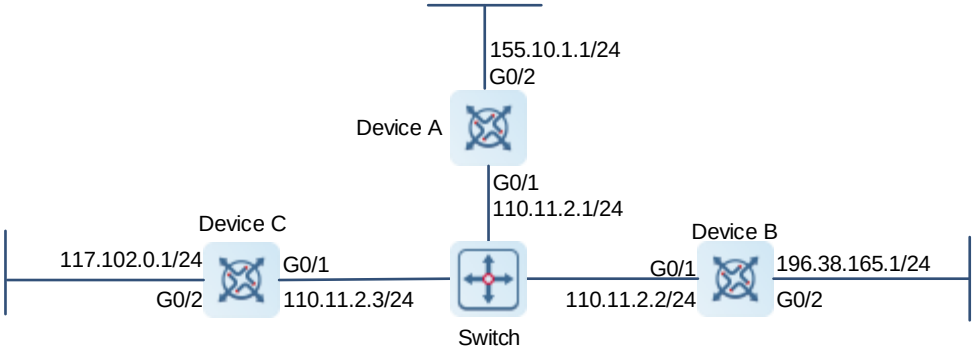
Table 1-2 RIP Monitoring

Command	Purpose
display ip rip-instance	Displays the basic information about a RIP process.
display ip rip-instance database [**count** | *network-number network-mask* | **vrf-instance** *vrf-name* [*network-number network-mask*]]	Displays the RIP routing table.
display ip rip-instance external-type [**bgp** | **connected** | **isis-instance** [*process-id*] | **ospf-instance** *process-id* | **static**] [**vrf-instance** *vrf-name*]	Displays information about external routes redistributed by RIP.
display ip rip-instance interface [**vrf** *vrf-name*] [*interface-type interface-number*]	Displays the RIP interface information.

Command	Purpose
display ip rip-instance peer [*ipv4-address*] [**vrf** *vrf-name*]	Displays the RIP neighbor information.
debugging ip rip event	Debugs events that occur when the RIP process is running.
debugging ip rip frr	Debugs RIP fast reroute.
debugging ip rip nsm	Debugs interaction with the NSM process.
debugging ip rip packet [**recv** | **packet-send**] [**interface** *interface-type interface-number*] [**deeply**]	Debugs the sent and received packets.
debugging ip rip restart	Debugs the RIP GR process.
debugging ip rip route	Debugs the route changes of the RIP process.

1.19 Configuration Examples

1.19.1 Building a RIP Routing Domain



1. Requirements

Device A, Device B, and Device C implement interworking through the RIPv2 routing protocol.

To save the device performance, all interfaces of the three devices are configured as passive interfaces by default, and passive interface is disabled only for the interfaces directly connected to RIP neighbors.

2. Topology

Figure 1-9 Configuring a RIP Routing Domain

3. Notes

- Configure interface IP addresses for all the devices.
- Configure the RIP basic functions for all the devices.

4. Procedure

(1) Configure an IP address for each interface and start the unicast routing protocol.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ip address 110.11.2.1 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/2)# ip address 155.10.1.1 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/2)# exit
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/1)# ip address 110.11.2.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface gigabitethernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/2)# ip address 196.38.165.1 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/2)# exit
```

Configure Device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/1)# ip address 110.11.2.3 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/1)# exit
Device C(cfg)# interface gigabitethernet 0/2
Device C(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/2)# ip address 117.102.0.1 255.255.0.0
Device C(cfg-if-GigabitEthernet 0/2)# exit
```

(2) Configure the RIP basic functions for the devices. Except the RIP neighbor interface, configure the other interfaces as passive interfaces.

Configure Device A.

```
Device A(cfg)# router-protocol rip
Device A(cfg-router)# version 2
Device A(cfg-router)# network-advertise 0.0.0.0 255.255.255.255
Device A(cfg-router)# disable-interface reset
Device A(cfg-router)# unset disable-interface gigabitethernet 0/1
```

Configure Device B.

```
Device B(cfg)# router-protocol rip
Device B(cfg-router)# version 2
Device B(cfg-router)# network-advertise 0.0.0.0 255.255.255.255
Device B(cfg-router)# disable-interface reset
Device B(cfg-router)# unset disable-interface gigabitethernet 0/1
```

Configure Device C.

```
Device C(cfg)# router-protocol rip
Device C(cfg-router)# version 2
Device C(cfg-router)# unset auto-aggregation
Device C(cfg-router)# network-advertise 0.0.0.0 255.255.255.255
Device C(cfg-router)# disable-interface reset
Device C(cfg-router)# unset disable-interface gigabitethernet 0/1
```

5. Verification

Check the IP routing tables on Device A, Device B, and Device C. Verify that RIP has learned the routes to remote networks.

- Device A

```
Device A# display ip route-config

Codes:   C - connected, S - static, R - RIP, B - BGP
         O - OSPF, IA - OSPF inter area
         N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
         E1 - OSPF external type 1, E2 - OSPF external type 2
         i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
         ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
C       110.11.2.0/24 is directly connected, GigabitEthernet 0/1
C       110.11.2.1/32 is local host.
R       117.0.0.0/8 [120/1] via 110.11.2.2, 00:00:47, GigabitEthernet 0/1
C       155.10.1.0/24 is directly connected, GigabitEthernet 0/2
```

```
C       155.10.1.1/32 is local host.

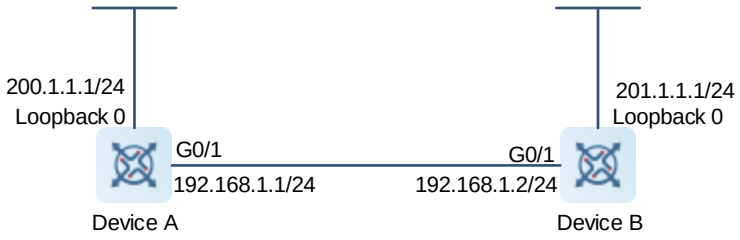
7. Common Errors

- The IPv4 address is not configured on an interface.
- The RIP version is not defined on a device, or the RIP version No. on the device is different from that on other devices.
- The address range configured using the **network-advertise** command does not cover a specific interface.
- The IP address comparison bit parameter in the **network-advertise** command is not correctly configured. Value 0 indicates accurate matching, and 1 indicates that no comparison is performed.
- The interface used for interworking between devices is configured as a passive interface.

1.19.2 Configuring RIP to Prevent Route Loop

1. Requirements



Device A, Device B, and Device C implement interworking through the RIP routing protocol.

To avoid route loop, you need to configure split horizon with poison reverse and triggered updates.

To improve reliability, enable GR, and then enable BFD on the connection interface of Device A and Device B.

2. Topology

Figure 1-10 Configuring RIP to Prevent Route Loop

3. Notes

(1) Configure interface IP addresses for all devices (omitted).

(2) Configure the RIP basic functions for all the devices.

(3) Enable RIP triggered updates and poison reverse on Device A and Device B.

4. Procedure

(1) Configure interface IP addresses for all devices (omitted).

(2) Enable the RIP process of the device and advertise the network information of each interface.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# router-protocol rip
Device A(cfg-router)# network-advertise 192.168.1.0
Device A(cfg-router)# network-advertise 200.1.1.0
Device A(cfg-router)# exit
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# router-protocol rip
Device B(cfg-router)# network-advertise 192.168.1.0
Device B(cfg-router)# network-advertise 201.1.1.0
Device B(cfg-router)# exit
```

(3) Enable RIP poison reverse and triggered updates.

Configure Device A.

```
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ip rip triggered-ext
Device A(cfg-if-GigabitEthernet 0/1)# ip rip horizon-split-enable poisoned-reverse
```

Configure Device B.

```
Device B(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/1)# ip rip triggered-ext
Device B(cfg-if-GigabitEthernet 0/1)# ip rip horizon-split-enable poisoned-reverse
```

5. Verification

Check the RIP databases of Device A and Device B, and verify that the corresponding route attributes are permanent.

- Device A

```
Device A# display ip rip-instance database
201.1.1.0/24      auto-aggregation
201.1.1.0/24
[1] via 192.168.12.2 GigabitEthernet 0/1    06:25       permanent
```

- Device B

```
Device B# display ip rip-instance database
200.1.1.0/24      auto-aggregation
200.1.1.0/24
      [1] via 192.168.12.1 GigabitEthernet 0/1    06:25       permanent
```

6. Configuration Files

- Device A configuration file

```
!
interface gigabitethernet 0/1
ip rip horizon-split-enable poisoned-reverse
  ip rip triggered-ext
!
!
router-protocol rip
network-advertise 192.168.1.0
network-advertise 200.1.1.0
!
```

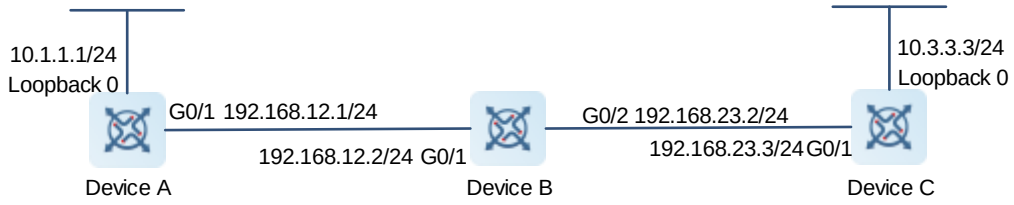
- Device B configuration file

```
!
interface gigabitethernet 0/1
ip rip horizon-split-enable poisoned-reverse
  ip rip triggered-ext
!
router-protocol rip
network-advertise 192.168.1.0
network-advertise 201.1.1.0
!
```

7. Common Errors

- The triggered updates function is enabled when the RIP configurations at both ends of the link are consistent.
- Both the triggered updates and BFD functions are enabled.
- The triggered updates function is not enabled on all devices on the same link.

1.19.3 Configuring External Routes Imported by RIP



1. Requirements

Device B communicates with Device A through RIP, and Device B obtains the route 10.3.3.3 through a static route.

To enable Device A to obtain the routing information of 10.3.3.3, enable the OSPF routing protocol in Device B. The reliability of introducing external routes is low. Set the external default metric to 5.

2. Topology

Figure 1-11 Configuring External Routes Imported by RIP

3. Notes

(1) Configure an IP address for each interface and start the unicast routing protocol (omitted).

(2) Configure a static route for Device B.

(3) Configure the basic functions of RIP on Device A and Device B (omitted).

(4) Configure route redistribution on Device B and set the default metric of the redistributed route.

4. Procedure

(1) Configure an IP address for each interface and start the unicast routing protocol (omitted).

(2) Configure a static route to 10.3.3.3/24 on Device B, and set the next hop to 192.168.23.3.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# ip route-config 10.3.3.3 255.255.255.0 192.168.23.3
```

(3) Configure the basic functions of RIP on Device A and Device B (omitted).

(4) Set the default metric of the redistributed route to 5 on Device B.

```
Device B(cfg)# router-protocol rip
Device B(cfg-router)# default-metric 5
```

(5) Configure the redistribution of static route to RIP on Device B.

```
Device B(cfg-router)# redistribute-route static
```

5. Verification

Check the routing table on Device A. Verify that the RIP route of 10.3.3.0/24 is available, and the metric is 6.

```
Device A# display ip route-config rip
R       10.3.3.0/24 [120/6] via 192.168.12.2, 00:06:11, GigabitEthernet 0/1
```

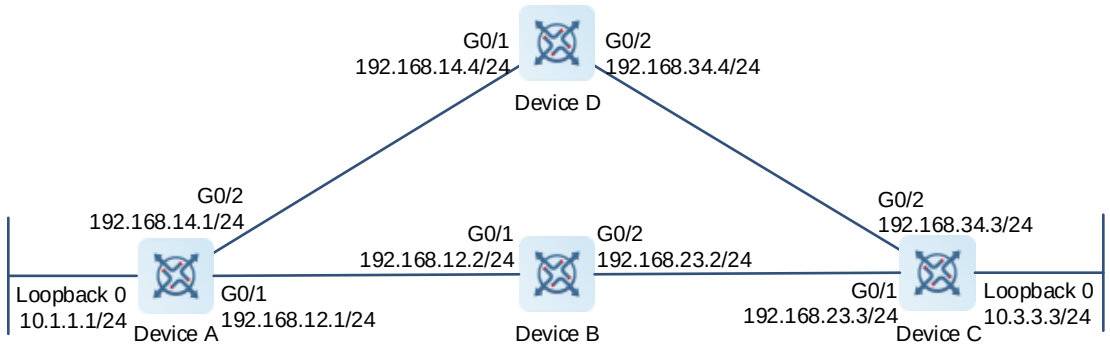
6. Configuration Files

Device B configuration file.

```
!
```

```
ip route-config 10.3.3.3 255.255.255.0 192.168.23.3
!
router-protocol rip
 default-metric 5
 redistribute-route static
!
```

1.19.4 Configuring Increasing the Metric of a RIP Interface



1. Requirements

Device A, Device B, Device C, and Device D implement interworking through the RIPv2 routing protocol.

There are two equal-cost paths from Device A to 10.3.3.3/24 of Device C. In consideration of the old model and low performance of Device D, increase the metric of the Gigabit Ethernet 0/2 interface of Device A so that Device A can go to 10.3.3.3 to prefer Device B.

2. Topology

Figure 1-12 Configuring Metric Increment of a RIP Interface

3. Notes

(1) Configure interface IP addresses for all the devices. (Omitted)

(2) Configure the RIP basic functions for all the devices. (Omitted)

(3) Configure ACL on Device C, and enable offset-list on the interface connected to Device B.

4. Procedure

(1) Configure ACL on Device C, and match the route 10.3.3.3/24.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# access-control-list 1 permit 10.3.3.3 0.0.0.255
```

(2) Configure Offset-List on Device C, associate with ACL 1, and enable the offset-list on the GigabitEthernet 0/2 interface.

```
Device C(cfg)# router-protocol rip
Device C(cfg-router)# metric-offset-list 1 out 3 gigabitEthernet 0/2
```

5. Verification

Check the routing table of Device A.

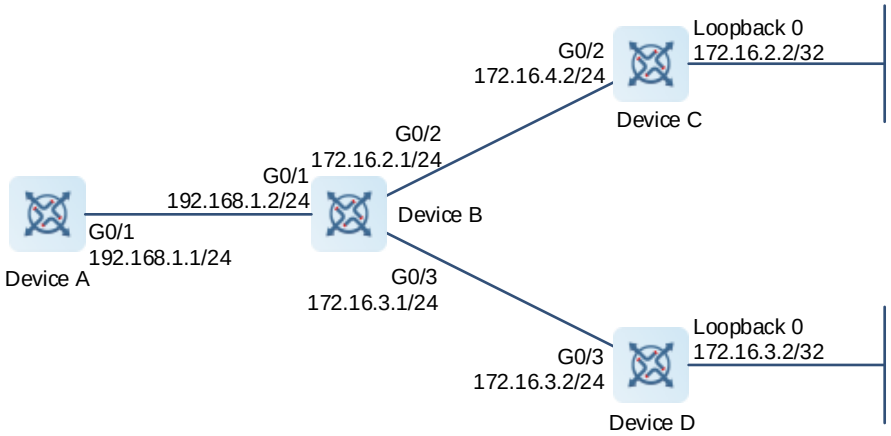
```
Device A# display ip route-config rip
R       10.3.3.0/24 [120/5] via 192.168.14.4, 00:06:11, GigabitEthernet 0/1
```

6. Configuration Files

Device C configuration file.

```
!
access-control-list 1 permit 10.3.3.3 0.0.0.255
!
router-protocol rip
 metric-offset-list 1 out 3 gigabitEthernet 0/2
!
```

1.19.5 Configuring RIP to Distribute a Summarized Route



1. Requirements

Device B, implements interworking with Device A, Device C, and Device D through the RIPv2 routing protocol.

To reduce the size of the routing table of Device A, configure route summarization to 172.16.0.0/21 on Device B.

2. Topology

Figure 1-13 Configuring RIP to Distribute a Summarized Route

3. Notes

(1) Configure interface IP addresses for all devices (omitted).

(2) Configure the RIP basic functions for all the devices (omitted).

(3) Disable automatic summarization on Device B and configure route summarization.

4. Procedure

(1) Configure an IP address for each interface and start the unicast routing protocol (omitted).

(2) Configure RIP basic functions on the devices (omitted).

(3) Disable automatic summarization on Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# router-protocol rip
Device B(cfg-router)# version 2
Device B(cfg-router)# unset auto-aggregation
Device B(cfg-router)# exit
```

(4) Configure 172.16.0.0/21 route summarization on the GigabitEthernet 0/1 interface of Device B.

```
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip rip summary-address 172.16.0.0 255.255.248.0
```

5. Verification

Check the routing table of Device A, and verify that the entry 172.16.0.0/16 is generated.

```
Device A# display ip route-config rip
R 172.16.0.0/21 [120/2] via 192.168.1.2, 00:01:04, gigabitethernet 0/1
```

6. Configuration Files

Device B configuration file.

```
!
interface gigabitethernet 0/1
ip address 196.38.165.1 255.255.255.0
!
router-protocol rip
 version 2
 unset auto-aggregation
!
```

1 Configuring RIPng

1.1 Introduction

1.1.1 Overview

RIP next generation (RIPng) is a unicast routing protocol that applies to IPv6 networks. RIPng-enabled routers exchange routing information to obtain routes to remote networks.

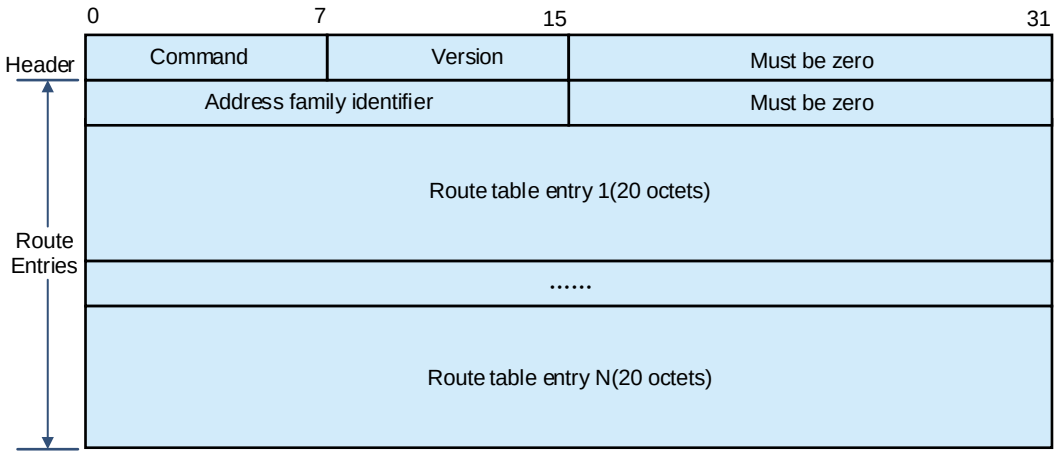
As an Interior Gateway Protocol (IGP), RIPng can run only within an autonomous system (AS) and is applicable to small-sized networks.

Note

In this chapter, the term “router” refers to any network device that supports the routing function. These network devices can be Layer-3 switches, routers, or firewalls.

1.1.2 Principles

1. Basic Concepts



- IGP and EGP

  IGP runs within an AS. For example, RIPng is a type of IGP.

  Exterior Gateway Protocol (EGP) runs between ASs. For example, BGP is a type of EGP.

- RIPng packet format

Figure 1-1 RIPng Packet Format

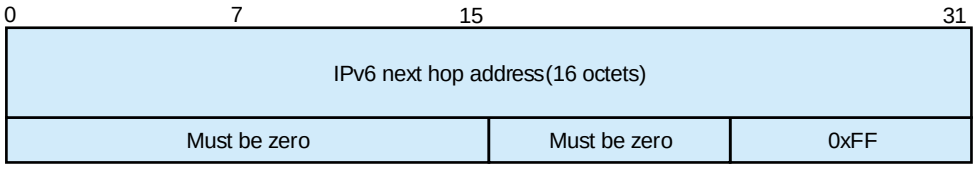
RIPng packets can contain one or more routing table entries. The number of routing table entries depends on the size of the maximum transmission unit (MTU) value of the interface. Route table entry (RTE) is classified into two types:

- Next hop RTE: Located in the foremost of a set of routing table entries with the same next hop, that is,

the position of Route table entry 1 shown in Figure 1-1.

- IPv6 prefix RTE: Located behind the next hop RTE. Multiple different IPv6 prefix RTEs can exist after a next hop RTE. An IPv6 prefix RTE describes the destination IP address, prefix length, route tag, and metric of an RIPng route.

Figure 1-2 Format of Next Hop RTE



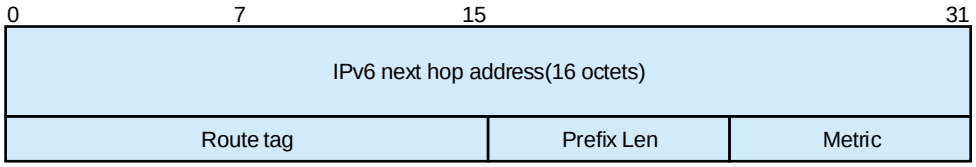


Figure 1-3 Format of IPv6 Prefix RTE

2. RIPng and RIP

RIP applies to IPv4 networks. Two RIP versions are available: RIPv1 and RIPv2.

RIPng is an extension of RIPv2 on the basis of IPv6. Both are similar in functions and configurations. The main differences are as follows:

- The UDP port ID of RIP is 520, and that of RIPng is 521.
- IPv6 features.
  - The RIPv2 multicast address is 224.0.0.9, and the RIPng multicast address is FF02::9.
  - The source address of RIPng route update packets is FE80::/10.

3. Route Control

Compared with static routing, the dynamic routing protocol shows an advantage, that is, by exchanging routing information, devices can automatically obtain routes to a remote network and update the routes in real time.

- Routing switching process

  After RIPng is enabled on a router, the router sends a request packet to its neighbor router, requesting all routing information, that is, the routing table. After receiving the request packet, the neighbor device returns a response packet containing the local routing table. After receiving the response packet, the router updates the local routing table, and sends an update packet to the neighbor router, informing the neighbor router of the route update information. After receiving the update packet, the neighbor router updates the local routing table, and sends the update packet to other adjacent routers. After receiving and processing an update advertisement, all the routers can obtain and retain the latest routing information.

- Periodical update

By default, periodical update is enabled for RIPng. Adjacent routers exchange complete routing information with each other every 30s, that is, the entire routing table is sent to neighbor routers.

Note

For every non-local route, if the route is not updated within 180s (Invalid timer), the metric of the route is changed to 16 (unreachable). If the route is still not updated in the next 120s (Flush timer), the route is deleted from the routing table.

The timer details are as follows:

- Update timer: Route update packets are sent regularly, and the update interval is 30s by default.
- Invalid timer: If an update packet for refreshing the existing route has not been received after 180s (default value), the metric for the route to set to 16, marking the route as invalid.
- Flush timer: By default, the flush timer is set to 240s, 60s greater than the invalid timer. When the flush timer times out, the route is deleted from the routing table.
- Hold-down timer: It prevents route loop caused by route flapping. When the device receives a route update with a cost of 16, the route will be set to hold-down state, and the hold-down timer will be started at the same time. Before the hold-down timer expires, even if an update packet with a metric less than 16 for this route is received, the route will not be updated.

- Default route

  In the routing table, a route to the destination network ::/0 is called default route.

  The default route can be learned from a neighbor device, or sent to a neighbor device.

- Route redistribution

  For RIPng, other types of routes (such as direct routes, static routes, and routes of other routing protocols) are called external routes.

  External routes (excluding the default route) can be redistributed to RIPng and advertised to neighbors.

- Route Filtering

  Filtering conditions can be configured to limit the routing information exchanged between adjacent routers. Only the routing information that meets filtering conditions can be sent or received.

4. Routing Algorithm

RIPng is a protocol based on the distance-vector algorithm. It uses the vector addition method to compute the routing information.

- Distance-vector algorithm

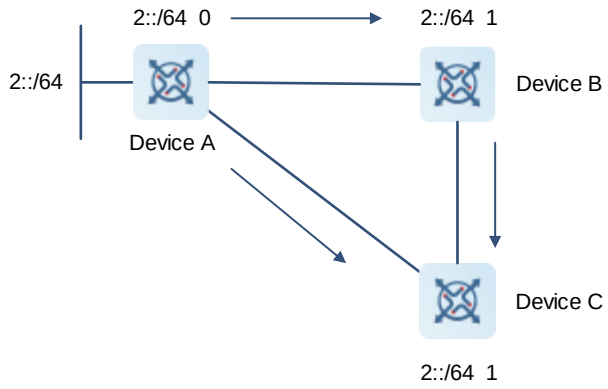
  RIPng is a protocol based on the distance-vector algorithm. The distance-vector algorithm treats a route as a vector that consists of the destination network and distance. The router obtains a route from its neighbor and adds the distance vector from itself to the neighbor to the route to form its own route.

  RIPng uses the hop count to evaluate the distance to the destination network. By default, the hop count from a router to its directly connected network is 0, the hop count from a router to a network that can be reached through a router is 1, and so on. That is, the metric is equal to the number of routers from the local network to the destination network. To restrict the convergence time, RIPng stipulates that the metric must

be an integer in the range from 0 to 15. If the metric is equal to or greater than 16, the destination network or host is unreachable. For this reason, RIPng cannot be applied on a large-scale network.

As shown in Figure 1-4, Device A is connected to the network 2::/64. Device B obtains the route (2::/64, 0) from Device A and adds the metric 1 to the route to obtain its own route (2::/64, 1), and the next hop points to Device A.

Figure 1-4 Diagram of Distance-vector Algorithm



- Selecting the optimum route

  RIPng selects an optimum route based on the following principle: If multiple routes to the same destination network are available, a router preferentially selects the route with the smallest metric.

  As shown in Figure 1-5, Device A is connected to the network 2::/64. Device C obtains the route (2::/64, 0) from Device A and the route (2::/64, 1) from Device B. Device C will select the route that is obtained from Device A and add metric 1 to this route to form its own route (2::/64, 1), and the next hop points to Device A.

Figure 1-5 Diagram of Selecting the Optimum Route

Note

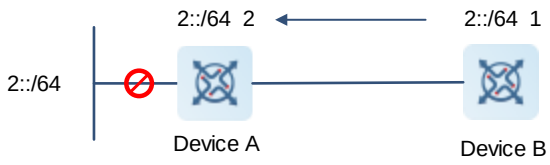
When routes coming from different sources exist on a router, the route with the smallest distance is preferentially selected.

Table 1-1 Distance-vector Table

Route Source	Default Distance
Directly-connected network	0
Static route	1

Route Source	Default Distance
OSPF route	110
IS-IS route	115
RIP route	120
Unreachable route	255

5. Avoiding Route Loops



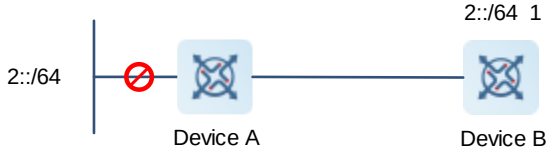
RIPng uses functions such as split horizon and poison reverse to avoid route loops.

- Route loop

  An RIPng route loop occurs due to inherent defects of the distance-vector algorithm.

  As shown in Figure 1-6, Device A is connected to the network 2::/ 64, and sends an update packet every 30s. Device B receives the route to 2::/64 from Device A every 30s. If Device A is disconnected from 2::/64, the route to 2::/64 will be deleted from the routing table on Device A. Next time, the update packet sent by Device A no longer contains this route. As Device B does not receive an update packet related to 2::/64, Device B determines that the route to 2::/64 is valid within 180s and uses the update packet to send this route to Device A. As the route to 2::/64 does not exist on Device A, the route learned from Device B is added to the routing table. Device B determines that data can reach 2::/64 through Device A, and Device A determines that data can reach 2::/64 through Device B. In this way, a route loop is formed.

Figure 1-6 Diagram of Route Loop

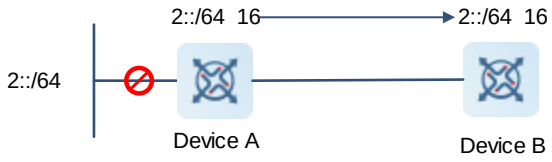


- Split horizon

  Split horizon can prevent route loops. After split horizon is enabled, a route received on this interface will not be sent out from this interface.

  As shown in Figure 1-7, after split horizon is enabled on Device B, Device B will not send the route to 2::/64 back to Device A. Device B will learn 180s later that 2::/64 is not reachable.

Figure 1-7 Diagram of Split Horizon



- Poison reverse

Poison reverse can also prevent route loops. Compared with slit horizon, poison reverse is more reliable, but brings more protocol packets, which makes network congestion more severe.

After poison reverse is enabled on an interface, a route received from this interface will be sent out from this interface again, but the metric of this router will be changed to 16 (unreachable).

As shown in Figure 1-8, after poison reverse is enabled on Device A, if Device A detects a disconnection from 2::/64, Device A will not delete the route to 2::/64. Instead, Device A changes the number of hops to **16**, and advertises the route through the update packet. Upon receiving the update packet, Device B learns that 2::/64 is not reachable.

Figure 1-8 Diagram of Poison Reverse

6. RIPng Authentication

IPv6 provides two authentication mechanisms, that is, authentication header (AH) and encapsulating security payload (ESP). RIPng use the authentication mechanisms to prevent routers that access the network illegally and hosts that forge RIPng packets from participating in RIPng routing switching. RIPng packets received on the RIPng interface are authenticated and decrypted. If authentication or decryption fails, the packets are dropped and do not participate in route learning.

Enabling authentication can avoid learning unauthenticated or invalid routes, thus preventing advertising valid routes to unauthenticated devices. At present, RIPng authentication is implemented by associating with the security association (SA) authentication of IPsec. SA defines a set of security algorithms and keys to ensure IP security. If a service is associated with IPsec SA authentication, the RIPng service will use an SA authentication key to authenticate and encrypt packets. For example, the definition of SM3 (OSCCA algorithm) authentication is added to SA authentication. For the RIPng service, only the SA authentication needs to be associated to encrypt/decrypt packets using SM3 authentication keys.

1.1.3 Protocols and Standards

- RFC 2080: RIPng for IPv6
- RFC 2081: RIPng Protocol Applicability Statement

1.2 Configuration Task Summary

The RIPng configuration includes the following tasks:

(1) Configuring RIPng Basic Functions

a Enabling an RIPng Routing Process

b Configuring RIPng on an Interface

c (Optional) Configuring Split Horizon or Poison Reverse

d (Optional) Configuring a Passive Interface

(2) (Optional) Configuring RIPng Route Distribution The following configuration tasks are optional. Select tasks for configuration according to actual condition.

- Generating a Default Route
- Configuring External Route Redistribution

(3) (Optional) Configuring RIPng Route Filtering Rules

(4) (Optional) Configuring to Adjust RIPng Routing The following configuration tasks are optional. Select tasks for configuration according to actual condition.

- Configuring to Modify the Management Distance of an RIPng Route
- Configuring to Modify the Metric Offset on an Interface
- Configuring the Default Metric of a Route Redistributed to RIPng Metric

(5) (Optional) Modifying Timers

(6) (Optional) Enabling GR

(7) (Optional) Configuring a Super VLAN to Enable RIPng

1.3 Configuring RIPng Basic Functions

1.3.1 Overview

This function can be used to build an RIPng routing domain on the network, and routers in the domain obtain routes to a remote network through RIPng.

1.3.2 Restrictions and Guidelines

- IPv6 addresses must be configured.
- IPv6 unicast routes must be enabled.

1.3.3 Configuration Tasks

The basic function configuration of RIPng includes the following tasks:

(1) Enabling an RIPng Routing Process

(2) Configuring RIPng on an Interface

(3) (Optional) Configuring Split Horizon or Poison Reverse

(4) (Optional) Configuring a Passive Interface

1.3.4 Enabling an RIPng Routing Process

1. Overview

This command is used to create an RIPng routing process and enter the routing configuration mode.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable an RIPng routing process and enter route configuration mode.

ipv6 router-protocol ripng

The RIPng routing process is disabled by default.

1.3.5 Configuring RIPng on an Interface

1. Overview

In RIPv2, the **network-type** command is configured in the routing configuration mode to define an IP address range. In RIPng, if the IP address of an interface belongs to this IP address range, RIPng automatically runs on this interface.

After RIPng runs on an interface, RIPng packets can be exchanged on the interface and RIPng can learn routes to the network segments directly connected to the device.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*
- Enter the virtual PPP interface configuration mode.
  - **interface virtual-ppp** *interface-number*
- Enter the virtual template interface configuration mode.
  - **interface virtual-template** *interface-number*

(4) Configure RIPng on an interface.

ipv6 rip enable

By default, an interface is not added to the RIPng process.

1.3.6 Configuring Split Horizon or Poison Reverse

1. Overview

Split horizon can prevent route loops. After split horizon is enabled, a route received on this interface will not be sent out from this interface.

After poison reverse is enabled on an interface, a route received from this interface will be sent out from this interface again, but the metric will be changed to **16** (unreachable).

2. Restrictions and Guidelines

- You are advised to enable split horizon on the interfaces of broadcast type network (such as Ethernet) and point-to-point type network (such as PPP and HDLC). (Retain the default setting.)
- It is recommended that split horizon and poison reverse be disabled on an interface to a non-broadcast multi-access network such as FR and X.25; otherwise, some devices cannot learn the complete routing information.
- If the secondary IP address is configured for an interface connected to a non-broadcast network, it is recommended that split horizon and poison reverse be disabled.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the routing configuration mode.

ipv6 router-protocol rip

(4) Configure split horizon.

horizon-split-enable [**poisoned-reverse**]

By default, split horizon is enabled and poison reverse is disabled on an interface.

1.3.7 Configuring a Passive Interface

1. Overview

A passive interface is set with the boundary of RIPng routing domain. The network segment of the passive interface belongs to the RIPng routing domain, but RIPng packets cannot be sent over the passive interface.

The interface set to a passive interface suppresses RIPng update packets. The passive interface defines the boundary of RIPng routing domain to avoid unwanted flooding of RIPng packets. If the interface connection device does not run the RIPng routing protocol (such as a PC and a device running other routing protocols), you are advised to configure this interface as a passive interface.

2. Restrictions and Guidelines

If RIPng routes need to be exchanged on an interface (such as the router interconnect interface) in the RIPng routing domain, this interface cannot be configured as a passive interface.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the routing configuration mode.

ipv6 router-protocol rip

(4) Configure passive interfaces.

disable-interface { **default** | *interface-type interface-number* }

The passive interface function is disabled by default.

1.4 Configuring RIPng Route Distribution

1.4.1 Overview

RIPng can distribute the routes of other routing protocols or default routes in the local routing domain so that the devices in the routing domain can access other routing domains.

1.4.2 Configuration Tasks

The configuration of RIPng route distribution includes the following tasks, and these tasks are optional. Select tasks for configuration according to actual condition.

- Generating a Default Route
- Configuring External Route Redistribution

1.4.3 Generating a Default Route

1. Overview

This function is used to introduce a default route to an AS edge router so that other routers in the RIPng domain access other AS domains through this AS edge router by default. In the routing table, a route to the destination network ::/0 is called default route. The default route can be learned from a neighbor device, or sent to a neighbor device. Please configure and distribute the default route according to the actual situation of networking, or specify the cost of the distributed default route.

2. Restrictions and Guidelines

- When there are no special requirements and this command is configured on the interface, an IPv6 default route is advertised to the external devices through this interface, but the route itself is not added to the route forwarding table of the device and the RIPng route database.
- To prevent occurrence of a route loop, once this command is configured on an interface, RIPng refuses to receive the default route updates advertised by neighbors.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure external route redistribution.

ipv6 ripng default-info { **only** | **originate** } [**metric-value** *metric-value*]

1.4.4 Configuring External Route Redistribution

1. Overview

This function is used to introduce external routes of the RIPng domain to the AS edge device.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the routing configuration mode.

ipv6 router-protocol rip

(4) Generate a default route.

redistribute-route { **bgp** | **connected** | **isis** [*area-tag*] **| ospf** process-id **| static** } [**metric-value** *metric-value* | **route-map** *route-map-name*] *

By default, the function of redistributing routes from other routing domains to RIPng is not configured.

1.5 Configuring RIPng Route Filtering Rules

1.5.1 Overview

Routes that do not meet filtering criteria cannot be loaded to the routing table, or advertised to neighbors. In this way, users within the network can be prevented from accessing specified destination networks.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a prefix list.

ip prefix-list-info *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv4-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*]

(4) Enter the routing configuration mode.

ipv6 router-protocol ripng

(5) Configure to filter the sent and received RIP routing information.

route-filtering prefix-list *prefix-list-name* { **in** | **out** } [*interface-type interface-number*]

By default, the distribution list is disabled.

1.6 Configuring to Adjust RIPng Routing

1.6.1 Overview

Change the RIPng routes to enable the traffic pass through specified nodes or avoid passing through specified nodes. Change the sequence that a router selects various types of routes so as to change the priorities of RIPng routes.

1.6.2 Configuration Tasks

The configuration for modifying routing parameters includes the following tasks, and these tasks are optional. Select tasks for configuration according to actual condition.

- Configuring to Modify the Management Distance of an RIPng Route
- Configuring to Modify the Metric Offset on an Interface
- Configuring the Default Metric of a Route Redistributed to RIPng Metric

1.6.3 Configuring to Modify the Management Distance of an RIPng Route

1. Overview

This function is used to set the management distance of a RIPng route and change the priority of a router in routing.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the routing configuration mode.

ipv6 router-protocol rip

(4) Configure to modify the management distance of an RIPng route.

distance *distance*

The management distance is **120** by default.

1.6.4 Configuring to Modify the Metric Offset on an Interface

1. Overview

Before a route is added to the routing table, the metric of the route must be added with the metric offset set on the interface. You can control the use of a route by setting the interface metric offset.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*
- Enter the virtual PPP interface configuration mode.
  - **interface virtual-ppp** *interface-number*
- Enter the virtual template interface configuration mode.
  - **interface virtual-template** *interface-number*

(4) Configure to modify the metric offset to be added to the interface of an RIPng route.

ipv6 ripng metric-adjustment *value*

By default, the metric on an interface is **1**.

1.6.5 Configuring the Default Metric of a Route Redistributed to RIPng

1. Overview

The default metric of a redistributed route is **1**. If you want to preferably select an internal RIP route on some networks, just increase the default metric.

2. Restrictions and Guidelines

- Unless otherwise required, perform this configuration on an AS edge device to which external routes are introduced.
- If the metric is not specified during redistribution of a routing protocol process, RIPng uses the metric defined by the **default-metric** command. If the metric is specified, the metric defined by the **default-metric** command is overwritten by the specified metric.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the routing configuration mode.

ipv6 router-protocol rip

(4) Configure the default metric of a route redistributed to RIPng.

default-metric *metric*

By default, the metric for route redistribution is 1.

1.7 Modifying Timers

1.7.1 Overview

By adjusting the timers, you can reduce the convergence time and fault rectification time of the routing protocol. For devices connected to the same network, values of the three RIPng timers must be the same. Generally, you are not advised to modify the RIP timers unless otherwise required.

Setting timers to small values on a low-speed link brings risks because a lot of Update packets consume the bandwidth. You can set timers to small values generally on the Ethernet or a 2 Mbps (or above) link to reduce the convergence time of network routes.

1.7.2 Restrictions and Guidelines

- The RIPng basic functions must be configured.
- Modifying the protocol control parameters may result in protocol running failures. Therefore, you are advised not to modify the timers.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the routing configuration mode.

ipv6 router-protocol rip

(4) Configure to modify the RIPng timers.

timers-set *update invalid flush*

By default, the update timer is 30s, the invalid timer is 180s, and the flush timer is 120s.

1.8 Enabling GR

1.8.1 Overview

GR ensures uninterrupted data transmission when the protocol is restarted. The GR period is the maximum time from restart of the RIPng process to completion of GR. During this period, the forwarding table before the restart is retained, and the RIPng route is restored so as to restore the RIPng state before the restart. After the restart period expires, RIPng exits the GR state and performs common RIPng operations.

1.8.2 Restrictions and Guidelines

- The RIPng basic functions must be configured.
- The GR period is at least twice the RIP route update period.
- The **gr grace-period** command allows you to explicitly modify the GR period. Note that GR must be completed before the invalid timer of the RIPng route expires. An inappropriate GR period cannot ensure uninterrupted data forwarding during the GR process. A typical case is as follows: If the GR period is longer than the duration of the invalid timer, GR is not completed when the invalid timer expires. The route is not re-advertised to the neighbor, and forwarding of the route of the neighbor stops after the invalid timer expires, causing interruption of data forwarding on the network. Unless otherwise required, you are not advised to adjust the GR period. If it is necessary to adjust the GR period, ensure that the GR period is at least twice the RIP route update period based on the configuration of the **timers-set** command. The GR period must be also smaller than the duration of the invalid timer.
- During the RIPng GR process, ensure that the network environment is stable.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the routing configuration mode.

ipv6 router-protocol rip

(4) Enable GR.

gr [**grace-period** *grace-period*]

The GR function is enabled by default.

1.9 Configuring a Super VLAN to Enable RIPng

Note

This function is not supported by the S6980-64QC, S6580-48CQ8QC, or S6580-24DC8QC.

1.9.1 Overview

In normal cases, a super VLAN contains multiple sub VLANs. Multicast packets of a super VLAN are also sent to its sub VLANs. In this case, when RIP multicast packets are sent over a super VLAN containing multiple sub VLANs, the RIP multicast packets are replicated multiple times, and the device processing capability is insufficient. As a result, a large number of packets are discarded, causing protocol flapping.

In most scenarios, the RIPng function does not need to be enabled on a super VLAN, and it is disabled by default. However, in some scenarios, the RIPng function must be run on the super VLAN, but packets need to be sent to only one sub VLAN. In this case, you can decide to send multicast packets to a certain sub VLAN or to all sub VLANs as actually needed. You can run this command to specify a particular sub VLAN. You must be cautious when configuring packet transmission to all sub VLANs, as the large number of sub VLANs may cause a device processing bottleneck, which will lead to the neighbor flapping.

1.9.2 Restrictions and Guidelines

- The RIPng basic functions must be configured.
- The designated sub VLAN must be connected to neighbors.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the SVI interface configuration mode.

interface vlan *interface-number*

(4) Enable RIPng on a super VLAN.

ipv6 rip subvlan [**all |** *vlan-id*]

By default, the RIPng function is disabled on a super VLAN.

1.10 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

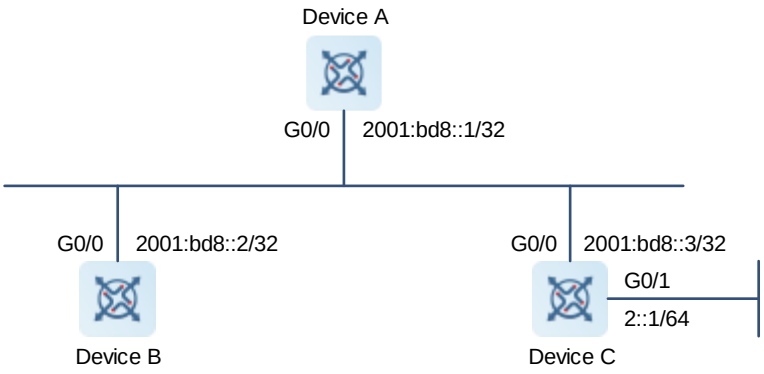
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-2 Monitoring

Command	Purpose
display ipv6 rip	Displays information about the RIPng process.
display ipv6 rip database	Displays the RIPng routing table.
debugging ipv6 rip [interface *interface-type interface-number* | **nsm** | **restart** | **event** [**ipsec**]]	Debugs RIPng.

1.11 Configuration Examples



1.11.1 Configuring Basic Functions of RIPng

1. Requirements

On an IPv6 network, configure RIPng to realize internetworking.

2. Topology

Figure 1-9 Configuring Basic Functions of RIPng

3. Notes

- Configure IPv6 addresses on the related devices.
- Enable the RIPng routing function on all the devices.

4. Procedure

(1) Configure an IPv6 address for each interface.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# interface gigabitethernet 0/0
Device A(cfg-if-GigabitEthernet 0/0)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::1/32
Device A(cfg-if-GigabitEthernet 0/0)# exit
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# interface gigabitethernet 0/0
Device B(cfg-if-GigabitEthernet 0/0)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::2/32
Device B(cfg-if-GigabitEthernet 0/0)# exit
```

Configure Device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# interface gigabitethernet 0/0
Device C(cfg-if-GigabitEthernet 0/0)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::3/32
Device C(cfg-if-GigabitEthernet 0/0)# exit
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/0)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/1)# ipv6 address 2::1/64
Device C(cfg-if-GigabitEthernet 0/1)# exit
```

(2) Enable the RIPng routing function on all the devices.

Configure Device A.

```
Device A(cfg)# ipv6 router-protocol rip
Device A(cfg-router)# exit
Device A(cfg)# interface gigabitethernet 0/0
Device A(cfg-if-GigabitEthernet 0/0)# ipv6 rip enable
```

Configure Device B.

```
Device B(cfg)# ipv6 router-protocol ripng
Device B(cfg-router)# exit
Device B(cfg)# interface gigabitethernet 0/0
Device B(cfg-if-GigabitEthernet 0/0)# ipv6 ripng enable
```

Configure Device C.

```
Device C(cfg)# ipv6 router-protocol ripng
Device C(cfg-router)# exit
Device C(cfg)# interface gigabitethernet 0/0
Device C(cfg-if-GigabitEthernet 0/0)# ipv6 ripng enable
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# ipv6 ripng enable
```

5. Verification

Check the routing tables of Device A, Device B, and Device C. Verify that RIPng has learned the routes to remote networks.

- Check the routing table of Device A.

```
Device A# display ipv6 route-config
IPv6 routing table name - Default - 6 entries
```

```
Codes:  C - Connected, L - Local, S - Static
        R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
        N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
        E1 - OSPF external type 1, E2 - OSPF external type 2
        SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
        IA - Inter area

R       2::/64 [120/2] via FE80::2D0:F8FF:FEFB:D521, GigabitEthernet 0/0
C       2001:DB8::/32 via GigabitEthernet 0/0, directly connected
L       2001:DB8::1/128 via GigabitEthernet 0/0, local host
C       FE80::/10 via ::1, Null0
C       FE80::/64 via GigabitEthernet 0/0, directly connected
L       FE80::2D0:F8FF:FEFB:E7CE/128 via GigabitEthernet 0/0, local host
```

- Check the routing table of Device B.

```
Device B# display ipv6 route-config

IPv6 routing table name - Default - 6 entries
Codes:  C - Connected, L - Local, S - Static
        R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
        N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
        E1 - OSPF external type 1, E2 - OSPF external type 2
        SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
        IA - Inter area

R       2::/64 [120/2] via FE80::2D0:F8FF:FEFB:D521, GigabitEthernet 0/0
C       2001:DB8::/32 via GigabitEthernet 0/0, directly connected
L       2001:DB8::2/128 via GigabitEthernet 0/0, local host
C       FE80::/64 via GigabitEthernet 0/0, directly connected
L       FE80::2D0:F8FF:FEFB:C9BA/128 via GigabitEthernet 0/0, local host
```

- Check the routing table of Device C.

```
Device C# display ipv6 route-config

IPv6 routing table name - Default - 9 entries
Codes:  C - Connected, L - Local, S - Static
        R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
        N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
        E1 - OSPF external type 1, E2 - OSPF external type 2
        SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
        IA - Inter area

C       2::/64 via GigabitEthernet 0/1, directly connected
L       2::2/128 via GigabitEthernet 0/1, local host
C       2001:DB8::/32 via GigabitEthernet 0/0, directly connected
L       2001:DB8::3/128 via GigabitEthernet 0/0, local host
C       FE80::/10 via ::1, Null0
```

```
C        FE80::/64 via GigabitEthernet 0/0, directly connected
L        FE80::2D0:F8FF:FEFB:D521/128 via GigabitEthernet 0/0, local host
C        FE80::/64 via GigabitEthernet 0/1, directly connected
L        FE80::2D0:F8FF:FEFB:D521/128 via GigabitEthernet 0/1, local host
```

6. Configuration Files

- Device A configuration file

```
!
ipv6 router-protocol rip
!
interface gigabitethernet 0/0
 unset switch-port
 ipv6 address 2001:db8::1/32
 ipv6 rip enable
!
```

- Device B configuration file

```
!
ipv6 router-protocol rip
!
interface gigabitethernet 0/0
 unset switch-port
 ipv6 address 2001:db8::2/32
 ipv6 rip enable
!
```

- Device C configuration file

```
!
ipv6 router-protocol rip
!
interface gigabitethernet 0/0
 unset switch-port
 ipv6 address 2001:db8::3/32
 ipv6 rip enable
!
interface gigabitethernet 0/1
 unset switch-port
 ipv6 address 2::1/64
 ipv6 rip enable
!
```

7. Common Errors

- The IPv6 address is not configured on an interface.
- The interface used for interworking between devices is configured as a passive interface.

1.11.2 Advertising Default Routes/External Routes

1. Requirements

On a network adopting OSPFv3 networking, Device A and Device B are egress devices on the network, Device A is the default egress used to advertise the default route to Device B, and Device B communicates with the internal network through a static route.

2. Topology

Figure 1-10 Configuring Default Routes/External Routes

3. Notes

- Configure interface IPv6 addresses for all devices (omitted).
- Configure the RIPng basic functions on all devices (omitted).
- Redistribute the static route on Device B.
- On the GigabitEthernet 0/1 interface of Device A, configure advertisement of the default route.

4. Procedure

(1) Configure redistribution of a static route on Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# ipv6 router-protocol rip
Device B(cfg-router)# redistribute-route static
```

(2) Configure redistribution of a default route on Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 rip default-info originate
```

5. Verification

Check the routing tables on Device A and Device B, and verify that Device A can learn the route 3001:10:10::/64, and Device B can learn the default route ::/0.

```
Device A# display ipv6 route-config rip

IPv6 routing table name - Default - 17 entries
Codes:   C - Connected, L - Local, S - Static
         R - RIP, O - OSPF, B - BGP, I - IS-IS
         N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
         E1 - OSPF external type 1, E2 - OSPF external type 2
```

```
            SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
            IA - Inter area
R           3001:10:10::/64 [120/2] via FE80::2D0:F8FF:FE22:334A, GigabitEthernet 0/1
Device B# display ipv6 route-config rip

IPv6 routing table name - Default - 17 entries
Codes:    C - Connected, L - Local, S - Static
            R - RIP, O - OSPF, B - BGP, I - IS-IS
            N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
            E1 - OSPF external type 1, E2 - OSPF external type 2
            SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
            IA - Inter area
R           ::/0 [120/2] via FE80::21A:A9FF:FE41:5B06, GigabitEthernet 0/1
```

6. Configuration Files

- Device A configuration file

```
!
interface gigabitethernet 0/1
 unset switch-port
 ipv6 rip default-info originate
!
```

- Device B configuration file

```
!
ipv6 router-protocol ripng
 redistribute-route static
!
```

1 Configuring OSPFv2

1.1 Introduction

1.1.1 Overview

The open shortest path first (OSPF) is an Interior Gateway Protocol (IGP) that is used within the autonomous system (AS) to allow routers to obtain a route to a remote network.

In the early stage after dynamic routing emerges, Routing Information Protocol (RIP) was mainly used on the network. RIP is a distance vector routing protocol, facing some problems such as slow convergence, routing loop, poor scalability, and use for simple networks only. OSPF Version 2 (OSPFv2) is a link-state routing protocol, which can effectively fix the above problems. Therefore, OSPFv2 is widely used on large and medium-sized networks.

Note

- OSPFv2 is applicable to IPv4, and OSPF Version 3 (OSPFv3) is applicable to IPv6. The protocol running mechanism and most configurations are the same.
- Unless otherwise specified, "OSPF" in the following descriptions refers to OSPF Version 2.

OSPF has the following characteristics:

- Wide scope of application: OSPF is applicable to a larger-scale network that supports hundreds of routers.
- Fast convergence: Once the network topology changes, advertisements can be quickly sent between routers to update routes.
- No self-loop: Only the link status information is synchronized between routers. Each router computes routes independently, and a self-loop will not occur.
- Area division: A large routing domain is divided into multiple small areas to save system resources and network bandwidth and ensure stability and reliability of routes.
- Route classification: Routes are classified into several types to support flexible control.
- Equivalent routes: OSPF supports equivalent routes.
- Authentication: OSPF supports packet authentication to ensure security of protocol interaction.
- Multicast transmission: Protocol packets are sent using the multicast address to avoid interfering with irrelevant entities and save system resources.

Note

In this chapter, the term "router" refers to any network device that supports the routing function. These network devices can be Layer-3 switches, routers, or firewalls.

1.1.2 Basic Concepts

1. Routing domain

All routers in an AS must be interconnected and use the same routing protocol. Therefore, an AS is also called a routing domain.

An AS on which OSPF runs is also called OSPF routing domain, or OSPF domain for short.

2. OSPF process

OSPF supports multiple instances, and each instance corresponds to an OSPF process. One or more OSPF processes can be started on a router. Each OSPF process runs OSPF independently, and the processes are mutually isolated. The process ID takes effect only on the local router, and does not affect exchange of OSPF packets on adjacent interfaces.

3. Router ID

The router ID uniquely identifies a router in an OSPF domain. Router IDs of any two routers cannot be the same.

If multiple OSPF processes exist on a router, each OSPF process uses one router ID. Router IDs of any two OSPF processes cannot be the same.

A router ID can be manually configured or automatically selected by the router. To prevent conflicts between Router IDs obtained by different routers through automatic selection, you are advised to select manual configuration. If no router ID is specified manually, the automatic selection rules are as follows:

(1) The largest IP address from the lookback interface addresses is selected as the router ID;

(2) If no lookback interface is configured, the largest IP address from the physical interface addresses is selected as the router ID.

4. Area

An area is a logical group of routers, and each group is identified by an area ID. As shown in Figure 1-1, OSPF supports dividing the network topology into multiple areas, which can alleviate the computing pressure of large-scale networks.

The border between areas is a router. A router may belong to one area or multiple areas. One network segment (link) can belong to only one area, or each OSPF-enabled interface must belong to a specified area.

OSPF areas can be classified into following types:

- Backbone area and normal area

  Area 0 is the backbone area, and other areas are normal areas. Normal areas must be directly connected to the backbone area.

- Stub area (OSPF stubby area)

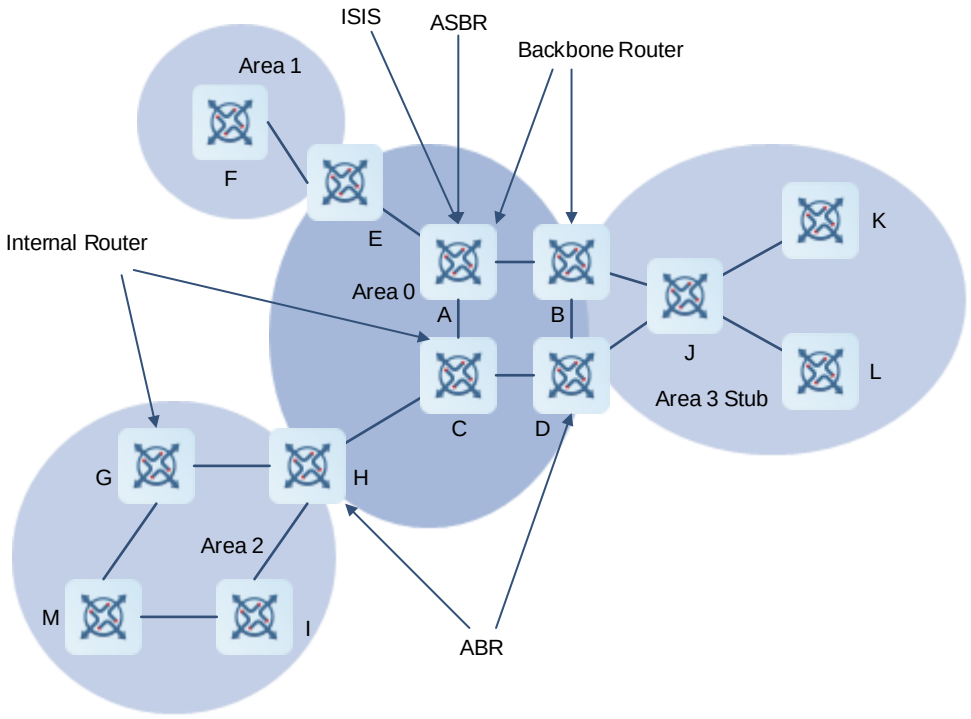
  Configuring a stub area can reduce the number of LSAs in the area. The area border router (ABR) in the stub area will not transfer the Type-5 LSA (external route), and will advertise a Type 3 default route to the stub area.

- Totally stub area

A totally stub area is upgraded from a stub area. The router in the totally stub area will not transfer Type-3 LSA (inter-domain route) and Type-5 LSA (external route). ABR only advertises a Type 3 default route to the totally stub area.

- Not-so-stubby area (NSSA)

  An NSSA is similar to a stub area, but allows the autonomous system boundary router (ASBR). The route redistributed by ASBR will be transferred in the NSSA in the form of Type-7 LSA, and the Type-7 LSA will be converted into Type-5 LSA on ABR and then transferred to other areas. The ABR also advertises one default route to the NSSA.



- Totally not-so-stubby area (NSSA)

  The relationship between the totally NSSA and NSSA is similar to that between the totally stub area and stub area. The totally NSSA forbids transfer of the Type-3 LSA (inter-domain route) on the basis of NSSA.

Note

- The backbone area cannot be configured as a stub area, totally stub area, NSSA, or totally NSSA.
- The stub area and totally stub area cannot contain any ASBR.
- The stub area, totally stub area, NSSA, and totally NSSA cannot contain any virtual link.

Figure 1-1 Types of OSPF Areas and Routers

5. Types of OSPF routers

The following types of routers are defined in OSPF, and assigned with different responsibilities:

- Internal router

  All interfaces of an interval router belong to the same area. See A, C, F, G, I, M, J, K, and L shown in Figure 1-1.

- ABR

  An ABR is used to connect the backbone area with a normal area. An ABR belongs to two or more areas, and one of the areas must be the backbone area. See B, D, E, and H shown in Figure 1-1.

- Backbone router

  A backbone router has at least one interface that belongs to the backbone area. All ABRs and all routers in Area 0 are backbone routers. See A, B, C, D, E, and H shown in Figure 1-1.

- ASBR

  An ASBR is used to exchange routing information with other ASs. An ASBR is not necessarily located on the border of an AS. It may be a router inside an area, or an ABR. See A shown in Figure 1-1.

6. LSA

OSPF encapsulates and advertises the description of routing information through a Link State Advertisement (LSA). Common LSA types are shown in Table 1-1.

Table 1-1 OSPF LSA Types

LSA Type	Description
Router-LSA (Type 1)	This LSA is originated by each router. It describes the link state and cost of the router, and is advertised only within the area where the originating router is located.
Network-LSA (Type 2)	This LSA is originated by a DR on the non-broadcast multiple access (NBMA) network. It describes the link state in the current network segment, and is advertised only within the area where the DR is located.
Network-summary-LSA (Type 3)	This LSA is originated by an ABR. It describes a route to another area, and is advertised to areas except totally stub areas and NSSAs.
ASBR-summary-LSA (Type 4)	This LSA is originated by an ABR. It describes a route to an ASBR, and is advertised to areas except the area where the ASBR is located.
AS-external-LSA (Type 5)	This LSA is originated by an ASBR. It describes a route to a destination outside the AS, and is advertised to all areas except stub areas and NSSAs.
NSSA LSA (Type 7)	This LSA is originated by an ASBR. It describes a route to a destination outside the AS, and is advertised only within the NSSA.

LSA Type	Description
Opaque LSA (Type 9/Type 10/Type 11)	Opaque LSAs provide a generalized mechanism to allow for the future extensibility of OSPF, wherein: ● Type-9 LSAs are advertised only within the network segment where interfaces are located. The grace LSA used to support graceful restart (GR) is one of Type-9 LSAs. ● Type-10 LSAs are advertised within an area. The LSA used to support traffic engineering (TE) is one of Type-10 LSAs. ● Type-11 LSAs are advertised within an AS. At present, there are no application examples of Type-11 LSAs.

The format of LSA packet header is described as follows.

Figure 1-2 LSA Packet Header Format

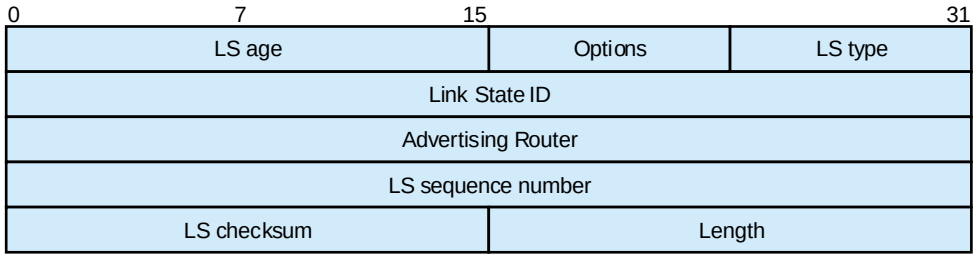


Table 1-2 Description of Fields of LSA Packet Header

Field	Description
LS age	The age of the LSA.
Options	Options of the LSA.
LS type	LSA type, as shown in Table 1-1.
Link State ID	Describes the LSA information. The content varies with the LS type.
Advertising Router	Advertises the router ID of the LSA.
LS sequence number	Serial number of the LSA. The larger the serial number is, the newer the LSA is.
LS checksum	Checksum of other parts except the LS age field.
Length	Total length of the LSA including the LSA Header, in bytes.

Table 1-3 shows the support of various areas for different types of LSAs. Stub area, NSSA, Totally Stub area, and Totally NSSA, as special forms of conventional areas, help reduce the number of LSAs transferred in the OSPF area, eliminate the propagation of a large number of Type 3 LSAs and Type 5 LSAs in the area, reduce the burden on routers, and enhance the stability of OSPF routing.

Table 1-3 Support of LSAs by Different Areas

Area	Type1 and Type 2	Type 3	Type 4	Type 5	Type 7
Non-Stub/Totally Stub and NSSA/Totally NSSAs	Allowed	Allowed	Allowed	Allowed	Blocked
Stub Area	Allowed	Allowed, including one default route	Blocked	Blocked	Blocked
Totally Stub Area	Allowed	Only one default route is allowed	Blocked	Blocked	Blocked
NSSA	Allowed	Allowed, including one default route	Allowed	Blocked	Allowed
Totally NSSA	Allowed	Only one default route is allowed	Allowed	Blocked	Allowed

Note

ABR advertises a default route to Stub/Totally Stub and NSSA/Totally NSSAs using a Type 3 LSA.

ABR converts LSA Type 7 to LSA Type 5 in NSSA/Totally NSSA, and advertise the route to the backbone area.

7. OSPF Packets

OSPF packets are encapsulated in IP packets and transmitted in multicast or unicast mode. When the interfaces running the OSPF process on any network belong to this group, the router running the OSPF process receives all the multicast packets of 224.0.0.5; when the router is used as a DR/BDR on a multi-access network, 224.0.0.6 is used as the multicast receiving address. The OSPF data packet format is shown as follows:

OSPF involves the following five types of packets, as shown in Table 1-4.

Table 1-4 Types of OSPF Packets

Packet Type	Description
Hello	Hello packets are sent periodically to discover and maintain OSPF neighbor relationships.

Packet Type	Description
DD	DD (Database Description) packets carry brief information about the local LSDB and are used to synchronize the LSDBs between OSPF neighbors.
LSR	LSR (Link State Request) packets are used to request the required LSAs from neighbors. LSR packets are sent only after DD packets are exchanged successfully between OSPF neighbors.
LSU	LSU (Link State Update) packets are used to send the required LSAs to peers.
LSAck	LSAck (Link State Acknowledgment) packets are used to acknowledge the received LSAs.

Format of OSPF packets is shown in the figure below.

Figure 1-3 Format of OSPF Packets

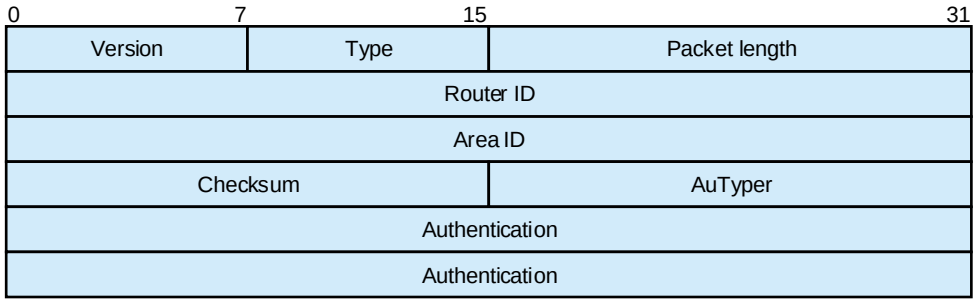

Table 1-5 Description of OSPF Packet Format Fields

Packet Field	Description
Version	Indicates the OSPF version No. The value of OSPFv2 is 2.
Type	Indicates the type of OSPF packet: 1: Indicates hello packet. 2: Indicates DD packet. 3: Indicates LSR packet. 4: Indicates LSU packet. 5: Indicates LSAck packet.
Packet length	Indicates the total length of the OSPF packet including the header, in bytes.
Router ID	Indicates the ID of the router sending the packet.
Area ID	Indicates the area of the router sending the packet.

Packet Field	Description
Checksum	Indicates the checksum of the whole packet excluding the authentication field.
AuType	Indicates the authentication type: 0: Indicates no authentication. 1: Indicates simple authentication. 2: Indicates MD5 authentication.
Authentication	The meaning of this field varies with the authentication type: No authentication: This field is not defined. Simple authentication: This field indicates the password. MD5 authentication: This field includes the key ID, MD5 authentication data length, and sequence number information.

8. OSPF route types

A mark is displayed in front of each OSPF route to indicate the type of the route. There are six types of OSPF routes:

- O: Internal route

  This type of route describes how to arrive at a destination network in the local area. The cost of this type of route is equal to the cost of the route from the local router to the destination network.

- IA: Inter-area route

  This type of route describes how to arrive at a destination network in another area. The cost of this type of route is equal to the cost of the route from the local router to the destination network.

- E1: Type-1 external route

  This type of route describes how to arrive at a destination network outside the AS. The cost of this type of route is equal to the cost of the route from the local router to the ASBR plus the cost of the route from the ASBR to the destination network. This type of route does not exist on routers in the stub or NSSA.

- E2: Type-2 external route

  This type of route describes how to arrive at a destination network outside the AS. The cost of this type of route is equal to the cost of the route from the ASBR to the destination network. This type of route does not exist on routers in the stub or NSSA.

- N1: Type-1 external route of the NSSA

  This type of route describes how to arrive at a destination network outside the AS through the ASBR in the NSSA. The cost of this type of route is equal to the cost of the route from the local router to the ASBR plus the cost of the route from the ASBR to the destination network. This type of route exists only on routers in the NSSA.

- N2: Type-2 external route of the NSSA

This type of route describes how to arrive at a destination network outside the AS through the ASBR in the NSSA. The cost of this type of route is equal to the cost of the route from the ASBR to the destination network. This type of route exists only on routers in the NSSA.

Note

Reliability of E2 and N2 routes is poor. OSPF believes that the cost of the route from the ASBR to a destination outside an AS is far greater than the cost of the route to the ASBR within the AS. Therefore, when the route cost is computed, only the cost of the route from the ASBR to a destination outside an AS is considered.

Configuring an area as a Stub/Totally Stub area or NSSA/Totally NSSA can reduce a large number of E1, E2, and IA routes in the routing table of routers in the area.

Table 1-6 Route Types in a Stub/NSSA

Area	Routes in the routing table of routers in the area
Non-Stub/Totally Stub, and NSSA/Totally NSSA	O: Route to a destination network in the local area. IA: Route to a destination network in another area. E1 or E2: Route or default route to a destination network outside the AS through any ASBR in the AS.
Stub area	O: Route to a destination network in the local area. IA: Route to a destination network in another area.
Totally Stub area	O: Route to a destination network in the local area. IA: Default route.
NSSA	O: Route to a destination network in the local area. IA: Route to a destination network in another area. N1or N2: Route or default route to a destination network outside the AS through any ASBR in the area.
Totally NSSA	O: Route to a destination network in the local area. IA: Default route. N1or N2: Route or default route to a destination network outside the AS through any ASBR in the area.

9. OSPF neighbor state

On the OSPF network, neighbor devices need to reach the adjacency state before exchanging link information. Any two devices form an OSPF neighborhood relation or adjacency relation.

- Neighborhood: If two routers can send and receive Hello packets from each other, and can successfully negotiate the parameters carried in the Hello packets, then they are neighbors to each other.
- Adjacency: When neighbor devices successfully exchange LSA and realize LSDB synchronization, then an adjacency relation is successfully established.

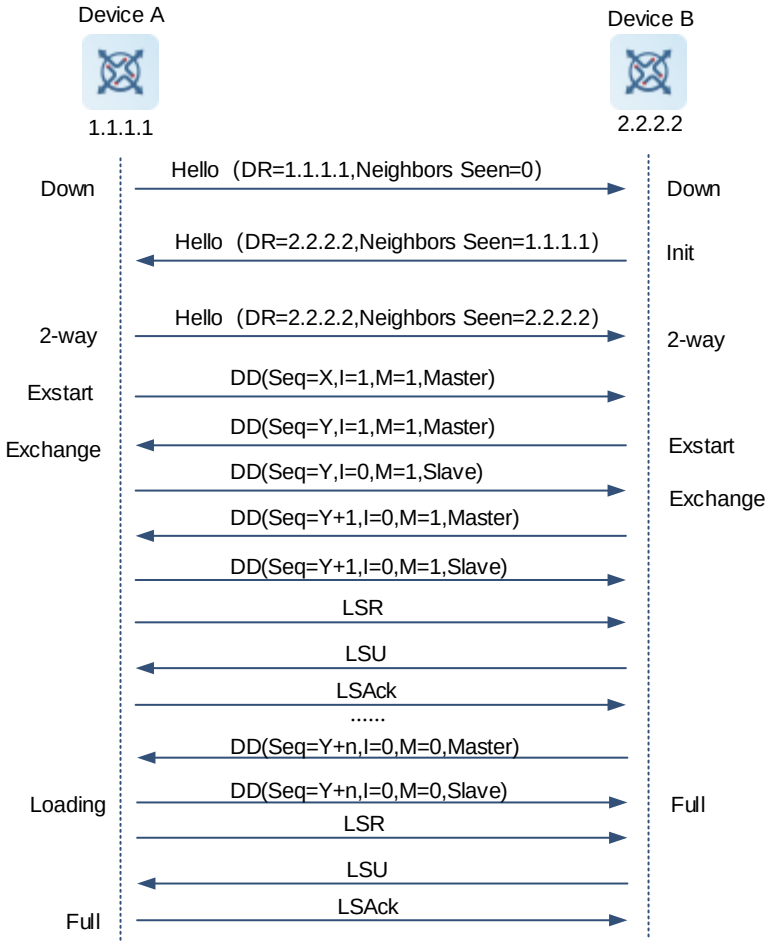

Table 1-7 shows the 8 OSPF neighbor states.

Table 1-7 OSPF Neighbor State Machine and Description

State	Description
Down	The state of the First OSPF neighbor, which indicates that the neighbor's hello packet is not received within the neighbor dead interval.
Attempt	The attempt state router sends a hello packet to the manually configured neighbor periodically. The attempt state applies to the interfaces of NBMA type only.
Init	A hello packet has been received from the neighbor, but the packet does not contain the router ID of the neighbor receiving router, that is, the peer end does not receive the hello packet sent by the local end.
Two-Way	Indicates mutual neighbors. ● When the neighbor router ID field in the received hello packet is each other's router ID, and both ends receive the hello packet sent from the peer end, a neighbor relationship is established. ● After this phase ends, DR and BDR will be selected for broadcast and non-broadcast multi-access.
Exstart	Indicates negotiation about the master/slave relationship. ● Selects the initial sequence number for forming an adjacency. ● The master/slave relationship ensures orderly transmission in the subsequent exchange of DD packets.
Exchange	Indicates exchange of DD packets. Checks whether the neighbor can provide new or updated link state information.
Loading	Indicates that, based on the information provided by DBD, the router will send LSR and interactive LSU to implement synchronization with LSDB.
Full	Indicates establishment of an adjacency. Indicates that the LSDBs of the two devices have been synchronized, and the adjacency state has been established between the local device and the neighbor device.

Figure 1-4 shows the OSPF adjacency establishment process on the broadcast network. When the neighbor state is Full, the adjacency is established.

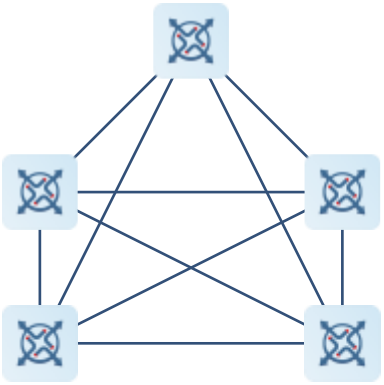
Figure 1-4 OSPF Adjacency Establishment Process on Broadcast Network

10. DR and BDR

On the broadcast or NBMA network, many unwanted LSAs will be created when an adjacency is set up with related routers. If there are n routers, n*(n-1)/2 adjacency relationships will be set up, and n^2 LSAs will be generated on the network. In the process of setting up the adjacency and exchanging LSAs, many unwanted copies will be produced, which leads to chaos in the flooding of a multi-access network. To avoid these problems on a multi-access network, OSPF defines the concepts of DR and BDR.

After the DR and BDR are elected, all routers will set up an adjacency relationship with the DR and BDR only, send information to the DR/BDR, and the DR will broadcast the network link state. The routers other than DR and BDR are called DR Other. DR Other will no longer set up an adjacency relationship or exchange any routing information with each other, thus reducing the number of adjacency relationships between routers on the broadcast and NBMA networks, as shown Figure 1-5 and Figure 1-6.

Figure 1-5 Number of Adjacency Relationships Before DR Election



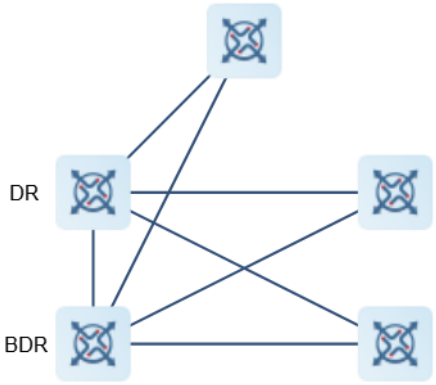


Figure 1-6 Number of Adjacency Relationships After DR Election

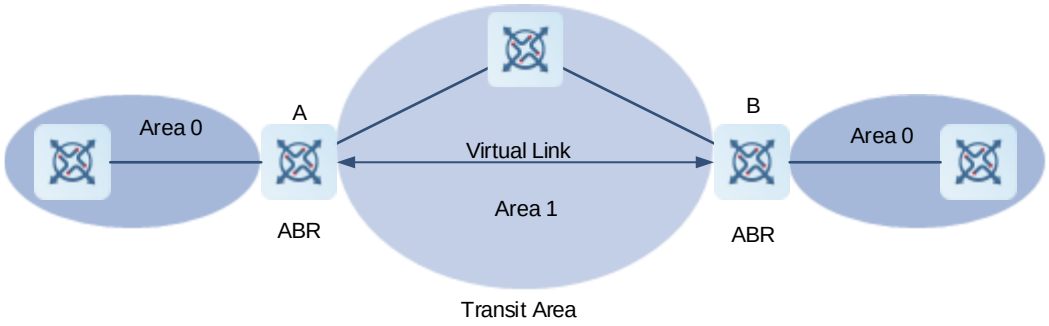
11. OSPF network types

A router does not necessarily need to exchange LSAs with every neighbor or set up an adjacency with every neighbor. To improve efficiency, OSPF classifies networks that use various link layer protocols into five types so that LSAs are exchanged in different ways to set up an adjacency.

By default, Ethernet and fiber distributed data interface (FDDI) belong to the broadcast type, X.25, frame relay, and ATM belong to the NBMA type, and PPP, HDLC, and LAPB belong to the P2P type.

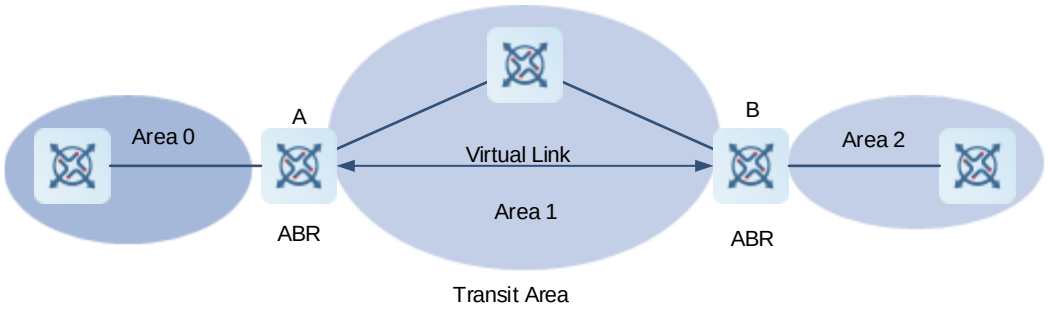
Table 1-8 Introduction to OSPF Network Types



Network Type	Link Layer Protocol	Neighbor Relationship and DR Election
Broadcast	Ethernet and FDDI belong to the broadcast network type by default.	● Neighbors are discovered, and the DR and BDR are elected. ● The DR or BDR exchanges LSAs with all other routers to set up an adjacency. ● Except the DR and BDR, all other routers do not exchange LSAs with each other, and the adjacency is not set up.
NBMA	X.25, frame relay, and ATM belong to NBMA networks by default.	● Neighbors are manually configured, and the DR and BDR are elected. ● The DR or BDR exchanges LSAs with all other routers to set up an adjacency. ● Except the DR and BDR, all other routers do not exchange LSAs with each other, and the adjacency is not set up.
Point-to-Point (P2P)	PPP, HDLC, and LAPB belong to the P2P network type by default.	● Neighbors are automatically discovered, and the DR or BDR is not elected. ● LSAs are exchanged between routers at both ends of the link, and the adjacency is set up.
Point-to-Multipoint (P2MP)	Networks without any link layer protocol belong to the P2MP network type by default.	● Neighbors are automatically discovered, and the DR or BDR is not elected. ● LSAs are exchanged between any two routers, and the adjacency is set up.
P2MP broadcast	Networks without any link layer protocol belong to the P2MP network type by default.	● Neighbors are manually configured, and the DR or BDR is not elected. ● LSAs are exchanged between any two routers, and the adjacency is set up.

12. Virtual link

OSPF supports virtual links. A virtual link is a logical link that belongs to the backbone area. It is used to resolve the problems such as a discontinuous backbone area or a failure to directly connect a normal area to the backbone area on the physical network. A virtual link supports traversal of only one normal area, and this area is called transit area. Routers on both ends of a virtual link are ABRs.



A virtual link relies on an OSPF intra-domain route, making two ABRs adjacent. The OSPF packet information exchanged by ABRs is transparent to the intermediate device.

Figure 1-7 Discontinuous Backbone Area on the Physical Network

As shown in Figure 1-7, a virtual link is set up between A and B to connect to Area 0. Area 1 is a transit area, and A and B are ABRs of Area 1.

Figure 1-8 Failure to Directly Connect a Normal Area to the Backbone Area on the Physical Network

As shown in Figure 1-8, a virtual link is set up between A and B to extend Area 0 to B so that Area 0 can be directly connected to Area 2 on B. Area 1 is a transit area, A is an ABR of Area 1, and B is an ABR of Area 1 and Area 2.

1.1.3 Principles

OSPF is a type of link-state routing protocols. Its working process consists of three phases:

(1) Neighbor discovery → Bidirectional communication

An OSPF neighbor relationship is set up between adjacent routers, and bidirectional communication is maintained.

Routers send hello packets through all OSPF-enabled interfaces or virtual links. If hello packets can be exchanged between two routers, and parameters carried in the hello packets can be successfully negotiated, the two routers become neighbors. Routers that are mutual neighbors find their own router IDs from hello packets sent from neighbors, and bidirectional communication is set up.

A hello packet includes, but is not limited to, the following information:

- Router ID of the originating router.
- Area ID, subnet mask, authentication information, Hello interval and neighbor dead interval of the originating

router interface or virtual link.

- IP addresses of the designated router (DR) and backup designated router (BDR).
- Priority of the originating router interface (used for DR/BDR election).
- Router ID of the neighbor of the originating router.

(2) Database synchronization → Full adjacency

A router uses link-state advertisements (LSAs) to advertise all its link states. LSAs are exchanged between neighbors and the link state database (LSDB) is synchronized to achieve full adjacency.

After bidirectional communication is established between neighbor routers, database description (DD), link state request (LSR), link state update (LSU), and link state acknowledgment (LSAck) packets are used to exchange LSAs and establish an adjacency relationship. The brief process is as follows:

- A router generates an LSA to describe all link states on the router.
- The LSA is exchanged between neighbors. When a router receives the LSA from its neighbor, it copies the LSA and saves the copy in the local LSDB, and then advertises the LSA to other neighbors.
- When the router and its neighbors obtain the same LSDB, full adjacency is achieved.

Note

OSPF will not generate LSDB updates and advertisements without changes in link costs or network addition/deletion. If any change takes place, the changed link states are advertised to quickly synchronize the LSDB.

(3) Shortest path tree (SPT) computation → Formation of a routing table

The router computes the shortest path to each destination network based on the LSDB and forms an OSPF routing table.

After the complete LSDB is obtained from the router, the Dijkstra algorithm is run to generate an SPT from the local router to each destination network. The SPT records the destination networks, next-hop addresses, and costs. OSPF generates a routing table based on the SPT.

If changes in link costs or network addition/deletion take place, the LSDB will be updated. The router again runs the Dijkstra algorithm, generates a new SPT, and updates the routing table.

Note

The Dijkstra algorithm is used to find the shortest path from a vertex to other vertices in a weighted directed graph.

1.1.4 OSPF Routing

- Route cost

  If redundancy links or devices exist on the network, multiple paths may exist from the local device to the destination network. OSPF selects the path with the minimum total cost to form an OSPF route. The total cost of a path is equal to the sum of the costs of individual links along the path. The total cost of a path can be

minimized by modifying the costs of individual links along the path. In this way, OSPF selects this path to form a route.

With configuration commands, you can modify the following link costs:

- Cost from an interface to a directly connected network segment and cost from the interface to a neighbor.
- Cost from an ABR to the inter-area summarization network segment and cost from the ABR to the default network segment.
- Cost from an ASBR to an external network segment and cost from the ASBR to the default network segment.

Note

Cost value refers to the cost of a link and the link quality value after calculation. Metric is the cost of a complete path and the total cost of the links passed.

- OSPF administrative distance

  The administrative distance (AD) evaluates reliability of a route. Its value is an integer ranging from 0 to 255. A smaller AD value indicates that the route is more trustworthy. If multiples exist to the same destination, the route preferentially selects a route with a smaller AD value. The route with a greater AD value becomes a floating route, that is, a standby route of the optimum route.

  By default, the route coming from one source corresponds to an AD value. The AD value is a local concept. Modifying the AD value affects route selection only on the current router.

Table 1-9 Routing Protocols and Default Administrative distances

Route Source	Directly-connected network	Static route	EBGP route	OSPF route	IS-IS route	RIP route	IBGP route	Unreachable route
Default AD	0	1	20	110	115	120	200	255

1.1.5 OSPF Route Advertisement

- Route redistribution

  Route redistribution refers to the process of introducing routes of other routing protocols, routes of other OSPF processes, static routes, and direct routes that exist on the device to an OSPF process so that these routes can be advertised to neighbors using Type-5 and Type-7 LSAs. A default route cannot be introduced during route redistribution.

  Route redistribution is often used for interworking between ASs. You can configure route redistribution on an ASBR to advertise routes outside an AS to the interior of the AS, or routes inside an AS to the exterior of the AS.

- Default route introduction

By configuring a command on an ASBR, you can introduce a default route to an OSPF process so that the route can be advertised to neighbors using Type 5 and Type 7 LSAs.

Default route introduction is often used for interworking between ASs. One default route is used to replace all the routes outside an AS.

1.1.6 OSPF Route Summarization

Route summarization is a process of summarizing routing information with the same prefix into one route, and advertising the summarized route to neighbors by replacing a large number of individual routes. Route summarization helps reduce the protocol interaction load and the size of the routing table.

By default, the ABR advertises inter-area routing information by using Type-3 LSAs within a network segment, and advertises redistributed routing information by using Type-5 and Type-7 LSAs. If continuous network segments exist, you are advised to configure route summarization.

When configuring route summarization, the summarization range may exceed the actual network scope of routes. If the data is sent to a network beyond the summarization range, a routing loop may be formed and the router processing load may increase. To prevent these problems, ABR or ASBR will automatically add a discard route to the routing table. This route will not be advertised.

1.1.7 OSPF Route Filtering

OSPF allows filtering of the learned and exchanged routes and LSAs so as to meet the security requirements in specific scenarios, for example, the routes of some network segments are not intended to be learned by other areas.

With configuration commands, you can configure route filtering for the following items:

- Interface: The interface is prevented from sending any LSAs or exchanging any LSAs with neighbors.
- Routing information advertised between areas: Only the Type-3 LSA that meets the filtering conditions can be advertised to another area.
- Routing information outside an AS: Only the Type-5 and Type-7 LSAs that meet the filtering conditions can be redistributed to the OSPF process.
- LSAs received by a router: In the OSPF routing table, only the routes that are computed based on the LSAs meeting the filtering conditions can be advertised.

1.1.8 Enhanced Security and Reliability

1. Authentication

Authentication prevents routers that illegally access the network and hosts that forge OSPF packet from participating in the OSPF process. OSPF packets received on the OSPF interface or at both ends of the virtual link are authenticated. If authentication fails, the packets are discarded and no adjacency can be set up.

Enabling authentication can avoid learning unauthenticated or invalid routes, thus preventing advertising valid routes to unauthenticated devices. On the broadcast-type network, authentication also prevents unauthenticated devices from becoming designated devices, ensuring stability of the routing system and protecting the routing system against intrusions.

Authentication is classified into following two types:

- Area authentication: This area-level authentication authenticates the packets transmitted by all the interfaces in the area. This type is configured in OSPF routing process mode.
- Interface authentication: This neighbor-level authentication authenticates the packets transmitted on the related interface. This type is configured in interface mode.

2. MTU verification

Upon receiving a DD packet, OSPF checks whether the MTU of the neighbor interface is the same as that of the local interface. If the MTU of the interface specified in the received DD packet is greater than that of the interface that receives the packet, the adjacency cannot be set up. Disabling MTU verification can avoid this problem.

3. Source address verification

Generally, the source address of a packet received by OSPF is in the same network segment as the receiving interface. The addresses at both ends of a P2P link are configured separately and are not necessarily in the same network segment. In this scenario, as the peer address information will be notified during the P2P link negotiation process, OSPF checks whether the source address of the packet is the address advertised by the peer during negotiation. If not, OSPF determines that the packet is invalid and discards this packet. In particular, OSPF never verifies the address of an interface not configured with an IP address.

In some scenarios, the source address of a packet received by OSPF may not be in the same network segment as the receiving interface, so the OSPF address verification fails. For example, the negotiated peer address cannot be obtained on a P2P link. In this scenario, source address verification must be disabled to ensure that the OSPF adjacency can be properly set up.

4. Two-way maintenance

OSPF routers periodically send hello packets to each other to maintain the adjacency. On a large network, a lot of packets may be sent or received, occupying a great proportion of CPU and memory. As a result, some packets are delayed or discarded. If the processing time of hello packets exceeds the neighbor dead interval, the adjacency will be destroyed.

If the two-way maintenance function is enabled, in addition to the hello packets, the DD, LSU, LSR, and LSAck packets can also be used to maintain the bidirectional communication between neighbors, which makes the adjacency more stable.

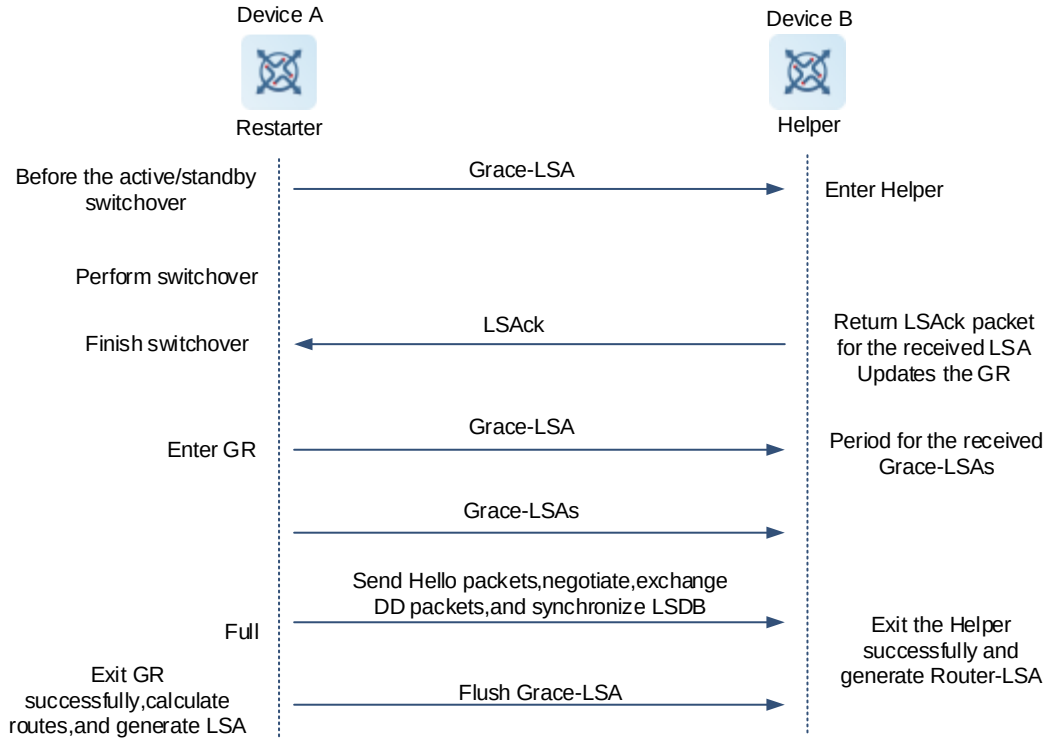
5. Concurrent neighbor interaction restriction

When a router simultaneously exchanges data with multiple neighbors, its performance may be affected. If the maximum number of neighbors that concurrently initiate or accept interaction with the OSPF process is restricted, the router can interact with neighbors by batches, which ensures data forwarding and other key services.

6. Overflow

OSPF requires that routers in the same area store the same LSDB. The number of routers keeps increasing on the network. Some routers, however, cannot store so much routing information due to the limited system resources. The large amount of routing information may exhaust the system resources of routers, causing failures of the routers.

The overflow function limits the number of external routes in the LSDB to control the size of the LSDB.



When the number of external routes on a router exceeds the upper limit, the router enters the overflow state. The router deletes the external routes generated by itself from the LSDB, and does not generate new external routes. In addition, the router discards the newly received external routes. After the overflow state timer (5s) expires, if the number of external routes is lower than the upper limit, the normal state is restored.

7. GR

The control and forwarding separated technology is widely used among routers. On a relatively stable network topology, when a GR-enabled router is restarted on the control plane, data forwarding can continue on the forwarding plane. In addition, actions (such as adjacency re-forming and route computation) performed on the control plane do not affect functions of the forwarding plane. In this way, service interruption caused by route flapping can be avoided, thus enhancing reliability of the entire network.

Currently, the GR function is used only during active/standby switchover and system upgrade.

Figure 1-9 Normal OSPF GR Process

- The GR process requires collaboration between the restarter and the helper. The restarter is the router where GR occurs. The helper is a neighbor of the restarter.
- When entering or exiting the GR process, the restarter sends a grace-LSA to the neighbor, notifying the neighbor to enter or exit the helper state.
- When the adjacency between the restarter and the helper reaches the full state, the router can exit the GR process successfully.

8. NSR

During nonstop routing (NSR), OSPF-related information is backed up from the active supervisor module of a distributed device to the standby supervisor module, or from the active host of a virtual switching unit (VSU) to the standby host. In this way, the device can automatically recover the link state and re-generate routes without the help of the neighbor devices during the active/standby switchover. The specific information of NSR active/standby synchronization includes configuration information backup, process information backup, interface information backup, neighbor information backup, and LSA information backup.

9. Fast convergence

When a link or a router on the OSPF network fails, the packets that need to be transmitted through the faulty link or the faulty router to reach the destination will be lost or cause a routing loop, and the data traffic will be interrupted. After a link fails, it takes a period of time (about 40s) before OSPF can sense the failure of the neighbor. Then, OSPF advertises the information and re-computes the SPT. During this period, traffic is interrupted. During this period, the traffic will be interrupted. The interrupted traffic cannot resume normal transmission until OSPF completes convergence according to the new topology network.

- To minimize the traffic interruption time caused by a network failure, the administrator can configure the fast hello function, correlation with BFD, or OSPF fast reroute function to speed up network convergence.
  - After the fast hello function is enabled (that is, the neighbor dead interval is set to 1s), OSPF can sense the failure of the neighbor within 1s once a link is faulty. This greatly accelerates route convergence and prevents traffic interruption.
  - BFD is used to test connectivity between devices. A link fault can be detected in as short as 150 ms. After OSPF is correlated with BFD, OSPF can sense the failure of a neighbor in as short as 150 ms once a link is faulty. This greatly accelerates route convergence and prevents traffic interruption.
  - Fast reroute prepares a backup route for OSPF. Once the OSPF senses the failure of a neighbor, the traffic is immediately switched over to the standby route, thus preventing traffic interruption.

10. iSPF feature

- The OSPF topology is area based. The SPF algorithm is run for independent computation in each area. The standard SPF algorithm re-computes the topology of the entire area each time even if only the leave nodes change in the area topology.
- When computing the network topology, the incremental shortest path first (iSPF) method corrects only the nodes on the SPT that are affected by the topology changes, and does not re-build the entire SPT. This can effectively ease the pressure on the router processors on a large network, especially when the network is not stable.

1.1.9 Network Management Functions

Functions such as management information base (MIB) and Syslog are used to facilitate OSPF management.

- MIB

  MIB is the device state information set maintained by a device. You can use the management program to view and set the MIB node.

Multiple OSPF processes can be simultaneously started on a router, but the OSPF MIB can be bound to only one OSPF process.

- Trap

  A trap message is a notification generated when the system detects a fault. This message contains the related fault information.

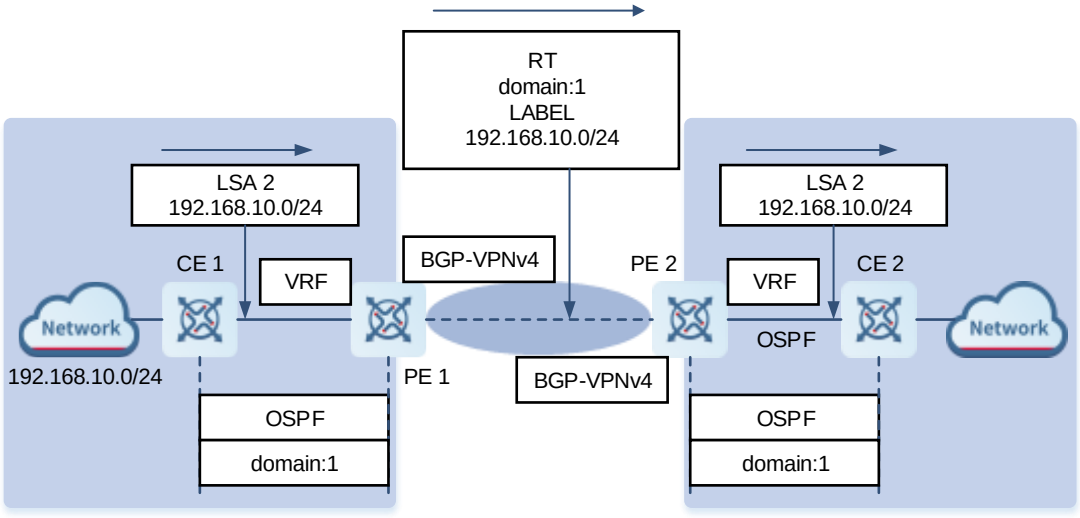
  If the trap function is enabled, the router can actively send the trap messages to the network management device.

- Syslog

  The syslog records the operations (such as command configuration) performed by users on routers and specific events (such as network connection failures).

  If the syslog is allowed to record the adjacency changes, the network administrator can view the logs to learn the entire process that the OSPF adjacency is set up and maintained.

1.1.10 VPN Extended Feature of OSPF



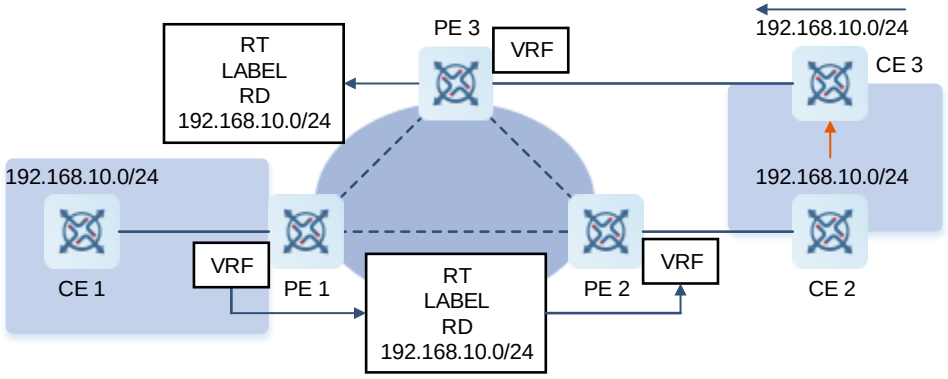
OSPF is a widely used IGP. In most of the existing application solutions, OSPF is generally selected as an internal routing protocol for VPN users. If OSPF is also used between provider edges (PE) and customer edge (CE), other routing protocols are not needed, which simplifies the configuration and management of CEs.

- Domain ID

  A domain ID identifies an OSPF domain to which a route belongs. When a CE learns an OSPF route in a VPN internal site, and this route is advertised to a PE as a Type-1/2/3 LSA, and is redistributed to the Border Gateway Protocol (BGP) domain and converted into a VPN route, the domain ID is also redistributed to the BGP domain along with the route. Then, this domain is also advertised as the extcommunity attribute of the VPN route. When another PE receives this VPN route and redistributes it to a VRF OSPF process, the domain ID is redistributed to the VRF OSPF process along with the route. If the VRF OSPF process confirms that the domain ID in the route is the same as that in the local VRF OSPF process, it advertises the route to the CE as an internal route. If the VRF OSPF process confirms that the domain ID in the route is different from that in the local VRF OSPF process, the VRF OSPF process advertises the route to the CE as an external route.

  As shown in Figure 1-10, for internal routes belonging to the same OSPF domain, CE1 advertises the routes to PE1 as Type-2 LSAs, which are converted into VPN routes and advertised to PE2. After receiving the routes, PE2 redistributes them to the VRF OSPF process. The domain IDs in the VRF OSPF process are the same as those of the VPN routes, and therefore, the VPN routes are advertised to the VPN site as internal routes.

Figure 1-10 Diagram of Domain ID



- DN bit technology

  DN bit is a bit in the optional field of the LSA header. The DN bit is a loop detection technology running the OSPF protocol between a PE and a CE. In some scenarios, loops may arise when OSPF runs between a PE and a CE, for example, multiple CEs are connected to one VPN site. If one PE advertises learned VPN routes to the VPN site, and the VPN site advertises the routes to another PE via OSPF, a loop may occur.

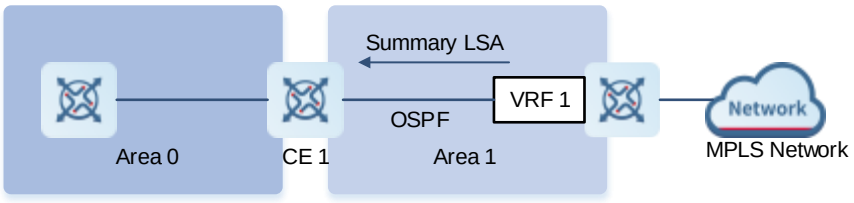
  As shown in Figure 1-11, PE1 advertises the 192.168.10.0/24 route to PE2 and PE3, CE2 advertises the route to CE3 via OSPF, and CE3 advertises the route to PE3, which redistributes the route to the BGP domain of PE3. PE3 selects the route that is redistributed via OSPF and converts this route into a VPNv4 route for advertisement. As a result, a loop may occur.

Figure 1-11 Diagram of DN Bit Technology

For the purpose of loop prevention, when a PE advertises a Type-3/5/7 LSA to a CE, the DN bit is set to ON in the optional field of the LSA, to prevent possible loops. When an LSA received by another PE contains the DN bit whose value is 1 in the optional field, the OSPF of the PE will not use this LSA for OSPF calculation.

- VPN router tag

  Router-tag is another loop detection technology running OSPF between a PE and a CE. When OSPF runs between a PE and a CE, the VRF OSPF process of the PE has a router tag by default, which is called VPN router tag. When a VPN route is imported into the VRF OSPF process of a PE and is converted into a Type-5/7 LSA and advertised to a CE, the LSA carries the VPN router-tag. When multiple PEs are connected to one VPN site, if the Type-5/7 LSA received by a PE contains the VPN router tag and the VPN router tag is the same as the VPN router tag of the OSPF process, the LSA will not be used for OSPF route calculation.



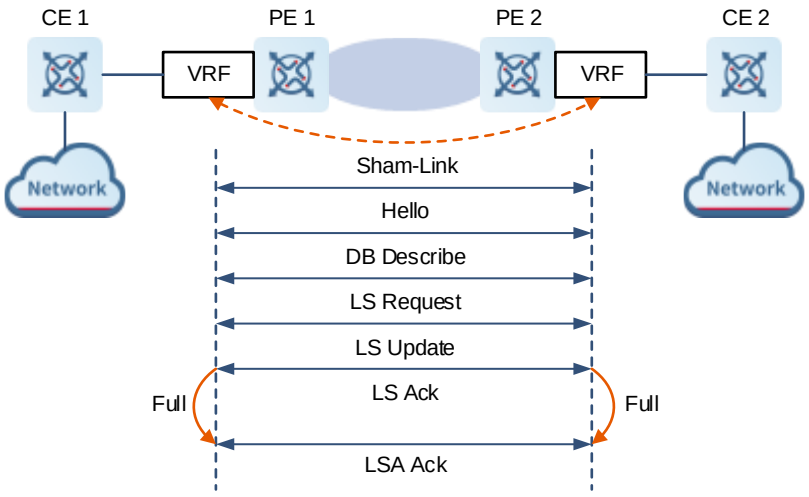
- Area deployment

  In normal cases, links between a PE and a CE may belong to any OSPF area. If links between a PE and a CE belong to a non-zero area, the PE is an ABR for the OSPF area where the CE resides. This may cause problems because the ABR running OSPF has the following features:

  - The ABR calculates Type-3 LSAs in the backbone area only.
  - The ABR forwards only Type-3 LSAs in the backbone area to a non-backbone area.

  As shown in Figure 1-12, if the link between a PE and a CE belongs to a non-zero area, the PE redistributes the VPNv4 routes advertised by Multiprotocol Extensions for BGP (MP-BGP) to the OSPF domain, restores them to type-3 LSAs, and advertises them to CE1. CE1 does not calculate LSAs in non-backbone areas. Therefore, these LSAs are not advertised to routers in Area 0 and the VPN internal sites cannot learn routes of other sites.

Figure 1-12 Diagram of Area Deployment



In L3VPN application, if OSPF is run between a PE and a CE to exchange VPN routes, do not deploy the backbone area at VPN internal sites if possible. If a router at a VPN internal site belongs to a backbone area in addition to a PE, at least one router at the VPN internal site must be connected to the PE and the links between the CE and PE must belong to Area 0. In this way, inter-area routes and external routes can be transmitted between the PE and the VPN site.

- Sham link

  The sham link is not a real link but a virtual link established between VRF OSPF instances of two PEs. Like a normal OSPF link, a sham link has its OSPF interfaces, and is capable of sending OSPF protocol packets, establishing neighbor relationships, and sending LSAs. When LSAs are flooded on a sham link, no types of the OSPF routes will change, as shown in Figure 1-13.

Figure 1-13 Diagram of Sham Link

The purposes of establishing sham-links between VRF OSPF processes of different PEs are as follows:

- When the Multiprotocol Interior Border Gateway Protocol (MP-IBGP) is used to carry private routes, it only transfers routes; after the routes reach the peer PE and restored, MP-IBGP imports the original OSPF routes in a best-effort manner, and the OSPF topology information cannot be communicated properly. With sham-link, an OSPF link can be established to implement actual interworking between OSPF processes at each site and establish a complete topology.
- Different sites in the same VPN exchange information via the MPLS backbone network. One link is connected between these VPN sites. The purpose of this link is that VPN sites can communicate with each other through this link when the MPLS backbone network is unavailable. This link is called backdoor link.

If two VPN sites belong to the same OSPF area and one backdoor link is connected in between, routes inside the two sites are exchanged through both the MPLS backbone network and the backdoor link. Routes exchanged through the MPLS backbone network are inter-domain routes while routes exchanged through the backdoor link are intra-domain routes. The intra-domain routes advertised by the backdoor link are prior to the inter-domain routes advertised by the MPLS backbone network. Therefore, the forwarding of the routes inside the two sites takes the backdoor link first, which is against the intention of backdoor link connection as a standby link for VPN users. In this case, a sham link is also required.

1.1.11 Protocols and Standards

- RFC 2328: OSPF Version 2
- RFC 2370: The OSPF Opaque LSA Option
- RFC 3137: OSPF Stub Router Advertisement
- RFC 3623: Graceful OSPF Restart
- RFC 3630: Traffic Engineering (TE) Extensions to OSPF Version 2
- RFC 3682: The Generalized TTL Security Mechanism (GTSM)

- RFC 3906: Calculating Interior Gateway Protocol (IGP) Routes Over Traffic Engineering Tunnels
- RFC 4576: Using a Link State Advertisement (LSA) Options Bit to Prevent Looping in BGP/MPLS IP Virtual Private Networks (VPNs)
- RFC 4577: OSPF as the Provider/Customer Edge Protocol for BGP/MPLS IP Virtual Private Networks (VPNs)
- RFC 4750: OSPF Version 2 Management Information Base

1.2 Configuration Task Summary

The OSPFv2 configuration includes the following tasks:

(1) Configuring Basic Features

- Configuring OSPF Process
- (Optional) Configuring Router ID
- Enabling OSPF on a Network Segment
- Enabling OSPF on an Interface
- (Optional) Creating a Virtual Link

(2) (Optional) Configuring OSPF Network Type

- Configuring the Interface Network Type
- (Optional) Configuring a Neighbor
- (Optional) Configuring the Interface Priority
- (Optional) Disabling Source Address Verification

(3) (Optional) Configuring Stub and NSSAs. The following tasks are optional. Select tasks for configuration according to actual condition.

- Configuring a Stub Area
- Configuring an NSSA

(4) (Optional) Adjusting OSPF Routing The following tasks are optional. Select tasks for configuration according to actual condition.

- Configuring the AD
- Configuring the Reference Bandwidth
- Configuring the Cost of an Interface
- Configuring Cost Fallback Value for an AP
- Configuring the Cost of the Default Route in a Stub Area or an NSSA
- Configuring the Default Metric Value for Redistribution Value
- Configuring the Maximum Metric
- Configuring RFC 1583 Compatibility
- Configuring Association of External Route Forwarding Addresses with Interface Configuration

(5) (Optional)Configuring OSPF Route Advertisement

- Configuring External Route Redistribution
-
- (Optional) Configuring a Device as ASBR

(6) (Optional)Configuring OSPF Route Summarization. The following tasks are optional. Select tasks for configuration according to actual condition.

- Configuring Inter-Area Route Summarization
- Configuring External Route Summarization
- Configuring a Discard Route

(7) (Optional)Configuring OSPF Route Filtering. The following tasks are optional. Select tasks for configuration according to actual condition.

- Configuring a Passive Interface
- Disabling Interfaces from Sending OSPF Packets
- Configuring Inter-area Route Filtering
- Configuring Redistributed Route Filtering
- Configuring Learned Route Filtering

(8) (Optional)Adjusting OSPF Network Convergence Speed. The following tasks are optional. Select tasks for configuration according to actual condition.

- Configuring the Hello Interval
- Configuring the Dead Interval
- Configuring LSU Transmission Delay
- Configuring LSU Retransmission Interval
- Configuring LSU Generation Time
- Configuring LSA Group Refresh Time
- Configuring LSA Group Refresh Interval
- Configuring Duplicate LSA Receiving Delay
- Configuring Inter-Area Route Computation Delay
- Configuring External Route Computation Delay
- Configuring SPF Computation Delay
- Configuring Route Calculation Suppression Time

(9) (Optional)Configuring OSPF Authentication

- Configuring the Authentication Type of an Area
- Configuring the Authentication Type of an Interface
- (Optional) Configuring a Plain Text Authentication Key for an Interface

- (Optional) Configuring an MD5 Authentication Key for an Interface

(10) (Optional)Enabling Fast Reroute

- Configuring Fast Reroute
- (Optional)Configuring Interface LFA Protection
- (Optional)Preventing an Interface From Becoming a Backup Interface

(11) (Optional)Modifying the Maximum Number of Concurrent Neighbors. The following tasks are optional. Select tasks for configuration according to actual condition.

- Configuring the Maximum Number of Concurrent Neighbors on the Current Process
- Configuring the Maximum Number of Concurrent Neighbors on All Processes

(12) (Optional)Configuring the GR Function. The following tasks are optional. Select tasks for configuration according to actual condition.

- Enabling the GR Function
- Configuring the OSPF GR Helper Function

(13) (Optional)Correlating OSPF with BFD. The following tasks are optional. Select tasks for configuration according to actual condition.

- Configuring BFD Correlation with OSPF on an Interface
- Configuring BFD Correlation with OSPF Globally

(14) (Optional)Enabling Overflow. The following tasks are optional. Select tasks for configuration according to actual condition.

- Configuring the Memory Overflow Function
- Configuring the Database Overflow Function
- Configuring the External LSA Database Overflow Function

(15) (Optional) Configuring VPN Extended Feature of OSPF. The following tasks are optional. Select tasks for configuration according to actual condition.

- Configuring Domain ID
- Configuring a Sham Link
- Configuring a Domain Label
- Disabling Loop Detection for a VRF OSPF Process
- Configuring Extcommunity Attribute for a VPN Route
- Disabling Loop Detection Using the DN Bit of LSA
- Disabling Loop Detection Using the Route Tag of LSA

(16) (Optional)Configuring Network Management Functions. The following tasks are optional. Select tasks for configuration according to actual condition.

- Binding the MIB with an OSPF Process
- Configuring the Trap Function

- Configuring the Logging Function

(17) (Optional)Enabling NSR

(18) (Optional)Enabling the iSPF Feature

(19) (Optional)Configuring to Disable MTU Verification

(20) (Optional)Configuring to Enable Conflict Detection of Type-4 LSAs

(21) (Optional)Enabling the Function of Securely Promoting a BDR to DR

1.3 Configuring Basic Features

1.3.1 Overview

Set up an OSPF routing domain on the network to provide IPv4 unicast routing service for users on the network.

1.3.2 Restrictions and Guidelines

- Ensure that the IP unitcast routing function is enabled, that is, **ip routing** is not disabled; otherwise, OSPF cannot be enabled.
- When OSPF is enabled, you are strongly advised to manually configure the router ID.
- After **ip ospf disable all** is configured, the interface neither sends or receives any OSPF packet, nor participates in OSPF computation even if the interface belongs to the advertisement range of the **network-advertise** command.

1.3.3 Configuration Tasks

The basic function configuration of OSPF includes the following tasks:

(1) Configuring OSPF Process

(2) (Optional) Configuring Router ID

(3) Enabling OSPF on a Network Segment

(4) Enabling OSPF on an Interface

(5) (Optional) Creating a Virtual Link

1.3.4 Configuring OSPF Process

1. Overview

To enable OSPF on the device, the OSPF process must be created by specifying the process ID.

2. Restrictions and Guidelines

- OSPF supports multiple instances. One or more OSPF processes can be started on a router. Each OSPF process runs OSPF independently, and the processes are mutually isolated.

- The process ID takes effect only on the local router, and does not affect exchange of OSPF packets on adjacent interfaces.
- This configuration must be performed on every router that requires OSPF.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an OSPF process and enter OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

1.3.5 Configuring Router ID

1. Overview

Router ID is the unique identifier of a router in the OSPF domain, so the router ID must be unique on the entire network; otherwise it will lead to problems such as abnormality in neighbor relationship establishment and routing information error. Moreover, different OSPF processes in the same router need to use different router IDs.

2. Restrictions and Guidelines

- You are strongly advised to manually configure the router ID.
- Different OSPF processes on the same router must have different Router IDs.
- When a router ID is not manually configured, OSPF automatically selects an interface IP address. If no IP address is configured for any interface, or the configured IP addresses have been used by other OSPF processes, you must manually configure the router ID.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure a router ID.

router-id *router-id*

By default, the OSPF routing process elects the largest IP address among all the loopback interfaces as the router ID. If the loopback interfaces configured with IP addresses are not available, the OSPF process elects the largest one among the IP addresses of all its physical interfaces as the router ID.

1.3.6 Enabling OSPF on a Network Segment

1. Overview

To realize interaction of OSPF routing information between devices, interfaces of the devices must be added to the OSPF process. Through enabling OSPF on a network segment, all interfaces whose IP addresses fall within the range of the network segment join the OSPF process, and are associated with the area.

2. Restrictions and Guidelines

- All routers running OSPF must be configured to join interfaces into the OSPF process.
- When an interface IP address matches the IP address range defined by the **network-advertise area** command of multiple OSPF processes at the same time, the OSPF process that the interface joins will be determined by the optimal matching method.
- If the IP address range defined by the **network-advertise area** command only includes the secondary IP address of the interface, OSPF will not run on the interface.

When both the network-advertise area command in the OSPF process configuration mode, and the ip ospf set-area command in the interface configuration mode are configured, the latter will prevail.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Enable OSPF on the network segment, and specify an Area ID.

network-advertise *ipv4-address wildcard* **area** *area-id*

No interface IP address is configured to join the OSPF area by default.

1.3.7 Enabling OSPF on an Interface

1. Overview

To realize interaction of OSPF routing information between devices, interfaces of the devices must be added to the OSPF process. By enabling OSPF on the specified interface, all IP addresses under the interface will automatically join the OSPF process, and be associated with the area.

2. Restrictions and Guidelines

- The configuration is mandatory for each OSPF-enabled router.
- You can also add an interface to OSPF process using the **network-advertise** command on the instance. If two commands are run at the same time, the configuration on the interface takes effect first.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Enable OSPF on an interface and specify an area ID.

ip ospf *process-id* **set-area** *area-id*

OSPF is disabled on an interface by default.

(5) Allow the interface to generate OSPF packets.

unset ip ospf disable filter

By default, an interface is allowed to generate OSPF packets.

1.3.8 Creating a Virtual Link

1. Overview

In the OSPF routing domain, all the areas must be connected to the backbone area. If the backbone area is disconnected, a virtual link must be configured to connect to the backbone area; otherwise, network communication problems will occur. A virtual link must be created between two ABRs, and the area to which both ABRs belong is the transit area. A stub area or an NSSA cannot be used as a transit area. A virtual link can also be used to connect other non-backbone areas.

2. Restrictions and Guidelines

- Only the authentication key of the virtual link is defined in a virtual link. To enable OSPF packet authentication in the areas connected to the virtual link, run the **area auth-algorithm** command to enable the authentication.
- The virtual link supports the fast hello function.
  - If the fast hello function is configured for a virtual link, the hello interval field of the hello packet advertised on the virtual link is set to 0, and the hello interval field of the hello packet received on this virtual link is ignored.
  - No matter whether the fast hello function is enabled, the neighbor dead interval must be always consistent on the devices at both ends of the virtual link.
  - The **dead-period**, **minimum hello-multiplier**, and **hello-period** parameters introduced for the fast hello function cannot be configured simultaneously.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure a virtual link.

area *area-id* **vlink** *router-id* [**auth-algorithm** [**keychain** *kechain-name* | **auth-secret** | **null**] | **dead-period** { *dead-interval* | **minimum hello-multiplier** *multiplier-time* } | **hello-period** *hello-interval* | **retransmit-period** *retransmit-interval* | **transmit-lsu-delay** *transmit-delay*] * [**auth-algorithm-key** [**0** | **7**] *key* | **auth-secret-key** *key-id* **md5** [**0** | **7**] *key*]

No virtual link is configured by default.

1.4 Configuring OSPF Network Type

1.4.1 Overview

If the physical network is X.25, frame relay, or ATM, set an OSPF network type so that the network can also run OSPF and provide IPv4 unicast routing service.

OSPF classifies networks into five types according to the link layer protocol type so that LSAs are exchanged in different ways to set up an adjacency. You can configure to forcibly change the network type of an interface.

1.4.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- The network types must be consistent for the devices at both ends of the link. Otherwise, the neighbor relationship cannot be set up.
- The broadcast network sends multicast OSPF packets, automatically discovers neighbors, and elects a DR and a BDR.
- The P2P network sends multicast OSPF packets and automatically discovers neighbors.
- The NBMA network sends unicast OSPF packets. Neighbors must be manually specified, and a DR and a BDR must be elected.
- The P2MP network (without carrying the **non-broadcast** parameter) sends multicast OSPF packets. Neighbors are automatically discovered.
- The P2MP network (carrying the **non-broadcast** parameter) sends unicast OSPF packets. Neighbors must be manually specified.

1.4.3 Configuration Tasks

The OSPF network type configuration includes the following tasks:

(1) Configuring the Interface Network Type

(2) (Optional) Configuring a Neighbor

(3) (Optional) Configuring the Interface Priority

(4) (Optional) Disabling Source Address Verification

1.4.4 Configuring the Interface Network Type

1. Overview

There are five OSPF network types. By default, Ethernet and FDDI belong to the broadcast type, X.25, frame relay, and ATM belong to the NBMA type, and PPP, HDLC, and LAPB belong to the P2P type. This configuration allows you to forcibly modify the network type of the interface.

2. Restrictions and Guidelines

- The configuration is required on routers at both ends of the link.
- The broadcast type requires that the interface must have the broadcast capability.
- The P2P type requires that the interfaces are interconnected in one-to-one manner.
- The NBMA type requires full-meshed connections, and all interconnected routers can directly communicate with each other.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure a network type for the interface.

ip ospf= network-type { **broadcast** | **non-broadcast** | **point-to-multipoint** [**non-broadcast**] | **point-to-point** }

By default, the network interface of OSPF is not configured, and no interface is set to P2MP type.

1.4.5 Configuring a Neighbor

1. Overview

On the NBMA network, routers cannot send or receive broadcast packets, and cannot discover neighbors through hello packets. You need to specify neighbors manually and send unicast hello packets.

If a neighbor router becomes inactive on the NBMA network, OSPF still sends hello packets to this neighbor even if no hello packet is received within the router failure time. The interval at which the hello packet is sent is called polling interval. When running for the first time, OSPF sends hello packets only to neighbors whose priorities are not 0. In this way, neighbors with priorities set to 0 do not participate in the DR/BDR election. After a DR/BDR is elected, the DR/BDR sends the hello packets to all neighbors to set up a neighbor relationship.

2. Restrictions and Guidelines

- If the network type of an interface is set to NBMA or P2MP (carrying the **non-broadcast** parameter), neighbors must be configured.
- Neighbors are configured on routers at both ends of the NBMA or P2MP (carrying the **non-broadcast** parameter) network.
- The neighbor IP address must be the primary IP address of this neighbor interface.
- The P2MP (non-broadcast) network cannot dynamically discover neighbors because it does not have the broadcast capability. Therefore, you must run this command to manually configure neighbors for the P2MP (non-broadcast) network.
- You can use the **advertise-metric** parameter to specify the cost to reach each neighbor on the P2MP network.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf= *process-id* [**vrf-instance** *vrf-name*]

(4) Configure a neighbor.

peer *ipv4-address* [**metric** *cost* | [**poll-interval** *poll-interval* | **priority-value** *priority*] *]

No neighbor is configured by default. Neighbors must be specified for the NBMA or P2MP (non-broadcast) interfaces. The neighbor IP address must be the primary IP address of this neighbor interface. In addition, you can use the **metric** parameter to specify the cost to reach each neighbor on the P2MP network.

1.4.6 Configuring the Interface Priority

1. Overview

When the DR/BDR election occurs on the OSPF broadcast network, the router with the highest priority becomes the DR or BDR. If the priorities are the same, the router with the largest router ID becomes the DR or BDR. A router with the priority set to 0 does not participate in the DR/BDR election. The priority value of an OSPF interface is contained in the hello packet.

2. Restrictions and Guidelines

- This command is applicable only to the OSPF broadcast and NBMA interfaces.
- You must configure the interface priority if a router must be specified as a DR, or a router cannot be specified as a DR.
- Configure the interface priority on a router that must be specified as a DR, or cannot be specified as a DR.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.

- **interface overlayrouter** *interface-number*

(4) Configure the interface priority.

ip ospf priority-value *priority*

The priority value is 1 by default.

1.4.7 Disabling Source Address Verification

1. Overview

Generally, the source address of a packet received by OSPF is in the same network segment as the receiving interface. The addresses at both ends of a P2P link are configured separately and are not necessarily in the same network segment. In this scenario, as the peer address information is notified during the P2P link negotiation, OSPF checks whether the source address of the packet is the address advertised by the peer end during negotiation. If not, OSPF determines that the packet is invalid and discards it. Besides, OSPF does not verify the address of an unnumbered interface.

In some scenarios, the source address of a packet received by OSPF may not be in the same network segment as the receiving interface, so the OSPF address verification fails. For example, the negotiated peer address cannot be obtained on a P2P link. In this scenario, source address verification must be disabled to ensure that the OSPF adjacency can be properly set up.

2. Restrictions and Guidelines

- The OSPF basic functions must be configured.
- Source address verification cannot be disabled on a broadcast or NBMA network.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*

- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Disable source address verification.

ip ospf source-check-ignore

The source address verification on a P2P link is enabled by default.

1.5 Configuring Stub and NSSAs

1.5.1 Overview

Configuring a stub area as the Stub area or NSSA helps to reduce the number of LSAs in the area, reduce the amount of routing information interaction, reduce the size of the routing table, and enhance routing stability.

1.5.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- A backbone area and transmission area cannot be configured as a Stub area or NSSA.
- Routers in the Stub area cannot import external routes, while routers in the NSSA can import external routes.

1.5.3 Configuration Tasks

The configuration includes the following tasks, which are optional. Select tasks for configuration according to actual condition.

- Configuring a Stub Area
- Configuring an NSSA

1.5.4 Configuring a Stub Area

1. Overview

Stub area is the stub area of OSPF. Configuring a Stub Area can reduce the number of LSAs in the area. The ABR router in the Stub area will not transmit Type 5 LSAs (external routes), but will also advertise a Type 3 default route to the Stub area.

Totally Stub area is a totally stub area, which is an upgrade of the Stub area. Routers in the Totally Stub area will not transmit Type 3 LSAs (inter-domain routes) and Type 5 LSAs (external routes). The ABR will only advertise a Type 3 default route to the Totally Stub area.

To reduce the size of the routing table of the routers in the area, you can configure a Stub area or Totally Stub area.

2. Restrictions and Guidelines

- The area must be configured as Stub area on all routers in the area.
- To configure a Totally Stub area, you only need to select the **unset-summary** keyword when running the **area stub** command on the ABR. The routing devices in the Totally Stub area can only learn the routes in the area and the internal default routes generated by the ABR.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configuring a Stub Area.

area *area-id* **stub** [**unset-summary**]

By default, the Stub area function is disabled.

1.5.5 Configuring an NSSA

1. Overview

NSSA is similar to the Stub area, but allows ASBR. ASBR redistributed routes will be transmitted in the NSSA in the form of a Type 7 LSA. On the ABR, the Type 7 LSA is converted to Type 5 LSA and then transmitted to other areas. This ABR is also called the translator. The ABR will also advertise the default route to the NSSA.

Totally NSSA area is an upgrade of NSSA. Compared with routers in the NSSA, routers in the Totally NSSA can only advertise a default inter-domain route, and other Type 3 LSAs (inter-domain routes) are not allowed to be transmitted.

You are advised to configure NSSA or Totally NSSA if you want to reduce the size of the routing table of routers in the area and the number of LSAs in the area, and to import OSPF routes outside the area.

2. Restrictions and Guidelines

- The area must be configured as NSSA on all routers in the area.
- When the **default-originate** parameter is executed on the ABR of the NSSA, the Type 7 LSA default route will be generated regardless of whether there is a default route in the route table. When this parameter is executed

on the ASBR (also not an ABR) of the NSSA, the Type 7 LSA default route will be generated only if there is a default route in the route table.

- Configuring a Totally NSSA area can further reduce the number of LSAs sent to the NSSA. If the **unset-summary** attribute is configured on the ABR, the ABR will be prevented from sending summary LSAs (Type 3 LSAs) to the NSSA.
- In one NSSA, you are advised to specify only one ABR as the translator.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configuring an NSSA.

area *area-id* **nssa** [**default-originate** [**metric-value** *metric* | **metric-class** *metric-type*] * | **unset-redistribute** | **unset-summary** | **translator** { **constantly** | **stability-interval** *stability-interval* } * | **zero-address-forwarding**] *

By default, the NSSA function is disabled.

1.6 Adjusting OSPF Routing

1.6.1 Overview

Configuring routing parameters such as administrative distance, reference bandwidth, and interface cost, can change the order in which routers select various routes to increase or decrease the priority of OSPF routes, and change OSPF routes to allow traffic to pass through or bypass certain nodes.

1.6.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- If you run the **ip ospf metric** command to configure the cost of an interface, the configured cost will automatically overwrite the cost that is computed based on the auto cost.

1.6.3 Configuration Tasks

The configuration for adjusting OSPF routing includes the following tasks, which are optional. Select tasks for configuration according to actual condition.

- Configuring the AD
- Configuring the Reference Bandwidth

- Configuring the Cost of an Interface
- Configuring Cost Fallback Value for an AP
- Configuring the Cost of the Default Route in a Stub Area or an NSSA
- Configuring the Default Metric Value for Redistribution value
- Configuring the Maximum Metric
- Configuring RFC 1583 Compatibility
- Configuring Association of External Route Forwarding Addresses with Interface Configuration

1.6.4 Configuring the AD

1. Overview

AD is used to select the best path when multiple routing protocols are used to reach the same target. AD defines the reliability of routing protocol. A smaller AD indicates higher reliability and higher routing priority. The default AD values of OSPF intra-domain routes, inter-domain routes, and external routes are all 110. Different ADs can be set to control routing.

2. Restrictions and Guidelines

- Perform this configuration if you hope to change the priorities of OSPF routes on a router that runs multiple unicast routing protocols.
- Run this command to specify different ADs for different types of OSPF routes.
- Configure the **route-map** parameter and set an AD for the specific route through a policy. If the route map is configured with **set-rule distance**, then:
  - Through the matched route: the AD is set by the **set-rule distance** command.
  - Not through the matched route: the AD is set by the **distance** command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure an AD.

distance { *distance* [**route-map** *map-name*] | **ospf** { **external-routes** *distance* [**route-map** *map-name*] | **inter-area-routes** *distance* [**route-map** *map-name*] | **intra-area** *distance* [**route-map** *map-name*] } * }

By default, the administrative distance is **110** for all the OSPF routes.

1.6.5 Configuring the Reference Bandwidth

1. Overview

The default value of OSPF reference bandwidth is 100 Mbps, and the cost is the reference bandwidth divided by interface bandwidth. In the Gigabit and 10 Gigabit network environments, the calculated cost value is 1, so the default bandwidth value cannot adapt to the current high-speed transport network. A router is connected to lines with different bandwidths. You are advised to adjust the configuration according to the actual bandwidth if you want to preferentially select the line with a larger bandwidth.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the reference bandwidth.

auto-gen-cost reference-bandwidth *reference-bandwidth*

By default, the reference bandwidth value of interface metric calculation is 100 Mbps.

1.6.6 Configuring the Cost of an Interface

1. Overview

Modifying the interface cost of OSPF can optimize routing. A lower cost of the link indicates a higher priority during routing.

2. Restrictions and Guidelines

- By default, the cost of an OSPF interface is equal to the reference value of the auto cost divided by the interface bandwidth.
- A router is connected with multiple lines. You are advised to configure a lower cost for a specific interface if you wish to manually specify a preferential line.
- Run the **auto-gen-cost** command to obtain the reference value of the auto cost. The default value is 100 Mbps.
- Run the **bandwidth** command to set the interface bandwidth.
- The default costs of OSPF interfaces on several typical lines are as follows:
  - 64 Kbps serial line: The cost is 1562.
  - E1 line: The cost is 48.
  - 10M Ethernet: The cost is 10.

- 100M Ethernet: The cost is 1.

- If you run the **ip ospf metric** command to configure the cost of an interface, the configured cost will automatically overwrite the cost that is computed based on the auto cost.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure the cost of an interface.

ip ospf metric *cost*

By default, the cost of an OSPF interface is equal to the reference value of the auto cost divided by the interface bandwidth (the reference bandwidth is 100 Mbps by default).

1.6.7 Configuring Cost Fallback Value for an AP

1. Overview

The bandwidth of an AP is equal to the sum of the bandwidths of all the valid member ports. When a member port fails, the bandwidth of the AP will be reduced. You can set a cost fallback value for the AP to enable OSPF to select other paths preferably. When the failed member port of the AP recovers, the cost fallback value becomes invalid, and the metric of the AP returns to normal.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

(4) Configure the cost fallback value for an AP.

ip ospf cost-fallback *cost* **threshold** *bandwidth*

The cost fallback function is disabled on an AP by default.

1.6.8 Configuring the Cost of the Default Route in a Stub Area or an NSSA

1. Overview

After an area is set to a stub area/NSSA, ABR will advertise the default route to the stub area/NSSA, ensuring that the routes from the stub area/NSSA to other areas are reachable. The default cost of a default route is 1. This function can adjust the cost of the default route and flexibly control the routes of the stub area and NSSA.

2. Restrictions and Guidelines

This command takes effect only on an ABR in a stub area or on an ABR/ASBR in an NSSA.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the cost of the default route in a stub area or an NSSA.

area *area-id* **default-metric** *cost*

By default, the cost of a route is 1.

1.6.9 Configuring the Default Metric Value for Redistribution

1. Overview

When redistributing external routes, you can configure the costs of external routes to adjust routing flexibly.

2. Restrictions and Guidelines

- This configuration is mandatory if the cost of external routes of the OSPF domain should be specified when external routes are introduced to an ASBR.
- The **default-metric** command must be used together with the **redistribute-route** command in routing process configuration mode to modify the initial metrics of all redistributed routes.
- The **default-metric** command does not take effect on external routes that are injected to the OSPF routing domain using the **default-info originate** command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the default metric for redistribution.

default-metric *metric*

By default, the metric of a redistributed route is 20.

1.6.10 Configuring the Maximum Metric

1. Overview

In the scenarios of restarting a device and using a device as a candidate path, the OSPF information advertised by the current device can be configured with the maximum metric value so that the data traffic will not pass through the current device.

2. Restrictions and Guidelines

- A router may be unstable in the restart process or a period of time after the router is restarted, and users do not want to forward data traffic through this router. In this case, this configuration is recommended.
- After the **max-advertise-metric router-lsa** command is configured, the metrics of the non-stub links in the router LSAs generated by the router will be set to the maximum value (0xFFFF). If you cancel this configuration or the timer expires, the normal metrics of the links are restored.
- The **ip ospf max-advertise-metric neighborup** *seconds* command in interface configuration mode has the same function as the **max-advertise-metric router-lsa neighbor** command configured on an instance except the following: In interface configuration mode, the configuration takes effect from the interface's first neighbor in full neighbor relationship; in instance configuration mode, the configuration takes effect from the first neighbor in full neighbor relationship of the entire instance.
- By default, if the **max-metric router-lsa** command is configured, the stub links still advertise common metrics, that is, the costs of outbound interfaces. If the **include-stub-links** parameter is configured, the stub links will advertise the maximum metric.
- If an ABR is not intended to transfer inter-area traffic, use the **summary-lsa-metric** parameter to set the metric of the summary LSA to the maximum value.
- If an ASBR does not wish to transfer external traffic, use the **external-lsa** parameter to set the metric of the external LSA to the maximum value.
- The **maxadvertise-metric router-lsa** command is generally used in the following scenarios:
  - Restart a device. After the device is restarted, IGP generally converges faster, and other devices attempt to forward traffic through the restarted device. If the current device is still building the BGP routing table and some BGP routes are not learned yet, packets sent to these networks are discarded. In this case, you can use the **startup** parameter to set a delay after which the restarted device acts as the transmission mode.
  - Add a device to the network but the device is not used to transfer traffic. The device is added to the network. If a candidate path exists, the current device is not used to transfer traffic. If a candidate path does not exist, the current device is still used to transfer traffic.
  - Delete a device gracefully from the network. After the **max-metric router-lsa** command is configured, the current device advertises the maximum metric among all the routes. In this way, other devices on the network can select the backup path for data transmission before the device is shut down.
  - In the earlier OSPF version (RFC1247 or earlier), the links with the maximum metric (0xFFFF) in the LSAs do not participate in the SPF computation, that is, no traffic is sent to routers that generate these LSAs.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the maximum metric.

max-advertise-metric router-lsa [**external-lsa** [*max-metric-value*] | **neighborup** [*full-interval-time*] | **include-stub-links** | **startup** [*startup-interval-time*] | **summary-lsa-metric**

By default, the LSAs of normal metric are advertised.

1.6.11 Configuring RFC 1583 Compatibility

1. Overview

When there are multiple paths to an ASBR or the forwarding address of an external route, RFC 1583 and RFC 2328 define different routing rules. If RFC 1583 compatibility is configured, a path in the backbone area or an inter-area path is preferentially selected. If RFC 1583 compatibility is not configured, a path in a non-backbone area is preferentially selected.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure compatible RFC 1583.

reference rfc1583

The RFC1583 rule function is enabled by default.

1.6.12 Configuring Association of External Route Forwarding Addresses with Interface Configuration

1. Overview

Setting the forwarding address (FA) of relevant flag bit can associate the interface configuration with the external route forwarding address to calculate the reachability and metric.

2. Restrictions and Guidelines

- In the case of interconnection with a Cisco device, the FA configuration compatible with the Cisco device must be enabled.
- When the FA of an external route is 0, external route computation of OSPF will compute the reachability and metric to the advertiser. When the FA is not 0, the reachability and metric to the forwarding address will be

computed.

- When the following conditions are met simultaneously in default configuration, the ASBR of OSPF fills the forwarding address field of the external route with digits other than 0:
  - OSPF is enabled on the next hop interface for connecting the ASBR to external network.
  - The next hop interface for connecting the ASBR to the external network is in the network scope advertised in the OSPF protocol.
- When the following conditions are met simultaneously after association of forwarding address rules with interface configuration is configured, the ASBR of OSPF fills the forwarding address field of the external route with digits other than 0:
  - OSPF is enabled on the next hop interface for connecting the ASBR to external network.
  - The next hop interface for connecting the ASBR to the external network is in the network scope advertised in the OSPF protocol.
  - The next hop interface for connecting the ASBR to the external network is not configured as a passive interface.
  - The next hop interface for connecting the ASBR to the external network is not P2P or P2MP type of OSPF.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf- *process-id* [**vrf-instance** *vrf-name*]

(4) Configure association of external route forwarding addresses with interface configuration.

reference forward-address

By default, the external route forwarding address is set according to the default rules.

1.7 Configuring OSPF Route Advertisement

1.7.1 Overview

The function aims to introduce unicast routes for other AS domains or default routes to other AS domains to the OSPF domain and provide the unicast routing service to other AS domains for users in the OSPF domain. The router that introduces routes will automatically become an ASBR.

OSPF has two types of external routes. The metric of the Type-1 external route changes, but the metric of the Type-2 external route is fixed. If two parallel paths to the same destination network have the same route metric, the

priority of Type-1 route is higher than that of Type-2 route. Therefore, the display ip route-config command displays only the Type-1 route.

1.7.2 Restrictions and Guidelines

The OSPF basic functions must be configured.

1.7.3 Configuration Tasks

The configuration of OSPF route advertisement includes the following tasks:

(1) Configuring External Route Redistribution

(2) Configuring VRF-based External Route Redistribution

(3) (Optional) Configuring a Device as ASBR

1.7.4 Configuring External Route Redistribution

1. Overview

Configure external route redistribution if external routes of the OSPF domain need to be introduced to an ASBR.

2. Restrictions and Guidelines

- Perform this configuration on an ASBR.
- After this command is configured, the router becomes an ASBR, imports related routing information to the OSPF domain, and advertises the routing information as Type-5 LSAs to other OSPF routers in the domain.
- If the **level** parameter is not carried when IS-IS route redistribution is configured, only Level-2 routes can be redistributed by default. The **level** parameter is carried during initial configuration of redistribution, the routes configured with the **level** parameter can be redistributed. If both **level 1** and **level 2** are configured, the two levels are combined and saved as **level-1-2**.
- If you configure redistribution of OSPF routes without specifying the **match** parameter, OSPF routes of all sub-types can be distributed by default. The latest setting of the **match** parameter is used as the initial **match-rule** parameter. Only routes that match the sub-types can be redistributed. You can run the **unset** form of the command to restore the default value of **match-rule**.
- If **route-map** is specified, the **match-rule** filtering rules specified in **route-map** are applicable to the original parameters of redistribution. For redistribution of OSPF or IS-IS routes, **route-map** is used for filtering only when the redistributed routes meet the criteria specified by **match-rule** or **level**.
- The **set metric-value** value range of the associated **route-map** is from 0 to 16777214. If the value exceeds this range, routes cannot be introduced.
- The configuration rules for the **unset** form of the **redistribute-route** command are as follows:
  - If some parameters are specified in the **unset** form of this command, default values of these parameters will be restored.
  - If no parameter is specified in the **unset** form of this command, the entire command will be deleted.

- For example, if **redistribute-route isis 112 level-2** is configured, you can run the **unset redistribute-route isis 112 level-2** command to restore the default value of level-2. As **level-2** itself is the default value of the parameter, the configuration saved is still **redistribute-route isis 112 level-2** after the preceding **unset** form of the command is executed. To delete the entire command, run the **unset redistribute-route isis 112** command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure external route redistribution.

redistribute-route { **arp**-**host** | **bgp** | **connected** | **isis** [*area-tag*] [**level-1** | **level-1-2** | **level-2**] | **ospf** *process-id* [**match-rule** { **externa**l [**1** | **2**] | **internal-type** | **nssa-external-route** [**1** | **2**] }] | **rip** | **static** } [**metric-value** *metric-value* | **metric-class** { **1** | **2** } | **route-map** *route-map-name* | **subnets** | **tag-value** *tag-value*]

The route redistribution function is not configured by default.

1.7.5 Configuring VRF-based External Route Redistribution

1. Overview

Configure VRF-based external route redistribution if external routes of the OSPF domain need to be introduced to an ASBR.

2. Restrictions and Guidelines

- Perform this configuration on an ASBR.
- After this command is configured, the router becomes an ASBR, imports related routing information into the OSPF domain, and advertises routing information as Type-5 LSAs to other OSPF routers in the domain. When this function is configured together with the **redistribute-route** command configured on an instance, the parameter configuration of the instance is used for LSA generation.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure VRF-based external route redistribution.

router-protocol ospf redistribute-route { **bgp** | **connected** | **Isis** | **ospf** | **rip** | **static** } [**vrf-instance** *vrf-name*] [**route-map** *route-map-name*]

VRF-based route redistribution is not configured by default.

1.7.6 Generating a Default Route

1. Overview

A default route needs to be introduced to an ASBR so that other routers in the OSPF domain access other AS domains through this ASBR by default.

2. Restrictions and Guidelines

- When the **redistribute-route** or **default-info** command is executed, the OSPF router automatically becomes an ASBR. The ASBR, however, does not automatically generate or advertise a default route to all routers in the OSPF routing domain. To enable an ASBR to generate a default route, configure the **default-info originate** command.
- The metric of the external default route can only be defined in the **default-info originate** command, instead of the **default-metric** command.
- A router in a stub area cannot generate an external default route.
- The **set metric-value** value range of the associated **route-map** is from 0 to 16777214. If the value exceeds this range, routes cannot be introduced.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Generate a default route.

default-info originate [**constantly** | **metric-value** *metric* | **metric-class** *type* | **route-map** *map-name*] *

No default route is generated by default.

If the **constantly** parameter is specified, the OSPF routing process advertises an external default route to neighbors regardless of whether a default route exists. This default route, however, is not displayed on the local router. To confirm whether the default route is generated, run the **display ip ospf database-info** command to display the OSPF LSDB. The external link with the ID 0.0.0.0 describes the default route. On an OSPF neighbor, you can run the **display ip route-config** command to see the default route.

1.7.7 Configuring a Device as ASBR

1. Overview

Configure a device as ASBR in the AS domain or AS boundary.

2. Restrictions and Guidelines

After the redistribute-route or default-info command is executed, the OSPF router automatically becomes an ASBR. If you want the device to become an ASBR without configuring the above command, configure the asbr enable command. If the asbr enable command is deleted, but the redistribute-route or default-info command is still configured, the device is still an ASBR.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure a device as ASBR.

asbr enable

ASBR is disabled by default.

1.8 Configuring OSPF Route Summarization

1.8.1 Overview

Summarize routes to reduce interaction of routing information and the size of routing table, and enhance stability of routes. Shield or filter routes.

1.8.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- The address range of the route to be summarized may exceed the actual network range in the routing table. If data is sent to a network beyond the summarization range, a routing loop may be formed and the router processing load may increase. To prevent these problems, a discard route must be added to the routing table to shield or filter routes.

1.8.3 Configuration Tasks

The configuration of OSPF route summarization includes the following tasks, which are optional. Select tasks for configuration according to actual condition.

- Configuring Inter-Area Route Summarization
- Configuring External Route Summarization
- Configuring a Discard Route

1.8.4 Configuring Inter-Area Route Summarization

1. Overview

On a large-scale OSPF network, configuring route summarization can reduce the size of a routing table and the LSA information, thus reducing the system loss.

2. Restrictions and Guidelines

- Perform this configuration when routes of the OSPF area need to be summarized.
- Unless otherwise required, perform this configuration on an ABR in the area where routes to be summarized are located.
- This command can be executed only on the ABR. It is used to combine or summarize multiple routes of an area into one route, and then advertise the route to other areas. Combination of the routing information occurs only on the boundary of an area. Routers inside the area can learn specific routing information, whereas routers in other areas can learn only one summarized route. You can set **advertise** or **not-advertise** to determine whether to advertise this summarized route to shield and filter routes. By default, the summarized route is advertised. You can use the **advertise-metric** parameter to set the metric of the summarized route.
- You can configure the route summarization command for multiple areas. This simplifies routes in the entire OSPF routing domain, and improves the network forwarding performance, especially for a large-sized network.
- When multiple routes for summarization are configured and have an inclusive relationship with each other, the range of routes to be summarized is determined based on the longest match principle.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure inter-area route summarization.

area *area-id* **summary** *ipv4-address mask* [**advertise** | **not-advertise**] [**metric** *cost* | **inherit-minimum**]

The inter-area route summarization function is disabled by default.

1.8.5 Configuring External Route Summarization

1. Overview

When a lot of OSPF domain routes need to be introduced, configuring route summarization can reduce the size of a routing table and the LSA information, thus reducing the system loss.

2. Restrictions and Guidelines

- Perform this configuration when routes outside the OSPF domain need to be summarized.
- Unless otherwise required, perform this configuration on an ASBR, to which routes that need to be summarized are introduced.
- When routes are redistributed from other routing processes and injected to the OSPF routing process, every route is advertised to the OSPF routers using an external LSA respectively. If the injected routes are in a continuous address space, the ASBR can advertise only one summarized route to significantly reduce the size of the routing table.
- The **area summary** command summarizes the routes between OSPF areas, whereas **summary-address** summarizes external routes of the OSPF routing domain.
- When configured on the NSSA ABR translator, **summary-address** summarizes redistributed routes and routes obtained based on the LSAs that are converted from Type 7 to Type 5. When configured on the ASBR (not an NSSA ABR translator), **summary-address** summarizes only redistributed routes.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure external route summarization.

summary-address *ipv4-address mask* [**not-advertise** | [**tag** *tag-value* | **advertise-metric** *cost* | **distribute-delay** *interval* | **nssa-only**] *]

The route summarization function is disabled by default.

1.8.6 Configuring a Discard Route

1. Overview

The address range of summarized routes may exceed the actual network range in the routing table. If data is sent to a network beyond the summarization range, a routing loop may be formed and the router processing load may increase. To prevent these problems, a discard route must be added to the routing table on the ABR or ASBR. This route is automatically generated, and is not advertised.

The discard route means adding a route whose egress is Null 0 to the routing table, and it will not generate the corresponding LSA, so it will not be received by neighbors. The packets matching the route are discarded.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure a discard route.

discard-route-reinstall { **external-routes** | **internal** }

The discard route adding function is enabled by default.

1.9 Configuring OSPF Route Filtering

1.9.1 Overview

Routes that do not meet filtering conditions cannot be loaded to the routing table, or advertised to neighbors. Network users cannot access specified destination network.

1.9.2 Restrictions and Guidelines

The OSPF basic functions must be configured.

- There are three ways to implement route filtering:
  - Run the **disable-interface** command to configure the interface as a passive interface so that the interface no longer receives and sends Hello packets.
  - Run the **route-filtering out** command when the ASBR imports external routes, and you want to filter the imported external routes.
  - If it is necessary to restrict users' access to the specified destination network, run the **route-filtering in** command to filter the routes calculated by the received LSA. Only the routes that meet the filtering conditions can be used for packet forwarding. It does not affect the link state database, nor does it affect the

neighbor's routing table.

1.9.3 Configuration Tasks

The configuration of OSPF route filtering includes the following tasks, which are optional. Select tasks for configuration according to actual condition.

- Configuring a Passive Interface
- Disabling Interfaces from Sending OSPF Packets
- Configuring Inter-area Route Filtering
- Configuring Redistributed Route Filtering
- Configuring Learned Route Filtering

1.9.4 Configuring a Passive Interface

1. Overview

To prevent other routers on the network from learning the routing information of the local router, you can configure a specified network interface of the local router as the passive interface, or a specified IP address of a network interface as the passive address. A passive interface cannot send and receive OSPF packets.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure a passive interface.

disable-interface { **default** | *interface-type interface-number* | *interface-type interface-number ipv4-address* }

By default, the passive modes of all interfaces are disabled, and all interfaces are allowed to send and receive OSPF packets.

1.9.5 Disabling Interfaces from Sending OSPF Packets

1. Overview

Enable this function on an interface to prevent sending the LSA update packet from this interface. After this function is enabled, the local router does not advertise the LSA update packet to neighbors, but still sets up an adjacency with neighbors and receives LSAs from neighbors.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Disable the interface from sending OSPF packets.

ip ospf outgoing-lsa filter out

By default, the function of diffusing LSA packets to the outside is enabled on an interface, that is, any LSA update packet can be sent from the interface.

1.9.6 Configuring Inter-area Route Filtering

1. Overview

- Configuring inter-area route filtering on an ABR can filter Type3 LSAs, which can restrict route learning between different areas, and restrict users' access to the designated OSPF area network.

2. Restrictions and Guidelines

- This command can be configured only on an ABR.
- Unless otherwise required, perform this configuration on an ABR in the area where filtered routes are located.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an ACL or prefix list. Please configure only one task.

- Configure an ACL.

  access-control-list *acl-number* { **deny** | **permit | comment | list-comment | sequence number**} { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *tm-range-name*] [**log**]

- Configure a prefix list.

  ip prefix-list-info *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit | description** } *ipv4-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*]

(4) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(5) Configure inter-area route filtering.

area *area-id* **filter-rule-list** { **access** *acl-number* | **prefix** *prefix-list-name* } { **in** | **out** }

By default, the filtering list function is not configured on an ABR.

1.9.7 Configuring Redistributed Route Filtering

1. Overview

The redistributed route filtering function refers to filtering routes redistributed from other protocols to OSPF. The route-filtering out command is similar to the redistribute-route route-map command, but it does not redistribute routes, and is generally used together with the redistribute-route command.

2. Restrictions and Guidelines

- Perform this configuration if external routes introduced by the ASBR need to be filtered.
- Unless otherwise required, perform this configuration on an ASBR to which filtered routes are introduced.
- The ACL and prefix list filtering rules are mutually exclusive in the configuration. In other words, if the ACL is used for filtering routes coming from a certain a source, the prefix list cannot be configured to filter the same routes.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an ACL or prefix list. Please configure only one task.

- Configure an ACL.

  access-control-list *acl-number* { **deny** | **permit | comment | list-comment | sequence number** } { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *tm-range-name*] [**log**]

- Configure a prefix list.

  ip prefix-list *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv4-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*]

(4) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(5) Configure redistributed route filtering.

route-filtering { [*acl-name* | *acl-number*] | **prefix-filter** *prefix-list-name* } out [**arp-host** | **bgp** | **connected** | **isis** [*area-tag*] **| ospf** *process-id* **| rip | static**]

By default, the filtering function of redistributed routes is disabled, that is, all the redistributed routes get past.

1.9.8 Configuring Learned Route Filtering

1. Overview

This function filters the routes that are computed based on received LSAs. Only the routes meeting the filtering conditions can be forwarded.

2. Restrictions and Guidelines

Filtering routes by using the route-filtering in command affects forwarding of local routes only, but does not affect route computation based on LSAs. Therefore, if route filtering is configured on the ABR, Type-3 LSAs will still be generated and advertised to other areas because routes can still be computed based on LSAs. As a result, black hole routes are generated. In this case, you can run the area filter-rule-list or area summary (containing the not-advertise parameter) command on the ABR to prevent generation of black hole routes.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an ACL or prefix list. Please configure only one task.

- Configure an ACL.

  access-control-list *acl-number* { **deny** | **permit | comment | list-comment | sequence number** } { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *tm-range-name*] [**log**]

- Configure a prefix list.

  ip prefix-list-info *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit | descripton** } *ipv4-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*]

(4) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(5) Configure learned route filtering.

route-filtering { [*acl-name* | *acl-number*] | **gateway-filter** *prefix-list-name* | **prefix-filter** *prefix-list-name* [**gateway** *prefix-list-name*] | **route-map** *route-map-name* } **in** [*interface-type interface-number*]

By default, the filtering function of the routes calculated based on the received LSA is disabled, that is, all these routes get passed.

1.10 Adjusting OSPF Network Convergence Speed

1.10.1 Overview

This function aims to modify protocol control parameters to change the protocol running status, thus adjusting the convergence speed of OSPF network.

1.10.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- The neighbor relationship maintenance time cannot be shorter than the hello interval.

1.10.3 Configuration Tasks

The configuration for adjusting the convergence speed of OSPF network includes the following tasks, which are optional. Select tasks for configuration according to actual condition.

- Configuring the Hello Interval
- Configuring the Dead Interval
- Configuring LSU Transmission Delay
- Configuring LSU Retransmission Interval
- Configuring LSU Generation Time
- Configuring LSA Group Refresh Time

- Configuring LSA Group Refresh Interval
- Configuring Duplicate LSA Receiving Delay
- Configuring Inter-Area Route Computation Delay
- Configuring External Route Computation Delay
- Configuring SPF Computation Delay

1.10.4 Configuring the Hello Interval

1. Overview

The hello packet interval is contained in the hello packet. A shorter hello interval indicates that OSPF can detect topology changes more quickly, but the network traffic increases.

2. Restrictions and Guidelines

- This configuration is performed on routers at both ends of a link.
- The hello packet interval must be the same on all routers in the same network segment. If you want to manually modify the neighbor dead interval, ensure that the neighbor dead interval is longer than the hello packet interval.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*

- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure the hello interval.

ip ospf hello-period *hello-interval*

By default, the hello packet interval is 10s for Ethernet, HDLC encapsulation interfaces, and frame relay point-to-point sub-interfaces; the hello packet interval is 30s for non-frame relay point-to-point sub-interfaces and X.25 interfaces.

1.10.5 Configuring the Dead Interval

1. Overview

This configuration can be adjusted if you wish to accelerate OSPF convergence when a link fails. The failure determining interval of an OSPF neighbor is contained in the hello packet. If OSPF does not receive a hello packet from a neighbor within the neighbor dead interval, it declares that the neighbor is invalid and deletes this neighbor record from the neighbor list.

2. Restrictions and Guidelines

- This configuration is performed on routers at both ends of a link.
- By default, the dead interval is four times the hello packet interval. If the hello packet interval is modified, the dead interval is modified automatically.
- Run this command to manually modify the interval for OSPF to judge failure of a neighbor with caution. Pay attention to the following two issues:
  - The neighbor dead interval cannot be smaller than the hello packet sending interval;
  - The neighbor dead interval must be the same on all routers in the same network segment.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.

- **interface aggregateport** *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure the dead interval.

ip ospf dead-period { *dead-period* | **minimum hello-multiplier** *multiplier* }

By default, the fast hello function is disabled, and the neighbor dead interval is four times the sending interval of hello packet.

1.10.6 Configuring LSU Transmission Delay

1. Overview

On a low speed network, a device can be configured with the delay before sending LSU packets.

2. Restrictions and Guidelines

- Before an LSU packet is transmitted, the **Age** fields in all LSAs in this packet will increase based on the amount specified by the LSU transmission delay. Considering the transmission delay and line propagation delay on the interface, you need to set the LSU transmission delay to a greater value for a low-speed line or interface. The LSU packet transmission delay of a virtual link is defined by the **transmit-lsu-delay** parameter in the **area vlink** command.
- If the value of the **Age** field of an LSA reaches 3600, the packet will be retransmitted or a retransmission request will be sent. If the LSA is not updated in time, the expired LSA will be deleted from the LSDB.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure the LSU transmission delay.

ip ospf transmit-lsu-delay *transmit-delay*

The LSU packet transmission delay is 1s by default.

1.10.7 Configuring LSU Retransmission Interval

1. Overview

When a network is congested, frequent LSU retransmission will aggravate the congestion. The retransmission delay can be set to a greater value on a serial line or virtual link to prevent unwanted retransmission. The LSU retransmission interval of a virtual link is defined by the retransmit-period parameter in the area vlink command.

After a router finishes sending an LSU packet, this packet is still kept in the transmit buffer queue. If an acknowledgment from the neighbor is not received within the LSU retransmission interval, the router retransmits the LSU packet.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure the LSU retransmission interval.

ip ospf retransmit-period *retransmit-interval*

By default, the LSU retransmission interval is 5s.

1.10.8 Configuring LSU Generation Time

1. Overview

The LSU generation time can be adjusted according to different requirements for network performance and convergence speed.

2. Restrictions and Guidelines

- If a high convergence requirement is raised when a link changes, you can set *delay-time* to a smaller value. You can also appropriately increase the values of *delay-time, hold-time* and *max-wait-time* to reduce the CPU usage.
- When configuring this command, the value of *hold-time* cannot be smaller than the value of *delay-time*, and the value of *max-wait-time* cannot be smaller than the value of *hold-time*.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the exponential backoff algorithm for generating LSAs.

timers-set throttling lsa all *delay-time hold-time max-wait-time*

By default, the minimum delay of LSA generation is 0 ms, the minimum interval between the first update and the second update of LSA is 5000 ms, and the maximum interval between consecutive LSA updates is 5000 ms.

1.10.9 Configuring LSA Group Refresh Time

1. Overview

Every LSA has its time to live (LSA age). When the LSA age reaches 3600s, a refreshment is needed to prevent normal LSAs from being cleared because their ages reaching the maximum. If LSA update and aging computation are performed for every LSA, the device will consume a lot of CPU resources. To use CPU resources effectively, you can refresh LSAs by group on the device. Allocate the LSAs received within a certain time (pacing interval) to the same group. The device will maintain a refresh timer for this group. After the timer expires, the LSAs in the group will be refreshed uniformly.

2. Restrictions and Guidelines

If the total number of LSAs does not change, a larger group pacing interval indicates that more LSAs need to be processed after timeout, which will lead to a high load of the CPU in a certain period of time. For CPU stability, the number of LSAs processed upon each timeout cannot be too large. If the number of LSAs is large, you are advised to reduce the group pacing interval. For example, if there are 10,000 LSAs in the database, you can reduce the pacing interval; if there are 40 to 100 LSAs, you can set the pacing interval to 10-20 minutes.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the LSA group refresh time.

timers-set packet-pacing lsa-batch *pacing-interval*

The group pacing interval of LSA is 30s by default.

1.10.10 Configuring LSA Group Refresh Interval

1. Overview

If a router has a large number of routing entries, synchronizing LSDB will send a large number of LSU packets, easily causing network congestion. The LSU packets can be grouped and sent at an interval to ensure stability of the network.

2. Restrictions and Guidelines

- If the number of LSAs is large and the device load is heavy in an environment, properly configuring *transimit-time* and *transimit-count* can limit the number of LS-UPD packets flooded on the network.
- If the CPU usage is not high and the network bandwidth load is not heavy, reducing the value of *transimit-time* and increasing the value of *transimit-count* can accelerate the environment convergence.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the LSA group refresh interval.

timers-set packet-pacing lsa-transmit *transmit-interval transmit-count*

By default, the interval for sending LSU group is 40 ms, and the number of LS-UPD packets in each group is 1.

1.10.11 Configuring Duplicate LSA Receiving Delay

1. Overview

To prevent excessive usage of network bandwidth and device resources caused by frequent network connection or routing turbulence, you can configure the device to not process duplicate LSAs within a specified time according to the network connection and device resources in the current network.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure duplicate LSA receiving delay.

timers-set lsa repeat-delay *arrival-time*

By default, the delay for receiving a duplicate LSA is 1000 ms.

1.10.12 Configuring Inter-Area Route Computation Delay

1. Overview

In case of route flapping, frequent inter-area route computation will consume a lot of device performance, and delaying the process of inter-area route computation can reduce the device load.

2. Restrictions and Guidelines

- This delay cannot be modified if strict requirements are raised for the network convergence time.
- If a lot of inter-area or external routes exist on the network and the network is not stable, you can adjust the corresponding delays.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure inter-area route computation delay.

timers-set throttling route inter-area *ia-delay*

By default, the waiting time for inter-area route calculation is 0 ms.

1.10.13 Configuring External Route Computation Delay

1. Overview

In case of route flapping, frequent external route computation will consume a lot of device performance, and delaying the process of external route computation can reduce the device load.

2. Restrictions and Guidelines

- This delay cannot be modified if strict requirements are raised for the network convergence time.

- If a lot of inter-area or external routes exist on the network and the network is not stable, you can adjust the corresponding delays.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the external route computation delay.

timers-set throttling route ase *ase-delay*

By default, the waiting time for external route calculation is 0 ms.

1.10.14 Configuring SPF Computation Delay

1. Overview

Changes to LSDB will trigger SPF computation. Frequent network jitter will consume a lot of CPU resources. Setting a reasonable delay for SPF computation can avoid occupying excessive router memory and bandwidth resources.

2. Restrictions and Guidelines

- Compared with the **timers-set spf** command, the **timers-set throttling spf** command supports more flexible settings to accelerate the convergence speed of SPF computation and further reduce the system resources consumed by SPF computation when the topology continuously changes. Therefore, you are advised to run the **timers-set throttling spf** command to adjust the SPF computation time.
- The value of *spf-holdtime* cannot be smaller than that of *spf-delay*; otherwise, *spf-holdtime* will be automatically set to the value of *spf-delay*.
- The value of *spf-max-waittime* cannot be smaller than that of *spf-holdtime*; otherwise, *spf-max-waittime* will be automatically set to the value of *spf-holdtime*.
- The configurations of **timers-set throttling spf** and **timers-set spf** are mutually overwritten.
- When neither **timers-set spf** nor **timers-set throttling spf** is configured, the default value of **timers-set throttling spf** prevails.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the SPF computation delay. Select one of the following items to configure.

- **timers-set throttling spf** *spf-delay spf-holdtime spf-max-waittime*

By default, the delay for SPF computation is 50 ms, the minimum interval for two SPF calculations is 200 ms, and the maximum interval between two SPF calculations is 5000 ms.

- **timers-set spf** *spf-delay spf-holdtime*

- By default, the **timers-set spf** command does not take effect. The SPF calculation delay is subject to the default configuration of the **timers-set throttling spf** command.

1.10.15 Configuring Route Calculation Suppression Time

1. Overview

When devices are started, the devices have different route calculation time due to differences in device performance and database size after a neighbor is in full neighbor relationship. This may cause abnormal traffic interruption in the routing table. Therefore, it is necessary to suppress route calculation of an interface after the interface is in full neighbor relationship state, so as to ensure that calculated routes are the latest.

2. Restrictions and Guidelines

- After route calculation suppression is enabled on an interface, the interface is suppressed from participating in route calculation when the first neighbor of the interface is in full neighbor relationship. The interface recovers after the suppression period expires. This function is usually used in combination with the **max-metric** command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) The following example configures the route calculation suppression time after the first neighbor of an interface is in full neighbor relationship.

ip ospf suppress neighborup *second*

Route calculation is not suppressed by default.

1.10.16 Enabling Two-Way Maintenance

1. Overview

On a large network, a lot of packets may be sent or received, occupying too much CPU and memory. As a result, some packets are delayed or discarded. If the time required for processing hello packets exceeds the neighbor dead interval, the corresponding adjacency times out and is removed. If the two-way maintenance function is enabled, in addition to the hello packets, the DD, LSU, LSR, and LSAck packets from a neighbor can also be used to maintain the bidirectional communication between neighbors when a large number of packets exist on the network. This prevents termination of the adjacency caused by delayed or discarded hello packets. The function is enabled by default. You are advised to retain the default configuration.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Enable two-way maintenance.

two-way-maintain

By default, the two-way maintenance function is enabled for an OSPF process.

1.11 Configuring OSPF Authentication

1.11.1 Overview

Authentication prevents routers that illegally access the network and hosts that forge OSPF packet from participating in the OSPF process. All routers connected to the OSPF network must be authenticated to ensure stability of OSPF and protect OSPF against intrusions.

1.11.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- If authentication is configured for an area, the configuration takes effect on all interfaces that belong to this area.
- If authentication is configured for both an interface and the area to which the interface belongs, the configuration for the interface takes effect preferentially.

1.11.3 Configuration Tasks

The OSPF authentication configuration includes the following tasks:

- Configuring the Authentication Type of an Area
- Configuring the Authentication Type of an Interface
- (Optional) Configuring a Plain Text Authentication Key for an Interface
- (Optional) Configuring an MD5 Authentication Key for an Interface

1.11.4 Configuring the Authentication Type of an Area

1. Overview

OSPF area authentication can improve the security of an OSPF area. The consistency in the authentication type and password is a requisite for establishing a neighbor relationship. If the same authentication type must be enabled on all interfaces in an area, you are advised to make the configuration through the area authentication type. If the router accesses the network that requires authentication, then area authentication or interface authentication must be configured.

2. Restrictions and Guidelines

- The device supports three authentication types:
  - Type 0: No authentication is required. When the OSPF authentication command is not run to enable OSPF authentication, the authentication type carried in OSPF data packets is type 0.
  - Type 1: The authentication type is plain text authentication if this command is configured but does not contain the **auth-secret** parameter.
  - Type 2: The authentication type is MD5 authentication if this command is configured and contains the **auth-secret** parameter.
- All routers in the same OSPF area must use the same authentication type. If authentication is enabled, the authentication key must be configured on interfaces that are connected to neighbors.
- If keychain authentication is configured, the authentication key must be configured using the **key chain** command. Currently, keychain supports plain-text authentication.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the authentication type of an area.

area *area-id* **auth-algorithm** [**keychain** *keychain-name* | **message-digest**]

The OSPF area authentication function is disabled by default.

1.11.5 Configuring the Authentication Type of an Interface

1. Overview

- OSPF interface authentication can improve the communication security of neighbors. The consistency in the authentication type and password is a requisite for establishing a neighbor relationship. This configuration is mandatory if different authentication types are enabled on different interfaces in the same area. If the router accesses the network that requires authentication, then area authentication or interface authentication must be configured.

2. Restrictions and Guidelines

- If the **ip ospf auth-algorithm** command does not contain any option, plain text authentication is enabled. If the authentication type is set to **null**, authentication is disabled forcibly. When authentication is configured for both an interface and the area to which the interface belongs, the authentication type configured for the interface is used preferentially.
- If keychain authentication is configured, the key and authentication type configured for keychain are used. Currently, keychain supports plain text authentication, MD5 authentication, and SM3 authentication.
- If area authentication has been configured, the interface authentication mode is determined by the area authentication configuration when the **unset** option is used to restore the interface authentication mode to the default value.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*

- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure the authentication type of an interface.

ip ospf auth-algorithm [**keychain** *keychain-name* | **message-digest** | **null**]

By default, no authentication mode is set on an interface. In this case, the authentication type of the related area is used on the interface.

1.11.6 Configuring a Plain Text Authentication Key for an Interface

1. Overview

This configuration is required when a router accesses a network that requires plain text authentication. The key information will be inserted to the headers of all OSPF packets. If the keys are inconsistent, two directly connected devices cannot set up an OSPF neighbor relationship and cannot exchange routing information.

2. Restrictions and Guidelines

- Different keys can be configured for different interfaces, but all the routers connected to the same physical network segment must be configured with the same key.
- You must set the authentication type to plain text authentication on the related interface or in the area in advance.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure plain text authentication for an interface.

ip ospf auth-algorithm

(5) Configure a plain text authentication key for an interface.

ip ospf auth-algorithm-key [**0** | **7**] *key*

The authentication key is disabled by default.

1.11.7 Configuring an MD5 Authentication Key for an Interface

1. Overview

The MD5 cipher text authentication mode can be used to enhance security to a certain extent.

2. Restrictions and Guidelines

- MD5 authentication features high security, and therefore is recommended. You must configure either plain text authentication or MD5 authentication. The HMAC-SHA256 algorithm features the highest security and consumes the maximum performance, while the MD5 algorithm features the lowest security and consumes the minimum performance. Select one according to the actual situation.
- This configuration is required if a router accesses a network that requires MD5 authentication.
- You must set the authentication type to cipher text authentication on the related interface or in the area in advance.
- Authentication succeeds only when both *key-id* and key are matched.
- Multiple *key-id* values are configured for the same interface, and the last *key-id* configured takes effect when packets are sent, but all *key-id* values can participate in the authentication when packets are received.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure cipher text authentication for an interface.

ip ospf auth-algorithm message-digest

(5) Configure an MD5 authentication key for an interface.

ip ospf auth-secret-key *key-id* **md5** [**0** | **7**] *key*

The cipher text key function is disabled by default.

1.12 Enabling Fast Reroute

1.12.1 Overview

After the fast reroute function is enabled, once OSPF detects a route failure, the router can immediately switch to the second-best route, helping shorten the traffic interruption time.

1.12.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.

- The LAF configuration for fast reroute is mutually exclusive with the virtual link configuration.
- The **carrier-delaytime** value must be set to **0** for an interface.

1.12.3 Configuration Tasks

The configuration for enabling fast reroute includes the following tasks:

- Configuring Fast Reroute
- (Optional) Configuring Interface LFA Protection
- (Optional) Preventing an Interface From Becoming a Backup Interface

1.12.4 Configuring Fast Reroute

1. Overview

Fast reroute will prepare a backup route for OSPF. Once OSPF detects a neighbor failure, the router will immediately forward the traffic to the backup route to avoid traffic interruption. This configuration is required if you want to increase the OSPF network convergence speed to the millisecond level.

2. Restrictions and Guidelines

- This configuration is performed on a router that has multiple paths to a destination network.
- It is recommended that automatic computation of loop-free alternate (LFA) for the backup path be disabled if any of the following cases exists on the network:
  - Virtual links exist.
  - Alternative ABRs exist.
  - An ASBR is also an ABR.
  - Multiple ABSRs advertise the same external route.
- When the OSPF fast reroute function is used, it is recommended that BFD be enabled at the same time so that the device can quickly detect any link failure and therefore shorten the forwarding interruption time. If the interface is Up or Down, to shorten the forwarding interruption time during OSPF fast reroute, you can configure **carrier-delaytime 0** in Layer-3 interface configuration mode to achieve the fastest switchover speed.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure fast reroute.

frr { **lfa** [**downstream-paths**] | **route-map** *route-map-name* }

The fast reroute function is disabled by default.

1.12.5 Configuring Interface LFA Protection

1. Overview

A backup route is generated for the primary route based on the LFA protection mode specified in interface configuration mode. By default, LFA protection is enabled on each OSPF interface, and a failure of the primary link does not affect data forwarding on the backup route.

2. Restrictions and Guidelines

This command does not take effect if frr route-map is configured.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure interface LFA protection.

ip ospf frr protection { **node | link-node | disable** }

The LFA link protection function is enabled by default.

1.12.6 Preventing an Interface From Becoming a Backup Interface

1. Overview

This configuration is mandatory if you hope that data traffic is not switched over to a specified path after the best path fails. After the best path fails, the traffic will be switched over to another second-best path, but a new best path will be selected based on the interface costs after OSPF converges again. If you do not want to forward the data traffic to the specified path after the optimal path fails, you must disable an interface as a backup interface for fast rerouting. When the optimal path fails, the traffic will switch to other suboptimal paths. After the OSPF protocol finally converges again, a new optimal path will be selected according to the interface cost.

2. Restrictions and Guidelines

- If the remaining bandwidth of an interface is small or if the interface and its primary interface may fail at the same time, the interface cannot be used as a backup interface. Therefore, you need to run this command in interface configuration mode to prevent this interface from becoming a backup interface during OSPF fast reroute computation. After this command is executed, a backup interface will be selected from the other interfaces. If the remaining bandwidth of an interface is small or an interface may fail with the primary interface at the same time, the interface is not suitable as a backup interface. In this case, you need to disable the interface as a backup interface in the interface configuration mode of the interface. After an interface is disabled as a backup interface, the backup interface will be selected from other interfaces during OSPF fast rerouting calculation.
- This command does not take effect if **frr route-map** is configured.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Prevent an interface from becoming a backup interface.

ip ospf frr no-eligible-backup

By default, all interfaces can be used as a backup interface of OSPF fast reroute.

1.13 Modifying the Maximum Number of Concurrent Neighbors

1.13.1 Overview

Modifying the maximum number of concurrent neighbors can control the maximum number of concurrent neighbors on the OSPF process to ease the pressure on the device.

1.13.2 Restrictions and Guidelines

The OSPF basic functions must be configured.

1.13.3 Configuration Tasks

The configuration of modifying the maximum number of concurrent neighbors includes the following tasks, which are optional. Select tasks for configuration according to actual condition.

- Configuring the Maximum Number of Concurrent Neighbors on the Current Process
- Configuring the Maximum Number of Concurrent Neighbors on All Processes

1.13.4 Configuring the Maximum Number of Concurrent Neighbors on the Current Process

1. Overview

When the performance of a router is affected because the router exchanges data with multiple neighbors, you can use this command to restrict the maximum of neighbors with which each OSPF process can concurrently initiate or accept interaction. This configuration is recommended if you want to set up an OSPF adjacency more quickly when a router is connected to a lot of other routers.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the maximum number of concurrent neighbors on the current process.

max-concurrent-dd *neighbor-num*

The maximum number of neighbors of a single OSPF routing process is 5 by default.

1.13.5 Configuring the Maximum Number of Concurrent Neighbors on All Processes

1. Overview

When the performance of a router is affected because the router exchanges data with multiple neighbors, you can configure this command to restrict the maximum of neighbors with which all OSPF processes can concurrently initiate or accept interaction. This configuration is recommended if you want to set up an OSPF adjacency more quickly when a router is connected to a lot of other routers.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the maximum number of concurrent neighbors on all processes.

router-protocol ospf max-concurrent-dd *max-neighbor*

The maximum number of neighbors of all OSPF routing processes is 10 by default.

1.14 Configuring the GR Function

1.14.1 Overview

When a GR-enabled router is restarted on the control plane, data forwarding can be still guided on the forwarding plane. In addition, actions such as neighbor relationship re-forming and route computation performed on the control plane do not affect functions of the forwarding plane. In this way, service interruption caused by route flapping can be avoided, thus enhancing reliability of the entire network.

1.14.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- The neighbor router must support the GR helper.
- The GR time cannot be shorter than the neighbor relationship maintenance time of the neighbor router.

1.14.3 Configuration Tasks

The configuration for enabling the GR function includes the following tasks:

(1) Enabling the GR Function

(2) (Optional) Configuring the OSPF GR Helper Function

1.14.4 Enabling the GR Function

1. Overview

The GR function is configured based on the OSPF process. You can configure different parameters for different OSPF processes based on the actual conditions. This command is used to configure the GR restarter capability of a device. The grace period is the maximum time of the entire GR process, during which link state is rebuilt so that the original state of the OSPF process is restored. After the GR period expires, OSPF exits the GR state and performs common OSPF operations.

The precondition for successful execution of GR and uninterrupted forwarding is that the topology remains stable. If the topology changes, OSPF quickly converges without waiting for further execution of GR, thus avoiding long-time forwarding black hole. When the topology detection function is enabled, the device can detect the topology changes during GR.

2. Restrictions and Guidelines

- You are advised to retain the default configuration.
- If the topology detection function is disabled, the topology change in the GR process cannot be converged in time, which may cause a long-time forwarding black hole.
- If the topology detection function is enabled, forwarding may be interrupted when the topology changes, but the interruption time is far shorter than that when the topology detection function is disabled.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Enable the opaque LSA processing capability.

capability opaque

The opaque LSA processing capability is enabled by default.

(5) Enable the GR function.

gr [**grace-period** *grace-period* | **inconsistent-lsa-checking | helper**]

The GR capability is enabled by default.

1.14.5 Configuring the OSPF GR Helper Function

1. Overview

When a neighbor router implements GR, GR Helper advertises a Grace-LSA to all neighbor routers. If the GR helper function is enabled on the local router, the local router becomes the GR helper upon receiving the Grace-LSA, and helps the neighbor to complete GR. The disable option indicates that the GR helper is not provided for any device that implements GR.

2. Restrictions and Guidelines

- You are advised to retain the default configuration.
- After a device becomes a GR helper, the network changes are not detected by default. If any change takes place on the network, the network topology converges after GR is completed. If you hope that network changes can be quickly detected during the GR process, you can configure **check-rigid** to check Type-1 to Type-5 and Type-7 LSAs that indicate the network information or **internal-lsa-checking** to check Type-1 to Type-3 LSAs that indicate internal routes of the AS domain. When the network scale is large, it is recommended that you disable the LSA checking options (strict-lsa-checking and internal-lsa-checking) because regional network changes may trigger termination of GR and consequently reduce the convergence of the entire network.
- The **disable** option indicates that the GR helper is not provided for any device that implements GR.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the OSPF GR helper function.

gr helper { **disable** | **internal-lsa-checking** | **check-rigid** }

The GR helper capability is enabled by default. After the GR helper is enabled on the device, LSA changes are not checked.

1.15 Correlating OSPF with BFD

1.15.1 Overview

After OSPF is correlated with BFD, once a link is faulty, OSPF can quickly detect the failure of the route. This configuration helps shorten the traffic interruption time.

1.15.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- The BFD parameters must be configured for the interface in advance.
- If correlation with BFD is configured for both the OSPF process and an interface, the interface-based configuration takes effect preferentially.
- The configuration must be performed on routers at both ends of the link.

1.15.3 Configuration Tasks

The configuration for correlating OSPF with BFD includes the following tasks, which are optional. Select tasks for configuration according to actual condition.

- Configuring BFD Correlation with OSPF on an Interface
- Configuring BFD Correlation with OSPF Globally

1.15.4 Configuring BFD Correlation with OSPF on an Interface

1. Overview

Correlating OSPF with BFD on a specified interface can quickly detect the interface fault and accelerate OSPF convergence.

2. Restrictions and Guidelines

- The BFD configured on an interface takes precedence over that configured in OSPF process configuration mode.
- Based on the actual environment, you can run the **ip ospf set-bfd** command to enable BFD on a specified interface for link detection, or run the **bfd whole-interfaces** command in OSPF process configuration mode to enable BFD on all interfaces of the OSPF process, or run the **ip ospf set-bfd disable** command to disable BFD on a specified interface.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure BFD function on an OSPF-enabled interface.

ip ospf set-bfd [**disable**]

By default, the BFD function is disabled on an interface, and the BFD configuration is subject to that configured in RIP process configuration mode.

1.15.5 Configuring BFD Correlation with OSPF Globally

1. Overview

OSPF dynamically discovers neighbors through the hello packets. After OSPF enables the BFD function, a BFD session will be set up to achieve the full adjacency, and the BFD mechanism is used to detect the neighbor state. Once a neighbor failure is detected through BFD, OSPF performs network convergence immediately.

2. Restrictions and Guidelines

You can also run the ip ospf set-bfd [disable] command in interface configuration mode to enable or disable the BFD function on a specified interface, and this configuration takes precedence over the bfd whole-interfaces command used in OSPF process configuration mode.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Enable the BFD function on all interfaces in the OSPF process.

bfd whole-interfaces

By default, the BFD function is disabled on all the interfaces.

1.16 Enabling Overflow

1.16.1 Overview

When the overflow function is enabled, new routes are not loaded to routers when the router memory is insufficient or the usage of the database space reaches the upper limit.

1.16.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- After a router enters the overflow state, you can run the **cleanup ip ospf instance** command, or stop and then restart the OSPF protocol to exit the overflow state.

1.16.3 Configuration Tasks

The configuration of enabling overflow includes the following tasks, which are optional. Select tasks for configuration according to actual condition.

- Configuring the Memory Overflow Function
- Configuring the Database Overflow Function
- Configuring the External LSA Database Overflow Function

1.16.4 Configuring the Memory Overflow Function

1. Overview

The OSPF process enters the overflow state to discard newly-learned external routes. This behavior can effectively prevent the memory usage from increasing.

2. Restrictions and Guidelines

- This configuration is recommended if a large number of routes exist in the domain and may cause insufficiency of the router memory.
- After the overflow function is enabled, the OSPF process enters the overflow state and discards newly-learned

external routes, which may cause a routing loop on the entire network. To reduce the occurrence probability of this problem, OSPF generates a default route to the null interface, and this route always exists in the overflow state.

- You can run the **cleanup ip ospf instance** command to reset the OSPF process so that the OSPF process can exit the overflow state. You can run the **unset** form of the command to prevent the OSPF process from entering the overflow state when the memory is insufficient. This, however, may lead to over-consumption of the memory resource, after which the OSPF process will stop and delete all the learned routes.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the memory overflow function.

overflow memory-lack

By default, the OSPF process is allowed to enter the overflow state when the memory is insufficient.

1.16.5 Configuring the Database Overflow Function

1. Overview

This function controls the maximum number of routes in LSDB to avoid abnormal operation of a router due to insufficient memory.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the database overflow function.

overflow database *max-lsa* [**hard** | **soft**]

The maximum number of LSAs is not configured by default.

1.16.6 Configuring the External LSA Database Overflow Function

1. Overview

This function controls the maximum number of external routes in LSDB to avoid abnormal operation of a router due to insufficient memory.

2. Restrictions and Guidelines

- This configuration is recommended if the ASBR introduces a large number of external routes and the router memory may be insufficient.
- When using the overflow function, ensure that the same *max-dbsize* is configured on all routers in the OSPF backbone area and common areas; otherwise, the following problems may occur:
  - The LSDBs throughout the network are inconsistent, and the neighbor relationship fails to reach the full state.
  - Routes are incorrect, including routing loops.
  - AS external LSAs are frequently retransmitted.
- If the maximum number of external LSAs is set, when the number of external LSAs exceeds the maximum, the normal state will not be restored.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the external LSA database overflow function.

overflow database external *max-dbsize wait-time*

The maximum number of external LSAs is not configured by default.

1.17 Configuring VPN Extended Feature of OSPF

1.17.1 Overview

When OSPF is enabled on a VPN client network, OSPF runs between the PE and CE to simplify the configuration and management of CE.

1.17.2 Restrictions and Guidelines

The router ID of Label Distribution Protocol (LDP) must consist of 32 bits.

1.17.3 Configuration Tasks

The configuration of VPN extended feature of OSPF includes the following tasks, which are optional. Select tasks for configuration according to actual condition.

- Configuring Domain ID
- Configuring a Domain Label
- Configuring a Sham Link
- Disabling Loop Detection for a VRF OSPF Process
- Configuring Extcommunity Attribute for a VPN Route
- Disabling Loop Detection Using the DN Bit of LSA
- Disabling Loop Detection Using the Route Tag of LSA

1.17.4 Configuring Domain ID

1. Overview

Domain ID is used to indicate the domain information of an OSPF process.

A VRF OSPF process can be configured with multiple domain IDs, but only one is the primary domain ID, and the remaining ones are secondary domain IDs. When an OSPF route is converted into a VPN route for advertising, only the primary domain ID is included in a VPN route.

2. Restrictions and Guidelines

- This function takes effect only for the OSPF process associated with VRF.
- The domain IDs of different VRF OSPF processes can be the same and do not influence each other.
- VRF OSPF processes that belong to the same VPN must be configured with the same domain ID to ensure the correctness of route advertising.
- You are advised to configure all the VRF OSPF processes that belong to the same VPN with the same domain ID.

3. Prerequisites

Before configuring the VPN feature, complete the VRF configuration.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* **vrf-instance** *vrf-name*

(4) Configure a domain ID.

domain-id { *ipv4-address* [secondary] | null | type { 0005 | 0105 | 0205 | 8005 } value *hex-value* [secondary] }

By default, the domain ID value of an OSPF process is **null**, and the type value is 0x0005.

1.17.5 Configuring a Domain Label

1. Overview

Domain label is the VPN routing tag of the VRF OSPF process, and is used to detect loops between a PE and a CE running the OSPF protocol. If a VPN site is connected to multiple PEs, the VPN route is learned from the PE through MP-BGP. If the route is advertised to the VPN site through a Type-5 or Type-7 LSA, it may be learned and advertised by other PE routers connected to the VPN site, which may cause a loop. To prevent the preceding loop, the VRF OSPF processes connected to the same VPN site on the PEs are configured with the same VPN route tag. When a VRF OSPF process sends a Type-5 or Type-7 LSA to a VPN site, the VPN route tag information will also be attached to the LSA. When other PE sites receive such a Type-5 or Type-7 LSA, if they detect that the VPN route tag in the LSA is consistent with that of the local OSPF process, the LSA will not participate in the OSPF calculations. Generally, the OSPF processes belonging to the same VPN site are configured with the same tag value.

The VPN route tag occupies four bytes in an OSPF packet. If a VRF OSPF process is not configured with this command, when the OSPF process advertises a Type-5 or Type-7 LSA, the first two bytes of the VPN route tag are set to 0xD000 by default, and the last two bytes are the AS number of local BGP. For example, if the AS number of the local BGP is 1, the hexadecimal form of the VPN route tag is 0xD0000001.

2. Restrictions and Guidelines

This function takes effect only for the OSPF process associated with VRF and BGP redistributed routes.

3. Prerequisites

Before configuring the VPN feature, complete the VRF configuration.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *ospf-id* **vrf-instance** *vrf-name*

(4) Configure a VPN route tag.

domain-tag *tag*

By default, the default value of a VRF OSPF process is the AS number of the local BGP protocol.

1.17.6 Configuring a Sham Link

1. Overview

A sham link is used in an environment with backdoor links between VPN sites. If you still want VPN data to be transmitted through the MPLS backbone network in this case, you can establish a sham link between the VRF OSPF processes of two PEs. The VRF OSPF processes of two PEs can set up an OSPF neighbor relationship through the sham link and distribute LSA packets on the sham link.

2. Restrictions and Guidelines

- The area ID of sham link configured for the two PEs must be consistent.
- The combination of source address and destination address of a sham link configured on one PE must be equal to the combination of destination address and source address of a sham link configured on the other PE.
- Both the source address and destination address used to establish a sham link on the PEs must be a 32-bit loopback address bound to the corresponding VRF.
- Since the OSPF route advertised through a sham link has no VPN label, the route cannot be used for forwarding. Actually packets are still forwarded through the BGP VPNv4 route. Therefore, in the actual configuration, you must ensure that the route advertised through the sham link will also be learned through MP-BGP.
- The source address for establishing the sham link must participate in the BGP VPNv4 route advertisement, but cannot join the calculation of VRF OSPF process.

3. Prerequisites

Before configuring the VPN feature, complete the VRF configuration.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *ospf-id* **vrf-instance** *vrf-name*

(4) Configure a sham link.

area *area-id* **sham-link** *source-ipv4-address destination-ipv4-address* [[**auth-algorithm** [**keychain** *kechain-name* | **message-digest** | **null**] | **metric** *number* | **dead-period** *dead-period* | **hello-period**

hello-interval | **retransmit-period** *retransmit-interval* | **transmit-lsu-delay** *transmit-delay*] * | **auth-algorithm-key** [**0** | **7**] *key* | **auth-secret-key** *key-id* **md5** [**0** | **7**] *key*]

No sham link is configured by default.

1.17.7 Disabling Loop Detection for a VRF OSPF Process

1. Overview

Loop detection of OSPF processes aims to prevent possible loop of VPN routes in propagation.

2. Restrictions and Guidelines

- By default, the VRF OSPF process supports the PE-CE OSPF features (that is, conversion from domain ID to LSA, to DN bits, and to VPN route tag). If you do not want a VRF OSPF process to support the PE-CE OSPF features, disable the PE-CE OSPF features by running the **capability vrf-lite** command.
- This command takes effect only for the OSPF process associated with VRF.
- In some application scenarios, you may need to disable the loop detection function of VRF OSPF processes. For example, VPN users use MCE devices to exchange VPN routes with PEs, if the OSPF protocol runs between MCEs and PEs to exchange VPN routes, to enable the VPN site to learn the routes of other VPN sites, you need to run the **capability vrf-lite** command to disable the loop detection function of VRF OSPF processes on the MCE device.

3. Prerequisites

Before configuring the VPN feature, complete the VRF configuration.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *ospf-id* **vrf-instance** *vrf-name*

(4) Enable the loop detection function.

capability vrf-lite [**auto**]

By default, the loop detection is enabled for the OSPF processes associated with VRF.

1.17.8 Configuring Extcommunity Attribute for a VPN Route

1. Overview

When an OSPF route of VRF forms a VPN route, the Router-ID and Router-Type of the OSPF process will also be carried in the extcommunity attribute of the VPN route. To ensure compatibility with the implementations of different vendors, you can manually modify the Router-ID and Router-Type.

2. Restrictions and Guidelines

- When OSPF routes are redistributed to BGP to form VPN routes, the extcommunity attributes of OSPF routes, including the extcommunity attributes of **router-id** and **route-type**, will also be attached. By default, the extcommunity attribute type of **router-id** is 0x0107, and the extcommunity attribute of **route-type** is 0x0306.
- This function takes effect only for the OSPF process associated with VRF.

3. Prerequisites

Before configuring the VPN feature, complete the VRF configuration.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *ospf-id* **vrf-instance** *vrf-name*

(4) Configure the extcommunity type of a VPN route.

extcommunity-type { **router-id** { **0107 | 8001** } | **route-type** { **0306** | **8000** } }

By default, the type of **router-id** is 0107, and the type of **route-type** is 0306.

1.17.9 Disabling Loop Detection Using the DN Bit of LSA

1. Overview

In the CE dual-homing scenario of L3VPN, loop is avoided by suppressing the route computation of DN bit between PEs. However, in a specific scenario, PEs may be allowed to learn routes from each other without generating any loops. In this case, check of the DN bit can be cancelled by configuring this command. When a PE device is connected to an MCE device, the MCE device needs to calculate the route advertised by the PE and the DN bit will not be checked. Type-3, Type-5, and Type-7 LSAs of OSPF can all carry a DN bit.

2. Restrictions and Guidelines

This function takes effect only for the OSPF process associated with VRF.

3. Prerequisites

Before configuring the VPN feature, complete the VRF configuration.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *ospf-id* **vrf-instance** *vrf-name*

(4) Disable loop detection using the DN bit of LSA.

disable-dn-bit-check [**summary | ase | nssa**]

The DN bit loop detection function of LSA is enabled by default.

1.17.10 Disabling Loop Detection Using the Route Tag of LSA

1. Overview

In the CE dual-homing scenario of L3VPN, when the LSA route tag received by a PE is the same as its route tag, the route is not calculated, thus avoiding a loop. In a specific scenario, PEs are allowed to learn routes from each other without generating any loops. In this case, you can set different route tags for multiple PEs, or set to disable route tag check. When a PE device is connected to an MCE device, the MCE device needs to calculate the route advertised by the PE and the route tag will not be checked. Type-5 and Type-7 LSAs of OSPF can carry a route tag.

2. Restrictions and Guidelines

This command takes effect only for the OSPF process associated with VRF.

3. Prerequisites

Before configuring the VPN feature, complete the VRF configuration.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *ospf-id* **vrf-instance** *vrf-name*

(4) Disable loop detection using the route tag of LSA.

disable-tag-check

The loop detection function using the route tag of LSA is enabled by default.

1.18 Configuring Network Management Functions

1.18.1 Overview

Use the network management software to manage OSPF parameters and monitor the OSPF running status.

1.18.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- You must enable the MIB function of the SNMP-Server before enabling the OSPF MIB function.
- You must enable the Trap function of the SNMP-Server before enabling the OSPF Trap function.
- You must enable the logging function of the device before outputting the OSPF logs.

1.18.3 Configuration Tasks

The configuration of network management functions includes the following tasks, which are optional. Select tasks for configuration according to actual condition.

- Binding the MIB with an OSPF Process
- Configuring the Trap Function
- Configuring the Logging Function

1.18.4 Binding the MIB with an OSPF Process

1. Overview

- The OSPFv2 MIB does not have the OSPFv2 process information. Therefore, you must perform operations on a single OSPFv2 process through SNMP. By default, the OSPFv2 MIB is bound with the OSPFv2 process with the smallest process ID, and all user operations take effect on this process. If you want to manage the parameters of a specified OSPFv2 process through network management software, you must bind the MIB to the OSPFv2 process.

2. Restrictions and Guidelines

- If you want to perform operations on a specified OSPFv2 process through SNMP, run this command to bind the MIB to the process.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Bind the MIB with an OSPF process.

enable mib-binding

By default, the MIB is bound to the OSPFv2 process with the minimum process ID.

1.18.5 Configuring the Trap Function

1. Overview

This configuration is required if you want to use the network management software to monitor the OSPF running status.

2. Restrictions and Guidelines

- The function configured by this command is restricted by the **snmp-server** command. You need to configure the **snmp-server enable traps ospf** command and then the **enable traps** command before the corresponding OSPF trap can be correctly sent out.
- This command is not restricted by the MIB bound to the process. The trap switch can be enabled concurrently for different processes.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the trap function.

enable traps [**error** [**ifauthfailure** | **ifconfigerror** | **ifrxbadpacket** | **virtifauthfailure** | **virtifconfigerror** | **virtifrxbadpacket**] * | **lsa** [**lsdbapproachoverflow** | **lsdboverflow** | **maxagelsa** | **originatelsa**] * | **retransmit** [**iftxretransmit** | **virtiftxretransmit**] * | **status-change** [**ifstatechange** | **nbrrestarthelperstatuschange** | **nbrstatechange** | **nssatranslatorstatuschange** | **restartstatuschange** | **virtifstatechange** | **virtnbrrestarthelperstatuschange** | **virtnbrstatechange**] *]

The trap message sending function is disabled by default.

1.18.6 Configuring the Logging Function

1. Overview

The logging function can be enabled to record the change log of the adjacent state to facilitate the analysis and search of relevant information. By default, the logging function is enabled. The log records the log information of the following four types of events only: the adjacency reaches the full state; the adjacency leaves the full state; the adjacency reaches the down state; the adjacency leaves the down state.

2. Restrictions and Guidelines

You are advised to retain the default configuration. If you want to reduce the log output, disable this function.

- If the **detail** parameter is configured, the change log of all adjacent states will be recorded.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the logging function.

log-adj-changes [**detail**]

The logging function is enabled by default, without the **detail** parameter.

1.19 Enabling NSR

1.19.1 Overview

If the NSR function is enabled, the device can maintain a stable adjacency state during the active/standby switchover, so as to ensure that data forwarding continues and is not interrupted.

1.19.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- For the same OSPF process, either NSR or GR is enabled because they are mutually exclusive. Nevertheless, when NSR is enabled, the GR helper capability is supported.
- The active/standby switchover takes a period of time. If the OSPF neighbor keepalive duration is shorter than the switchover duration, the OSPF neighbor relationship with the neighbor device is removed, and services are interrupted during the switchover. Therefore, it is recommended that the OSPF neighbor keepalive duration be no smaller than the default value when the NSR function is. If the fast hello function is enabled, the OSPF

neighbor keepalive duration is less than 1s. therefore, you are advised to disable the fast hello function when the NSR function is enabled.

1.19.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Enable the NSR function.

nsr

The NSR function is disabled by default.

1.20 Enabling the iSPF Feature

1.20.1 Overview

OSPF adopts the iSPF algorithm to compute a network topology. The iSPF function is generally used on a large-sized network to ease the pressure on router processors.

1.20.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- This configuration is recommended if you hope to accelerate route convergence in a single area with more than 100 routers.
- This configuration is performed on all routers in the area.
- After iSPF is enabled, OSPF will use the iSPF algorithm to compute the network topology. That is, after the network topology changes, OSPF corrects only the nodes affected by the topological change, instead of re-building the entire SPT.

1.20.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure the **i**SPF feature.

ispf enable

The iSPF feature is disabled by default.

1.21 Configuring to Disable MTU Verification

1.21.1 Overview

On receiving the database description packet, OSPF checks whether the MTU of the interface on the neighbor is the same as the MTU of its own interface. If the interface MTU specified in the received database description packet is greater than the MTU of the local interface, the adjacency cannot be set up. To resolve this problem, you can disable MTU verification.

1.21.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- You are advised to retain the default configuration.
- This configuration is performed on two routers with different interface MTUs.

1.21.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*

- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure to disable MTU verification.

ip ospf skip-mtu-verify

The MTU verification function is disabled by default.

1.22 Configuring to Enable Conflict Detection of Type-4 LSAs

1.22.1 Overview

This function enables conflict detection for received Type-4 LSAs.

1.22.2 Restrictions and Guidelines

The OSPF basic functions must be configured before using this function.

1.22.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) Configure conflict detection of Type-4 LSAs.

detect-conflict lsa-4

Conflict detection for Type-4 LSAs is disabled by default.

1.23 Enabling the Function of Securely Promoting a BDR to DR

1.23.1 Overview

On broadcast and NBMA networks, if a DR goes offline, all devices on the network will promote a BDR to DR to ensure the reliable operation of the network. If the configured SPF latency is too short, SPF route calculation is triggered before some devices on the network promote the BDR to DR. As a result, some routes on the network are

unreachable. The function of securely promoting a BDR to DR can solve this problem. After the function is enabled, SPF route calculation is triggered only after all devices promote a BDR to DR.

1.23.2 Restrictions and Guidelines

The OSPF basic functions must be configured before this function is used.

1.23.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

router-protocol ospf *process-id* [**vrf-instance** *vrf-name*]

(4) The following example disables the function of securely promoting a BDR to DR.

unset capability bdr-security-promoted

The function of securely promoting a BDR to DR is enabled by default.

1.24 Configuring a Super VLAN to Enable OSPF

Note

This function is not supported by the S6980-64QC, S6580-48CQ8QC, or S6580-24DC8QC.

1.24.1 Overview

In normal cases, a super VLAN contains multiple sub VLANs. Multicast packets of a super VLAN are also sent to its sub VLANs. In this case, when OSPF multicast packets are sent over a super VLAN containing multiple sub VLANs, the OSPF multicast packets are replicated multiple times, and the device processing capability is insufficient. As a result, a large number of packets are discarded, causing protocol flapping. In certain application scenarios, OSPF must run on a super VLAN, and the packets only need to be sent over a sub VLAN of the super VLAN. In this case, you can run the ip ospf subvlan command to specify a sub VLAN ID for sending packets, so as to avoid the neighbor flapping caused by a device processing bottleneck.

1.24.2 Restrictions and Guidelines

- The OSPF basic functions must be configured.
- The designated sub VLAN must be connected to neighbors.

1.24.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the SVI configuration mode.

interface vlan *interface-number*

(4) Configure the Super VLAN feature.

ip ospf subvlan [**all** | *vlan-id*]

The OSPF function is not configured for a super VLAN by default.

1.25 Monitoring

Run the display command to check the running status of a configured function to verify the configuration effect.

You can run the cleanup commands to clear information.

Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

Run the debugging command to output debugging information.

Caution

When the **debugging** command is used to output debugging information, system resources are occupied. Therefore, disable the debugging function immediately after use.

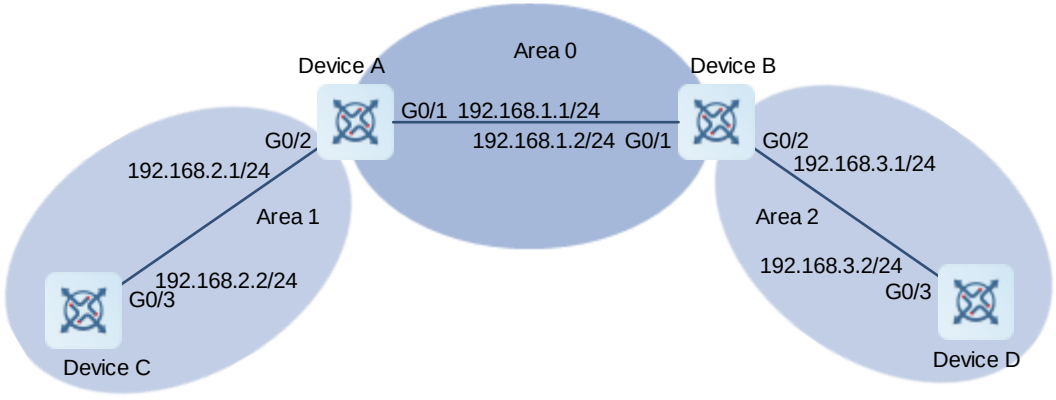
Table 1-10 OSPF Monitoring

Command	Purpose
display ip ospf-instance [*process-id* [*area-id*]]	Displays the OSPF process configuration information.
display ip ospf-instance [*process-id*] **border-routers**	Displays the OSPF internal routing table (the routes to ABRs and ASBRs).
display ip ospf-instance [*process-id* [*area-id*]] **database-info** [[**advertising-router** *ipv4-address* | **database-summary** | **detail** | **max-age** | **self-originate**] | { **asbr-summary** | external**-type** | **network** | **nssa-external-type** | **opaque-area** | **opaque-as** | **opaque-link** | **router** | **summary** } [*link-state-id*] [**advertising-router** *ipv4-address* | **self-originate** | **brief**]]	Displays the information of the OSPF LSDB.

Command	Purpose
display ip ospf-instance [*process-id*] **interface** [*interface-type interface-number* | **brief**]	Displays the OSPF-enabled interface.
display ip ospf-instance [*process-id*] **ispf**	Displays the number of times a route is computed in the OSPF area through iSPF.
display ip ospf-instance [*process-id*] **peer** [[*interface-type interface-number*] [*neighbor-id*] [**detail**] | **statistics**]	Displays the neighbor list of an OSPF process.
display ip ospf-instance [*process-id*] **route** [**count** | *ipv4-address mask*]	Displays the OSPF routing table.
display ip ospf-instance [*process-id*] **sham-links** [**area** *area-id*]	Displays the sham link information of an OSPF process.
display ip ospf-instance [*process-id*] **spf**	Displays the number of times SPT is computed in the OSPF area.
display ip ospf-instance [*process-id* [*area-id*]] **summary-address**	Displays the summarized route of OSPF redistributed routes.
display ip ospf-instance [*process-id* [*area-id*]] **topology** [**advertising-router** *adv-router-id* [*router-id*] | **self-originate** [*router-id*]]	Displays the OSPF network topology information.
display ip ospf-instance [*process-id*] **vlinks** [*ipv4-address*]	Displays OSPF virtual links.
display current-config router-protocol ospf	Displays the OSPF configuration.
cleanup ip ospf [*process-id*] **instance**	Clears and resets an OSPF process.
debugging ip ospf	Debugs the OSPF protocol globally.
debugging ip ospf events-info [**abr** | **asbr** | **lsa** | **mom** | **nssa** | **os** | **restart** | **router** | **slink** | **vlink**] *	Debugs OSPF events.
debugging ip ospf frr [ase | inter-area | intra-area | node | time] *	Debugs the OSPF fast reroute.
debugging ip ospf ifsm [**events-info** | **status** | **timers**]	Debugs OSPF interfaces.
debugging ip ospf nfsm [**events-info** | **status** | **timers**]	Debugs OSPF neighbors.

Command	Purpose
debugging ip ospf nsm [**bfd** | **interface** | **redistribute** | **route** [**add** | **delete** | **receive**]]	Debugs the OSPF NSM.
debugging ip ospf lsa [**flooding** | **generate** | **install** | **maxage** | **refresh**] *	Debugs OSPF LSAs.
debugging ip ospf packet [**dd | deeply** | **detail** | **hello** | **interface** | **ls-ack** | **ls-request** | **ls-update** | **recv** | **send**] *	Debugs OSPF packets.
debugging ip ospf route [**ase** | **ia** | **install** | **ispf** | **spf** | **time**] *	Debugs OSPF routes.

1.26 Configuration Examples



1.26.1 Configuring Basic Functions of OSPF

1. Requirements

OSPF is enabled on all the devices, and three areas are defined in total. Device A and device B are used as ABR forwarding inter-area routes so as to implement the interworking between all networks. After configuration, all devices can learn the routing of all network segments in the AS, and the neighbor relationships are correct.

2. Topology

Figure 1-14 Configuring Basic Functions of OSPF

3. Notes

- Configure interface IP addresses on all the devices.
- Enable the IPv4 unicast routing function on all the devices. (This function is enabled by default.)
- Configure the OSPF processes and router IDs on all the devices.
- Configure interface configuration OSPF on all the devices.

4. Procedure

(1) Configure interface IP addresses on all the devices.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# interface GigabitEthernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# ip address 192.168.2.1 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/2)# exit
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface gigabitethernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# ip address 192.168.3.1 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/2)# exit
```

Configure Device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# interface gigabitethernet 0/3
Device C(cfg-if-GigabitEthernet 0/3)# ip address 192.168.2.2 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/3)# exit
```

Configure Device D.

```
Device D> privilege
Device D# config-system terminal
Device D(cfg)# interface gigabitethernet 0/3
Device D(cfg-if-GigabitEthernet 0/3)# ip address 192.168.3.2 255.255.255.0
Device D(cfg-if-GigabitEthernet 0/3)# exit
```

(2) Configure the OSPF process, router ID, and add the interface IP address to the OSPF process.

Configure Device A.

```
Device A(cfg)# router-protocol ospf 1
Device A(cfg-router)# router-id 192.168.1.1
Device A(cfg-router)# network-advertise 192.168.1.0 0.0.0.255 area 0
Device A(cfg-router)# network-advertise 192.168.2.0 0.0.0.255 area 1
```

Configure Device B.

```
Device B(cfg)# router-protocol ospf 1
Device B(cfg-router)# router-id 192.168.1.2
Device B(cfg-router)# network-advertise 192.168.1.0 0.0.0.255 area 0
Device B(cfg-router)# network-advertise 192.168.3.0 0.0.0.255 area 2
```

Configure Device C.

```
Device C(cfg)# router-protocol ospf 1
Device C(cfg-router)# router-id 192.168.2.2
Device C(cfg-router)# network-advertise 192.168.2.0 0.0.0.255 area 1
```

Configure Device D.

```
Device D(cfg)# router-protocol ospf 1
Device D(cfg-router)# router-id 192.168.3.2
Device D(cfg-router)# network-advertise 192.168.3.0 0.0.0.255 area 2
```

5. Verification

(1) Check the OSPF neighbor and route of Device A.

Check the OSPF route of Device A.

```
Device A# display ip route-config ospf
O IA 192.168.3.0/24 [110/2] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1
```

Check the neighbor information of Device A.

```
Device A# display ip ospf-instance peer
OSPF instance 1, 2 Neighbors, 2 is Full:
Neighbor ID     Pri     State          Dead Time     Address          Interface
192.168.1.2     1       Full/DR        00:00:40      192.168.1.2      GigabitEthernet 0/1
192.168.2.2     1       Full/BDR       00:00:34      192.168.2.2      GigabitEthernet 0/2
```

(2) Check the OSPF neighbor and route of Device B.

Check the OSPF route of Device B.

```
Device B# display ip route-config ospf
O IA 192.168.2.0/24 [110/2] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1
```

Check the neighbor information of Device B.

```
Device B# display ip ospf-instance peer
OSPF instance 1, 2 Neighbors, 2 is Full:
```

```
Neighbor ID     Pri   State           Dead Time   Address         Interface
192.168.1.1     1       Full/BDR      00:00:32    192.168.1.1     GigabitEthernet 0/1
192.168.3.2     1       Full/BDR      00:00:30    192.168.3.2     GigabitEthernet 0/2
```

(3) Check the OSPF neighbor and route of Device C.

Check the OSPF route of Device C.

```
Device C# display ip route-config ospf
O IA 192.168.1.0/24 [110/2] via 192.168.2.1, 00:19:05, GigabitEthernet 0/3
O IA 192.168.3.0/24 [110/3] via 192.168.2.1, 00:19:05, GigabitEthernet 0/3
```

Check the neighbor information of Device C.

```
Device C# display ip ospf-instance peer
OSPF instance 1, 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State           Dead Time   Address         Interface
192.168.1.1     1       Full/BDR      00:00:32    192.168.2.1     GigabitEthernet 0/3
```

(4) Check the OSPF neighbor and route of Device D.

Check the OSPF route of Device D.

```
Device D# display ip route-config ospf
O IA 192.168.1.0/24 [110/2] via 192.168.3.1, 00:19:05, GigabitEthernet 0/3
O IA 192.168.2.0/24 [110/3] via 192.168.3.1, 00:19:05, GigabitEthernet 0/3
```

Check the neighbor information of Device D.

```
Device D# display ip ospf-instance peer
OSPF instance 1, 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State           Dead Time   Address         Interface
192.168.1.2     1       Full/BDR      00:00:30    192.168.3.1     GigabitEthernet 0/3
```

(5) Ping 192.168.2.2 on Device D. The network is reachable.

```
Device D# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
< press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

6. Configuration Files

- Device A configuration file

```
!
interface gigabitethernet 0/1
 ip address 192.168.1.1 255.255.255.0
!
interface gigabitethernet 0/2
 ip address 192.168.2.1 255.255.255.0
!
```

```
router-protocol ospf 1
 router-id 192.168.1.1
 network-advertise 192.168.1.0 0.0.0.255 area 0
 network-advertise 192.168.2.0 0.0.0.255 area 1
!
```

- Device B configuration file

```
!
interface gigabitethernet 0/1
 ip address 192.168.1.2 255.255.255.0
!
interface gigabitethernet 0/2
ip address 192.168.3.1 255.255.255.0
!
router-protocol ospf 1
 router-id 192.168.1.2
 network-advertise 192.168.1.0 0.0.0.255 area 0
network-advertise 192.168.3.0 0.0.0.255 area 2
!
```

- Device C configuration file

```
!
interface gigabitethernet 0/3
 ip address 192.168.2.2 255.255.255.0
!
router-protocol ospf 1
 router-id 192.168.2.2
 network-advertise 192.168.2.0 0.0.0.255 area 1
!
```

- Device D configuration file

```
!
interface gigabitethernet 0/3
 ip address 192.168.3.2 255.255.255.0
!
router-protocol ospf 1
 router-id 192.168.3.2
 network-advertise 192.168.3.0 0.0.0.255 area 2
!
```

7. Common Errors

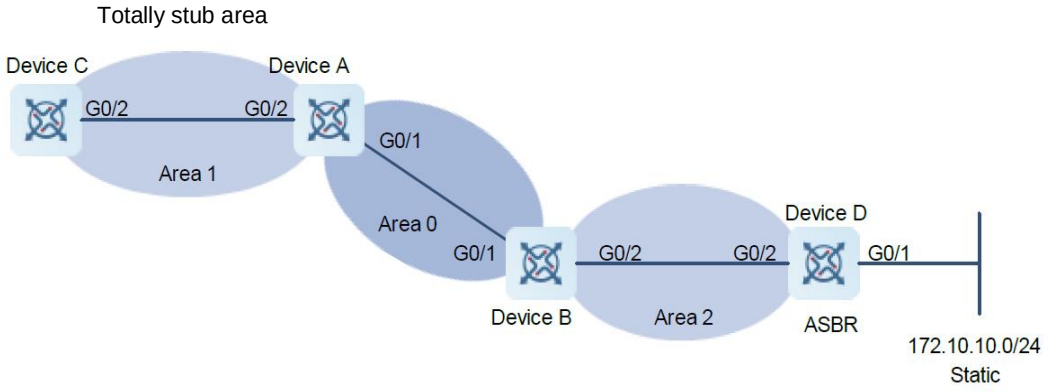
- OSPF cannot be enabled because the IP unicast routing function is disabled.
- The network segment configured by the **network-advertise** command does not include the interface IP

addresses.

- The area IDs configured for adjacent interfaces are inconsistent.
- The same router ID is configured on multiple devices, resulting in a router ID conflict.
- The same interface IP address is configured on multiple devices, resulting in a running error of the OSPF network.

1.26.2 Configuring a Stub Area

1. Requirements



Device A, Device B, Device C, and Device D are interconnected through the OSPF routing protocol.

As ABRs, Device A and Device B are responsible for the routing information transfer between OSPF areas, and Device D functions as an ASBR to introduce the external static route.

To reduce the number of LSAs in Area 1 and save the device performance, Area 1 is configured as a totally stub area.

2. Topology

Figure 1-15 Configuring a Stub Area

3. Notes

- Configure interface IP addresses for all devices (omitted).
- Configure OSPF basic functions on all devices (omitted).
- Configure Area 1 as a stub area on Device A and Device C.

4. Procedure

(1) Introduce an external static route to Device D.

```
Device D> privilege
Device D# config-system terminal
```

```
Device D(cfg)# router-protocol ospf 1
Device D(cfg-router)# redistribute-route static subnets
```

(2) Configure Area 1 as a stub area on Device A and Device C.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# router-protocol ospf 1
Device A(cfg-router)# area 1 stub unset-summary
```

Configure Device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# router-protocol ospf 1
Device C(cfg-router)# area 1 stub
```

5. Verification

On Device C, run the display ip route-config ospf command to display the routing table. Verify that there is only one default inter-area route, and no external static route is introduced from Device D.

```
Device C# display ip route-config ospf
O*IA 0.0.0.0/0 [110/2] via 192.168.2.1, 00:30:53, GigabitEthernet 0/2
```

6. Configuration Files

- Device A configuration file

```
!
router-protocol ospf 1
 area 1 stub unset-summary
!
```

- Device C configuration file

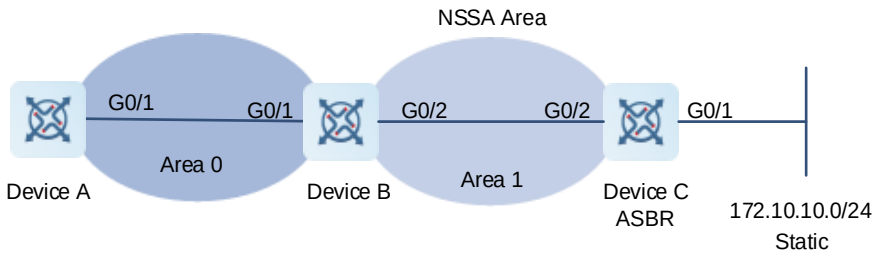
```
!
router-protocol ospf 1
 area 1 stub
!
```

- Device D configuration file

```
!
router-protocol ospf 1
 redistribute-route static subnets
!
```

1.26.3 Configuring an NSSA

1. Requirements



Device A, Device B, and Device C are interconnected through the OSPF routing protocol.

Device B, as an ABR, is responsible for the routing information transfer between OSPF areas, and Device C functions as an ASBR to import the external static route.

To reduce the number of LSAs in Area 1 and save the device performance, Area 1 is configured as an NSSA.

2. Topology

Figure 1-16 Configuring an NSSA

3. Notes

- Configure interface IP addresses for all devices (omitted).
- Configure OSPF basic functions on all devices (omitted).
- Device C needs to import an external static route to the OSPF process.
- Configure Area 1 as NSSA on Device B and Device C.

4. Procedure

(1) Configure a static route for Device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# ip route-config 172.10.10.0 255.255.255.0 192.168.6.2
```

(2) Introduce an external static route to Device C.

```
Device C(cfg)# router-protocol ospf 1
Device C(cfg-router)# redistribute-route static subnets
```

(3) Configure Area 1 as NSSA on Device B and Device C.

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# router-protocol ospf 1
Device B(cfg-router)# area 1 nssa
```

Configure Device C.

```
Device C(cfg-router)# area 2 nssa
```

5. Verification

On Device C, check the Type-7 LSAs generated from 172.10.10.0/24.

```
Device D# display ip ospf-instance database-info nssa-external-type
                OSPF Router with ID (192.168.6.2) (Process ID 1)
                    NSSA-external Link States (Area 0.0.0.1 [NSSA])
  LS age: 61
  Options: 0x8 (-|-|-|-|N/P|-|-|-)
  LS Type: AS-NSSA-LSA
  Link State ID: 172.10.10.0 (External Network Number For NSSA)
  Advertising Router: 192.168.6.2
  LS Seq Number: 80000001
  Checksum: 0xc8f8
  Length: 36
  Network Mask: /24
        Metric Type: 2 (Larger than any link state path)
        TOS: 0
        Metric: 20
        NSSA: Forward Address: 192.168.6.2
        External Route Tag: 0
```

On Device B, verify that Type-5 and Type-7 LSAs are generated from 172.10.10.0/24.

```
Device B# display ip ospf-instance database-info nssa-external-type
                OSPF Router with ID (192.168.3.1) (Process ID 1)
                    NSSA-external Link States (Area 0.0.0.1 [NSSA])
  LS age: 314
  Options: 0x8 (-|-|-|-|N/P|-|-|-)
  LS Type: AS-NSSA-LSA
  Link State ID: 172.10.10.0 (External Network Number For NSSA)
  Advertising Router: 192.168.6.2
  LS Seq Number: 80000001
  Checksum: 0xc8f8
  Length: 36
  Network Mask: /24
        Metric Type: 2 (Larger than any link state path)
```

```
        TOS: 0
        Metric: 20
        NSSA: Forward Address: 192.168.6.2
        External Route Tag: 0
```

On Device B, check the Type-N2 routes generated from 172.10.10.0/24.

```
Device B# display ip ospf-instance database-info external-routes
            OSPF Router with ID (192.168.3.1) (Process ID 1)
                AS External Link States
  LS age: 875
  Options: 0x2 (-|-|-|-|-|-|E|-)
  LS Type: AS-external-LSA
  Link State ID: 172.10.10.0 (External Network Number)
  Advertising Router: 192.168.3.1
  LS Seq Number: 80000001
  Checksum: 0xd0d3
  Length: 36
  Network Mask: /24
        Metric Type: 2 (Larger than any link state path)
        TOS: 0
        Metric: 20
        Forward Address: 192.168.6.2
        External Route Tag: 0
```

6. Configuration Files

- Device B configuration file

```
!
router-protocol ospf 1
 area 1 nssa
!
```

- Device D configuration file

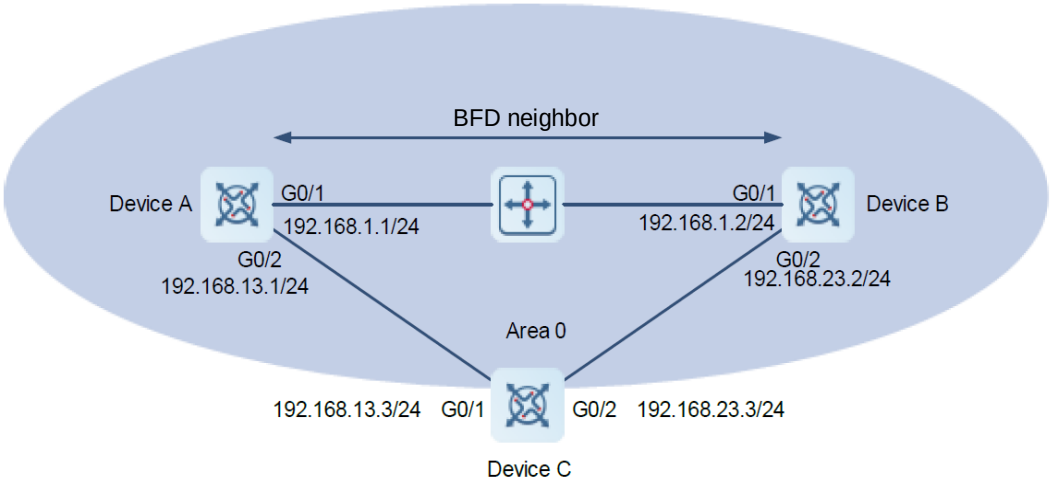
```
!
ip route-config 172.10.10.0 255.255.255.0 192.168.6.2
!
router-protocol ospf 1
 redistribute-route static subnets
 area 1 nssa
!
```

7. Common Errors

- Configurations of the area type are inconsistent on devices in the same area.

- External routes cannot be introduced because route redistribution is configured on a device in the stub area.

1.26.4 Correlating OSPF Process with BFD



1. Requirements

Device A, Device B, and Device C implement internetworking by running OSPFv2.

Device A and Device B use a switch as the primary link. When the switch or the link connected to it fails, BFD can quickly detect the failure and switch to Device C for communication.

2. Topology

Figure 1-17 Correlating OSPF Process with BFD

3. Notes

- Configure interface IP addresses for all devices (omitted).
- Configure OSPF basic functions on all devices (omitted).
- Configure the BFD parameters for the interfaces of all devices.
- Correlate OSPF with BFD on all the devices.

4. Procedure

(1) Configure BFD parameters for the interfaces of all devices.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# bfd period 200 min_rx 200 multiplier 5
Device A(cfg-if-GigabitEthernet 0/1)# exit
```

```
Device A(cfg)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# bfd period 200 min_rx 200 multiplier 5
Device A(cfg-if-GigabitEthernet 0/2)# exit
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# bfd period 200 min_rx 200 multiplier 5
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface gigabitethernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# bfd period 200 min_rx 200 multiplier 5
Device B(cfg-if-GigabitEthernet 0/2)# exit
```

(2) Correlate OSPF with BFD on all the devices.

Configure Device A.

```
Device A(cfg)# router-protocol ospf 1
Device A(cfg-router)# bfd whole-interfaces
```

Configure Device B.

```
Device B(cfg)# router-protocol ospf 1
Device B(cfg-router)# bfd whole-interfaces
```

5. Verification

On Device A, verify that correlating OSPF with BFD is up.

```
Device A# display ip ospf-instance peer
OSPF instance 1, 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State           BFD State  Dead Time   Address         Interface
192.168.1.2       1   Full/BDR        Up         00:00:40    192.168.1.2     GigabitEthernet 0/1
192.168.13.3      1   Full/BDR        Up         00:00:40    192.168.13.3    GigabitEthernet 0/2
```

On Device B, verify that correlating OSPF with BFD is up.

```
Device B# display ip ospf-instance peer
OSPF instance 1, 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State           BFD State  Dead Time   Address         Interface
192.168.1.1       1   Full/BDR        Up         00:00:40    192.168.1.1     GigabitEthernet 0/1
192.168.13.3      1   Full/BDR        Up         00:00:40    192.168.23.3    GigabitEthernet 0/2
```

6. Configuration Files

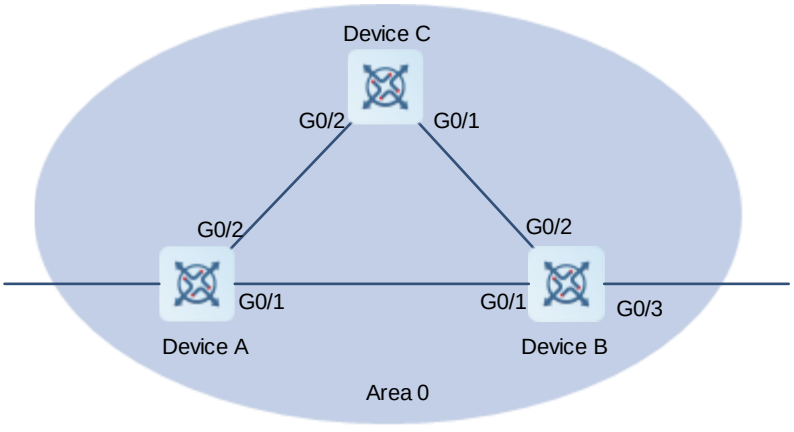
- Device A configuration file

```
!
interface gigabitethernet 0/1
 bfd period 200 min_rx 200 multiplier 5
```

```
!
interface gigabitethernet 0/2
 bfd period 200 min_rx 200 multiplier 5
!
router-protocol ospf 1
 bfd whole-interfaces
!
```

- Device B configuration file

```
!
interface gigabitethernet 0/1
 bfd period 200 min_rx 200 multiplier 5
!
interface gigabitethernet 0/2
 bfd period 200 min_rx 200 multiplier 5
!
router-protocol ospf 1
 bfd whole-interfaces
!
```



1.26.5 Configuring Fast Reroute

1. Requirements

Devices A, B, and C belong to the same OSPF area, and any two of them implement internetworking through the OSPF protocol. When a link of Device A fails, the service can be quickly switched to the backup link. The handover delay should be reduced as much as possible.

2. Topology

Figure 1-18 Configuring Fast Reroute

3. Notes

- Configure fast reroute on Device A.
- Configure **carrier-delay 0** on the interfaces on Device A.

4. Procedure

(1) Configure interface IP addresses for all devices (omitted).

(2) Configure OSPF basic functions on all devices (omitted).

(3) Configure fast reroute on Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# router-protocol ospf 1
Device A(cfg-router)# frr lfa
Device A(cfg-router)# exit
```

(4) Configure carrier-delay 0 on all the interfaces of Device A.

```
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# carrier-delaytime 0
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# carrier-delaytime 0
```

5. Verification

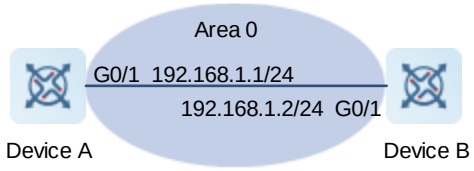
On Device A, check the routing table to verify that a backup route exists for the entry 192.168.4.0/24.

```
Device A# display ip route-config frr    | begin 192.168.4.0
O    192.168.4.0/24 [ma] via 192.168.1.2, 00:39:28, GigabitEthernet 0/1
                        [b] via 192.168.2.2, 00:39:28, GigabitEthernet 0/2
```

6. Configuration Files

Device A configuration file

```
!
router-protocol ospf 1
frr lfa
!
interface gigabitethernet 0/1
carrier-delaytime 0
!
interface gigabitethernet 0/2
 carrier-delaytime 0
!
```



1.26.6 Configuring Network Management Functions

1. Requirements

Configure network management functions on Device A to realize information management interaction from the NMS to the agent through SNMP. The NMS server IP address is 192.168.2.2.

2. Topology

Figure 1-19 Configuring Network Management Functions

3. Notes

- Bind MIB to the OSPF process on Device A.
- Configure the trap function on Device A.

4. Procedure

(1) Configure interface IP addresses for all devices (omitted).

(2) Configure OSPF basic functions on all devices (omitted).

(3) Bind MIB to the OSPF process on Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# snmp-agent host 192.168.2.2 traps version 2c public
Device A(cfg)# snmp-agent community public rw
Device A(cfg)# snmp-agent enable traps
```

(4) Configure the trap function in OSPF process 10.

```
Device A(cfg)# router-protocol ospf 10
Device A(cfg-router)# enable mib-binding
Device A(cfg-router)# enable traps
```

5. Verification

Verify the SNMP information before the trap function is configured for the OSPF process.

```
Device A# display snmp-agent
Chassis: 60FF60
0 SNMP packets input
   0 Bad SNMP version errors
```

```
    0 Unknown community name
    0 Illegal operation for community name supplied
    0 Encoding errors
    0 Number of requested variables
    0 Number of altered variables
    0 Get-request PDUs
    0 Get-next PDUs
    0 Set-request PDUs
    0 Drop PDUs
    0 UDP parse errors
0 SNMP packets output
    0 Too big errors (Maximum packet size 1472)
    0 No such name errors
    0 Bad values errors
    0 General errors
    0 Response PDUs
    0 Trap PDUs
SNMP global trap: disabled
SNMP logging: disabled
SNMP trap logging: disabled
SNMP agent: enabled
SNMP v1:    enabled
SNMP v2c: enabled
SNMP v3:    enabled
```

Verify the SNMP information after the trap function is configured for the OSPF process.

```
Device A# display snmp-agent
Chassis: 60FF60
0 SNMP packets input
    0 Bad SNMP version errors
    0 Unknown community name
    0 Illegal operation for community name supplied
    0 Encoding errors
    8 Number of requested variables
    0 Number of altered variables
    0 Get-request PDUs
    0 Get-next PDUs
    0 Set-request PDUs
    0 Drop PDUs
    0 UDP parse errors
2 SNMP packets output
    0 Too big errors (Maximum packet size 1472)
```

```
0 No such name errors
0 Bad values errors
0 General errors
0 Response PDUs
2 Trap PDUs
```

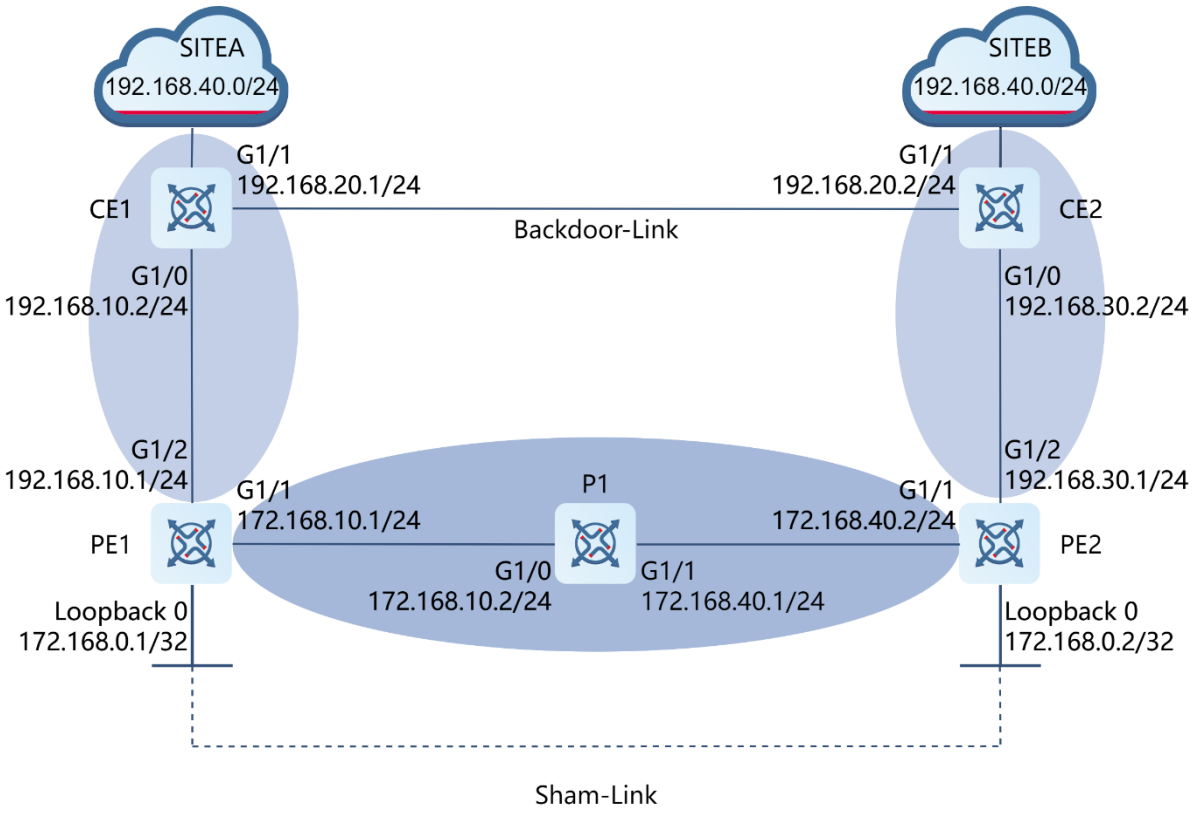
6. Configuration Files

- Device A configuration file

```
!
snmp-agent host 192.168.2.2 traps version 2c public
snmp-agent community public rw
snmp-agent enable traps
!
router-protocol ospf 10
enable mib-binding
enable traps
!
```

7. Common Errors

- Configurations on the SNMP server are incorrect. For example, the MIB or trap function is not enabled.



1.26.7 Configuring the Sham Link Function

1. Requirements

Two different sites of the client interact VPN routes through the MPLS backbone network. At the same time, a "backdoor link" is assumed between the two sites, and aims to ensure that, when the MPLS backbone network fails, information interaction between the two sites can be still implemented normally through this backup link.

2. Topology

Figure 1-20 Configuring a Sham Link Function

3. Notes

- Configure on CE1 to run the OSPF protocol with PE 1 and CE2, where the OSPF protocol runs with CE2 through the backdoor link. Configure the OSPF cost for the interface.
- Configure on CE2 to run the OSPF protocol with PE 2 and CE1, where the OSPF protocol runs with CE1 through the backup link. Configure the OSPF cost for the interface.
- Configure a loopback interface on PE 1, create a VRF: VPN A, define the RD value and RT value, associate VRF with the corresponding interface, and associate the interface connecting to the CE with VRF; configure a loopback interface of VRF to establish a sham link, configure BGP, establish an MP-IBGP session with PE 2, implement route interaction with CE through the OSPF protocol, establish a sham link with the OSPF process on PE 2, configure MPLS signaling of the backbone network, enable the MPLS capability of public network interface, and configure the backbone network routing protocol.
- Configure a loopback interface on PE 2, create a VRF: VPN A, define the RD value and RT value, associate VRF with the corresponding interface, and associate the interface connecting to the CE with VRF; configure a loopback interface of VRF to establish a sham link, configure BGP, establish an MP-IBGP session with PE 1, implement VPN route interaction with CE through the OSPF protocol, and configure to establish a sham link with PE 1; configure MPLS signaling of the backbone network, enable the MPLS capability of public network interface, and configure the backbone network routing protocol.
- Configure backbone network MPLS signaling on P 1, enable the MPLS capability of interface, and configure the backbone network routing protocol.

4. Procedure

(1) Make configuration on CE1.

Configure an IP address for the interface.

```
CE1> privilege
CE1# config-system terminal
CE1(cfg)# interface GigabitEthernet 1/0
CE1(cfg-GigabitEthernet 1/0)# ip address 192.168.10.2 255.255.255.0
CE1(cfg-GigabitEthernet 1/0)# ip ospf metric 1
CE1(cfg-GigabitEthernet 1/0)# exit
CE1(cfg)# interface GigabitEthernet 1/1
CE1(cfg-GigabitEthernet 1/1)# ip address 192.168.20.1 255.255.255.0
CE1(cfg-GigabitEthernet 1/1)# ip ospf metric 200
CE1(cfg-GigabitEthernet 1/1)# exit
```

Advertise the interface network to the OSPF process.

```
CE1(cfg)# router-protocol ospf 10
CE1(cfg-router)# network-advertise 192.168.10.0 255.255.255.0 area 0
CE1(cfg-router)# network-advertise 192.168.20.0 255.255.255.0 area 0
```

(2) Make configuration on CE2.

Configure an IP address for the interface.

```
CE2> privilege
CE2# config-system terminal
CE2(cfg)# interface gigabitethernet 1/0
CE2(cfg-GigabitEthernet 1/0)# ip address 192.168.30.2 255.255.255.0
CE2(cfg-GigabitEthernet 1/0)# ip ospf metric 1
CE2(cfg-GigabitEthernet 1/0)# exit
CE2(cfg)# interface gigabitethernet 1/1
CE2(cfg-GigabitEthernet 1/1)# ip address 192.168.20.2 255.255.255.0
CE2(cfg-GigabitEthernet 1/1)# ip ospf metric 200
CE2(cfg-GigabitEthernet 1/1)# exit
```

Advertise the interface network to the OSPF process.

```
CE2(cfg)# router-protocol ospf 10
CE2(cfg-router)# network-advertise 192.168.30.0 255.255.255.0 area 0
CE2(cfg-router)# network-advertise 192.168.20.0 255.255.255.0 area 0
```

(3) Make configuration on PE 1.

Configure loopback interface 0.

```
PE1> privilege
PE1# config-system terminal
PE1(cfg)# interface loopback 0
```

```
PE1(cfg-Loopback 0)# ip address 172.168.0.1 255.255.255.255
PE1(cfg-Loopback 0)# exit
```

Create a VRF VPNA and define its RD and RT attribute values.

```
PE1(cfg)# ip vrf VPNA
PE1(cfg-vrf)# rd 1:100
PE1(cfg-vrf)# route-target both 1:100
PE1(cfg-vrf)# exit
```

Configure an interface IP address and associate VRF with the corresponding interface.

```
PE1(cfg)# interface gigabitethernet 1/2
PE1(cfg-GigabitEthernet 1/2)# ip vrf binding VPNA
PE1(cfg-GigabitEthernet 1/2)# ip address 192.168.10.1 255.255.255.0
PE1(cfg-GigabitEthernet 1/2)# exit
PE1(cfg)# interface loopback 10
PE1(cfg-Loopback 10)# ip vrf binding VPNA
PE1(cfg-Loopback 10)# ip address 192.168.0.1 255.255.255.255
PE1(cfg-Loopback 10)# exit
```

Configure BGP and establish an MP-IBGP session with PE 2.

```
PE1(cfg)# router-protocol bgp 1
PE1(cfg-router)# peer 172.168.0.2 remote-as 1
PE1(cfg-router)# peer 172.168.0.2 update-source loopback 0
PE1(cfg-router)# address-family-mode vpnv4
PE1(cfg-router-af)# peer 172.168.0.2 activate
PE1(cfg-router-af)# exit
PE1(cfg-router)# exit
```

Configure to establish a sham link with the OSPF process on PE 2.

```
PE1(cfg)# router-protocol ospf 10 vrf VPNA
PE1(cfg-router)# network-advertise 192.168.10.0 255.255.255.0 area 0
PE1(cfg-router)# redistribute-route bgp subnets
PE1(cfg-router)# area 0 sham-link 192.168.0.1 192.168.0.2
PE1(cfg-router)# exit
```

Configure OSPF and direct route redistribution by BGP.

```
PE1(cfg)# router-protocol bgp 1
PE1(cfg-router)# address-family-mode ipv4 vrf VPNA
PE1(cfg-router-af)# redistribute-route ospf 10
PE1(cfg-router-af)# redistribute-route connected
PE1(cfg-router-af)# exit
PE1(cfg-router)# exit
```

Configure backbone network MPLS signaling, and enable the MPLS capability of public network interface.

```
PE1(cfg)# mpls ip
```

```
PE1(cfg)# mpls router-protocol ldp
PE1(cfg-mpls-router)# ldp router-id interface loopback 0 force
PE1(cfg-mpls-router)# exit
PE1(cfg)# interface gigabitethernet 1/1
PE1(cfg-GigabitEthernet 1/1)# ip address 172.168.10.1 255.255.255.0
PE1(cfg-GigabitEthernet 1/1)# label-switching
PE1(cfg-GigabitEthernet 1/1)# mpls ip
PE1(cfg-GigabitEthernet 1/1)# exit
```

Advertise the interface network to the OSPF process.

```
PE1(cfg)# router-protocol ospf 1
PE1(cfg-router)# network-advertise 172.168.10.0 0.0.0.255 area 0
PE1(cfg-router)# network-advertise 172.168.0.1 0.0.0.0 area 0
```

(4) Make configuration on PE 2

Configure loopback interface 0.

```
PE2> privilege
PE2# config-system terminal
PE2(cfg)# interface loopback 0
PE2(cfg-Loopback 0)# ip address 172.168.0.2 255.255.255.255
PE2(cfg-Loopback 0)# exit
```

Create a VRF VPNA and define its RD and RT attribute values.

```
PE2(cfg)# ip vrf VPNA
PE2(cfg-vrf)# rd 1:100
PE2(cfg-vrf)# route-target both 1:100
PE2(cfg-vrf)# exit
```

Configure an interface IP address and associate VRF with the corresponding interface.

```
PE2(cfg)# interface gigabitethernet 1/2
PE2(cfg-GigabitEthernet 1/2)# ip vrf binding VPNA
PE2(cfg-GigabitEthernet 1/2)# ip address 192.168.30.1 255.255.255.0
PE2(cfg-GigabitEthernet 1/2)# exit
PE2(cfg)# interface loopback 10
PE2(cfg-Loopback 10)# ip vrf-instance binding VPNA
PE2(cfg-Loopback 10)# ip address 192.168.0.2 255.255.255.255
PE2(cfg-Loopback 10)# exit
```

Configure BGP and establish an MP-IBGP session with PE 2.

```
PE2(cfg)# router-protocol bgp 1
PE2(cfg-router)# peer 172.168.0.1 remote-as 1
PE2(cfg-router)# peer 172.168.0.1 update-source loopback 0
PE2(cfg-router)# address-family-mode vpnv4
PE2(cfg-router-af)# peer 172.168.0.1 activate
```

```
PE2(cfg-router-af)# exit
PE2(cfg-router)# exit
```

Configure to establish a sham link with the OSPF process on PE 2.

```
PE2(cfg)# router-protocol ospf 10 vrf VPNA
PE2(cfg-router)# network-advertise 192.168.30.0 255.255.255.0 area 0
PE2(cfg-router)# redistribute-route bgp subnets
PE2(cfg-router)# area 0 sham-link 192.168.0.2 192.168.0.1
PE2(cfg-router)# exit
```

Configure OSPF and direct route redistribution by BGP.

```
PE2(cfg)# router-protocol bgp 1
PE2(cfg-router)# address-family-mode ipv4 vrf VPNA
PE2(cfg-router-af)# redistribute-route ospf 10
PE2(cfg-router-af)# redistribute-route connected
PE2(cfg-router-af)# exit
```

Configure backbone network MPLS signaling, and enable the MPLS capability of public network interface.

```
PE2(cfg)# mpls ip
PE2(cfg)# mpls router-protocol ldp
PE2(cfg-mpls-router)# ldp router-id interface loopback 0 force
PE2(cfg-mpls-router)# exit
PE2(cfg)# interface gigabitethernet 1/1
PE2(cfg-GigabitEthernet 1/1)# ip address 172.168.40.2 255.255.255.0
PE2(cfg-GigabitEthernet 1/1)# label-switching
PE2(cfg-GigabitEthernet 1/1)# mpls ip
PE2(cfg-GigabitEthernet 1/1)# exit
```

Advertise the interface network to the OSPF process.

```
PE2(cfg)# router-protocol ospf 1
PE2(cfg-router)# network-advertise 172.168.40.0 0.0.0.255 area 0
PE2(cfg-router)# network-advertise 172.168.0.2 0.0.0.0 area 0
```

(5) Make configuration on P 1.

Configure loopback interface 0 on P 1.

```
P1> privilege
P1# config-system terminal
P1(cfg)# interface loopback 0
P1(cfg-Loopback 0)# ip address 172.168.0.3 255.255.255.255
P1(cfg-Loopback 0)# exit
```

Make basic configuration of OSPF.

```
P1(cfg)# router-protocol ospf 1
P1(cfg-router)# network-advertise 172.168.40.0 0.0.0.255 area 0
P1(cfg-router)# network-advertise 172.168.10.0 0.0.0.255 area 0
```

```
P1(cfg-router)# network-advertise 172.168.0.3 0.0.0.0 area 0
P1(cfg-router)# exit
```

Configure backbone network MPLS signaling on P 1, and enable the MPLS capability of interface.

```
P1(cfg)# interface gigabitethernet 1/0
P1(cfg-GigabitEthernet 1/0)# ip address 172.168.10.2 255.255.255.0
P1(cfg-GigabitEthernet 1/0)# mpls ip
P1(cfg-GigabitEthernet 1/0)# label-switch
P1(cfg-GigabitEthernet 1/0)# exit
P1(cfg)# interface gigabitethernet 1/1
P1(cfg-GigabitEthernet 1/1)# ip address 172.168.40.1 255.255.255.0
P1(cfg-GigabitEthernet 1/1)# mpls ip
P1(cfg-GigabitEthernet 1/1)# label-switch
P1(cfg-GigabitEthernet 1/1)# exit
P1(cfg)# mpls ip
P1(cfg)# mpls router-protocol ldp
P1(cfg-mpls-router)# ldp router-id interface loopback 0 force
P1(cfg-mpls-router)# exit
```

5. Verification

(1) Verify the configuration on PE 1.

Verify that an OSPF sham link route exists on PE 1.

```
PE1# display ip ospf-instance 10 sham-links
Sham Link SLINK0 to address 192.168.0.2 is up
  Area 0.0.0.0 source address 192.168.0.1, Cost: 1
  Output interface is GigabitEthernet 1/1
  Nexthop address 172.16.40.2
  Transmit Delay is 1 sec, State Point-To-Point,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:01
    Adjacency state Full
```

Check the OSPF neighbor of PE 1.

```
PE1# display ip ospf-instance 10 peer

OSPF instance 10, 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State           BFD State   Dead Time   Address         Interface
192.168.0.2       1   Full/ -         -           00:00:34    192.168.0.2     SLINK0
```

Check the VRF route of PE 1.

```
PE1# display ip route-config vrf VPNA
Routing Table: VPNA
```

```
Codes:    C - connected, S - static, R - RIP, B - BGP
          O - OSPF, IA - OSPF inter area
          N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
          E1 - OSPF external type 1, E2 - OSPF external type 2
          i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
          ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
C         192.168.10.0/24 is directly connected, GigabitEthernet 1/2
O         192.168.20.0/24 [110/101] via 192.168.1.2, 00:56:23, GigabitEthernet 1/2
O         192.168.30.0/24 [110/2] via 172.168.0.2, 00:00:36
O         192.168.40.0/24 [110/2] via 172.168.0.2, 00:00:36
```

(2) Verify the configuration on PE 2.

Verify that an OSPF sham link route exists on PE 2.

```
PE2# display ip ospf-instance 10 sham-links
Sham Link SLINK0 to address 192.168.0.1 is up
  Area 0.0.0.0 source address 192.168.0.2, Cost: 1
  Output interface is GigabitEthernet 1/1
  Nexthop address 172.16.10.1
  Transmit Delay is 1 sec, State Point-To-Point,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:01
    Adjacency state Full
```

Check the OSPF neighbor of PE 2.

```
PE2# display ip ospf-instance 10 peer

OSPF process 10, 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State           BFD State   Dead Time   Address         Interface
192.168.0.1       1   Full/ -         -           00:00:34    192.168.0.1     SLINK0
```

Check the VRF route of PE 2.

```
PE2# display ip route-config vrf VPNA
Routing Table: VPNA

Codes:    C - connected, S - static, R - RIP, B - BGP

1.26.8 Configuring a Virtual Link

1. Requirements

Area 2 is not directly connected to Area 0. To ensure the normal operation of OSPF on the network, a virtual link is configured between Device B and Device C.

2. Topology

Figure 1-21 Configuring a Virtual Link

3. Notes

- Configure interface IP addresses for all devices (omitted).
- Configure OSPF basic functions on all devices (omitted).
- Configure a virtual link on Devices B and C.

4. Procedure

(1) Configure an IP address for each interface and the OSPF routing protocol (omitted).

(2) Configure a virtual link on Devices B and C.

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# router-protocol ospf 1
Device B(cfg-router)# area 1 vlink 192.168.23.3
```

Configure Device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# router-protocol ospf 1
Device C(cfg-router)# area 1 vlink 192.168.12.2
```

5. Verification

Verify that the route of Area 2 can be learned by running the **display ip ospf-instance database-info** command on Device A.

```
Device A# display ip ospf database-info
                OSPF Router with ID (192.168.12.1) (Process ID 1)
                    Router Link States (Area 0)

!
```

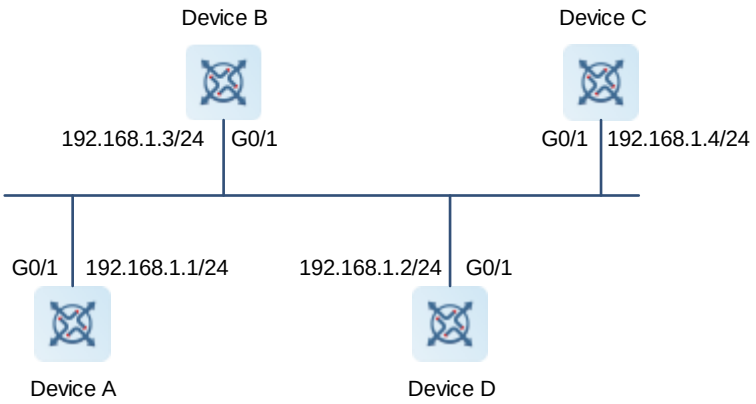
1.26.9 Selecting a DR of OSPF



1. Requirements

Devices A, B, C, and D are on the same broadcast network.

Configure the priority of Device A as 10 to turn it into a DR, and the priority of Device B as 5 to turn it into a BDR, set the default priority for Device C, and set the priority of Device D to 0 to avoid participating in DR election.

2. Topology

Figure 1-22 Selecting a DR of OSPF

3. Notes

Set the priorities to 10, 5, and 0 on Devices A, B, and D respectively.

4. Procedure

(1) Configure an IP address for each interface and the OSPF routing protocol (omitted).

(2) Set the priorities on Devices A, B, and D.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# ip ospf priority-value 10
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip ospf priority-value 5
```

Configure Device D.

```
Device D> privilege
Device D# config-system terminal
Device D(cfg)# interface gigabitethernet 0/1
Device D(cfg-if-GigabitEthernet 0/1)# ip ospf priority-value 0
```

5. Verification

Verify that the displayed neighbor is correct when the display ip ospf-instance peer command is run on Device D.

```
Device D# display ip ospf-instance peer
Neighbor ID     Pri   State           Dead Time   Address         Interface
192.168.1.1     10    FULL/DR         00:00:38    192.168.1.1     GigabitEthernet0/1
192.168.1.2     5     FULL/BDR        00:00:30    192.168.1.2     GigabitEthernet0/1
```

6. Configuration Files

- Device A configuration file

```
!
interface gigabitethernet 0/1
ip ospf priority-value 10
!
```

- Device B configuration file

```
!
interface gigabitethernet 0/1
ip ospf priority-value 5
!
```

- Device D configuration file

```
!
interface gigabitethernet 0/1
ip ospf priority-value 0
```

```
!
```

1 Configuring OSPFv3

1.1 Introduction

1.1.1 Overview

The open shortest path first version 3 (OSPFv3) is an Interior Gateway Protocol (IGP) that is used within the autonomous system (AS) to allow routers to obtain a route to a remote network.

Note

OSPFv2 is applicable to IPv4, and OSPFv3 is applicable to IPv6. The protocol running mechanism and most configurations are the same.

OSPFv3 has the following characteristics:

- Wide scope of application: OSPFv3 is applicable to a larger-scale network that supports hundreds of routers.
- Fast convergence: Once the network topology changes, advertisements can be quickly sent between routers to update routes.
- No self-loop: Only the link status information is synchronized between routers. Each router computes routes independently, and a self-loop will not occur.
- Area division: A large routing domain is divided into multiple small areas to save system resources and network bandwidth and ensure stability and reliability of routes.
- Route classification: Routes are classified into several types to support flexible control.
- Equivalent routes: OSPFv3 supports equivalent routes.
- Authentication: OSPFv3 supports packet authentication to ensure security of protocol interaction.
- Multicast transmission: Protocol packets are sent using the multicast address to avoid interfering with irrelevant entities and save system resources.

Note

In this chapter, the term "router" refers to any network device that supports the routing function. These network devices can be layer-3 (L3) switches, routers, or firewalls.

1.1.2 Basic Concepts

1. Routing domain

All routers in an AS must be interconnected and use the same routing protocol. Therefore, an AS is also called a routing domain.

An AS in which OSPFv3 runs is also called OSPFv3 routing domain (short for OSPFv3 domain).

2. OSPFv3 process

OSPFv3 supports multiple instances, and each instance corresponds to an OSPFv3 process.

One or more OSPFv3 processes can be started on a router. Each OSPFv3 process runs OSPFv3 independently, and the processes are mutually isolated.

An OSPFv3 packet header contains the Instance ID field, and multiple OSPFv3 instances can run concurrently on a single link. The process ID is valid only on the local device.

3. Router ID

The router ID uniquely identifies a router in an OSPFv3 domain. Router IDs of any two routers cannot be the same.

If multiple OSPFv3 processes exist on a router, each OSPFv3 process uses one router ID. Router IDs of any two OSPFv3 processes cannot be the same.

4. OSPFv3 areas

OSPFv3 supports multiple areas. An OSPFv3 domain is divided into multiple areas to ease the computing pressure of a large-scale network.

An area is a logical group of routers, and each group is identified by an area ID. The border between areas is a router. A router may belong to one area or multiple areas. One network segment (link) can belong to only one area, or each OSPFv3 interface must belong to a specified area.

- Backbone area and normal area

  Area 0 is a backbone area, and other areas are normal areas. Normal areas must be directly connected to the backbone area.

- Stub area

  Configuring an OSPFv3 stub area can reduce the number of Link-State Advertisements (LSAs) in the area. The area border router (ABR) in the stub area will not transfer the Type 5 LSA (external route), and will advertise the default route to the stub area.

- Totally stub area

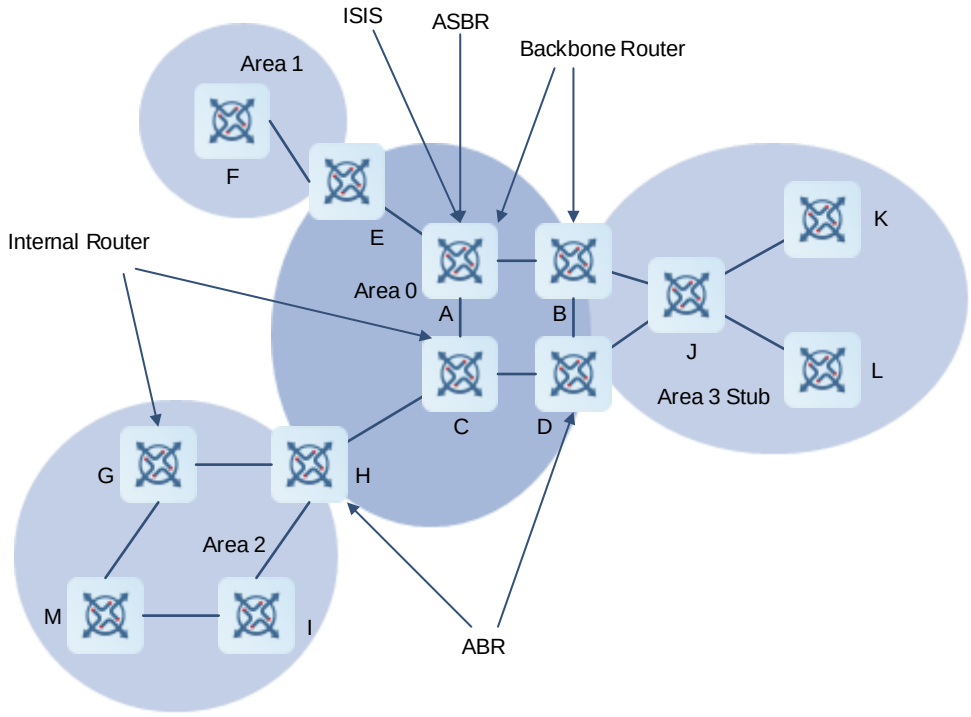
  A totally stub area is upgraded from a stub area. The router in the totally stub area will not transfer Type 3 LSA (inter-domain route) and Type 5 LSA (external route), and will advertise the default route to the stub area.

- NSSA

  A not-so-stubby area (NSSA) is similar to a stub area, but allows AS boundary routers (ASBRs). The route redistributed by an ASBR will be transferred in the NSSA in the form of Type 7 LSA, and the Type 7 LSA will be translated to Type 5 LSA on ABR and then transferred to other areas. The ABR also advertises the default route to the NSSA.

- Totally NSSA

  The relationship between the totally NSSA and NSSA is similar to that between the totally stub area and stub area. The totally NSSA forbids transfer of the Type 3 LSA (inter-domain route) on the basis of NSSA.



⚠ Caution

- The backbone area cannot be a stub area, totally stub area, NSSA, or totally NSSA.
- The stub area and totally stub area cannot contain any ASBR.

- The stub area, totally stub area, NSSA, and totally NSSA cannot contain any virtual link.

The stub area, totally stub area, NSSA, and totally NSSA are special forms of normal areas and help reduce the load of routers and enhance reliability of OSPFv3 routes.

Figure 1-1 Classification of OSPFv3 Areas

5. OSPFv3 routers

The following types of routers are defined in OSPFv3 and assigned with different responsibilities:

- Internal router

  All interfaces of an internal router belong to the same OSPFv3 area, for example, A, C, F, G, I, M, J, K, and L shown in Figure 1-1.

- ABR

  An ABR is used to connect the backbone area with a normal area. An ABR belongs to two or more areas, and one of the areas must be the backbone area, for example, B, D, E, and H shown in Figure 1-1.

- Backbone router

  A backbone router has at least one interface that belongs to the backbone area. All ABRs and all routers in area 0 are backbone routers, for example, A, B, C, D, E, and H shown in Figure 1-1.

- ASBR

  An ASBR is used to exchange routing information with other ASs. An ASBR is not necessarily located on the border of an AS. It may be a router inside an area or an ABR, for example, A shown in Figure 1-1.

6. OSPFv3 Route Types

Each OSPFv3 route is marked to indicate the type of the route. There are six types of OSPFv3 routes:

- O: Internal route

  This type of route describes how to arrive at a destination network in the local area. The cost of this type of route is equal to the cost of the route from the local router to the destination network.

- OI: Inter-area route

  This type of route describes how to arrive at a destination network in another area. The cost of this type of route is equal to the cost of the route from the local router to the destination network.

- OE1: Type 1 external route

  This type of route describes how to arrive at a destination network outside the AS. The cost of this type of route is equal to the cost of the route from the local router to the ASBR plus the cost of the route from the ASBR to the destination network. This type of route does not exist on routers in the stub or NSSA area.

- OE2: Type 2 external route

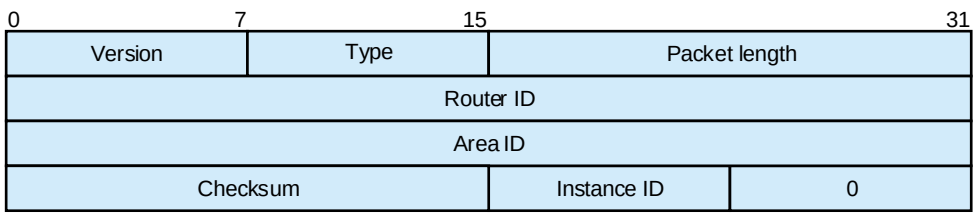
  This type of route describes how to arrive at a destination network outside the AS. The cost of this type of route is equal to the cost of the route from the ASBR to the destination network. This type of route does not exist on routers in the stub or NSSA area.

- ON1: Type 1 external route of the NSSA

  This type of route describes how to arrive at a destination network outside the AS through the ASBR in the NSSA. The cost of this type of route is equal to the cost of the route from the local router to the ASBR plus the cost of the route from the ASBR to the destination network. This type of route exists only on routers in the NSSA.

- ON2: Type 2 external route of the NSSA

  This type of route describes how to arrive at a destination network outside the AS through the ASBR in the NSSA. The cost of this type of route is equal to the cost of the route from the ASBR to the destination network. This type of route exists only on routers in the NSSA.



Note

Reliability of OE2 and ON2 routes is poor. OSPFv3 believes that the cost of the route from the ASBR to a destination network outside an AS is far greater than the cost of the route to the ASBR within the AS. Therefore, when the route cost is computed, only the cost of the route from the ASBR to a destination network outside an AS is considered.

7. OSPFv3 packets

The following table lists the OSPFv3 packets. These OSPFv3 packets are encapsulated in IP packets and transmitted in multicast or unicast mode.

Figure 1-2 OSPFv3 packet format

Version: indicates an OSPF version. The value is 3 for OSPFv3.

Type: indicates an OSPFv3 packet type.

Packet length: indicates the length of an OSPFv3 packet plus the packet head, in bytes.

Router ID: indicates the ID of a router that sends OSPFv3 packets.

Area ID: indicates the area of a router that sends OSPFv3 packets.

Checksum: indicates the checksum of an OSPFv3 packet, excluding the authentication field.

Instance ID: indicates an OSPFv3 instance ID.

0: reserved value.

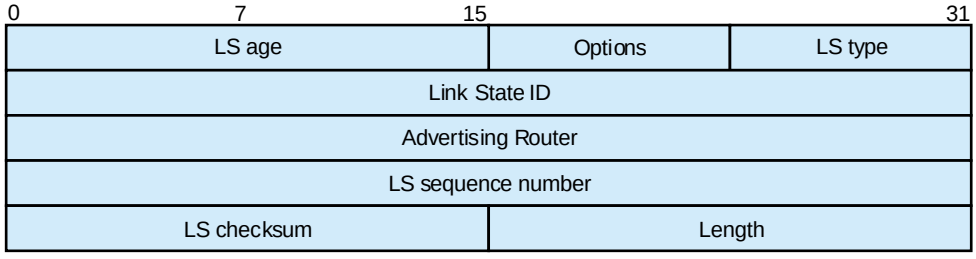


Table 1-1 Types of OSPFv3 Packets

Packet Type	Description
Hello	Hello messages are sent periodically to discover and maintain OSPFv3 neighbor relationships. The value of this OSPFv3 packet type is **1**.
Database description (DD)	DD packets carry brief information about the local link-state database (LSDB) and are used to synchronize databases between OSPFv3 neighbors. The value of this OSPFv3 packet type is **2**.
Link state request (LSR)	LSR packets are sent only after DD packets are exchanged successfully between OSPFv3 neighbors, and are used to request LSAs. The value of this OSPFv3 packet type is **3**.
Link state update (LSU)	LSU packets are used to send the required LSAs to peers. The value of this OSPFv3 packet type is **4**.
Link state acknowledgment (LSAck)	LSAck packets are used to acknowledge the received LSAs. The value of this OSPFv3 packet type is **5**.

8. LSA

OSPFv3 describes the routing information by means of LSAs.

Figure 1-3 LSA Packet Format

LS age: indicates the LS aging time of an LSA after it is generated, in seconds.

Option: is an optional field that decides whether to broadcast AS-external-LSAs, forward IP multicast packets, and process NSSA LSAs and on-demand links.

LS type: indicates different LSAs.

Link State ID: specifies a unique LSA in a routing domain together with the LSA type.

Advertising Router: indicates the ID of a router that generates this LSA.

LS sequence number: indicates the sequence number of an LSA, which is used to describe the generated sequence of LSAs.

LS checksum: indicates checksum of fields except the LS age field.

Length: indicates the total length of an LSA packet plus header, in bytes.

Table 1-2 Types of OSPFv3 LSAs

LSA Type	Description
Router-LSA (Type1)	This LSA is originated by every router. It describes the link state and cost of the router, and is advertised only within the area where the originating router is located.
Network-LSA (Type2)	This LSA is originated by a designated router (DR). It describes the state of the current link, and is advertised only within the area where the DR is located.
Inter-Area-Prefix-LSA (Type3)	This LSA is originated by an ABR. It describes a route to another area, and is advertised to areas except totally stub areas and NSSAs.
Inter-Area-Router-LSA (Type4)	This LSA is originated by an ABR. It describes a route to an ASBR, and is advertised to areas except the area where the ASBR is located.
AS-external-LSA (Type5)	This LSA is originated by an ASBR. It describes a route to a destination outside the AS, and is advertised to all areas except stub areas and NSSAs.
NSSA LSA (Type7)	This LSA is originated by an ASBR. It describes a route to a destination outside the AS, and is advertised only within the NSSA.
Link-LSA (Type8)	This LSA is originated by every router. It describes the link-local address and IPv6 prefix address of each link, and provides the link option that will be set in the Network-LSA. It is advertised only on the current link.
Intra-Area-Prefix-LSA (Type9)	Every router or DR generates one or more this type of LSAs, which are advertised in the area to which the router or DR belongs. The LSAs generated by a router describe the prefix of an IPv6 address associated with the Route-LSA. The LSAs generated by a DR describe the prefix of an IPv6 address associated with the Network-LSA.

9. OSPFv3 neighbor state

In the OSPFv3 network, neighbor devices need to reach the adjacency state before exchanging link information. There are several OSPFv3 neighbor states listed below. When a neighbor enters the full state, the adjacency relationship is established.

Table 1-3 OSPFv3 Neighbor State Machine and Description

State	Description
Down	The state of the first OSPFv3 neighbor, which indicates that the neighbor's hello packet is not received within the neighbor dead interval.
Attempt	The attempt state router sends a hello packet to the manually configured neighbor periodically. The attempt state applies to the interfaces of NBMA type only.
Init	A hello packet has been received from the neighbor, but the packet does not contain the router ID of the neighbor receiving router, that is, the peer end does not receive the hello packet sent by the local end.
Two-Way	Indicates mutual neighbors. When the neighbor router ID field in the received hello packet is each other's router ID, and both ends receive the hello packet sent from the peer end, a neighbor relationship is established. After this phase ends, DR and backup designated router (BDR) will be selected for broadcast and non-broadcast multi-access.
Exstart	Indicates negotiation about the master/slave relationship. The initial sequence number for forming an adjacency is selected, and the master/slave relationship ensures orderly transmission in the subsequent exchange of DD packets.
Exchange	Indicates exchange of DD packets. Checks whether the neighbor can provide new or updated link state information.
Loading	Indicates that, based on the information provided by DBD, the router will send LSR and interactive LSU to implement synchronization with LSDB.
Full	Indicates establishment of an adjacency. Indicates that the LSDBs of the two devices have been synchronized, and the adjacency state has been established between the local device and the neighbor device.

10. OSPFv3 network types

A router does not necessarily need to exchange LSAs with every neighbor or set up an adjacency with every neighbor. To improve efficiency, OSPFv3 classifies networks that use various link layer protocols into five types so that LSAs are exchanged in different ways to set up an adjacency.

By default, Ethernet and FDDI belong to the broadcast type, X.25, frame relay, and ATM belong to the NBMA type, and PPP, HDLC, and LAPB belong to the P2P type.

Table 1-4 Introduction to OSPFv3 Network Types

Network Type	Link Layer Protocol	Neighbor Relationship and DR Election
Broadcast	Ethernet and FDDI belong to the broadcast network type by default.	● Neighbors are automatically discovered, and the DR and BDR are elected. ● The DR or BDR exchanges LSAs with all other routers to set up an adjacency. ● Except the DR and BDR, all other routers do not exchange LSAs with each other, and the adjacency is not set up.
NBMA	X.25, frame relay, and ATM belong to NBMA networks by default.	● Neighbors are manually configured, and the DR and BDR are elected. ● The DR or BDR exchanges LSAs with all other routers to set up an adjacency. ● Except the DR and BDR, all other routers do not exchange LSAs with each other, and the adjacency is not set up.
Point-to-Point (P2P)	PPP, HDLC, and LAPB belong to the P2P network type by default.	● Neighbors are automatically discovered, and the DR or BDR is not elected. ● LSAs are exchanged between routers at both ends of the link, and the adjacency is set up.
Point-to-Multipoint (P2MP)	Networks without any link layer protocol belong to the P2MP network type by default.	● Neighbors are automatically discovered, and the DR or BDR is not elected. ● LSAs are exchanged between any two routers, and the adjacency is set up.
P2MP broadcast	Networks without any link layer protocol belong to the P2MP network type by default.	● Neighbors are manually configured, and the DR or BDR is not elected. ● LSAs are exchanged between any two routers, and the adjacency is set up.

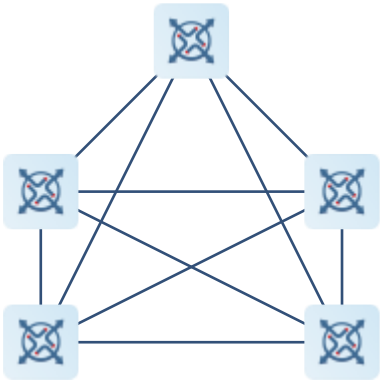
11. DR and BDR

In the broadcast or NBMA network, many unwanted LSAs will be created when an adjacency is set up with related routers. If there are n routers, n × (n-1)/2 adjacency relationships will be set up, and n^2 LSAs will be generated in the network. In the process of setting up the adjacency and exchanging LSAs, many unwanted copies will be produced, which leads to chaos in the flooding of a multi-access network. To avoid these problems on a multi-access network, OSPFv3 defines the concepts of DR and BDR.

After the DR and BDR are elected, all routers will set up an adjacency relationship with the DR and BDR only, send information to the DR/BDR, and the DR will broadcast the network link state. The routers other than DR and BDR are called DROther routers and they will no longer set up an adjacency relationship or exchange any

routing information with each other, thus reducing the number of adjacency relationships between routers on the broadcast and NBMA networks.

Figure 1-4 Number of Adjacency Relationships Before DR Election



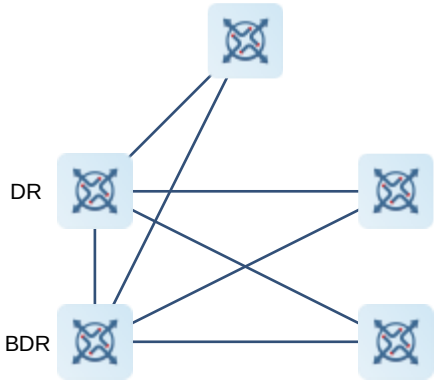


Figure 1-5 Number of Adjacency Relationships After DR Election

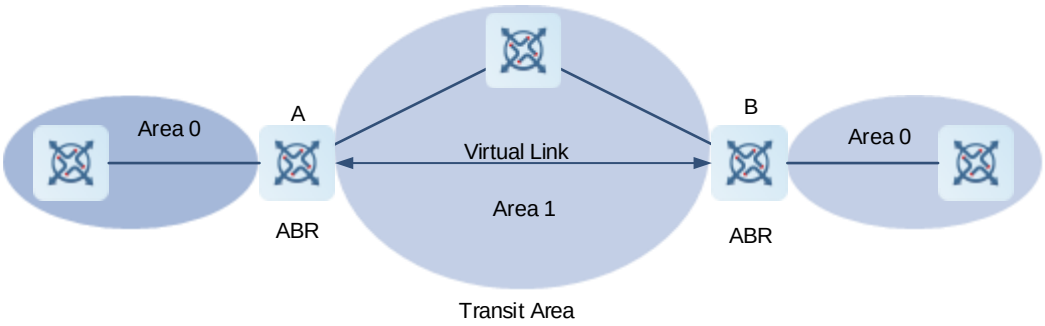
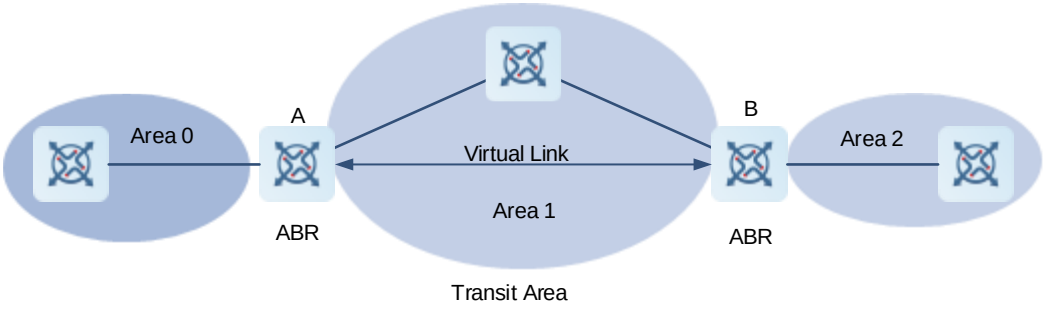


12. Virtual link

OSPFv3 supports virtual links. A virtual link is a logical link that belongs to the backbone area. It is used to resolve the problems such as a discontinuous backbone area or a failure to directly connect a normal area to the backbone area on the physical network. A virtual link supports traversal of only one normal area, and this area is called transit area. Routers on both ends of a virtual link are ABRs.



A virtual link relies on an OSPFv3 intra-domain route, making two ABRs adjacent. The OSPFv3 packet information exchanged by ABRs is transparent to the intermediate device.

Figure 1-6 Discontinuous Backbone Area on the Physical Network

As shown in Figure 1-6, a virtual link is set up between A and B to connect to Area 0. Area 1 is a transit area, and A and B are ABRs of Area 1.

Figure 1-7 Failure to Directly Connect a Normal Area to the Backbone Area on the Physical Network

As shown in Figure 1-7, a virtual link is set up between A and B to extend Area 0 to B so that Area 0 can be directly connected to Area 2 on B. Area 1 is a transit area, A is an ABR of Area 1, and B is an ABR of Area 1 and Area 2.

1.1.3 Principles

1. Simple principles

OSPFv3 is a type of link-state routing protocols. Its working process consists of three phases:

(1) Neighbor discovery > Bidirectional communication

An OSPFv3 neighbor relationship is set up between adjacent routers, and bidirectional communication is maintained.

(2) Database synchronization > Full adjacency

A router uses LSAs to advertise all its link states. LSAs are exchanged between neighbors and the LSDB is synchronized to achieve full adjacency.

(3) Shortest Path Tree (SPT) computation > Formation of a routing table

The router computes the shortest path to each destination network based on the LSDB and forms an OSPFv3 routing table.

- Neighbor discovery > Bidirectional communication

  Routers send hello packets through all OSPFv3-enabled interfaces or virtual links. If hello packets can be exchanged between two routers, and parameters carried in the hello packets can be successfully

negotiated, the two routers become neighbors. When routers that are mutual neighbors find their own router IDs from hello packets sent from neighbors, bidirectional communication is set up.

A hello packet includes, but is not limited to, the following information:

- ID of the originating router
- Area ID of the originating router interface or virtual link
- Instance ID of the originating router interface or virtual link
- Interface ID of the originating router interface or virtual link
- Priority of the originating router interface (used for DR/BDR election)
- Hello interval of the originating router interface or virtual link
- Neighbor dead interval of the originating router interface or virtual link
- IDs of the DR and BDR
- Router ID of the neighbor of the originating router

- Database synchronization > Full adjacency

  After bidirectional communication is set up between neighbor routers, the DD, LSR, LSU, and LSAck packets are used to exchange LSAs and set up the adjacency. The brief process is as follows:

  - A router generates an LSA to describe all link states on the router.
  - The LSA is exchanged between neighbors. When a router receives the LSA from its neighbor, it copies the LSA and saves the copy in the local LSDB, and then advertises the LSA to other neighbors.
  - When the router and its neighbors obtain the same LSDB, full adjacency is achieved.

Note

OSPFv3 will be very stable without change in link cost or network addition or deletion. If any change takes place, the changed link states are advertised to quickly synchronize the LSDB.

- SPT computation > Formation of a routing table

  After the complete LSDB is obtained from the router, the Dijkstra algorithm is run to generate an SPT from the local router to each destination network. The SPT records the destination networks, next-hop addresses, and cost. OSPFv3 generates a routing table based on the SPTs.

  If change in link cost or network addition or deletion takes place, the LSDB will be updated. The router again runs the Dijkstra algorithm, generates a new SPT, and updates the routing table.

Note

The Dijkstra algorithm is used to find the shortest path from a vertex to other vertices in a weighted directed graph.

2. OSPFv3 routing

- Routing cost

  If redundancy links or devices exist in the network, multiple paths may exist from the local device to the destination network. OSPFv3 selects the path with the minimum total cost to form an OSPFv3 route. The

total cost of a path is equal to the sum of the costs of individual links along the path. The total cost of a path can be minimized by modifying the costs of individual links along the path. In this way, OSPFv3 selects this path to form a route.

With configuration commands, you can modify the following link costs:

- Cost from the interface to the directly-connected network segment
- Cost from the interface to the neighbor (from local device to a specified neighbor)
- Cost from the ABR to the default network segment (cost of the default route that the ABR automatically advertises to the stub area and NSSA)
- Cost from the ASBR to an external network segment (cost of the default route that the ABR automatically advertises to the stub area and NSSA)
- Cost from the ASBR to the default network segment (cost of the default route that is manually introduced)

- OSPFv3 administrative distance

  The administrative distance (AD) is used to evaluate the reliability of various route sources. Its value is an integer ranging from 0 to 255. A smaller AD value indicates that the route is more trustworthy. If there are multiple routes to the same destination, the router preferentially selects a route with a smaller AD value. The route with a greater AD value becomes a floating route, that is, a standby route of the optimum route.

  By default, the route coming from one source corresponds to an AD value. The AD value is a local concept. Modifying the AD value affects route selection only on the current router.

Table 1-5 Routing Protocols and Default Administrative Distances

Route Source	Directly-connected network	Static route	EBGP route	OSPFv3 route	IS-IS route	RIP route	IBGP route	Unreachable route
Default AD	0	1	20	110	115	120	200	255

3. OSPFv3 route advertisement

- Route redistribution

  Route redistribution refers to the process of introducing routes of other routing protocols, routes of other OSPFv3 processes, static routes, and direct routes that exist on the device to an OSPFv3 process so that these routes can be advertised to neighbors using Type 5 and Type 7 LSAs. A default route cannot be introduced during route redistribution.

  Route redistribution is often used for interworking between ASs. You can configure route redistribution on an ASBR to advertise routes outside an AS to the interior of the AS, or routes inside an AS to the exterior of the AS.

- Default route introduction

  By configuring a command on an ASBR, you can introduce a default route to an OSPFv3 process so that the route can be advertised to neighbors using Type 5 and Type 7 LSAs.

Default route introduction is often used for interworking between ASs. One default route is used to replace all the routes outside an AS.

After configuration of route redistribution and introduction of a default route, the router automatically becomes an ASBR.

4. OSPFv3 route summarization

Route summarization is a process of summarizing routing information with the same prefix into one route, and advertising the summarized route (replacing a large number of individual routes) to neighbors. Route summarization helps reduce the protocol interaction load and the size of the routing table.

By default, the ABR advertises inter-area routing information by using Type 3 LSAs within a network segment, and advertises redistributed routing information by using Type 5 and Type 7 LSAs. If continuous network segments exist, you are advised to configure route summarization.

After route summarization is configured, the ABR sends only Type 3 LSAs that summarize prefix of IPv6 addresses, and the ASBR sends only Type 5 and Type 7 LSAs that summarize prefix of IPv6 addresses and will not send LSAs with the prefix of IPv6 addresses.

5. OSPFv3 route filtering

OSPFv3 allows filtering the learned and exchanged routes and LSAs so as to meet the security requirements in specific scenarios, for example, the routes of some network segments are not intended to be learned by other areas.

With configuration commands, you can configure route filtering for the following items:

- Interface: The interface is prevented from sending routing information (any LSA) or exchanging routing information (any LSA) with neighbors.
- Routing information outside an AS: Only the routing information that meets the filtering conditions can be redistributed to the OSPFv3 process (Type 5 and Type 7 LSAs).
- LSAs received by a router: In the OSPFv3 routing table, only the routes that are computed based on the LSAs meeting the filtering conditions can be advertised.

6. Stub area and NSSA

The stub/totally stub area and NSSA/totally NSSA help reduce the protocol interaction load and the size of the routing table.

- If an appropriate area is configured as a stub/totally stub area or NSSA/totally NSSA, advertisement of a large number of Type 5 and Type 3 LSAs can be avoided within the area.

Table 1-6 LSAs in Stub Area/NSSA

Area	LSA Types 1 and 2	LSA Type 3	LSA Type 4	LSA Type 5	LSA Type 7
Non-stub/totally stub area and non-NSSA/totally NSSA	Allowed	Allowed	Allowed	Allowed	Not allowed

Area	LSA Types 1 and 2	LSA Type 3	LSA Type 4	LSA Type 5	LSA Type 7
Stub area	Allowed	Allowed (containing one default route)	Not allowed	Not allowed	Not allowed
Totally stub area	Allowed	Only one default route is allowed.	Not allowed	Not allowed	Not allowed
NSSA	Allowed	Allowed (containing one default route)	Allowed	Not allowed	Allowed
Totally NSSA	Allowed	Only one default route is allowed.	Allowed	Not allowed	Allowed

Note

- The ABR uses Type 3 LSAs to advertise a default route to the stub/totally stub area or NSSA/totally NSSA.
- The ABR translates Type 7 LSAs in the NSSA and totally NSSA to Type 5 LSAs, and advertises Type 5 LSAs to the backbone area.

- If an appropriate area is configured as a stub/totally stub area or NSSA/totally NSSA, a large number of OE1, OE2, and OI routes will not be added to the routing table of a router in the area.

Table 1-7 Route Types in Stub Areas/NSSAs

Area	Routes Available in the Routing Table of a Router Inside the Area
Non-stub/totally stub area and non-NSSA/totally NSSA	O: a route to a destination network in the local area OI: a route to a destination network segment in another area OE1 or OE2: a route or default route to a destination network segment outside the AS (via any ASBR in the AS)
Stub area	O: a route to a destination network in the local area OI: a route or a default route to a destination network segment in another area
Totally stub area	O: a route to a destination network in the local area OI: a default route

Area	Routes Available in the Routing Table of a Router Inside the Area
NSSA	O: a route to a destination network in the local area OI: a route or a default route to a destination network segment in another area ON1 or ON2: a route or default route to a destination network segment outside the AS (via an ASBR in the local area)
Totally NSSA	O: a route to a destination network in the local area OI: a default route ON1 or ON2: a route or default route to a destination network segment outside the AS (via an ASBR in the local area)

Note

- A backbone area cannot be configured as a stub area or an NSSA.
- A transit area with virtual links going through cannot be configured as a stub area or an NSSA.
- An area containing an ASBR cannot be configured as a stub area.

7. Enhanced security and reliability

The functions such as authentication and bidirectional forwarding detection (BFD) correlation are used to enhance security, stability, and reliability of OSPFv3.

- Authentication

  OSPFv3 uses IPv6 to provide two authentication mechanisms: authentication header (AH) and encapsulating security payload (ESP), to prevent illegal routers from accessing the network and prevent hosts that forge OSPFv3 packets from participating in OSPFv3 route switching. OSPFv3 packets received on the OSPFv3 interface or at both ends of a virtual link are authenticated. If authentication fails, the packets are discarded and no adjacency can be set up. Enabling authentication can avoid learning unauthenticated or invalid routes, thus preventing advertising valid routes to unauthenticated devices. In the broadcast-type network, authentication also prevents unauthenticated devices from becoming designated devices, ensuring stability of the routing system and protecting the routing system against intrusions.

  Authentication is classified into following two types:

  - Area authentication: This area-level authentication authenticates the packets transmitted by all the interfaces in the area. This authentication type is configured in OSPFv3 routing process mode.
  - Interface authentication: This neighbor-level authentication authenticates the packets transmitted on the related interface. This authentication type is configured in interface mode.

- MTU verification

  Upon receiving a DD packet, OSPFv3 checks whether the MTU of the neighbor interface is the same as that of the local interface. If the MTU of the interface specified in the received DD packet is greater than that

of the interface that receives the packet, the adjacency cannot be set up. Disabling MTU verification can avoid this problem.

- Two-way maintenance

  OSPFv3 routers periodically send hello packets to each other to maintain the adjacency. In a large network, a lot of packets may be sent or received, occupying a great proportion of CPU and memory. As a result, some packets are delayed or discarded. If the processing time of hello packets exceeds the dead interval, the adjacency will be destroyed.

  If the two-way maintenance function is enabled, in addition to the hello packets, the DD, LSU, LSR, and LSAck packets can also be used to maintain the bidirectional communication between neighbors, which makes the adjacency more stable.

- Concurrent neighbor interaction restriction

  When a router simultaneously exchanges data with multiple neighbors, its performance may be affected. If the maximum number of neighbors that concurrently initiate or accept interaction with the OSPFv3 process is restricted, the router can interact with neighbors by batches, which ensures data forwarding and other key services.

- Allowing Type-9 LSAs to carry IPv6 prefixes

  You can run commands to configure the IPv6 address field in Type-9 LSAs to carry IPv6 addresses or IPv6 prefixes.

- GR

  The control and forwarding separated technology is widely used among routers. On a relatively stable network topology, when a graceful restart (GR) enabled router is restarted on the control plane, data forwarding can continue on the forwarding plane. In addition, actions (such as adjacency re-forming and route computation) performed on the control plane do not affect functions of the forwarding plane. In this way, service interruption caused by route flapping can be avoided, thus enhancing reliability of the entire network.

  Currently, the GR function is used only during active/standby switchover and system upgrade.

Figure 1-8 Normal OSPFv3 GR Process

- The GR process requires collaboration between the restarter and the helper. The restarter is the router where GR occurs. The helper is a neighbor of the restarter.
- When entering or exiting the GR process, the restarter sends a grace-LSA to the neighbor, notifying the neighbor to enter or exit the helper state.
- When the adjacency between the restarter and the helper reaches the full state, the router can exit the GR process successfully.

- **Fast hello**
  - OSPFv3 correlation with BFD

    After a link fails, it takes a period of time (about 40s) before OSPFv3 can sense the failure of the neighbor. Then, OSPFv3 advertises the information and re-computes the SPT. During this period, traffic is interrupted.
  - After the fast hello function is enabled (that is, the neighbor dead interval is set to 1s), OSPFv3 can sense the failure of the neighbor within 1s once a link is faulty. This accelerates route convergence and prevents traffic interruption.
  - BFD is used to test connectivity between devices. A link fault can be detected in as short as 150 ms. After OSPFv3 is correlated with BFD, OSPFv3 can sense the failure of a neighbor in as short as 150 ms once a link is faulty. This accelerates route convergence and prevents traffic interruption.

8. Network management functions

Functions such as management information base (MIB) and Syslog are used to facilitate OSPFv3 management.

- MIB

MIB is the device state information set maintained by a device. You can use the management program to view and set the MIB node.

Multiple OSPFv3 processes can be simultaneously started on a router, but the OSPFv3 MIB can be bound to only one OSPFv3 process.

- Trap

  A trap message is a notification generated when the system detects a fault. This message contains the related fault information.

  If the trap function is enabled, the router can actively send the trap messages to the network management device.

- Syslog

  The syslog records the operations (such as command configuration) performed by users on routers and specific events (such as network connection failures).

  If the syslog is allowed to record the adjacency changes, the network administrator can view the logs to learn the entire process from OSPFv3 adjacency setup to maintenance.

1.1.4 Protocols and Standards

- RFC 2740: This document describes the modifications to OSPFv3 to support version 6 of the Internet Protocol (IPv6).
- draft-ietf-ospf-ospfv3-graceful-restart: This document describes the OSPFv3 graceful restart. The OSPFv3 graceful restart is identical to OSPFv3v2 except for the differences described in this document. These differences include the format of the grace Link State Advertisements (LSA) and other considerations.
- draft-ietf-ospf-ospfv3-mib-11: This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in IPv6-based Internet. In particular, it defines objects for managing the Open Shortest Path First Routing Protocol for IPv6.

1.2 Configuration Task Summary

OSPFv3 configuration includes the following tasks:

(1) Configuring Basic OSPFv3 Functions
   - Configuring OSPFv3
   - (Optional) Creating a Virtual Link

(2) (Optional) Configuring OSPFv3 Network Types

(3) (Optional) Configuring OSPFv3 Route Advertisement. The following configuration tasks are optional. Select tasks for configuration according to the actual condition.
   - Configuring External Route Redistribution
   - Generating a Default Route
   - Configuring a Device as ASBR

(4) (Optional) Configuring Stub Area and NSSA

(5) (Optional) Configuring OSPFv3 Route Summarization

(6) (Optional) Configuring OSPFv3 Route Filtering

(7) (Optional) Adjusting OSPFv3 Routing

(8) (Optional) Adjusting OSPFv3 Network Convergence Speed. The following configuration tasks are optional. Select tasks for configuration according to the actual condition.

- Configuring Transmission Time of OSPFv3 Packets
- Configuring OSPFv3 Route Computation Time

(9) (Optional) Enabling OSPFv3 Authentication. The following configuration tasks are optional. Select tasks for configuration according to the actual condition.

- Configuring Area Authentication and Encryption
- Configuring Interface Authentication and Encryption

(10) (Optional) Configuring Fast Reroute

- Enabling the FRR Function
- Configuring Interface LFA Protection
- Configuring an Interface Not to Serve as a Backup Interface

(11) (Optional) Enabling Two-Way Maintenance

(12) (Optional) Correlating OSPFv3 with BFD

(13) (Optional) Enabling the GR Function

(14) (Optional) Enabling NSR

(15) (Optional) Enabling Conflict Detection of Type 4 LSAs

(16) (Optional) Modifying the Maximum Number of Concurrent Neighbors

(17) (Optional) Allowing Type-9 LSA to Carry IPv6 Prefixes

(18) (Optional) Configuring Network Management Functions

(19) (Optional) Disabling MTU Verification

(20) (Optional) Enabling the Function of Securely Promoting a BDR to DR

(21) (Optional) Enabling OSPFv3 on a Super VLAN

1.3 Configuring Basic OSPFv3 Functions

1.3.1 Overview

Set up an OSPFv3 routing domain in the network to provide IPv6 unicast routing service for users in the network.

1.3.2 Restrictions and Guidelines

- Ensure that the IPv6 routing function is enabled, that is, the **ipv6 routing** command is not disabled; otherwise, OSPFv3 cannot be enabled.
- The interface is configured with an IPv6 address.

1.3.3 Configuration Tasks

Basic OSPFv3 function configuration includes the following tasks:

(1) Configuring OSPFv3

(2) (Optional) Creating a Virtual Link

1.3.4 Configuring OSPFv3

1. Overview

The basic OSPFv3 functions are the prerequisites of all OSPFv3 functions. An OSPFv3 process must be created, a router ID can be specified for this process, and OSPFv3 must be configured on the interface.

2. Restrictions and Guidelines

- The configuration is mandatory for every OSPFv3 router.
- You are advised to configure the router ID.
- Run the **ipv6 ospf set-area** command in the interface configuration mode to enable the OSPFv3 function on the interface, and then run the **ipv6 router-protocol ospf** command to configure an OSPFv3 process. After the OSPFv3 process is configured, the interface will automatically participate in the related process. The adjacency can be set up only between devices with the same instance ID.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an OSPFv3 process and enter OSPFv3 configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) (Optional) Configure a router ID.

router-id *router-id*

By default, the OSPFv3 routing process elects the largest IPv4 address among all the loopback interfaces as the router ID. If the loopback interfaces configured with IP addresses are not available, the OSPFv3 process elects the largest one among the IP addresses of all its physical interfaces as the router ID.

(5) Return to the global configuration mode.

exit

(6) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregated interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*

- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the Overlay router interface configuration mode.
  - **interface overlayrouter** *interface-number*

(7) Enable OSPFv3 on the interface and specify an area ID.

ipv6 ospf *process-id* **set-area** *area-id* [**instance** *instance-id*]

OSPFv3 is disabled on an interface by default.

1.3.5 Creating a Virtual Link

1. Overview

In an OSPFv3 AS, all areas must be connected to the backbone area to properly learn the routing information of the entire OSPFv3 AS. If an area cannot be directly connected to the backbone area, the virtual link can be used to connect this area to the backbone area.

2. Restrictions and Guidelines

- The area where the virtual link is located cannot be a stub area or NSSA.
- At both ends of neighbors between which the virtual link is set up, settings of **hello-period**, **dead-period**, and **instance** must be consistent; otherwise, the adjacency cannot be set up properly.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Configure a virtual link.

area *area-id* **vlink** *router-id* [**dead-period** *dead-period* | **hello-period** *hello-period* | **instance** *instance-id* | **retransmit-period** *retransmit-period* | **transmit-lsu-delay** *transmit-delay*] * [**auth-algorithm ipsec spi** *spi* { **md5** | **sha1** } [**0** | **7**] *key* | **encipherment ipsec spi** *spi* **esp** [**3des** | **aes-cbc** { **128** | **192** | **256** } [**0** | **7**] *des-key* | **des** [**0** | **7**] *des-key* | **null**] { **md5** | **sha1** } [**0** | **7**] *key*]

No virtual link is configured by default.

1.4 Configuring OSPFv3 Network Types

1.4.1 Overview

If the physical network is X.25, frame relay, or ATM, OSPFv3 can also run to provide the IPv6 unicast routing service.

OSPFv3 classifies networks into five types according to the link layer protocol type so that LSAs are exchanged in different ways to set up an adjacency. You can configure to forcibly change the network type of an interface.

1.4.2 Restrictions and Guidelines

- The broadcast network sends OSPFv3 multicast packets, automatically discovers neighbors, and elects a DR and a BDR.
- The P2P network sends OSPFv3 multicast packets and automatically discovers neighbors.
- The NBMA network sends OSPFv3 unicast packets. Neighbors must be manually specified, and a DR and a BDR must be elected.
- The P2MP network (without carrying the **non-broadcast** parameter) sends OSPFv3 multicast packets and automatically discovers neighbors.
- The P2MP network (carrying the **non-broadcast** parameter) sends OSPFv3 unicast packets. Neighbors must be manually specified.
- On a broadcast network, a DR or BDR must be elected. During the DR/BDR election, the device with a higher priority will be preferentially elected as a DR or BDR. If the priority is the same, the device with a larger router ID will be preferentially elected as a DR or BDR. A device with the priority 0 does not participate in the DR or BDR election.

1.4.3 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.4.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregated interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*

- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the Overlay router interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure a network type for the interface.

ipv6 ospf network-type { **broadcast** | **non-broadcast** | **point-to-multipoint** [**non-broadcast**] | **point-to-point** } [**instance** *instance-id*]

No interface type of OSPFv3 is configured by default. Routers at both ends of a link must be configured with the same network type.

(5) (Optional) Configure neighbors.

ipv6 ospf peer *ipv6-address* [**metric** *cost* | [**poll-interval** *poll-interval* | **priority-value** *value*] *] [**instance** *instance-id*]

No neighbor is configured by default.

(6) (Optional) Configure the interface priority.

ipv6 ospf priority-value *priority* [**instance** *instance-id*]

The priority value is 1 by default.

1.5 Configuring OSPFv3 Route Advertisement

1.5.1 Overview

The function aims to introduce unicast routes for other AS domains or default routes to other AS domains to the OSPFv3 domain and provides the unicast routing service to other AS domains for users in the OSPFv3 domain. The router that introduces routes will automatically become an ASBR.

OSPFv3 has two types of external routes. The metric of the Type 1 external route changes, but the metric of the Type 2 external route is fixed. If two parallel paths to the same destination network have the same route metric, the priority of Type 1 route is higher than that of Type 2 route. Therefore, running the display ipv6 route-config command displays only the Type 1 route.

1.5.2 Configuration Tasks

The following configuration tasks are optional. Select tasks for configuration according to the actual condition.

- Configuring External Route Redistribution
- Generating a Default Route
- Configuring a Device as ASBR

1.5.3 Configuring External Route Redistribution

1. Overview

Configure external route redistribution if external routes of the OSPFv3 domain need to be introduced to an ASBR.

2. Restrictions and Guidelines

- Configure **redistribute-route** on an ASBR.
- During redistribution of IS-IS routes, **level-1**, **level-2**, or **level-1-2** parameters can be configured to indicate that IS-IS routes of the specified levels are configured. By default, level-2 IS-IS routes are redistributed.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Configure external route redistribution.

redistribute-route { **bgp** | **connected** | **isis** [*area-tag*] [**level-1** | **level-1-2** | **level-2**] * | **ospf** *process-id* [**filter** { **external-type** [**1** | **2**] | **internal-type** | **nssa-external-type** [**1** | **2**] } *] | **rip** | **static** } [**metric-value** *metric-value* | **metric-type** { **1** | **2** } | **route-map** *route-map-name* | **tag-value** *tag-value*] *

The route redistribution function is not enabled by default. The default metric type is **2**.

Level-2 routes are redistributed by default during IS-IS redistribution.

OSPFv3 routes of all sub-types are redistributed by default during OSPFv3 redistribution. The **route map** is not associated by default.

1.5.4 Generating a Default Route

1. Overview

A default route needs to be introduced to an ASBR so that other routers in the OSPFv3 domain access other AS domains through this ASBR by default.

2. Restrictions and Guidelines

- When the **redistribute-route** or **default-info** command is executed, the OSPFv3 router automatically becomes an ASBR.
- The ASBR, however, does not automatically generate or advertise a default route to all routers in the OSPFv3 routing domain. To enable an ASBR to generate a default route, run the **default-info originate** command.
- If the **constantly** parameter is specified, the OSPFv3 process advertises an external default route to neighbors no matter whether a default route exists in the core routing table. This default route, however, is not displayed on the local router. To confirm whether the default route is generated, run the **display ipv6**

ospf-instance database-info command to display the OSPFv3 link status database. On an OSPFv3 neighbor, you can run the **display ipv6 route-config ospf** command to see the default route.

- The metric of the external default route can be defined only by the **default-info originate** command, instead of the **default-metric** command.
- A router in a stub area cannot generate an external default route.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Generate a default route.

default-info originate [**constantly** | **metric-value** *metric* | **metric-class** *type* | **route-map** *map*] *

No default route is generated by default.

1.5.5 Configuring a Device as ASBR

1. Overview

Configure a device as ASBR in the AS domain or AS boundary.

1.5.6 Restrictions and Guidelines

After the redistribute-route or default-info command is executed, an OSPFv3 router automatically becomes an ASBR. If you want the device to become an ASBR without configuring the above command, run the asbr enable command.

If the asbr enable command is deleted, but the redistribute-route or default-info command configuration remains valid, the device is still an ASBR.

1. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Configure a device as ASBR.

asbr enable

No device is an ASBR by default.

1.6 Configuring Stub Area and NSSA

1.6.1 Overview

The function is used to configure an area located on the stub as a stub area to reduce interaction of routing information and the size of routing table, and enhance stability of routes. Devices in a stub area cannot learn the external routes (Type 5 LSAs) of the AS. In practice, external routes take up a large proportion of the LSDB. Therefore, devices in a stub area can learn only a small amount of routing information, which reduces the amount of system resources required to run the OSPFv3 protocol.

To reduce the size of the routing table on routers in the area and introduce OSPFv3 external routes to the area, configure the stub area as an NSSA.

1.6.2 Restrictions and Guidelines

- A backbone or transit area cannot be configured as a stub area or an NSSA.
- A router in the stub area cannot introduce external routes, but a router in the NSSA can introduce external routes.
- An area located on the stub of a network can be configured as a stub area. You must run the **area stub** command on all routers in a stub area.
- To configure a totally stub area, add the **unset-summary** keyword when you are running the **area stub** command on the ABR.
- To configure a totally NSSA, you can configure the **unset-summary** parameter on the ABR to prevent the ABR from sending the summary LSAs (Type 3 LSAs) to the NSSA.

1.6.3 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 routing configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Configure a special OSPFv3 area. Configure one of the following tasks.

- Configure a stub area.

  area *area-id* **stub** [**unset**-**summary**]

  The stub area function is disabled by default.

- Configure an NSSA.

  area *area-id* **nssa** [**default-originate** [**metric-value** *metric* | **metric-class** *metric-type*] | **unset-redistribution** | **unset-summary** | **translator** [**constantly** | **stability**-**interval** *stability-interval*] | **zero**-**address**-**forwarding**]

1.7 Configuring OSPFv3 Route Summarization

1.7.1 Overview

Summarize routes to reduce interaction of routing information and the size of routing table, and enhance stability of routes.

Route summarization is classified into two types:

- Inter-area route summarization means to summarize routes between OSPFv3 areas.
- External route summarization means to summarize external routes of an OSPFv3 routing domain.

1.7.2 Restrictions and Guidelines

- The address range of the routes to be summarized may exceed the actual network range in the routing table. If data is sent to a network beyond the summarization range, a routing loop may be formed and the router processing load may increase. To prevent these problems, a discard route must be added to the routing table to shield or filter routes.
- Inter-area route summarization is configured and only takes effect on an ABR.
- External route summarization is configured on the ASBR that introduces routes.
- When configured on the NSSA ABR translator, **summary-prefix** summarizes redistributed routes and routes obtained based on the LSAs that are translated from Type 7 to Type 5. When configured on the ASBR (not an NSSA ABR translator), **summary-prefix** summarizes only redistributed routes.

1.7.3 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 routing configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) (Optional) Configure inter-area route summarization.

area *area-id* **summary** *ipv6-prefix*/*prefix-length* [**advertise** | **not-advertise**]

Inter-area route summarization is not performed by default.

(5) (Optional) Configure external route summarization.

summary-prefix *ipv6-prefix*/*prefix-length* [[**metric** *cost* | **tag** *tag-value*] * | **not-advertise**]

Route summarization is disabled by default.

1.8 Configuring OSPFv3 Route Filtering

1.8.1 Overview

Route filtering can prevent routes from being loaded to the routing table or advertised to neighbors. Network users cannot access the specified destination network.

Routes are filtered using the following three methods:

- When an interface is configured as a passive interface, it no longer sends or receives hello packets.
- External routes are introduced to the ASBR.
- To prevent users from accessing the specified destination network, run the **route-filtering in** command to filter routes that are computed based on the received LSAs. Only routes meeting the filtering conditions can be forwarded. The command does not affect the LSDB or the routing tables of neighbors.

1.8.2 Restrictions and Guidelines

- The **disable-interface** command takes effect only on OSPFv3 interfaces, not on virtual links.
- The **route-filtering outbound** command is used with the **redistribute-route** command generally. The ACL filtering rules and prefix list filtering rules are mutually exclusive in the configuration. If the ACL is used for filtering routes coming from a source, the prefix list cannot be configured to filter the same routes.
- Filtering routes by using the **route-filtering in** command affects forwarding of local routes only, but does not affect route computation based on LSAs. Therefore, if route filtering is configured on the ABR, Type 3 LSAs will still be generated and advertised to other areas because routes can still be computed based on LSAs. As a result, black hole routes are generated. In this case, you can run the **area filter-rule-list** or **area status** (containing the **not-advertise** parameter) command on the ABR to prevent generation of black-hole routes.

1.8.3 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.8.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 routing configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) (Optional) Configure a passive interface.

disable-interface { **default** | *interface-type interface-number* }

The passive mode of interfaces is disabled by default, and all interfaces are allowed to send and receive OSPFv3 packets.

(5) (Optional) Configure redistributed route filtering.

route-filtering { *acl-name* | **prefix-list** *prefix-list-name* | **route-map** } **out** [**bgp** | **connected** | **isis** [*area-tag*] | **ospf** *process-id* | **rip** | **static**]

By default, the filtering function of redistributed routes is disabled, that is, all the redistributed routes pass the filtering rules.

(6) Configure learned route filtering.

route-filtering { *acl-name* | **prefix-list** *prefix-list-name* | **route-map** *route-map-name* } **in** [*interface-type interface-number*]

By default, the function of filtering routes computed based on the received LSAs is disabled, that is, all these routes get passed.

1.9 Adjusting OSPFv3 Routing

1.9.1 Overview

In actual network scenario, the network administrator expects to control OSPFv3 routes so that traffic passes or bypasses some nodes or to adjust priority of a type of OSPFv3 routes.

1.9.2 Restrictions and Guidelines

There are two methods of adjusting OSPFv3 routes:

- Adjust cost values.
  - Configure the reference bandwidth.
  - Configure the interface cost.
  - Configure cost of the default route in a stub area or an NSSA.
  - Configure redistributed route cost.
- Modify the administrative distance.

1.9.3 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.9.4 Configuration Tasks

The configuration tasks for adjusting OSPF routing are as follows. The following configuration tasks are optional. Select tasks for configuration according to the actual condition.

- Configuring Reference Bandwidth
- Configuring Interface Cost
- Configure the cost value of the default route in a stub area or an NSSA.
- Configuring Default Metric of Redistributed Routes
- Configuring Administrative Distance

1.9.5 Configuring Reference Bandwidth

1. Overview

The default value of OSPFv3 reference bandwidth is 100 Mbps, and the cost is the reference bandwidth/actual bandwidth. In gigabit and 10-gigabit network environments, the calculated cost is 1. The default bandwidth cannot meet the requirements of today's high-speed transmission networks. The router connects routes of

different bandwidths. You are advised to adjust the configuration according to the actual bandwidth if you want to give priority to lines with large bandwidth.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 routing configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Configure the reference bandwidth.

auto-gen-cost reference-bandwidth *reference-bandwidth*

The default reference bandwidth value computed based on the metric of an interface is **100** Mbps.

1.9.6 Configuring Interface Cost

1. Overview

You can modify the interface cost of OSPFv3 to optimize routing. The lower the link cost, the higher the priority in routing.

2. Restrictions and Guidelines

- By default, the OSPFv3 interface cost is equal to the automatic cost reference value/interface bandwidth.
- A router connects multiple lines. You are advised to configure this function if you want to manually specify the priority route.
- You can use the **auto-gen-post** command to configure the automatic reference cost. The default value is 100 Mbps.
- You can use the **bandwidth** command to configure the interface bandwidth.
- Default OSPF interface costs of typical lines:
  - For the 64K serial line, the cost is 1562;
  - For the E1 line, the cost is 48;
  - For the 10 Mbps Ethernet line, the cost is 10;
  - For the 100 Mbps Ethernet line, the cost is 1.
- If you have configured the interface cost using the **ipv6 ospf cost** command, the cost calculated automatically will be overwritten by the configured cost.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the Overlay router interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Configure the interface cost.

ipv6 ospf cost *cost* [**instance** *instance-id*]

The default cost value of an OSPFv3 interface is **100** Mbps/Bandwidth. Bandwidth indicates the bandwidth of the interface and it is configured by running the **bandwidth** command in the interface configuration mode.

1.9.7 Configure the cost value of the default route in a stub area or an NSSA.

1. Overview

After an area is configured as a Stub/NSSA area, the ABR will advertise the default route to the Stub/NSSA area to ensure that the route from the Stub/NSSA area to other areas is reachable. The default cost of the default route is 1. If you want to reduce the routing priority of the default route, you can configure a higher cost for the default route.

2. Restrictions and Guidelines

The configuration can only take effect on the ABR of the Stub area or the ABR/ASBR of the NSSA area.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 routing configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Configure the cost of the default route of the Stub/NSSA area.

area *area-id* **default-metric** *cost*

By default, the cost of the default route is 1.

1.9.8 Configuring Default Metric of Redistributed Routes

1. Overview

In the case of redistributing an external route, the cost of the external route can be flexibly adjusted for routing.

2. Restrictions and Guidelines

- This function must be configured when an external route is imported on the ASBR, in order to specify the cost of the external route.
- The **default-metric** command must be used with the **redistribute-route** routing configuration command to modify the initial metrics of all redistributed routes.
- The **default-metric** command does not take effect on external routes that are injected into the OSPFv3 routing domain using the **default-info originate** command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 routing configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Configure default metric of redistributed routes.

default-metric *metric*

By default, the metric for redistributed routes is 20.

1.9.9 Configuring Administrative Distance

1. Overview

Administrative distance can be used to select the best route when multiple routing protocols are used to reach the same destination. Administrative distance defines the reliability of a routing protocol. The lower the administrative distance, the higher the reliability, and the higher the priority of routing. The default administrative distance of OSPFv3 intra-domain routing, inter-domain routing and external routing is 110. You can set different administrative distances to control routing.

2. Restrictions and Guidelines

- This function must be configured if multiple unicast routing protocols run on the router at the same time, and you want to change the priority of OSPFv3 routing.
- You can use this command to specify different administrative distances for different OSPF routes.
- The lower the value of administrative distance, the higher the routing priority. If the value of administrative distance is 255, the routing table entry is not trusted and will not participate in packet forwarding.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 routing configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Configure an administrative distance.

distance { *distance* | **ospf** { **external-routes** *distance* | **inter-area-routes** *distance* | **intra-area** *distance* } * }

The default administrative distance of all OSPFv3 routes is **110**.

1.10 Adjusting OSPFv3 Network Convergence Speed

1.10.1 Overview

The OSPFv3 network convergence speed is controlled by adjusting the transmission time and route computation time of OSPFv3 packets.

1.10.2 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.10.3 Configuration Tasks

The following configuration tasks are optional. Select tasks for configuration according to the actual condition.

- Configuring Transmission Time of OSPFv3 Packets
- Configuring OSPFv3 Route Computation Time

1.10.4 Configuring Transmission Time of OSPFv3 Packets

1. Overview

The OSPFv3 network convergence speed is controlled by adjusting the hello packet sending interval, dead interval and LSU transmission time of an OSPFv3 interface.

2. Restrictions and Guidelines

- Hello packet sending interval
  - A shorter hello interval indicates that OSPFv3 can detect topology changes more quickly, but the network traffic increases.
  - By default, the neighbor dead interval is four times the hello packet sending interval. If the hello packet sending interval is modified, the dead interval is modified automatically.
  - The neighbor dead interval cannot be shorter than the hello packet sending interval.
  - The hello packet sending intervals and the neighbor dead intervals must be the same on all routers in the same network segment.
- Dead interval

- The dead interval cannot be smaller than the hello packet sending interval.
- The dead interval must be the same on all routers in the same network segment.

- The sending delay and line transmission delay of the interface must be considered when the **transmit-lsu-delay** command is configured. For a low-speed line, the transmission delay of the interface must be set to a value greater than the default value.
- If no acknowledgment is received from the neighbor within the time defined by the **retransmit-period** command, the LSU packet is retransmitted. The retransmission delay can be set to a value greater than the default value on a serial line or virtual link to prevent unwanted retransmission.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the Overlay router interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) (Optional) Configure the hello interval.

ipv6 ospf hello-period *hello-interval* [**instance** *instance-id*]

The default hello packet sending interval of the broadcast and P2P networks is **10** seconds. The default hello packet sending interval of the P2MP and NBMA networks is **30** seconds.

(5) (Optional) Configure the dead interval.

ipv6 ospf dead-period { *dead-period* | **minimum hello-multiplier** *multiplier* } [**instance** *instance-id*]

The fast hello function is disabled by default, and the neighbor dead interval is four times the sending interval of hello packets.

(6) (Optional) Configure the LSU transmission time.

ipv6 ospf transmit-lsu-delay *transmit-delay* [**instance** *instance-id*]

The default LSU packet transmission time is **1** second.

(7) (Optional) Configure the LSU retransmission interval.

ipv6 ospf retransmit-period *retransmit-period* [**instance** *instance-id*]

The default LSU retransmission interval is **5** seconds.

1.10.5 Configuring OSPFv3 Route Computation Time

1. Overview

OSPFv3 route convergence speed is controlled by adjusting the LSA generation time, LSA group refresh time, SPF computation time, and route computation time.

2. Restrictions and Guidelines

- LSA generation time
  - If a high requirement is raised for network convergence during link change, you can set *delay-time* to a smaller value. You can also appropriately increase the values of the preceding parameters to reduce the CPU usage.
  - The value of *hold-time* cannot be smaller than the value of *delay-time*, and the value of *max-wait-time* cannot be smaller than the value of *hold-time*.
- LSA group refresh time
  - Every LSA has a time to live (TTL) age. When the LSA age reaches 1800s, a refreshment is needed to prevent LSAs from being cleared because their ages reaching the maximum. If LSA update and aging computation are performed for every LSA, the device will consume a lot of CPU resources. To use CPU resources effectively, you can refresh LSAs by group on the device. The interval of group refreshment is called group pacing interval. The group refreshment operation is to organize the LSAs generated within a group pacing interval into a group and refresh the group as a whole.
  - If the total number of LSAs does not change, a larger group pacing interval indicates that more LSAs need to be processed after timeout. To maintain the CPU stability, the number of LSAs to be processed upon each timeout cannot be too large. If the number of LSAs is large, you are advised to reduce the group pacing interval. For example, if there are 10,000 LSAs in the database, you can reduce the pacing interval; if there are 40 to 100 LSAs, you can set the pacing interval to 10-20 minutes.
- LSA group sending interval

  If the number of LSAs is large and the device load is heavy in an environment, properly configuring *transimit-time* and *transimit-count* can limit the number of LS-UPD packets flooded in the network. If the CPU usage is not high and the network bandwidth load is not heavy, reducing the value of *transimit-time* and increasing the value of *transimit-count* can accelerate the environment convergence.
- SPF computation time
  - The *spf-delay* and *spf-holdtime* can be set to smaller values to accelerate topology convergence, and *spf-max-waittime* can be set to a larger value to reduce SPF computation.

- The value of *spf-holdtime* cannot be smaller than that of *spf-delay*; otherwise, the value of *spf-holdtime* will be automatically set to the value of spf-delay.
- The value of *spf-max-waittime* cannot be smaller than that of *spf-holdtime*; otherwise, *spf-max-waittime* will be automatically set to the value of *spf-holdtime*.
- The configurations of **timers-set throttling spf** and **timers-set spf** are mutually overwritten.
- When neither **timers-set spf** nor **timers-set throttling spf** is configured, the default value of **timers-set throttling spf** prevails.

- Computation delays of inter-area routes and external routes

  If a lot of inter-area or external routes exist in the network and the network is not stable, adjust the corresponding delays and optimize route computation to reduce the load on the device.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) (Optional) Configure the LSA generation time.

timers-set throttling lsa all *delay-time hold-time max-wait-time*

The default minimum delay of LSA generation is **0** ms, the minimum interval between the first update and the second update of LSA is **5000** ms, and the maximum interval between consecutive LSA updates is **5000** ms.

(5) (Optional) Configure the LSA group refresh time.

timers-set packet-pacing lsa-batch *update-time*

The default group refresh time of LSAs is **30** seconds.

(6) (Optional) Configure LSA group sending interval.

timers-set packet-pacing lsa-transmit *transmit-time transmit-count*

The default LSA group sending interval is **40** ms, and the number of LS-UPD packets in each group is **1**.

(7) (Optional) Configure the SPF computation delay.

timers-set throttling spf *spf-delay spf-holdtime spf-max-waittime*

The default delay for SPF computation is **50** ms, the minimum interval between two SPF computations is **200** ms, and the maximum interval between two SPF computations is **5000** ms.

(8) Configure the computation delays of inter-area routes and external routes.

timers-set throttling route { **ase** *ase-delay* | **inter-area** *ia-delay* }

The default delay for inter-area route and external route computation is **0** ms.

(9) (Optional) Configure duplicate LSA receiving delay.

timers-set lsa repeat-delay *arrival-time*

The default delay for receiving a duplicate LSA is **1000** ms.

1.11 Enabling OSPFv3 Authentication

1.11.1 Overview

OSPFv3 uses the authentication mechanism, that is, IP authentication header (AH) and IP encapsulating security payload (ESP), provided by IPv6 to prevent unauthorized routers from accessing the network and hosts that forge OSPFv3 packets from participating in OSPFv3 routing.

1.11.2 Restrictions and Guidelines

- If an OSPFv3 instance is associated with SA authentication, SA authentication takes effect on all the interfaces under this OSPFv3 instance.
- If SA authentication is configured for an area, the configuration takes effect on all interfaces that belong to this area.
- Authentication priority of OSPFv3 instances, areas, and interfaces are as follows: OSPFv3 instance authentication < area authentication < interface authentication.
- Area authentication and area associated SA authentication are mutually exclusive, and interface authentication and interface associated SA authentication are mutually exclusive.

1.11.3 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.11.4 Configuration Tasks

The following configuration tasks are optional. Select tasks for configuration according to the actual condition.

- Configuring Area Authentication and Encryption
- Configuring Interface Authentication and Encryption

1.11.5 Configuring Area Authentication and Encryption

1. Overview

When area authentication and encryption are enabled, the authentication mode and password of all devices in an area must be consistent to ensure normal setup of neighbor relationship.

2. Restrictions and Guidelines

- The device supports three authentication types:
  - No authentication (when authentication is not configured)
  - MD5
  - SHA1
- The device supports three encryption types:
  - DES
  - 3DES
  - AES-CBC

- After an OSPFv3 area is configured with encryption and authentication, the configuration takes effect on all interfaces (except virtual links) in the area, but the interface encryption and authentication configuration takes precedence over the area configuration.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 routing configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) (Optional) Configure area authentication.

area *area-id* **auth-algorithm ipsec spi** *spi* { **md5** [**string-key**] | **sha1** } [**0** | **7**] *key*

The OSPFv3 area authentication function is disabled by default.

(5) (Optional) Configure area encryption.

area *area-id* **encipherment ipsec spi** *spi* **esp** { { **3des** | **aes-cbc** { **128** | **192** | **256** } | **des** } [**0** | **7**] *des-key* | **null** } { **md5** | **sha1** } [**0** | **7**] *key*

Encryption is disabled by default.

1.11.6 Configuring Interface Authentication and Encryption

1. Overview

Applied between neighbor devices, interface authentication has higher priority than area authentication. The authentication mode and password for neighbor devices must be the same.

2. Restrictions and Guidelines

- The device supports three authentication types:
  - No authentication (when authentication is not configured)
  - MD5
  - SHA1
- The device supports three encryption types:
  - DES
  - 3DES
  - AES-CBC
- The OSPFv3 encryption and authentication parameters configured on interfaces must be consistent.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the Overlay router interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) (Optional) Configure interface authentication.

ipv6 ospf auth-algorithm { **ipsec spi** *spi* { **md5** [**string-key**] | **sha1** | **sha2-256** } [**0** | **7**] *key* | **null** } [**instance** *instance-id*]

By default, no authentication mode is configured on an interface. In this case, the authentication type of the related area is used on the interface.

(5) (Optional) Configure interface encryption.

ipv6 ospf encipherment { **ipsec spi** *spi* **esp** { { **3des** | **aes-cbc** { **128** | **192** | **256** } | **des** } [**0** | **7**] *des-key* | **null** } { **md5** | **sha1** } [**0** | **7**] *key* | **null** } [**instance** *instance-id*]

Encryption is disabled by default.

1.12 Configuring Fast Reroute

1.12.1 Overview

Once OSPFv3 detects a route failure, the fast reroute (FRR) function can immediately switch the route to the suboptimal path. This configuration helps shorten the traffic interruption time.

1.12.2 Restrictions and Guidelines

- The FRR loop-free alternate (LFA) configuration is mutually exclusive with the virtual link configuration.
- The **carrier-delay** parameter must be set to **0** for an interface.

1.12.3 Prerequisites

The OSPFv3 basic functions must be configured before this function is used.

1.12.4 Configuration Tasks

The configuration for enabling FRR includes the following tasks:

- Enabling the FRR Function
- (Optional) Configuring Interface LFA Protection
- (Optional) Configuring an Interface Not to Serve as a Backup Interface

1.12.5 Enabling the FRR Function

1. Overview

FRR provides a backup route for OSPFv3. Once OSPFv3 perceives the failure of a neighbor, it immediately switches traffic to the backup route, thereby preventing traffic interruption. You can configure the FRR function to shorten the OSPFv3 network convergence time to several milliseconds.

2. Restrictions and Guidelines

- Configure the **lfa** parameter.

If the lfa parameter is configured, LFA computation is enabled. You can also run the command in the interface configuration mode to specify the path protection mode for the interface. You are advised not to enable LFA to automatically compute the backup path if any of the following cases exists on the network:

- Virtual links exist.
- Alternative ABRs exist.
- An ASBR also serves as an ABR.
- Multiple ABSRs advertise the same external route.
- If both **lfa** and **downstream-paths** are configured, downstream path computation is enabled.
- You are advised to also enable BFD.

When using the OSPFv3 FRR function, you are advised to enable BFD so that the device can quickly detect any link failure, thereby shortening the forwarding interruption time. You can configure the carrier-delay 0 command in layer 3 interface configuration mode in interface up/down scenarios to achieve the fastest switchover speed.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

ipv6 router-protocol ospf[*process-id* [**vrf** *vrf-name*]]

(4) Configure FRR.

frr { lfa [downstream-paths] }

The FRR function is disabled by default.

1.12.6 Configuring Interface LFA Protection

1. Overview

A backup route is generated for the primary route based on the LFA protection mode specified in the interface configuration mode. By default, link protection is enabled on each OSPFv3 interface. This protection ensures that a failure of the primary link does not affect data forwarding on the backup route.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the L3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the L3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the L3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the L3 aggregate subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the tunnel interface configuration mode.

  interface tunnel *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the Overlay router interface configuration mode.

  interface overlayrouter *interface-number*

(4) Configure interface LFA protection.

ipv6 ospf frr protection { **disable** | **link**-**node** | **node** }

LFA link protection is disabled by default.

1.12.7 Configuring an Interface Not to Serve as a Backup Interface

1. Overview

To ensure that data traffic is not switched to a specified path after the optimal path fails, it is mandatory to configure an interface not to serve as a backup interface of FRR. After the optimal path fails, traffic is switched

to a suboptimal path, that is, a new optimal path is selected based on the interface costs after OSPFv3 performs convergence.

2. Restrictions and Guidelines

When an interface is unsuitable to serve as a backup interface, you need to enable the backup disabling command in the interface configuration mode. After this command is configured, this interface is excluded from serving a backup interface in the FRR calculation of OSPFv3, and a backup interface is selected from other interfaces. An interface is unsuitable to serve as a backup interface in the following cases:

- The available bandwidth of the interface is low.
- The interface and the master interface may fail at the same time.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

Enter the global configuration mode.

config-system terminal

(2) Enter the interface configuration mode.

- Enter the L3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the L3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the L3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the L3 aggregate subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the tunnel interface configuration mode.

  interface tunnel *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the Overlay router interface configuration mode.

  interface overlayrouter *interface-number*

(3) Configure an interface not to serve as a backup interface.

ipv6 ospf frr no-eligible-backup

By default, all interfaces can serve as backup interfaces of OSPF FRR.

1.13 Enabling Two-Way Maintenance

1.13.1 Overview

If the two-way maintenance function is enabled, in addition to the hello packets, the DD, LSU, LSR, and LSAck packets from a neighbor can also be used to maintain the bidirectional communication between neighbors. This prevents termination of the adjacency caused by delayed or discarded hello packets.

1.13.2 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.13.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 routing configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Enable two-way maintenance.

two-way-maintain

The two-way maintenance function of OSPFv3 is enabled by default.

1.14 Correlating OSPFv3 with BFD

1.14.1 Overview

The OSPFv3 protocol dynamically discovers a neighbor by using hello packets. After BFD is enabled, OSPFv3 establishes a BFD session with a neighbor in the full neighbor relationship. The neighbor state is detected using the BFD mechanism. When the BFD neighbor fails, OSFPv3 immediately performs network convergence. This configuration helps shorten the traffic interruption time.

1.14.2 Restrictions and Guidelines

- The BFD parameters must be configured for the interface in advance.
- If BFD is configured for both a process and an interface, the interface-based configuration takes effect preferentially.

1.14.3 Configuration Tasks

Correlating OSPFv3 with BFD includes the following configuration tasks. These configuration tasks are optional and can be configured according to the actual situation.

- Correlating OSPFv3 and BFD on an Interface
- Correlating OSPFv3 and BFD Globally

1.14.4 Correlating OSPFv3 and BFD on an Interface

1. Overview

You can configure to correlate OSPFv3 and BFD on a specified interface to quickly detect errors on the interface and to accelerate OSPFv3 convergence.

2. Restrictions and Guidelines

- The priority of BFD on an interface is higher than that of BFD in OSPFv3 routing process.

You can use the ipv6 ospf set-bfd command to select the specified interface to use BFD for link detection according to the actual environment, or use the bfd whole-interfaces command in the OSPFv3 routing configuration mode to configure all interfaces participating in OSPF operation to use BFD for link detection, and use the ipv6 ospf set-bfd disable command to disable the BFD detection function on the specified interface.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

a Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the Overlay router interface configuration mode.
  - **interface overlayrouter** *interface-number*

b Configure an OSPFv3 interface correlation with BFD.

ipv6 ospf set-bfd [**disable**] [**instance** *instance-id*]

The BFD function is disabled on an interface by default, and the BFD configuration is subject to the configuration in the OSFPv3 process configuration mode.

1.14.5 Correlating OSPFv3 and BFD Globally

1. Overview

OSPFv3 protocol dynamically discovers neighbors through Hello packet. When OSPFv3 enables the BFD detection function, BFD sessions will be established for neighbors that reach Full relationship, and detect neighbor status through BFD mechanism. Once a BFD neighbor fails, OSPFv3 will immediately conduct network convergence.

2. Restrictions and Guidelines

You can use the ipv6 ospf set-bfd [disable] [instance *instance-id*] command in the interface configuration mode to enable or disable the BFD function on the specified interface. The priority of BFD function configured in the interface configuration mode is higher than that of the BFD function configured using bfd whole-interfaces command on all interfaces in the routing configuration mode.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

a Configure an OSPFv3 interface correlation with BFD.

bfd whole-interfaces

The BFD function is disabled on all interfaces by default.

1.15 Enabling the GR Function

1.15.1 Overview

When a GR-enabled router is restarted on the control plane, data forwarding can be still guided on the forwarding plane. In addition, actions such as neighbor relationship re-forming and route computation performed on the control plane do not affect functions of the forwarding plane. In this way, service interruption caused by route flapping can be avoided, thus enhancing reliability of the entire network.

When a router implements GR, GR helper sends a Grace-LSA to notify all neighbor routers. If the GR helper function is enabled on the local router, the local router becomes the GR helper upon receiving the Grace-LSA, and helps the neighbor routers to complete GR.

1.15.2 Restrictions and Guidelines

- The neighbor router must support the GR helper.
- The GR time cannot be shorter than the neighbor relationship maintenance time of the neighbor router.

1.15.3 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.15.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Enable the GR function.

gr [**grace-period** *grace-period* | **inconsistent-lsa-checking**]

The GR function is enabled by default.

(5) Enable the OSPFv3 GR helper function.

gr helper { **disable** | **internal-lsa-checking** | **check-rigid** }

The GR helper capability is enabled by default. After the GR helper is enabled on the device, LSA changes are not checked.

1.16 Enabling NSR

1.16.1 Overview

During nonstop routing (NSR), OSPFv3-related information is backed up from the active supervisor module of a distributed device to the standby supervisor module, or from the active host of a virtual switching unit (VSU) to the standby host. In this way, the device can automatically recover the link state and re-generate routes without the help of the neighbor devices during the active/standby switchover. Information that should be backed up includes the neighbor relationship and link state.

1.16.2 Restrictions and Guidelines

- This command is used to enable the NSR function. For the same OSPFv3 process, either NSR or GR is enabled because they are mutually exclusive. Nevertheless, when NSR is enabled, the GR helper capability is supported.
- The switchover of devices in distributed or VSU mode takes a period of time. If OSPFv3 neighbor keepalive duration is shorter than the switchover duration, the OSPFv3 neighbor relationship with the neighbor device is removed, and services are interrupted during the switchover. Therefore, it is recommended that the OSPFv3 neighbor keepalive duration be no smaller than the default value when the NSR function is enabled. When the fast hello function is enabled, the OSPFv3 neighbor keepalive duration is less than 1s. As a result, it is recommended that the NSR function be disabled.

1.16.3 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.16.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Enable the NSR function.

nsr

The NSR function is disabled by default.

1.17 Enabling Conflict Detection of Type 4 LSAs

1.17.1 Overview

This function enables conflict detection for received Type 4 LSAs.

1.17.2 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.17.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Enable conflict detection of Type 4 LSAs.

detect-conflict lsa-4

Conflict detection for Type 4 LSAs is disabled by default.

1.18 Modifying the Maximum Number of Concurrent Neighbors

1.18.1 Overview

When the performance of a router is affected because the router exchanges data with multiple neighbors, you can configure this command to restrict the maximum number of neighbors with which each OSPFv3 instance can concurrently initiate or accept interaction. The maximum number of neighbors can be configured at the process or device level.

1.18.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Configure the maximum number of concurrent neighbors of all processes.

ipv6 router-protocol ospf max-concurrent-dd *number*

The maximum number of neighbors is **10** by default.

(4) Enter the OSPFv3 routing configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(5) (Optional) Configure the maximum number of concurrent neighbors of the current process.

max-concurrent-dd *number*

The default maximum number of concurrent neighbors for a single process is **5**.

1.19 Allowing Type-9 LSA to Carry IPv6 Prefixes

1.19.1 Overview

Type-9 LSAs generated by devices can carry IPv6 addresses or IPv6 prefixes. In specific scenarios, devices of earlier versions need to carry IPv6 addresses. When interworking with the Quagga server, only IPv6 prefixes can be carried; otherwise, the logic of the Quagga server becomes abnormal. You can configure this command as required.

1.19.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Disable the function of allowing Type-9 LSAs to carry IPv6 prefixes on all routers.

unset ipv6 **router-protocol ospf compatible lsa type-9**

The function of allowing Type-9 LSAs to carry IPv6 prefixes is enabled on all routers by default.

1.20 Configuring Network Management Functions

1.20.1 Overview

Use the network management software to manage OSPFv3 parameters and monitor the OSPFv3 running status.

1.20.2 Restrictions and Guidelines

- To enable the MIB function of the OSPFv3, you must enable the MIB function of the SNMP-agent.
- To enable the Trap function of the OSPFv3, you must enable the Trap function of the SNMP-agent.
- To output the OSPFv3 logs, you must enable the logging function of the device.

1.20.3 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.20.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPFv3 configuration mode.

ipv6 router-protocol ospf [*process-id* [**vrf** *vrf-name*]]

(4) Bind the MIB with an OSPFv3 process.

enable mib-binding

The MIB is bound to the OSPFv3 process with the minimum process ID by default.

(5) Configure the Trap function.

enable traps [**error** [ifc**onfig**e**rror** | ifr**x**b**ad**p**acket** | v**irt**I**f**c**onfig**e**rror** | v**irt**I**f**r**x**b**ad**p**acket**] * | **state**-**change** [if**s**t**ate**c**hange** | n**br**s**tate**c**hange** | n**ssa**t**ranslator**s**tatus**c**hange** | v**irt**I**f**s**tate**c**hange** | v**irt**n**br**s**tate**c**hange** | r**estart**s**tatus**c**hange** | n**br**r**estart**h**elper**s**tatus**c**hange** | v**irt**n**br**r**estart**h**elper**s**tatus**c**hange**] *]

The Trap function is disabled by default.

(6) (Optional) Configure the logging function.

log-adj-changes [**detail**]

The logging function is enabled by default, without the **detail** parameter. The log records the log information of the following four types of events only: the adjacency reaches the full state; the adjacency leaves the full state; the adjacency reaches the down state; the adjacency leaves the down state.

1.21 Disabling MTU Verification

1.21.1 Overview

When receiving a DD packet, OSPFv3 verifies whether the MTU of the neighbor's interface is the same as that of its own interface. If the neighbor interface MTU specified in the local received DD packet is greater than the MTU of the local interface, the neighbor relationship cannot be set up. After this function is enabled, adjacency can be set up and the unicast routing service can be provided even if the MTUs of interfaces on neighbor routers are different.

1.21.2 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.21.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
- **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
- **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
- **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
- **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
- **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
- **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
- **interface loopback** *interface-number*
- Enter the Overlay router interface configuration mode.
- **interface overlayrouter** *interface-number*

(4) Disable MTU verification.

ipv6 ospf skip-mtu-verify

The MTU verification function is disabled by default.

1.22 Enabling the Function of Securely Promoting a BDR to DR

1.22.1 Overview

On broadcast and non-broadcast multiple access (NBMA) networks, if the DR goes offline, all devices on the network promotes a BDR to DR to ensure the reliable operation of the network. If the configured SPF latency is too short, SPF route calculation is triggered before some devices on the network promote a BDR to DR. As a result, some routes on the network are unreachable. If the function of securely promoting a BDR to DR is enabled, SPF route calculation is triggered only after all devices promote a BDR to DR.

1.22.2 Restrictions and Guidelines

The OSPFv3 basic functions must be configured before this function is used.

1.22.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the OSPF configuration mode.

ipv6 router-protocol ospf [*process-id* [vrf *vrf-name*]]

(4) Disable the function of securely promoting a BDR to DR.

unset capability bdr-security-promoted

The function of securely promoting a BDR to DR is enabled by default.

1.23 Enabling OSPFv3 on a Super VLAN

Note

This function is not supported by the S6980-64QC, S6580-48CQ8QC, or S6580-24DC8QC.

1.23.1 Overview

In normal cases, a super VLAN contains multiple sub VLANs. Multicast packets of a super VLAN are also sent to its sub VLANs. In this case, when OSPFv3 multicast packets are sent over a super VLAN containing multiple sub VLANs, the OSPFv3 multicast packets are replicated multiple times, and the device processing capability is insufficient. As a result, a large number of packets are discarded, causing protocol flapping. In most scenarios, the OSPFv3 function does not need to be enabled in a super VLAN, and it is disabled by default. In some other scenarios, OSPFv3 needs to be run in the super VLAN, but packets need to be sent to only one sub VLAN. In this case, run this command to specify a particular sub VLAN. You must be cautious when configuring packet transmission to all sub VLANs, as the large number of sub VLANs may cause a device processing bottleneck, which will lead to the neighbor flapping.

1.23.2 Restrictions and Guidelines

- The specified sub VLAN must be connected to neighbors.

1.23.3 Prerequisites

The basic OSPFv3 functions must be configured before this function is used.

1.23.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the SVI configuration mode.

interface *vlan interface-number*

(4) Configure OSPFv3 to run on a super VLAN.

ipv6 ospf subvlan { **all** | *vlan-id* } [**instance** *instance*-id]

The OSPFv3 function takes effect in super VLANs only and is disabled by default.

1.24 Monitoring

Run the display command to check the running status of a configured function to verify the configuration effect.

Run the debugging command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the cleanup commands to clear information.

Caution

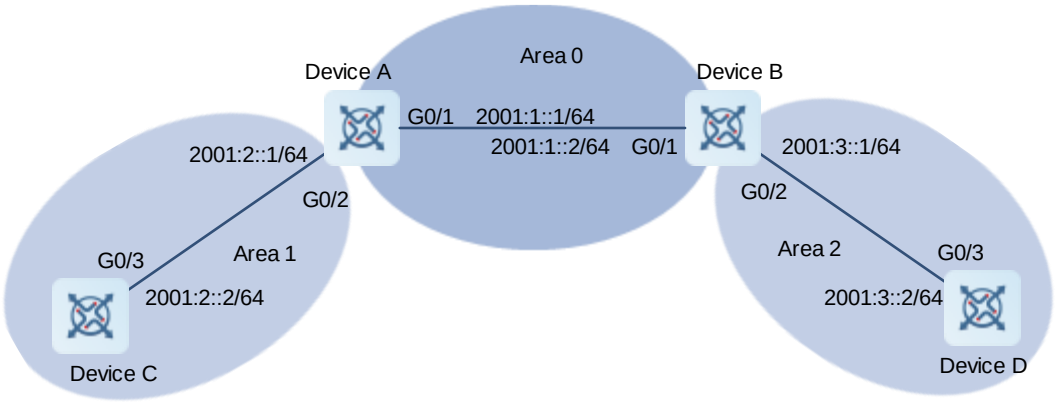
Running the **cleanup** command may lose vital information and thus interrupt services.

Table 1-8 Monitoring

Command	Purpose
display ipv6 ospf-instance [*process-id*]	Displays the configuration information of the OSPFv3 process.
display ipv6 **ospf-instance** [*process-id*] **database-info** [**database-summary |** *lsa-type* [**advertising-router** *router-id*]]	Displays the OSPFv3 LSDB.
display ipv6 ospf-instance [*process-id* [*area-id*]] **frr-topology** { **advertising-router** *adv-router-id* [*router-id*] | **self-originate** [*router-id*] }	Displays information about the topology calculated by OSPFv3 FRR SPF.
display ipv6 ospf-instance [*process-id*] **interface** [*interface-type interface-number* | **brief**]	Displays the OSPFv3 interface.
display ipv6 ospf-instance [*process-id*] **peer** [*interface-type interface-number* [**detail**] | *neighbor-id* | **statistics**]	Displays the neighbor list of OSPFv3.
display ipv6 ospf-instance [*process-id*] **route** [**count**]	Displays the OSPFv3 routing table.
display ipv6 ospf-instance [*process-id*] **spf**	Displays the number of times that SPT is computed in an OSPF area.
display ipv6 ospf-instance [*process-id*] **summary-prefix**	Displays the summarized routes of OSPFv3 redistributed routes.
display ipv6 ospf-instance [*process-id*] **topology** [**area** *area-id*]	Displays the OSPFv3 network topology information.
display ipv6 ospf-instance [*process-id*] **vlinks**	Displays the OSPFv3 virtual links.
cleanup ipv6 ospf [*process-id*] **instance**	Clears and resets the OSPFv3 process.
debugging ipv6 ospf events-info [**abr** | **asbr** | **ipsec** | **mom** | **nssa** | **os | rdnd-thread | restart | router** | **vlink**]	Debugs the OSPFv3 events.

Command	Purpose
debugging ipv6 ospf frr [ase | inter-area | intra-area | node | time]	Debugs the OSPFv3 FRR.
debugging ipv6 ospf ifsm [**events-info** | **status** | **timers**]	Debugs the OSPFv3 interfaces.
debugging ipv6 ospf nfsm [**events-info** | **status** | **timers**]	Debugs the OSPFv3 neighbors.
debugging ipv6 ospf nsm [**bfd | interface** | **redistribute** | **route** [**add | delete | receive**]]	Debugs the OSPFv3 NSM.
debugging ipv6 ospf lsa [**flooding** | **generate** | **install** | **maxage** | **refresh**]	Debugs the OSPFv3 LSAs.
debugging ipv6 ospf packet-info [**dd | deeply** | **detail** | **hello | interface** | **ls-ack** | **ls-request** | **ls-update** | **recv** | **send**]	Debugs the OSPFv3 packets.
debugging ipv6 ospf route [**ase** | **ia** | **install** | **spf** | **time**]	Debugs the OSPFv3 routes.

1.25 Configuration Examples



1.25.1 Configuring Basic Functions of OSPFv3

1. Requirements

OSPFv3 is enabled on all the devices, and three areas are defined in total. Device A and device B are used as ABRs forwarding inter-area routes so as to implement the interworking between all networks.

2. Topology

Figure 1-9 Configuring Basic Functions of OSPFv3

3. Notes

- Configure interface IP addresses on all the devices.
- Enable the IPv4 unicast routing function on all the devices. (This function is enabled by default.)
- Configure OSPFv3 instances and router IDs on all the devices.
- Configure OSPFv3 on interfaces of all the devices.

4. Procedure

(1) Perform the following configurations on Device A.

Enable the OSPFv3 process and configure a router ID.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# ipv6 router-protocol ospf 1
Device A(cfg-router)# router-id 1.1.1.1
Device A(cfg-router)# exit
```

Configure an IP address for the interface and enable OSPFv3 on the interface.

```
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 enable
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 address 2001:1::1/64
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 ospf 1 set-area 0
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/2)# ipv6 enable
Device A(cfg-if-GigabitEthernet 0/2)# ipv6 address 2001:2::1/64
Device A(cfg-if-GigabitEthernet 0/2)# ipv6 ospf 1 set-area 1
Device A(cfg-if-GigabitEthernet 0/2)# exit
```

(2) Perform the following configurations on Device B.

Enable the OSPFv3 process and configure a router ID.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# ipv6 router-protocol ospf 1
Device B(cfg-router)# router-id 2.2.2.2
Device B(cfg-router)# exit
```

Configure an IP address for the interface and enable OSPFv3 on the interface.

```
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/1)# ipv6 enable
Device B(cfg-if-GigabitEthernet 0/1)# ipv6 address 2001:1::2/64
Device B(cfg-if-GigabitEthernet 0/1)# ipv6 ospf 1 set-area 0
Device B(cfg-if-GigabitEthernet 0/1)# exit
```

```
Device B(cfg)# interface gigabitethernet 0/2
Device B(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/2)# ipv6 enable
Device B(cfg-if-GigabitEthernet 0/2)# ipv6 address 2001:3::1/64
Device B(cfg-if-GigabitEthernet 0/2)# ipv6 ospf 1 set-area 2
Device B(cfg-if-GigabitEthernet 0/2)# exit
```

(3) Perform the following configurations on Device C.

Enable the OSPFv3 process and configure a router ID.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# ipv6 router-protocol ospf 1
Device C(cfg-router)# router-id 3.3.3.3
Device C(cfg-router)# exit
```

Configure an IP address for the interface and enable OSPFv3 on the interface.

```
Device C(cfg)# interface gigabitethernet 0/3
Device C(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/3)# ipv6 enable
Device C(cfg-if-GigabitEthernet 0/3)# ipv6 address 2001:2::2/64
Device C(cfg-if-GigabitEthernet 0/3)# ipv6 ospf 1 set-area 1
Device C(cfg-if-GigabitEthernet 0/3)# exit
```

(4) Perform the following configurations on Device D.

Enable the OSPFv3 process and configure a router ID.

```
Device D> privilege
Device D# config-system terminal
Device D(cfg)# ipv6 router-protocol ospf 1
Device D(cfg-router)# router-id 4.4.4.4
Device D(cfg-router)# exit
```

Configure an IP address for the interface and enable OSPFv3 on the interface.

```
Device D(cfg)# interface gigabitethernet 0/3
Device D(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device D(cfg-if-GigabitEthernet 0/3)# ipv6 enable
Device D(cfg-if-GigabitEthernet 0/3)# ipv6 address 2001:3::2/64
Device D(cfg-if-GigabitEthernet 0/3)# ipv6 ospf 1 set-area 2
Device D(cfg-if-GigabitEthernet 0/3)# exit
```

5. Verification

(1) Display the following information on Device A.

Display OSPFv3 neighbor information.

```
Device A# display ipv6 ospf-instance peer
OSPFv3 Process (1), 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State           Dead Time   Instance ID  Interface
2.2.2.2           1   Full/BDR        00:00:30    0            GigabitEthernet 0/1
3.3.3.3           1   Full/BDR        00:00:35    0            GigabitEthernet 0/2
```

Display OSPFv3 routing table.

```
Device A# display ipv6 route-config ospf

IPv6 routing table name - Default - 0 entries
Codes:  C - Connected, L - Local, S - Static
        R - RIP, O - OSPFv3, B - BGP, I - IS-IS, V - Overflow route
        N1 - OSPFv3 NSSA external type 1, N2 - OSPFv3 NSSA external type 2
        E1 - OSPFv3 external type 1, E2 - OSPFv3 external type 2
        SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
        IA - Inter area

O   IA  2001:3::/64 [110/20] via FE80::2D0:F8FF:FE22:4524, GigabitEthernet 0/1
```

(2) Display the following information on Device B.

Display OSPFv3 neighbor information.

```
Device B# display ipv6 ospf-instance peer
OSPFv3 Process (1), 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State           Dead Time    Instance ID  Interface
1.1.1.1           1   Full/DR         00:00:30     0            GigabitEthernet 0/1
4.4.4.4           1   Full/BDR        00:00:35     0            GigabitEthernet 0/2
```

Display OSPFv3 routing table.

```
Device B# display ipv6 route-config ospf

IPv6 routing table name - Default - 0 entries
Codes:  C - Connected, L - Local, S - Static
        R - RIP, O - OSPFv3, B - BGP, I - IS-IS, V - Overflow route
        N1 - OSPFv3 NSSA external type 1, N2 - OSPFv3 NSSA external type 2
        E1 - OSPFv3 external type 1, E2 - OSPFv3 external type 2
        SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
        IA - Inter area

O   IA  2001:2::/64 [110/20] via FE80::2D0:F8FF:FE22:4536, GigabitEthernet 0/1
```

(3) Display the following information on Device C.

Display OSPFv3 neighbor information.

```
Device C# display ipv6 ospf-instance peer
OSPFv3 Process (1), 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State           Dead Time    Instance ID  Interface
1.1.1.1           1   Full/DR         00:00:30     0            GigabitEthernet 0/3
```

Display OSPFv3 routing table.

```
Device C# display ipv6 route-config ospf

IPv6 routing table name - Default - 0 entries
Codes:  C - Connected, L - Local, S - Static
        R - RIP, O - OSPFv3, B - BGP, I - IS-IS, V - Overflow route
```

```
          N1 - OSPFv3 NSSA external type 1, N2 - OSPFv3 NSSA external type 2
          E1 - OSPFv3 external type 1, E2 - OSPFv3 external type 2
          SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
          IA - Inter area

O   IA   2001:1::/64 [110/2] via FE80::2D0:F8FF:FE22:4537, GigabitEthernet 0/3
O   IA   2001:3::/64 [110/3] via FE80::2D0:F8FF:FE22:4537, GigabitEthernet 0/3
```

(4) Display the following information on Device D.

Display OSPFv3 neighbor information.

```
Device D# display ipv6 ospf-instance peer
OSPFv3 Process (1), 1 Neighbors, 1 is Full:
Neighbor ID      Pri    State           Dead Time     Instance ID     Interface
2.2.2.2            1    Full/DR         00:00:30      0               GigabitEthernet 0/3
```

Display OSPFv3 routing table.

```
Device D# display ipv6 route-config ospf

IPv6 routing table name - Default - 0 entries
Codes:   C - Connected, L - Local, S - Static
          R - RIP, O - OSPFv3, B - BGP, I - IS-IS, V - Overflow route
          N1 - OSPFv3 NSSA external type 1, N2 - OSPFv3 NSSA external type 2
          E1 - OSPFv3 external type 1, E2 - OSPFv3 external type 2
          SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
          IA - Inter area

O   IA   2001:1::/64 [110/2] via FE80::2D0:F8FF:FE22:4547, GigabitEthernet 0/3
O   IA   2001:2::/64 [110/3] via FE80::2D0:F8FF:FE22:4547, GigabitEthernet 0/3
```

Verify that 2001:2::2/64 can be pinged successfully on Device D.

```
Device D# ping 2001:2::2
Sending 5, 100-byte ICMP Echoes to 2001:2::2, timeout is 2 seconds:
< press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 5/9/14 ms.
```

6. Configuration Files

- Device A configuration file

```
!
ipv6 router-protocol ospf 1
 router-id 1.1.1.1
!
interface gigabitethernet 0/1
unset switch-port
 ipv6 enable
 ipv6 address 2001:1::1/64
 ipv6 ospf 1 set-area 0
```

```
!
interface gigabitethernet 0/2
unset switch-port
 ipv6 enable
 ipv6 address 2001:2::1/64
 ipv6 ospf 1 set-area 1
!
```

- Device B configuration file

```
!
ipv6 router-protocol ospf 1
 router-id 2.2.2.2
!
interface gigabitethernet 0/1
unset switch-port
 ipv6 enable
 ipv6 address 2001:1::2/64
 ipv6 ospf 1 set-area 0
!
interface gigabitethernet 0/2
unset switch-port
 ipv6 enable
 ipv6 address 2001:3::1/64
 ipv6 ospf 1 set-area 2
!
```

- Device C configuration file

```
!
ipv6 router-protocol ospf 1
 router-id 3.3.3.3
!
interface gigabitethernet 0/3
unset switch-port
 ipv6 enable
 ipv6 address 2001:2::2/64
 ipv6 ospf 1 set-area 1
!
```

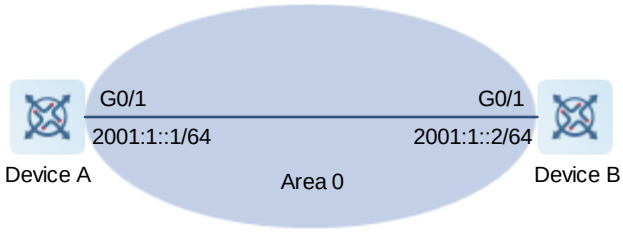
- Device D configuration file

```
!
ipv6 router-protocol ospf 1
 router-id 4.4.4.4
!
interface gigabitethernet 0/3
unset switch-port
 ipv6 enable
 ipv6 address 2001:3::2/64
 ipv6 ospf 1 set-area 2
```

```
!
```

7. Common Errors

- No IPv6 address is configured for the interface.
- OSPFv3 cannot be enabled because the IPv6 unicast routing function is disabled.
- The area IDs configured for adjacent interfaces are inconsistent.
- The same router ID is configured on multiple devices, resulting in a router ID conflict.



1.25.2 Configuring OSPFv3 Authentication

1. Requirements

OSPFv3 runs between Device A and Device B. MD5 authentication is configured to improve security of an OSPFv3 network.

2. Topology

Figure 1-10 Topology of OSPFv3 Authentication

3. Notes

Configure MD5 authentication on interfaces of all the devices.

4. Procedure

(1) Configure basic OSPFv3 functions (omitted).

(2) Enable OSPFv3 authentication on an interface.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 ospf auth-algorithm ipsec spi 256 md5
01234567890123456789012345678912
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# unset switch-port
```

```
Device B(cfg-if-GigabitEthernet 0/1)# ipv6 ospf auth-algorithm ipsec spi 256 md5
01234567890123456789012345678912
```

5. Verification

Verify whether neighbors of Device A and Device B are established.

- Check the neighbor information of Device A.

```
Device A# display ipv6 ospf peer
OSPFv3 Process (1), 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State           Dead Time     Instance ID   Interface
2.2.2.2           1   Full/DR         00:00:38      0             GigabitEthernet 0/1
```

- Check the neighbor information of Device B.

```
Device B# display ipv6 ospf peer
OSPFv3 Process (1), 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State           Dead Time     Instance ID   Interface
1.1.1.1           1   Full/BDR        00:00:38      0             GigabitEthernet 0/1
```

6. Configuration Files

- Device A configuration file

```
!
interface gigabitethernet 0/1
unset switch-port
  ipv6 ospf auth-algorithm ipsec spi 256 md5 01234567890123456789012345678912
!
```

- Device B configuration file

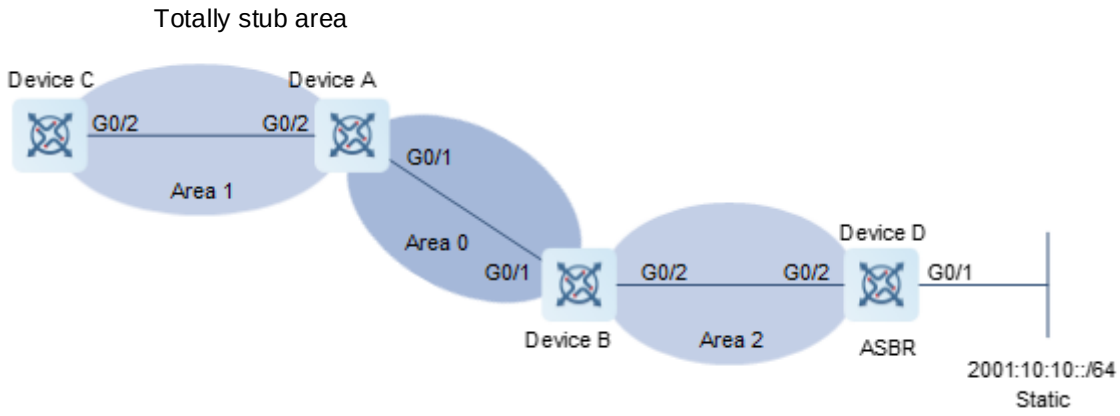
```
!
interface gigabitethernet 0/1
unset switch-port
  ipv6 ospf auth-algorithm ipsec spi 256 md5 01234567890123456789012345678912
!
```

7. Common Errors

- The configured authentication modes are inconsistent.
- The configured authentication keys are inconsistent.

1.25.3 Configuring a Stub Area

1. Requirements



Devices A, B, C, and D are interconnected through the OSPFv3 routing protocol.

As ABRs, Devices A and B are responsible for the routing information transfer between OSPFv3 areas, and Device D functions as an ASBR to introduce the external static routes.

To reduce the number of LSAs in Area 1 and save the device performance, Area 1 is configured as a totally stub area.

2. Topology

Figure 1-11 Topology for a Stub Area

3. Notes

- Configure IPv6 addresses on interfaces of all the devices.
- Configure the basic OSPFv3 functions for all the devices.
- Introduce an external static route to Device D.
- Configure Area 1 as a stub area on Device A and Device C.

4. Procedure

(1) Configure IPv6 addresses on interfaces of all the devices and enable basic OSPFv3 functions (omitted).

(2) Introduce an external static route to Device D.

```
Device D> privilege
Device D# config-system terminal
Device D(cfg)# ipv6 router-protocol ospf 1
Device D(cfg-router)# redistribute-route static
```

(3) Configure Area 1 as a stub area on Device A and filter Type 3 LSAs.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# ipv6 router-protocol ospf 1
Device A(cfg-router)# area 1 stub unset-summary
```

(4) Configure Area 1 as a stub area on Device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# ipv6 router-protocol ospf 1
Device C(cfg-router)# area 1 stub
```

5. Verification

Run the display ipv6 route-config ospf command on Device C to display the routing table. Verify that there is only one default inter-area route, and no external static route is introduced from Device D.

```
Device C# display ipv6 route-config ospf

IPv6 routing table name - Default - 0 entries
Codes:  C - Connected, L - Local, S - Static
        R - RIP, O - OSPFv3, B - BGP, I - IS-IS, V - Overflow route
        N1 - OSPFv3 NSSA external type 1, N2 - OSPFv3 NSSA external type 2
        E1 - OSPFv3 external type 1, E2 - OSPFv3 external type 2
        SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
        IA - Inter area

O   IA::/0 [110/3] via FE80::2D0:F8FF:FE22:4547, GigabitEthernet 0/2
```

6. Configuration Files

- Device A configuration file

```
!
ipv6 router-protocol ospf 1
area 1 stub unset-summary
!
```

- Device C configuration file

```
!
ipv6 router-protocol ospf 1
area 1 stub
!
```

- Device D configuration file

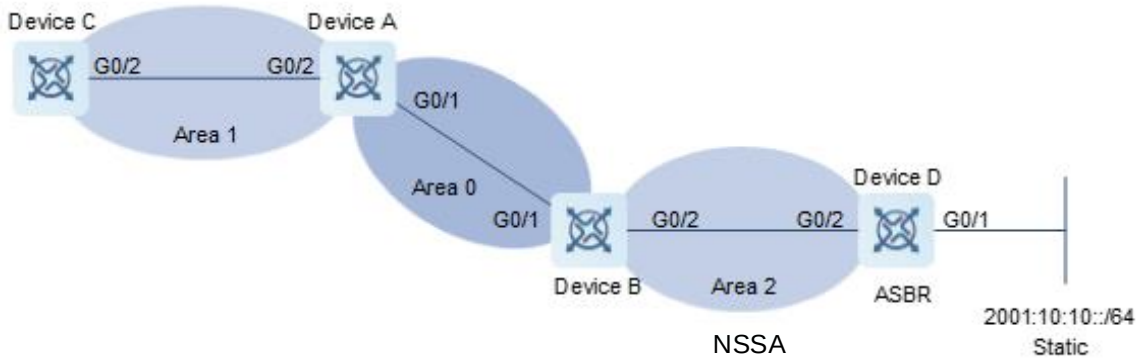
```
!
ipv6 router-protocol ospf 1
redistribute-route static
!
```

7. Common Errors

- Configurations of the area type are inconsistent on devices in the same area.
- External routes cannot be introduced because route redistribution is configured on a device in the stub area.

1.25.4 Configuring an NSSA

1. Requirements



Devices A, B, C, and D are interconnected through the OSPFv3 routing protocol.

As ABRs, Devices A and B are responsible for the routing information transfer between OSPFv3 areas, and Device D functions as an ASBR to introduce the external static routes.

To reduce the number of LSAs in Area 2 and save the device performance, Area 2 is configured as an NSSA.

2. Topology

Figure 1-12 Topology for an NSSA

3. Notes

- Configure IPv6 addresses on interfaces of all the devices.
- Configure the basic OSPFv3 functions for all the devices.
- Introduce an external static route to Device D.
- Configure Area 2 as an NSSA on Device B and Device D.

4. Procedure

(1) Configure IPv6 addresses on interfaces of all the devices and enable basic OSPFv3 functions (omitted).

(2) Introduce an external static route to Device D. Configure Area 2 as an NSSA.

```
Device D> privilege
Device D# config-system terminal
Device D(cfg)# ipv6 router-protocol ospf 1
Device D(cfg-router)# area 2 nssa
Device D(cfg-router)# redistribute-route static
```

(3) Configure Area 2 as an NSSA on Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# ipv6 router-protocol ospf 1
Device B(cfg-router)# area 2 nssa
```

5. Verification

(1) Run the **display ipv**6 **ospf-instance database-info** command on Device D to display the database information and verify that Type 7 LSAs are generated.

```
Device D# display ipv6 ospf-instance database-info nssa-external-type
                OSPFv3 Router with ID (1.1.1.1) (Process 1)
                    NSSA-external-LSA (Area 0.0.0.1)
  LS age: 1196
  LS Type: NSSA-external-LSA
  Link State ID: 0.0.0.3
```

```
  Advertising Router: 1.1.1.1
  LS Seq Number: 0x80000004
  Checksum: 0x1F25
  Length: 52
      Metric Type: 2 (Larger than any link state path)
      Metric: 20
Prefix: 2001:10::/64
Prefix Options: 8 (P|-|-|-)
Forwarding Address: 4000::1
```

(2) Run the **display ipv6 route-config ospf** command on Device A to display the routing table and verify that an external static route is introduced by Router D.

```
Device A# display ipv6 route-config ospf

IPv6 routing table name - Default - 0 entries
Codes:   C - Connected, L - Local, S - Static
         R - RIP, O - OSPFv3, B - BGP, I - IS-IS, V - Overflow route
         N1 - OSPFv3 NSSA external type 1, N2 - OSPFv3 NSSA external type 2
         E1 - OSPFv3 external type 1, E2 - OSPFv3 external type 2
         SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
         IA - Inter area

O   N2   2001:10::/64 [110/20] via FE80::2D0:F8FF:FE22:4547, GigabitEthernet 0/1
```

6. Configuration Files

- Device B configuration file

```
!
ipv6 router-protocol ospf 1
area 2 nssa
!
```

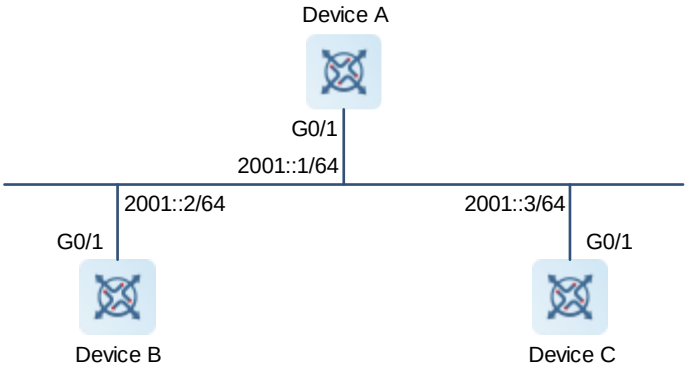
- Device D configuration file

```
!
ipv6 router-protocol ospf 1
area 2 nssa
 redistribute-route static
!
```

7. Common Errors

- Configurations of the area type are inconsistent on devices in the same area.

1.25.5 Selecting an OSPFv3 DR



1. Requirements

Devices A, B, and C are in the same broadcast network.

The priority of Device A is set to 10 and Device A is configured as a DR. The priority of Device B is set to 5 and Device B is configured as a BDR. The priority of Device C is set to 0 and Device C does not participate in DR election.

2. Topology

Figure 1-13 Topology of OSPFv3 DR Configuration

3. Notes

- Configure IPv6 addresses on interfaces of all the devices.
- Configure the basic OSPFv3 functions for all the devices.
- Modify the DR election priority of all the devices.

4. Procedure

(1) Configure basic functions of OSPFv3.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# ipv6 router-protocol ospf 1
Device A(cfg-router)# router-id 1.1.1.1
Device A(cfg-router)# exit
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# ipv6 router-protocol ospf 1
Device B(cfg-router)# router-id 2.2.2.2
Device B(cfg-router)# exit
```

Configure Device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# ipv6 router-protocol ospf 1
Device C(cfg-router)# router-id 3.3.3.3
Device C(cfg-router)# exit
```

(2) Configure IP addresses of interfaces, configure OSPFv3, and modify the DR election priority of all the devices.

Configure Device A.

```
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 address 2001::1/64
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 ospf 1 set-area 0
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 ospf priority-value 10
```

Configure Device B.

```
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/1)# ipv6 address 2001::2/64
Device B(cfg-if-GigabitEthernet 0/1)# ipv6 ospf 1 set-area 0
Device B(cfg-if-GigabitEthernet 0/1)# ipv6 ospf priority-value 5
```

Configure Device C.

```
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/1)# ipv6 address 2001::3/64
Device C(cfg-if-GigabitEthernet 0/1)# ipv6 ospf 1 set-area 0
Device C(cfg-if-GigabitEthernet 0/1)# ipv6 ospf priority-value 0
```

5. Verification

- Run the **display ipv6 ospf-instance interface** command on Device C to display the DR and BDR.

```
Device C# display ipv6 ospf-instance interface
GigabitEthernet 0/1 is up, line protocol is up
  Interface ID 4098
  IPv6 Prefixes
    fe80::250:56ff:feb5:820b/64 (Link-Local Address)
    2001::3/64
  OSPFv3 Process (1), Area 0.0.0.0, Instance ID 0
    Router ID 3.3.3.3, Network Type BROADCAST, Cost: 1
    Transmit Delay is 1 sec, State DROther, Priority 0
    Designated Router (ID) 1.1.1.1
      Interface Address fe80::250:56ff:feb5:694e
    Backup Designated Router (ID) 2.2.2.2
      Interface Address fe80::250:56ff:feb5:fdb4
    Timer period configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Neighbor Count is 2, Adjacent peer count is 2
  Hello received 73 sent 39, DD received 8 sent 7
  LS-Req received 1 sent 2, LS-Upd received 9 sent 5
  LS-Ack received 5 sent 5, Discarded 6
```

- Run the **display ipv6 ospf-instance peer** command on Device A to display DROther of the broadcast network as Device C.

```
Device A# display ipv6 ospf-instance peer
```

```
OSPFv3 Process (1), 2 Neighbors, 2 is Full:
Neighbor ID     Pri   State           BFD State  Dead Time     Instance ID  Interface
2.2.2.2           5   Full/BDR        -          00:00:36     0            GigabitEthernet 0/1
3.3.3.3           0   Full/DROther    -          00:00:38     0            GigabitEthernet 0/1
```

6. Configuration Files

- Device A configuration file

```
!
interface gigabitethernet 0/1
unset switch-port
ipv6 address 2001::1/64
ipv6 ospf priority-value 10
ipv6 ospf 1 set-area 0
!
ipv6 router-protocol ospf 1
 router-id 1.1.1.1
 gr
!
```

- Device B configuration file

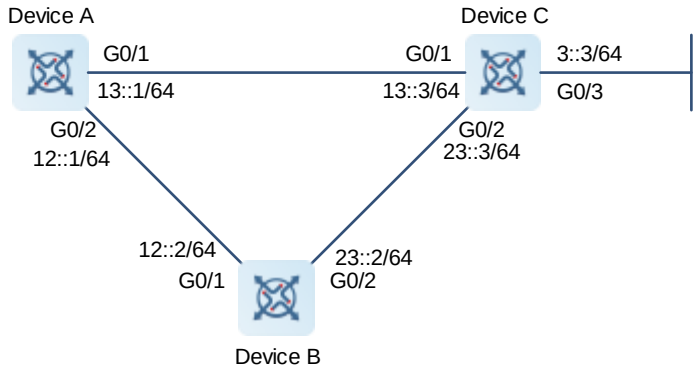
```
!
interface gigabitethernet 0/1
unset switch-port
 ipv6 address 2001::2/64
ipv6 ospf priority-value 5
 ipv6 ospf 1 set-area 0
!
ipv6 router-protocol ospf 1
 router-id 2.2.2.2
 gr
!
```

- Device C configuration file

```
!
interface gigabitethernet 0/1
unset switch-port
ipv6 address 2001::3/64
 ipv6 ospf priority-value 0
 ipv6 ospf 1 set-area 0
!
ipv6 router-protocol ospf 1
 router-id 3.3.3.3
 gr
!
```

1.25.6 Configuring BFD for OSPFv3

1. Requirements



Devices A, B, and C are interconnected through OSPFv3.

The active link from Device A to 3::3 is Device A > Device C, and the standby link is Device A > Device B > Device C.

When the link from Device A to Device C fails, BFD can detect the failure and notify OSPFv3 of the failure, and quickly switch to the standby link.

2. Topology

Figure 1-14 Configuring BFD for OSPFv3

3. Notes

- Configure IPv6 addresses on interfaces of all the devices.
- Configure the basic OSPFv3 functions for all the devices.
- Enable the BFD function in the OSPFv3 routing process mode.

4. Procedure

(1) Configure IP addresses for interfaces and configure basic OSPFv3 functions.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/2)# ipv6 address 12::1/64
Device A(cfg-if-GigabitEthernet 0/2)# ipv6 ospf 1 set-area 0
Device A(cfg-if-GigabitEthernet 0/2)# exit
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 address 13::1/64
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# ipv6 router-protocol ospf 1
```

```
Device A(cfg-router)# router-id 1.1.1.1
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/1)# ipv6 address 12::2/64
Device B(cfg-if-GigabitEthernet 0/1)# ipv6 ospf 1 set-area 0
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface gigabitethernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/2)# ipv6 address 23::2/64
Device B(cfg)# ipv6 router-protocol ospf 1
Device B(cfg-router)# router-id 2.2.2.2
```

Configure Device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/1)# ipv6 address 13::3/64
Device C(cfg-if-GigabitEthernet 0/1)# ipv6 ospf 1 set-area 0
Device C(cfg-if-GigabitEthernet 0/1)# exit
Device C(cfg)# interface gigabitethernet 0/2
Device C(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/2)# ipv6 address 23::3/64
Device C(cfg-if-GigabitEthernet 0/2)# ipv6 ospf 1 set-area 0
Device C(cfg-if-GigabitEthernet 0/2)# exit
Device C(cfg)# ipv6 router-protocol ospf 1
Device C(cfg-router)# router-id 3.3.3.3
```

(2) Enable the BFD function in the OSPFv3 routing process mode.

Configure Device A.

```
Device A(cfg-router)# bfd whole-interfaces
```

Configure Device B.

```
Device B(cfg-router)# bfd whole-interfaces
```

Configure Device C.

```
Device C(cfg-router)# bfd whole-interfaces
```

5. Verification

- Normal network environment

Check the routing table of Device A.

```
Device A# display ipv6 route-config ospf

IPv6 routing table name - Default - 11 entries
```

```
Codes:   C - Connected, L - Local, S - Static
         R - RIP, O - OSPFv3, B - BGP, I - IS-IS, V - Overflow route
         N1 - OSPFv3 NSSA external-routes class 1, N2 - OSPFv3 NSSA external-routes class 2
         E1 - OSPFv3 external-routes class 1, E2 - OSPFv3 external-routes class 2
         SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
         IA - Inter area-routes, EV - BGP EVPN, N - Nd to host

O        3::3/128 [110/1] via FE80::2D0:F8FF:FE22:358D, GigabitEthernet 0/1
O        23::/64 [110/2] via FE80::2D0:F8FF:FE22:358D, GigabitEthernet 0/1
                  [110/2] via FE80::274:9CFF:FEEE:53CB, GigabitEthernet 0/2
```

Run **traceroute 3::3** on Device A.

```
Device A# traceroute 3::3
  < press Ctrl+C to break >
Tracing the route to 3::3

 1                                    3::3      5 msec     8 msec     10 msec
```

- Link from Device A to Device C fails

  Check the routing table of Device A.

```
Device A# display ipv6 route-config ospf

IPv6 routing table name - Default - 7 entries
Codes:   C - Connected, L - Local, S - Static
         R - RIP, O - OSPFv3, B - BGP, I - IS-IS, V - Overflow route
         N1 - OSPFv3 NSSA external-routes class 1, N2 - OSPFv3 NSSA external-routes class 2
         E1 - OSPFv3 external-routes class 1, E2 - OSPFv3 external-routes class 2
         SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
         IA - Inter area-routes, EV - BGP EVPN, N - Nd to host

 gr
 bfd whole-interfaces
!
```

1.25.7 Configuring OSPFv3 Route Summarization

1. Requirements

Devices A and B reside in OSPFv3 Area 0, and Devices A and C reside in OSPFv3 Area 1. Two static routes are introduced to Device C. To reduce the number of routing entries, Device C summarizes introduced static routes as 2001:3::/32 and advertises the routes to the OSPFv3 domain. Device A summarizes routes in Area 1 as 2001:13::/32 and advertises the routes to the OSPFv3 neighbors.

2. Topology

Figure 1-15 Topology of OSPFv3 Route Summarization

3. Notes

- Configure IPv6 addresses on interfaces of all the devices.
- Configure the basic OSPFv3 functions for all the devices.
- Redistribute two static routes on Device C and configure external route summarization.
- Summarize routes in Area 1 on Device A.

4. Procedure

(1) Configure basic functions of OSPFv3 (omitted).

(2) Redistribute two static routes on Device C and summarize the redistributed routes as 2001:3::/32.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# ipv6 router-protocol ospf 1
Device C(cfg-router)# redistribute-route static
Device C(cfg-router)# summary-prefix 2001:3::/32
```

(3) Summarize routes in Area 1 as 2001:13::/32 on Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# ipv6 router-protocol ospf 1
Device A(cfg-router)# area 1 summary 2001:13::/32
```

5. Verification

- Display OSPFv3 routes on Device A. Summarized static routes are displayed, and route details cannot be displayed.

```
Device A# display ipv6 route-config ospf
```

```
IPv6 routing table name - Default - 11 entries
Codes:   C - Connected, L - Local, S - Static
         R - RIP, O - OSPFv3, B - BGP, I - IS-IS, V - Overflow route
         N1 - OSPFv3 NSSA external type 1, N2 - OSPFv3 NSSA external type 2
         E1 - OSPFv3 external type 1, E2 - OSPFv3 external type 2
         SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
         IA - Inter area, EV - BGP EVPN, N - Nd to host

O   E2   2001:3::/32 [110/20] via FE80::250:56FF:FEB5:7BF5, GigabitEthernet 0/2
O        2001:13::/32 [110/0] via ::1, Null0
```

- Display OSPFv3 routes on Device B. Area 1 summarized routes are displayed, and route details cannot be displayed.

```
Device B# display ipv6 route-config ospf

IPv6 routing table name - Default - 7 entries
Codes:   C - Connected, L - Local, S - Static
         R - RIP, O - OSPFv3, B - BGP, I - IS-IS, V - Overflow route
         N1 - OSPFv3 NSSA external type 1, N2 - OSPFv3 NSSA external type 2
         E1 - OSPFv3 external type 1, E2 - OSPFv3 external type 2
         SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
         IA - Inter area, EV - BGP EVPN, N - Nd to host

O   E2   2001:3::/32 [110/20] via FE80::250:56FF:FEB5:694E, GigabitEthernet 0/1
O   IA   2001:13::/32 [110/2] via FE80::250:56FF:FEB5:694E, GigabitEthernet 0/1
```

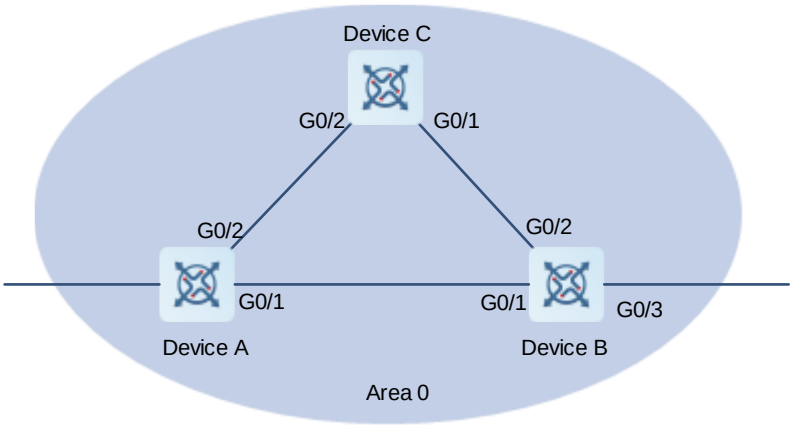
6. Configuration Files

- Device A configuration file

```
!
 router-id 1.1.1.1
 gr
 area 1 summary 2001:13::/32
!
```

- Device C configuration file

```
!
 router-id 3.3.3.3
 gr
 redistribute-route static
 summary-prefix 2001:3::/32
!
```



1.25.8 Configuring FRR

1. Requirements

Devices A, B, and C belong to the same OSPFv3 area, and every two of them interwork with each other through the OSPF protocol. When a link of device A fails, services can be quickly switched to the backup link. The switching latency should be as low as possible.

2. Topology

Figure 1-16 FRR Topology

3. Notes

- Configure FRR on device A.
- Configure **carrier-delay 0** on interfaces of device A.

4. Procedure

(1) Configure IPv6 addresses for interfaces of all devices (omitted).

(2) Configure the OSPFv3 basic functions on all the devices (omitted).

(3) Configure FRR on device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# ipv6 router-protocol ospf 1
Device A(cfg-router)# frr lfa
Device A(cfg-router)# exit
```

(4) Configure **carrier-delay 0** on all interfaces of device A.

```
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# carrier-delaytime 0
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/2)# carrier-delaytime 0
```

5. Verification

On device A, check the routing table to verify that a backup route exists for the entry 192.168.4.0/24.

```
Device A# display ipv6 route-config frr | begin 12::1/128
O          12::1/128[m]    [110/12] via FE80::A00:27FF:FE47:9335, GigabitEthernet 0/1
                     [b]    [110/12] via FE80::A00:27FF:FE47:9336, GigabitEthernet 0/2
```

6. Configuration Files

Device A configuration file

```
!
ipv6 router-protocol ospf 1
frr lfa
!
interface gigabitethernet 0/1
unset switch-port
carrier-delay 0
!
interface gigabitethernet 0/2

 carrier unset switch-port-delay 0
!
```

1 Configuring IS-IS

1.1 Overview

1.1.1 Overview

Intermediate System to Intermediate System (IS-IS) is an extensible, robust, and easy-to-use Interior Gateway Protocol (IGP) for route selection and applicable to an IP and ISO (connectionless network service) CLNS dual environment network.

IS-IS was designed for the Connection-Less Network Protocol (CLNP) at the very start. After TCP/IP became mainstream protocols, IETF modified IS-IS so that this protocol could apply to TCP/IP environment. The modified IS-IS is referred to as Integrated IS-IS or Dual IS-IS.

IS-IS has the common characteristics of a link state protocol. It sends Hello packets to discover and maintain neighbor relationships, and sends Link State Protocol Data Units (LSPs) to neighbors to advertise its link state. IS-IS supports Level-1 routing and Level-2 routing. All devices at the same level maintain the same link state database (LSDB), which stores the LSPs generated by the devices to notify each other of the network topology at this level. Each device uses the Dijkstra shortest path first (SPF) algorithm to perform best-route computation, path selection, and fast convergence.

Note

In this chapter, the term "router" refers to any network device that supports the routing function. These network devices can be Layer-3 switches, routers, or firewalls.

1.1.2 Principles

1. Basic Concepts

- IS-IS network hierarchy

  As shown in Figure 1-1, an IS-IS network is divided into Level-1 and Level-2. The nodes on which devices exchange information in the same area form one level (Level-1).

  - Level-1 routers perform routing in the local area and they can form neighbor relationship with local Level-1 routers and Level-1/Level-2 routers and maintain Level-1 LSDB. This LSDB includes routing information of local area and packets destined for another area are forwarded to the closest Level-1/Level-2 router.
  - Level-2 routers perform inter-area routing and they can form neighbor relationship with Level-2 routers in the same area or another area and Level-1/Level-2 routers and maintain Level-2 LSDB. This LSDB includes inter-area routing information. All Level-2 routers and Level-1/Level-2 routers form a backbone network of a routing domain and take charge of communication between different areas. The backbone network must be physically connected. Only Level-2 routers can exchange data packets and routing information with routers outside the routing domain.
  - Level-1/Level-2 routers, belonging to Level-1 and Level-2 areas, can form Level-1 neighbor relationship with Level-1 routers in the same area and Level-1/Level-2 routers and form Level-2 neighbor

relationship with Level-2 routers in the same or another area and Level-1/Level-2 routers. Level-1 routers must be connected to another area through Level-1/Level-2 routers. Level-1/Level-2 routers maintain two LSDBs. Level-1 LSDB is used for internal routing, and Level-2 LSDB is used for inter-area routing. By default, Level-1/Level-2 routers redistribute Level-1 routes to Level-2 routers. If there are many Level-1 routes, the routes must be summarized and then redistributed to Level-2 routers.

All devices in an area know the network topology of the area and exchange data within the area. Level-1/Level-2 devices are border devices that belong to different areas and provide inter-area connections. Areas are connected by Level-2 devices. The border devices in various areas form a Level-2 backbone network for inter-area data exchange.

Level-1 devices are only interested in the local area's topology, including all nodes in the local area and the next-hop devices destined for the nodes. Level-1 devices access other areas through Level-2 devices and forward packets from a target network outside the local area to the closest Level-2 device.

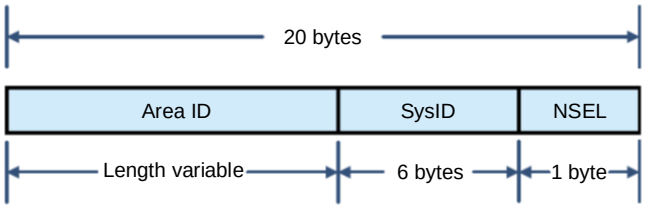

Figure 1-1 IS-IS Network Architecture

- IS-IS address coding mode

  An IS-IS address is called a network entity title (NET) and it consists of an area ID, a system ID, and a network service access point (NSAP) ID. An IS-IS address ranges from 8 to 20 bytes.

Figure 1-2 NET Address Format

  - The area ID identifies the routing domain length in an area and is fixed relative to the routing domain. It

ranges from 1 to 13 bytes.

The area ID consists of an authority and format identifier (AFI), an initial domain identifier (IDI), and a high order DSP (HODSP). The AFI represents an address assignment authority and address format, the IDI is used to identify a domain, and the HODSP is used to distinguish areas.

- The system ID is unique in an autonomous system (AS).

  Generally, a router ID (for example, 192.168.10.1) is translated to a system ID by extending each decimal in an IP address to three decimals. For if the decimals are less than three, 0 is added for supplementation. An extended IP address is 192.168.010.001. After the extended IP address is divided into three parts, the system ID is 1921.6801.0001.

- The NSAP is a network selector and sometimes called SEL. In IS-IS, SEL is typically set to 00 to indicate a device.

- IS-IS packet types

  There are three types of IS-IS packets:

  - LSPs

    LSPs are used to transmit link state records within an area and are classified into Level-1 LSPs and Level-2 LSPs. LSPs are only flooded at the local level.

  - IS-to-IS Hello (IIH) PDUs

    IIH PDUs are used to maintain adjacency. They carry multicast MAC addresses used to determine whether other systems run IS-IS.

  - Sequence number PDUs (SNPs), including complete SNP (CSNP) and partial SNP (PSNP)

    CSNPs are used for LSDB synchronization. By default, a designated IS (DIS) sends a CSNP every 10s in a broadcast network. In a P2P network, a CSNP is sent only after a neighbor relationship is established.

    PSNPs are also used for LSDB synchronization.

- IS-IS supported type-length-value (TLV) types

  IS-IS supports 26 types of TLV.

  Table 1 lists IS-IS supported TLV types.

Table 1-1 IS-IS Supported TLV Types

TLV Code	Description
Code=1	Area address
Code=2	Priority of an IS-IS neighbor
Code =3	ES neighbor
Code=6	MAC address of an IS-S neighbor
Code=8	Padded field
Code=9	LSP entity
Code=10	Verification field

TLV Code	Description
Code=14	Size of the source LSP buffer
Code=22	Extended IS reachability
Code=128	IP internal reachability information
Code=129	Supported protocol
Code =130	IP external reachability information
Code=131	Inter-domain routing protocol information
Code=132	IP interface address
Code=133	Verification information
Code=135	Extended IP reachability TLV
Code=137	Dynamic host name
Code = 211	Graceful Restart
Code = 222	MT IS TLV
Code = 229	Multi Topology TLV
Code=232	IPv6 interface
Code = 235	IPv4 MT IP reachability TLV
Code =236	IPv6 IP reachability TLV
Code = 237	IPv6 MT IP reachability TLV
Code =240	P2P three-way handshake TLV

- IS-IS supported network types

  IS-IS supported network types include P2P links and broadcast links.

2. Working Process of IS-IS

IS-IS working process consists of neighbor establishment, LSDB synchronization, and route computation. In a broadcast network, neighbor establishment involves DIS election.

- Neighbor establishment

  The IS-IS neighbor establishment procedure is similar to the OSPF neighbor establishment procedure. If the received hello packets do not contain any information, the neighbor state is reset to Initial. If the neighbor field in the received packets indicates the local MAC address, the neighbor state is Up. If the neighbor state of the local router and peer routers is Up, the neighbor relationship is successfully established.

- DIS election

  A DIS in a broadcast network works like a DR in OSPF.

A pseudonode is generated by a DIS and sets up a relationship with each device in the local network.

Like DR election in OSPF, a DIS is elected to reduce unnecessary neighbor relationships and route information exchanges. After neighbor establishment, the DIS election starts at respective levels of areas. The election priority also changes with the levels of areas.

A DIS simulates multiple access links as a pseudonode and generates LSPs for the pseudonode. The pseudonode sets up a relationship with each device in the local network and forbids direct communication between the devices. A broadcast subnet and a non-broadcast multiple access (NBMA) network are considered as pseudonodes externally. Non-DIS devices report local link states to the DIS in the same network, and the DIS reports the link states on behalf of all the IS devices in the network.

DIS election in IS-IS is preemptive. The election result can be manually controlled through interface priority configuration. The device with a higher interface priority is more likely to be elected as the DIS. A device with the priority 0 participates in DIS election as well.

- LSDB synchronization

  All devices running link state routing protocols send local link state and directly-connected network link state to neighbors. Upon receiving the link information, the neighbors record and forward the information to their neighbors. After link state update is completed, all routers obtain topological information of the entire network. This is referred to as LSDB flooding synchronization.

  Many neighbor actions such as neighbor or neighbor interface up/down, metric change, redistributed route change and periodic change, trigger LSDB synchronization.

  A router processes a received LSP as follows:

  a The router searches for this LSP in the LSDB. If the LSP does not exist in the LSDB, the router records this packet in the LSDB and broadcasts it for synchronization.

  b If the sequence number of this LSP is greater than that of the local LSP, the router updates the LSDB and broadcasts it for synchronization.

  c If the sequence number of this LSP is smaller than that of the local DPS, the router replies to the local LSP.

- Route computation

  After the LSDB is synchronized, IS-IS computes the SPF and generates IS-IS routes based on the SPF.

  In the LSP sent by the Level-1/Level-2 routers, ATT is set to 1. A Level-1 router gets to know the closest Level-1/Level-2 router based on the ATT and route computation result, and considers the Level-1/Level-2 router a routing transit to other areas.

3. IS-IS Route Control

- Route redistribution

  IS-IS can introduce routes of other routing protocols and routes of other IS-IS processes to the IS-IS process and mutually introduce routes between Level-1 and Level-2 areas.

  In IS-IS, a Level-2 area does not synchronize the known routing information of the backbone areas and other Level-1 areas to a Level-1 area. The Level-2 area cannot obtain external routing information outside Level-1 area. During routing, secondary routes may be generated. During route redistribution, routes of other Level-1 areas and backbone areas that meet conditions can be introduced to the local Level-1 area based on the routing policy.

- Route summarization

  Route summarization is a process of summarizing routing information with the same prefix into one route, and advertising the summarized route (replacing a large number of individual routes) to neighbors. Route summarization helps reduce the protocol interaction load, the size of the routing table, and the impact of route flapping on the routing table.

- Load balancing

  If multiple equal-cost routes exist in a network, IS-IS can distribute load to the equal-cost routes to improve link usage.

4. IS-IS Wide Metric

The default metric type of IS-IS is narrow. In narrow mode, the maximum metric value of an interface is **63**. In a large network, the metric value range in narrow mode is not wide enough. Therefore, wide metric is developed. The metric value can reach 16777215.

5. LSP Fragment Extension

IS-IS advertises link state information by flooding LSPs. The size of an LSP is limited by the MTU size of the link. When the content to be advertised exceeds one LSP, IS-IS will create LSP fragments to carry new link state information. Based on ISO, an LSP fragment is indicated by an LSP number that is one byte long. Therefore, an IS-IS device can generate a maximum of 256 LSP fragments.

The 256 LSP fragments are insufficient in any of the following situations:

(1) New applications (such as traffic engineering) extend new TLV or sub-TLV.

(2) The network is expanded continuously.

(3) Routes with reduced granularity are advertised, or other routes are redistributed to IS-IS.

After LSP fragments are used up, new routing information and neighbor information will be discarded, causing network exceptions such as routing black holes or loops. To ensure normal network operation, LSP fragments must be extended to carry more link state information.

By configuration of an additional system ID and an fragment extension switch, IS-IS can advertise more link state information in extended LSP fragments. Each virtual system can be considered as a virtual device that establishes a neighbor relationship (with the path value 0) with the originating system. Extended LSPs are advertised by the neighbor of the originating system, that is, the virtual system.

The following terms are related to fragment extension:

- Normal system ID

  The system ID defined by ISO is used to establish neighbor relationships and learn routes. It is further defined as the normal system ID in order to be distinguished from the additional system ID introduced to fragment extension.

- Additional system ID

  The additional system ID is configured by an administrator to generate extended LSPs. The additional system ID shares the usage rules of the normal system ID (for example, the additional system ID must be unique in the entire area), except that the additional system ID is not carried in Hello packets for neighbor relationship establishment.

- Originating system

An originating system is an IS-IS-enabled device and maps to a virtual system identified by the additional system ID.

- Virtual system

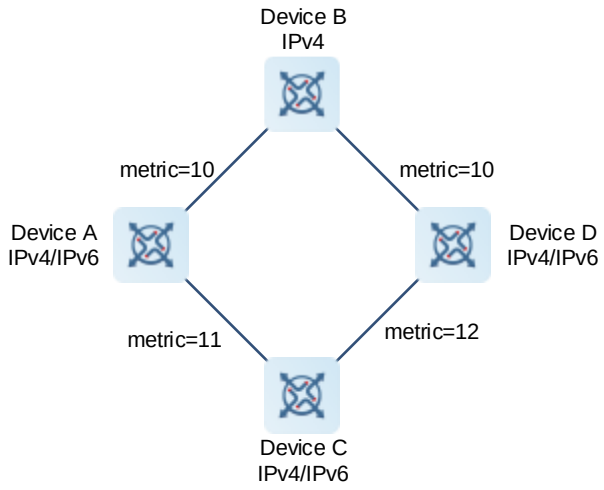
  A virtual system is identified by the additional system ID and used to generate extended LSPs. The concept of virtual system is proposed by RFC for distinguishing from the concept of originating system. Each virtual system can generate up to 256 LSP fragments. The administrator can configure multiple additional system IDs (virtual systems) to generate more LSP fragments.

- Original LSP

  An original LSP is the LSP whose system ID contained in the LSP ID is a normal system ID. Original LSPs are generated by an originating system.

- Extended LSP

  An extended LSP is the LSP whose system ID contained in the LSP ID is an additional system ID. Extended LSPs are generated by a virtual system.



6. IS-IS MTR

IS-IS multi-topology routing (MTR) is an extended feature used to separate IPv4 unicast route computation from IPv6 unicast route computation based on topologies. New TLV types introduced to IIH packets and LSP packets of IS-IS to transmit IPv6 unicast topology information. One physical network can be divided into an IPv4 unicast logical topology and an IPv6 unicast logical topology. The two topologies perform SPF computation separately and maintain respective independent IPv4 and IPv6 unicast routing tables. In this way, IPv4 unicast service traffic and IPv6 unicast service traffic are forwarded by different paths. The IS-IS MTR technique helps users deploy IPv6 unicast networks without the constraint on consistency between IPv4 and IPv6 unicast topology information.

IS-IS MTR is derived from IS-IS MT, which is used to separate IPv4 unicast topology from IPv6 unicast topology, unicast topology from multicast topology, and topologies using different protocol stacks (such as IPv4 and Pv6). IS-IS MTR separates IPv4 unicast topology from IPv6 unicast topology based on IS-IS MT.

Figure 1-3 shows a typical networking application with the following implementation requirements: Deploy an IPv6 unicast topology in incremental mode and upgrade some devices to support IPv4 and IPv6 dual protocol stacks while keeping other IPv4-enabled devices unchanged.

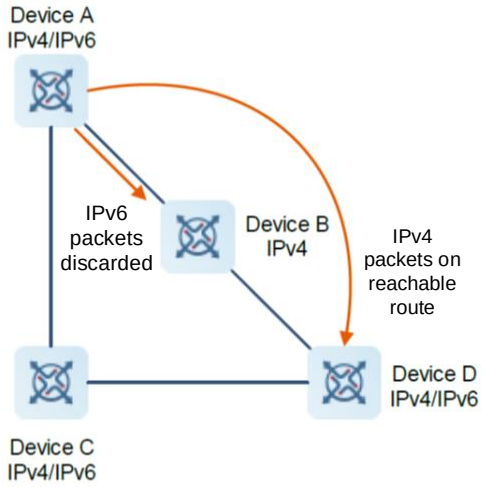


Figure 1-3 Physical Topology for IPv4/IPv6 Hybrid Deployment

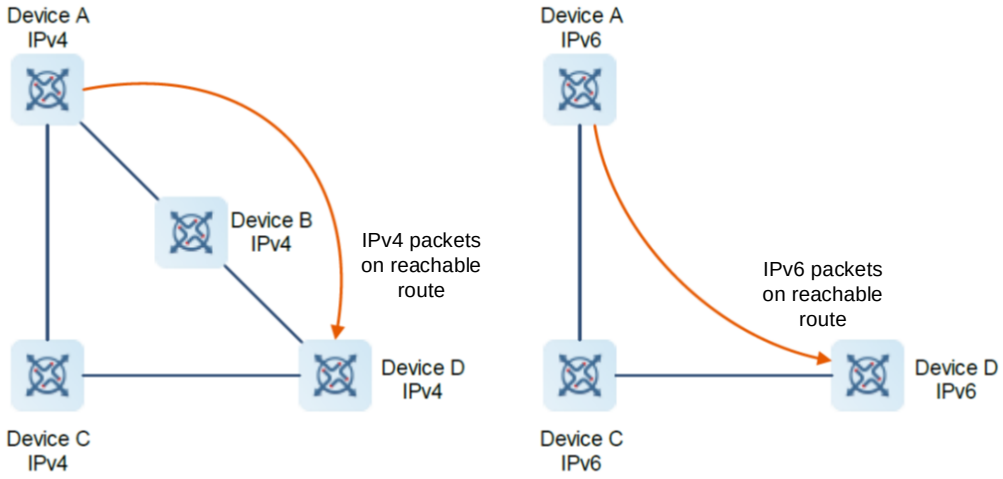
As shown in Figure 1-3, each link is marked by a number indicating its metric. Device B only supports the IPv4 protocol stack, whereas other devices support IPv4 and IPv6 dual protocol stacks.



The networking constraint on consistency between IPv4 and IPv6 unicast topologies must be removed to retain the use of Device B (supporting IPv4) so that Device B can establish a neighbor relationship with Device A or D. This, however, may cause new problems.

Figure 1-4 IPv4/IPv6 Hybrid Topology

As shown in Figure 1-4, without IS-IS MTR, SPF computation performed by Devices A, B, C, and D only take into account the single hybrid topology. The calculated shortest path is Device A -> Device B -> Device D, with the cost 20. Device B will discard IPv6 packets because it does not support IPv6.

Figure 1-5 Separation of IPv4 and IPv6 Topologies

As shown in Figure 1-5, after the IS-IS MTR technique is used to separate IPv4 unicast topology from IPv6 unicast topology, Devices A, B, C, and D establish neighbor relationships based on the IPv4 and IPv6 unicast topologies. The left part shows the IPv4 topology formed by IPv4-enabled routers. The calculated IPv4 shortest

path is Device A -> Device B -> Device C, which realizes IPv4 packet forwarding. The right part shows the IPv6 topology formed by IPv6-enabled routers. The calculated IPv6 shortest path is Device A -> Device C -> Device D, which realizes IPv6 packet forwarding.

General IS-IS MTR deployment: IS-IS MTR must be deployed to avoid routing black holes when some devices support only one protocol. IS-IS MTR is not required when all devices support IPv4 and IPv6 dual protocol stacks.

Deployment of a new network: IS-IS MTR is not required when devices only support the IPv4 protocol stack. For devices that only support the IPv6 protocol stack or devices that support IPv4 and IPv6 dual protocol stacks, enable the MT mode of IS-IS MTR. You are not advised to enable Multi-Topology Transition (MTT) because loops may occur.

Reconstruction of an existing network with devices supporting only one protocol stack: Enable the MTT mode of IS-IS MTR on devices that support IPv4 and IPv6 dual protocol stacks in sequence (starting from the device closest to a device supporting only one protocol stack in the network topology). After the MTT mode is enabled on all new devices, switch the MTT mode to the MT mode on these devices in sequence (starting from the device farthest from a device supporting only one protocol stack in the network topology).

7. IS-IS Neighbor

In a broadcast network, neighbors elect a DIS and routers send routing information to the DIS.

On a P2P link, neighbor relationship can be established in two ways:

- Two-way handshake

  As long as an IIH packet is received, neighbor relationship is established. This method comes with low reliability.

- Three-way handshake

  Neighbor relationship can be established after the IIH packet is sent three times. This method boasts high reliability.

  In a link with one down end, if a neighbor relationship is established based on the IIH packet received from the peer device, the established neighbor relationship is abnormal. In a three-way handshake, an acknowledgment packet must be received from the peer device to confirm that the peer device has received the IIH packet before the neighbor relationship is established.

The following conditions must be met for two routing devices to establish a neighbor relationship when IS-IS MTR is not configured:

- The interface addresses on both routing devices are in the same network segment.
- The interface levels on both routing devices match.
- The routing devices are authenticated by each other.
- The routing devices support the same protocol.

The following conditions must be met for two routing devices to establish a neighbor relationship when IS-IS MTR is configured:

- The interface addresses on both routing devices are in the same network segment.
- The interface levels on both routing devices match.
- The routing devices are authenticated by each other.
- The routing devices have at least one consistent MT ID when P2P links are configured.

- There are no constraints on the MT IDs that the routing devices support when LAN links are configured.

8. IS-IS Authentication

Internet requirements for information security increase. To avoid data theft and tampering, operators apply the IS-IS authentication function on specified areas or interfaces to ensure data security.

- IS-IS authentication types
  - Classification based on packet types:
  - Interface authentication: Authenticate Level-1 and Level-2 hello packets.
  - Area authentication: Authenticate Level-1 CSNP, PSNP, and LSP packets.
  - Routing domain authentication: Authenticate Level-2 CSNP, PSNP, and LSP packets.
  - Classification based on authentication mode:
  - Simple authentication: Add a configured password to a packet. This authentication mode comes with low security.
  - MD5 authentication: A password is encrypted using MD5 algorithms and then added to a packet.
  - Keychain authentication: A keychain is configured so that the password changes with time.
- Implementation procedure

  Upon receiving an IS-IS packet from another router, the local router checks whether the authentication password is correct. If not, the packet is discarded. The IS-IS packet carries authentication information by means of TLV. The TLV format is as follows:
  - Type: Indicates an authentication packet type. For TCP/IP packets, this value is 133.
  - Length: Indicates the length of a TLV.
  - Value: Indicates an authentication type and password.

  Interface authentication: Indicates that authentication is configured in interface configuration mode. Interconnected router interfaces must be configured with the same password.

  Area authentication: Indicates that authentication is configured in IS-IS routing configuration mode. If the authentication is performed between routers in the same area, the key string or password must be the same.

  Routing domain authentication: Indicates that authentication is configured in IS-IS routing configuration mode. If the authentication is performed between routers in the same routing domain, the key string or password must be the same.

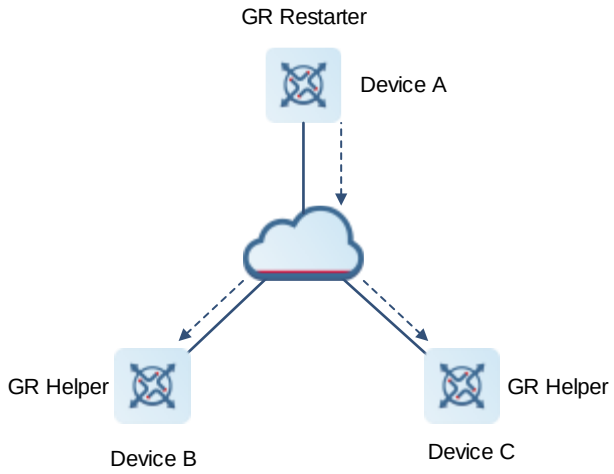
  SNP packets can be authenticated separately from LSP packets and authentication check can be enabled for the received LSP or SNP packets.

9. IS-IS GR

For GR to be successful, the following two conditions must be met:

- The network topology is stable.
- The device can ensure uninterrupted forwarding when it restarts IS-IS.

Two roles exist during the GR process: Restarter and Helper. Accordingly, the IS-IS GR function is divided into IS-IS GR Restart and IS-IS GR Help capabilities. A device with the IS-IS GR Restart capability can send GR requests and automatically execute GR. A device with the IS-IS GR Help capability can receive GR requests



and assist neighbors in executing GR. The GR process starts when the Restarter sends a GR request. After receiving the GR request, the neighboring device enters Help mode to help the Restarter reestablish its LSDB while maintaining the neighbor relationship with the Restarter.

When an IS-IS device performs GR, it notifies its neighbors to maintain their neighbor relationship so that other devices in the network cannot sense the change in the topological relationship and the neighbors will not recalculate the route and update its forwarding table. The IS-IS device synchronizes and restores the LSDB to its pre-GR state with the help of the neighbors to ensure that the routing table and forwarding table remain unchanged before and after GR implementation and data forwarding is not interrupted.

The Restarter performs the following operations during the GR process:

(1) The GR Restarter notifies the GR Helpers that the local device will be restarted.

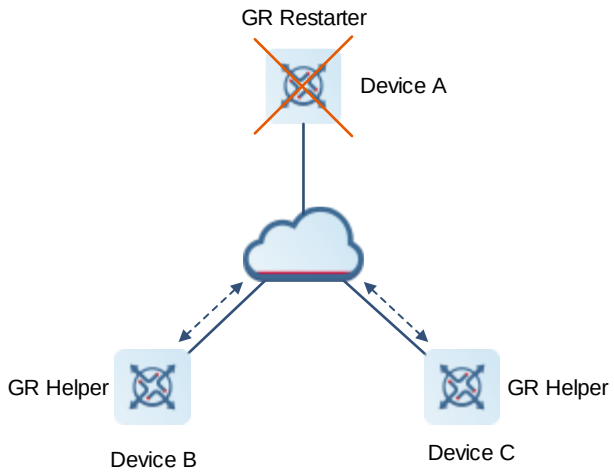


Figure 1-6 Restarter Notifying Helpers of GR

Device A acts as the GR Restarter, and Devices B and C are GR Helpers of Device A. Device A sends a GR request instructing all its neighbors not to delete the neighbor relationships with Device A when it is restarted. After receiving the GR request, the neighbors send GR responses to the GR Restarter, and maintain their neighbor relationships with the GR Restarter during the GR time (specified by GR grace-period) notified by the GR Restarter.

(2) The GR Restarter is restarted.

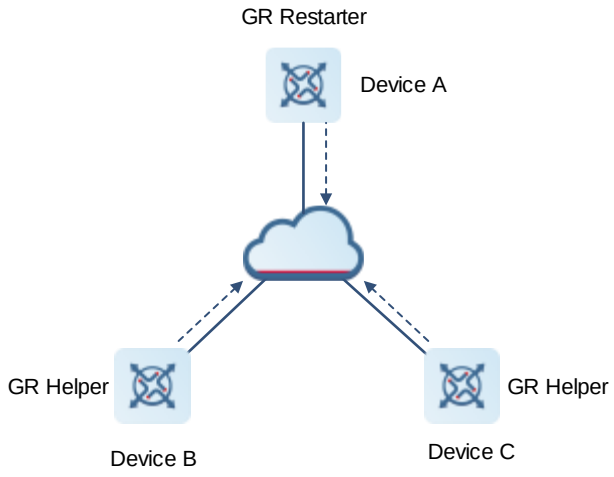

Figure 1-7 Restarter Restart

When the GR Restarter is restarted, its IS-IS interface changes from down state to up state. The GR Helpers know that the GR Restarter is in IS-IS restart state, they maintain their neighbor relationships with the GR Restarter during the GR time and retain the routes from the GR Restarter.

(3) The GR Restarter synchronizes topology and routing information from the GR Helpers.

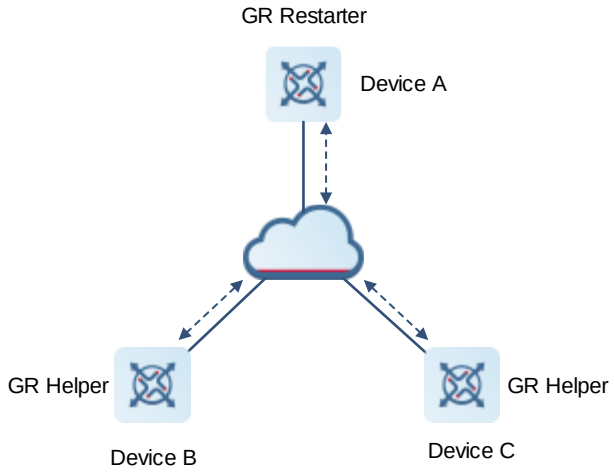

Figure 1-8 LSDB Synchronization

After IS-IS restart, the GR Restarter synchronizes topology or routing information from the GR Helpers and recalculates its routing table. During the process, any change in the routing table is not updated to the forwarding table.

(4) GR is completed when the GR Restarter finishes LSDB synchronization. Then all devices enter IS-IS interaction state.

Figure 1-9 GR Completion

After the GR Restarter synchronizes all required data, all devices enter IS-IS interaction state. The routing table of the GR Restarter is updated to the forwarding table and invalid entries are cleared. Because the GR Restarter is completely restored to the pre-restart state under stable network conditions, its routing table and forwarding table remain unchanged before and after GR.

10. Fast Convergence of IS-IS

IS-IS accelerates convergence by fast advertisement of LSPs and smart timer.

- Fast advertisement of LSPs

  By modification of LSP flooding interval and maximum number of LSPs sent on an interface, LSPs can be advertised to the IS-IS area in the route computation time to reduce route computation and accelerate convergence when the LSPs trigger route computation.

- Smart timer

  LSP packet generation time and SPF algorithm computation time are adjusted based on the smart timer. In a stable IS-IS network, the route computation frequency is low and the first SPF algorithm time is short. In a network with ever-changing topology and network jitter, route computation frequency increases, which consumes CPU resources. In this case, the smart timer will increase SPF computation delay to accelerate convergence and reduce CPU consumption.

1.1.3 Protocols and Standards

- RFC 1142: OSI IS-IS Intra-domain Routing Protocol
- RFC 1195: Use of OSI IS-IS for routing in TCP/IP and dual environments
- RFC 3786: Extending the Number of Intermediate System to Intermediate System (IS-IS) Link State PDU (LSP) Fragments Beyond the 256 Limit
- RFC 3373: Three-Way Handshake for Intermediate System to Intermediate System (IS-IS) Point-to-Point Adjacencies
- RFC 3358: Optional Checksums in Intermediate System to Intermediate System (ISIS)
- RFC 3784: Intermediate System to Intermediate System (IS-IS) Extensions for Traffic Engineering (TE)
- RFC 2763: Dynamic Hostname Exchange Mechanism for IS-IS

- RFC 6119(draft-ietf-isis-ipv6-te-00): IPv6 Traffic Engineering in IS-IS
- RFC 2966: Domain-wide Prefix Distribution with Two-Level IS-IS
- RFC 5306: Restart Signaling for IS-IS

1.2 Restrictions and Guidelines

The PIM mode enabled on all interfaces of a device for an instance must be consistent.

1.3 Configuration Task Summary

IS-IS configuration includes the following tasks:

(1) Configuring Basic Settings of IS-ISConfiguring Basic Settings of IS-IS

(2) (Optional) Configuring IS-IS network Levels

(3) (Optional) Configuring IS-IS Hello Packets

(4) (Optional) Configuring IS-IS LSPs

(5) (Optional) Configuring IS-IS SNPs

(6) (Optional) Configuring IS-IS Route Advertisement

(7) (Optional) Configuring IS-IS Route Summarization

(8) (Optional) Configuring an IS-IS Passive Interface

(9) (Optional) Controlling IS-IS Routing Factors

(10) (Optional) Configuring the Priority of an IS-IS Device

(11) (Optional) Configuring IS-IS Authentication

(12) (Optional) Configuring IS-IS GR

(13) (Optional) Configuring IS-IS NSR

(14) (Optional) Configuring IS-IS Fast Reroute

1.3.2 Overview

When a link fault occurs, it takes about 10 to 30 seconds for IS-IS to detect the neighbor disconnection, advertise the link fault, recalculate the Shortest Path Tree (SPT), and update the routing table. During this period, there is a traffic interruption due to the absence of valid routes.

To minimize the traffic interruption caused by network failures, administrators can configure IS-IS Fast Reroute (FRR). When FRR is enabled, IS-IS precomputes primary and backup paths for each route during normal route calculation. These paths are updated to the routing table. In the event of a link fault, the device quickly detects the fault on the primary path and switches the traffic to the backup path, eliminating the need for IS-IS to recalculate the routes. This significantly reduces the traffic interruption time. When used with BFD for path detection, IS-IS FRR allows the link interruption time to be reduced from over 10 seconds to about 50 milliseconds. When the device forwards packets over the backup path, IS-IS recalculates the routes based on the changed network topology and updates the routing table. Subsequently, the device uses the newly calculated optimal routes for packet forwarding.

Administrators can use IS-IS automatic calculation of backup paths or directly specify backup paths for eligible routes based on comprehensive network planning.

1.3.3 Restrictions and Guidelines

- IS-IS basic functions must be configured.
- When FRR is enabled for IS-IS, you are advised to enable BFD at the same time so that the device can quickly detect link faults, thereby shortening the forwarding interruption time. If the interface is up or down, to shorten the forwarding interruption time during IS-IS fast reroute, you can configure carrier-delay 0 in interface configuration mode to achieve the fastest switchover speed.
- If an interface has limited remaining bandwidth or may fail simultaneously with the primary interface, it cannot be a backup interface. In this case, the command needs to be enabled in interface configuration mode to exclude the interface from being used as a backup interface. After this command is run, a backup interface will be selected from other interfaces during IS-IS FRR calculation.

1.3.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Enable FRR for IS-IS.

frr { **lfa** [**downstream-paths**] **| route-map** *route-map-name* } { **level-1 | level-2** }

By default, FRR is disabled for IS-IS.

(5) Return to the global configuration mode.

exit

(6) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the tunnel interface configuration mode.

  interface tunnel *interface-number*

- Enter the loopback interface configuration mode.

interface loopback *interface-number*

(7) (Optional) Configure LFA protection mode for an IS-IS interface.

isis frr protection { node | link-node | disable }

By default, LFA link protection is enabled.

This command does not take effect if the **fast-rerotue route-map** command is configured.

(8) (Optional) Configure the function of excluding an interface from being a backup.

isis frr no-eligible-backup

By default, IS-IS is enabled and neighboring interfaces can be used as backup interfaces.

This command does not take effect if **frr route-map** command is configured.

(9) Correlating IS-IS with BFD

(10) (Optional) Configuring the IS-IS Overload Bit

(11) (Optional) Configuring IS-IS VRF

(12) (Optional) Configuring IS-IS MTR

(13) (Optional) Configuring IS-IS SNMP

(14) (Optional) Enabling Super VLAN for IS-IS

(15) (Optional) Configuring IS-IS Two-way Maintenance

(16) (Optional) Configuring IS-IS BGP-LS

(17) (Optional) The following configuration tasks are optional. Select tasks for configuration according to the actual condition.

- Configuring the Maximum Metric of a Neighbor
- Configuring the Maximum Number of Area Addresses
- Configuring SPF Calculation Interval
- Canceling Three-Way Handshake of a P2P Network
- Enabling TLV to Be Padded Based on Supported Protocol
- Configuring the Reachable Time of a Suppressed Neighbor
- Suppressing Advertisement of Directly Connected Routes on an Interface

2. Overview

By default, directly connected routes of an interface are advertised in LSPs for route calculation. If you want to exclude the directly connected routes from route calculation on a specific interface, you can configure this function. After this command is configured, the directly connected routes of a specified protocol will not be advertised on an IS-IS interface and the establishment of IS-IS neighbors is still allowed. This function can suppress the interface prefixes carried in LSPs to keep them invisible to external entities, thereby enhancing security and accelerating route convergence.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Enable the function of suppressing the advertisement of directly connected routes on an IS-IS interface.

isis suppress-reachability

By default, the advertisement of directly connected routes is not suppressed on an IS-IS interface.

- Enabling Adjacency Event Output

1.4 Configuring Basic Settings of IS-IS

1.4.1 Overview

Basic settings of IS-IS are a precondition for configuration of all IS-IS features and basic internetworking.

1.4.2 Restrictions and Guidelines

- The Level-1 IS-IS devices in an area must be configured with the same area ID.
- The core routing table does not distinguish the routing entries generated by different IS-IS routing processes.
- The IP addresses of interfaces connected between neighbors must be in the same network segment.
- If the IP addresses are in different network segments, a neighbor relationship cannot be established.
- If the parameter *tag* is specified in the creation of IS-IS routing process, the name of the IS-IS instance is the tag name of the process. If the parameter *tag* is not specified, the instance name of the process is **Null**.
- If you need to add an interface to the specified IS-IS routing process and configure the interface with the IPv4 IS-IS function, add the tag parameter after the **ip router-protocol isis** command to indicate the process name.
- If you run the **unset ip routing** command in global configuration mode, IS-IS will disable IPv4 routing on all interfaces. That is, the **unset ip router-protocol isis** *[tag]* command is automatically executed on all interfaces, with other IS-IS settings unchanged.
- If you need to add an interface to the specified IS-IS routing process and configure the interface with the IPv6 IS-IS function, add the tag parameter after the **ipv6 router-protocol isis** command to indicate the process name.
- If you run the **unset ipv6 unicast-routing** command in global configuration mode, IS-IS will disable IPv6 routing on all interfaces. That is, the **unset IPv6 router-protocol isis** *[tag]* command is automatically executed on all interfaces, with other IS-IS settings unchanged.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the IS-IS routing process and enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

No IS-IS instance is configured by default.

If you configure the *tag* parameter when you start an IS-IS routing process, you need to add this tag parameter when you stop the IS-IS routing process.

(4) Configure a NET address in IS-IS.

net *net-address*

No NET address is configured in IS-IS by default.

Different NET addresses must have the same system ID.

(5) (Optional) Modify the system ID in IS-IS. Configure one of the following tasks.

- Replace the system ID of an instance with the configured name.

  is-name *name*

  The default system ID is used.

- Replace the system ID of a router with the host name of the destination router.

  hostname dynamic

  The host name replacement function is enabled by default.

(6) Return to the global configuration mode.

exit

(7) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(8) Enable IS-IS on an interface.

- Enable IPv4 IS-IS on an interface.

  ip router-protocol isis [*tag*]

  IPv4 IS-IS is not enabled on an interface by default.

- Enable IPv6 IS-IS on an interface.

ipv6 **router-protocol isis** [*tag*]

IPv6 IS-IS is not enabled on an interface by default.

1.5 Configuring IS-IS network Levels

1.5.1 Overview

IS-IS supports a two-Level system to realize routing management and extensible route selection in a large network. Each level is only concerned about maintaining the topology of the corresponding area.

1.5.2 Restrictions and Guidelines

- If the circuit-type is set to Level-1 or Level-2-only, IS-IS will only send PDUs at the corresponding level.
- If the circuit type of an interface is set to **external**, this interface will work as an external domain interface and IS-IS will not send PDUs at the corresponding level.
- A device can have only one instance running at Level-2 (including Level-1/Level-2).

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Configure a level of IS-IS.

is-type { **level-1 | level-1-2 | level-2-only** }

IS-IS runs at Level-1/Level-2 by default.

(5) Return to the global configuration mode.

exit

(6) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.

- **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(7) Configure an IS-IS level on an interface.

isis circuit-level { **level-1 | level-1-2 | level-2-only** [**external**] }

The circuit type of an interface is set to Level-1/Level-2 by default.

(8) Configure a broadcast interface as a P2P interface.

isis network-type point-to-point

The broadcast network type is unchanged by default.

1.6 Configuring IS-IS Hello Packets

1.6.1 Overview

Hello packet control parameters, including hello packet sending interval, hello hold time, packet padding, and neighbor detection are configured. Neighbor establishment can be controlled to maintain neighbor interaction.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Configure the Hello packet sending interval of an interface.

isis hello-period { *interval* | **minimal** } [**level-1 | level-2**]

The Level-1 and Level-2 hello packets are sent at an interval of **10** seconds by default.

(5) Configure the Hello packet hold time multiplier on an interface.

isis iih-multiplier *multiplier-number* [**level-1** | **level-2**]

The default hello hold time multiplier is **3**. That is, the hello hold time is three times of the hello interval.

(6) Configure to pad IS-IS hello packets on an interface.

isis hello-packet padding

Padding is enabled by default for hello packets sent on an interface.

(7) Enable neighbor supported protocol detection for hello packets in IPv4 environment.

adjacency-support-check

The neighbor supported protocol detection function for hello packets is enabled by default.

(8) Enter the IS-IS IPv6 address family configuration mode.

address-family-mode ipv6 unicast

(9) Enable neighbor supported protocol detection for hello packets in IPv6 environment.

adjacency-support-check

The neighbor supported protocol detection function for hello packets is enabled by default.

(10) Exit the IS-IS IPv6 address family configuration mode.

exit-address-family-mode

1.7 Configuring IS-IS LSPs

1.7.1 Overview

Adjusting timer and packet length of LSPs will affect LSP update timeliness and LSP frequency.

1.7.2 Restrictions and Guidelines

- The LSP generation time and refresh time can be configured to prevent network topology change from affecting the LSP transmission frequency.
- During LSDB change, IS-IS notifies the change by LSP advertisement. If a great number of IS-IS routes and interfaces exist on a device, a too small sending interval and a too great LSP number may cause LSP bursts. Therefore, the LSP sending interval and LSP number must be set to proper values. LSP retransmission interval is used in P2P network. In such a network, an LSP response must be returned to indicate completion of an LSP retransmission.
- The value of *lsp-refresh-interval* must be smaller than that of *max-lsp-lifetime*.
- The value of *max-lsp-lifetime* must be greater than that of *lsp-refresh-interval*.
- The value of the configured *initial-interval* cannot be greater than that of *maximum-interval*. Otherwise, the value of *initial-interval* is changed to that of *maximum-interval*.
- The value of the configured *hold-interval* cannot be greater than that of *maximum-interval*. Otherwise, the value of *hold-interval* is changed to that of *maximum-interval*.
- The value of the configured *initial-interval* cannot be greater than that of *hold-interval*. Otherwise, the value of *initial-interval* is changed to that of *hold-interval*.

- If no particular level is specified in the command, the default level is Level-1/Level-2, which means that the interval configuration takes effect to Level-1 and Level-2 concurrently.
- When you need to configure **mesh-group** on an IS-IS interface, run the **isis csnp-period** command to configure the non-0 CSNP interval to ensure complete LSP synchronization between neighbors in the network. After that, CNSPs will be periodically sent to synchronize LSPs.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Modify LSP control parameters on the interface. The following configuration tasks are optional. Select tasks for configuration according to actual condition.

- Configure the LSP sending interval.
  - **isis lsp-transmit-period** *interval* [**level-1** | **level-2**]

  LSPs are sent at an interval of **33** ms by default on an IS-IS interface.
- Configure the maximum number of LSPs sent by an IS-IS interface at a time.

  isis lsp-flood *lsp-number* [**level-1** | **level-2**]

  An IS-IS interface sends at most 5 LSPs at a time by default.
- Configure the LSP retransmission interval.

  isis retransmit-interval *retransmit-interval* [**level**-1 | **level**-2]

  LSPs are retransmitted at an interval of **5** seconds by default.

  If *retransmit-interval* is set to **0**, no LSP is retransmitted.

(5) Return to the global configuration mode.

exit

(6) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(7) Modify LSP control parameters in the IS-IS process. The following configuration tasks are optional. Select tasks for configuration according to actual condition.

- Configure the LSP generation interval.

  lsp-gen-period [**level-1** | **level-2**] *maximum-interval* [*initial-interval hold-interval*]

  The default maximum interval between two LSP generation times is **5** seconds, the delay for generating an LSP is **50** ms, and the minimum interval between the first LSP generation time and the second LSP generation time is **200** ms.

- Configure the LSP refresh interval.

  lsp-refresh-period *interval*

  The default LSP refresh interval is **900** seconds.

- Configure the LSP lifetime.

  lsp-max-life *max-lifetime*

  The default maximum LSP lifetime is **1200** seconds.

- Configure the interval for receiving duplicate LSP packets.

  min-lsp-arrival [**level-1** | **level-2**] *minimum-interval initial-interval hold-interval*

  The function of receiving duplicate LSP packets is not supported by default.

- Configure to ignore LSP checksum errors.

  lsp-error-ignore

  LSP checksum errors are processed by default.

- Configure LSP fragment extension.

  lsp-fragments-extend [**level-1** | **level-2**] [**reference rfc3786**]

  The fragment extension function is disabled by default. To enable fragment extension, run this command to configure fragment extension at the specified level and run the **virtual-system** command to configure an additional system ID.

- Configure the additional system ID of the IS-IS routing process.

  virtual-system *system-id*

  No additional system ID is configured by default. To enable fragment extension, run this command to configure an additional system ID and run the **lsp-fragments-extend** command to configure fragment extension.

- Configure the maximum length of received LSPs.

  lsp-length receive *size*

  The default maximum length of received LSPs is **1492** bytes.

- Configure the maximum length of sent LSPs.

  lsp-length originate *size* [**level-1** | **level-2**]

The default maximum length of sent LSPs is **1492** bytes.

- Add an IS-IS interface to a specified mesh group.

  isis fully-connected-group { **blocked** | *mesh-group-id* }

  No interface joins any mesh group by default.

1.8 Configuring IS-IS SNPs

1.8.1 Overview

By default, a DIS in a broadcast network sends a CSNP every 10s for LSDB synchronization. In a P2P network, CSNPs are sent only after a neighbor relationship is established.

1.8.2 Restrictions and Guidelines

- If an interface is added to a mesh group, CSNP sending interval can be configured. If the CSNP interval is set to **0**, no CSNP is sent.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Configure the CSNP broadcast interval on an IS-IS interface.

isis csnp-period *interval* [**level-1** | **level-2**]

CSNPs are sent at an interval of **10** seconds in a broadcast network by default. No CSNPs are sent in a P2P network by default.

When you configure a new CSNP interval without specifying Level-1 or Level-2, the interval configuration takes effect for Level-1 and Level-2 CSNPs by default.

(5) Configure the minimum PSNP sending interval.

isis psnp-period *psnp-interval* [**level-1** | **level-2**]

The function of configuring the PSNP sending interval is disabled by default. In this case, the minimum PSNP sending interval is **2** seconds by default and it takes effect for Level-1 and Level-2 PSNPs.

1.9 Configuring IS-IS Route Advertisement

1.9.1 Overview

IS-IS can introduce routes of other routing protocols and routes of other IS-IS processes to the IS-IS process and mutually introduce routes between Level-1 and Level-2 areas.

1.9.2 Restrictions and Guidelines

- Because Level-2 domains do not generate any default route, the **default-info originate** command is run to allow a default route to enter a Level-2 domain.
- In the old versions of some vendors, if **metric-type** is set to **external-route**, the metric of redistributed routes is added by 64 during route calculation and used to determine routing. This practice does not comply with the related protocol. In the actual application, external routes may be preferred over internal routes. If this happens during interworking with old versions of some vendors, you can modify the related setting (such as **metric-value** or **metric-type**) of each device to ensure that internal routes are preferred over external routes.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Generate a default route.

default-info originate [**route-map** *route-map-name*]

No default route is generated by default.

(5) Redistribute other routes to IS-IS.

redistribute-route { **arp-host | bgp** | **connected** | **nd-route** | **ospf** *process-id* [**filter** { **external-type**[**1** | **2**] | **internal-type** | **nssa-external-type** [**1** | **2**] }] | **rip** | **static** } [[**level-1** | **level-1-2** | **level-2**] | **metric-value** *metric-value* | **metric**-**class** { **external-type** | **internal-type** } | **route**-**map** *route-map-name*]

Redistribution is disabled by default.

(6) Redistribute the Level-1 reachable routing information of the specified IS-IS instance to Level-2 of the current instance.

redistribute-route isis [*tag*] **level-1 to level-2** [**route-filtering** *acl-name* | **route-map** *route-map-name*]

Redistribution is disabled by default.

(7) Redistribute the Level-2 reachable routing information of the specified IS-IS instance to Level-1 of the current instance.

redistribute-route isis [*tag*] **level-2 to level-1** [**route-filtering** *acl-name* | { **ipv6-prefix** *ipv6-address/length* | **prefix** *ipv4-address net-mask* } | **route-map** *route-map-name*]

Redistribution is disabled by default.

1.10 Configuring IS-IS Route Summarization

1.10.1 Overview

Configuring route summarization can effectively reduce the size of a routing table and system resource usage. If the links in the range of the IP addresses to be summarized jitter (up and down), advertisement of the summarized routes is not affected to avoid route flapping. After route summarization, if any routing information about a reachable address or network segment exists, a summarized route, instead of a detailed route, is advertised externally.

1.10.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Configure an IPv4 summarized route.

summary-address *ipv4-address net-mask* [**level-1** | **level-1-2** | **level-2**] [**metric-value** *metric-value*]

The route summarization function is disabled by default.

(5) Enter the IS-IS IPv6 address family configuration mode.

address-family-mode ipv6 unicast

(6) Enable IPv6 route summarization.

summary-prefix *ipv6-prefix/prefix-length* [**level-1** | **level-1-2** | **level-2**]

The route summarization function is disabled by default.

1.11 Configuring an IS-IS Passive Interface

1.11.1 Overview

This function prevents the specified interface from receiving and sending IS-IS packets, but the IP address of this interface will be flooded by other interfaces.

1.11.2 Restrictions and Guidelines

- If the number of interfaces with IS-IS not enabled exceeds 255, only the first 255 interfaces will be configured as passive interfaces. The remaining interfaces are non-passive interfaces.

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Configure a passive interface in the IS-IS routing configuration mode.

disable-interface { **default** | *interface-type interface-number* }

The passive interface function is disabled by default.

(5) Return to the global configuration mode.

exit

(6) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(7) Configure a passive interface.

isis passive

The configured passive interface in the IS-IS routing configuration mode prevails by default.

1.12 Controlling IS-IS Routing Factors

1.12.1 Overview

IS-IS routing is determined by adjusting the number of equal-cost routes, reference bandwidth values, and interface costs.

1.12.2 Restrictions and Guidelines

- The **max-ecmp-paths** command is used by IS-IS to control the number of IS-IS equal-cost paths to be added to a routing table. There is also a routing table command used to control the number of equal-cost paths. The number of effective equal-cost paths is determined by either of the two command values, whichever is smaller.
- The **bandwidth-reference** command is used to calculate the interface metric in an instance based on the bandwidth value configured in the instance. If a metric is configured, the metric prevails.
- The metric, which is used in SPF calculation, is stored in the IP reachability information TLV. A greater metric value indicates a greater routing consumption of this interface and a longer path of SPF calculation. The Narrow-metric value is valid only when Metric-style is set to **Narrow**. The Wide-metric value is valid only when Metric-style is set to **Wide**.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Configure the administrative distance of an IS-IS route.

distance *distance-value*

The default administrative distance of IS-IS is **115**.

(5) Configure the metric for an instance.

metric *metric* [**level-1** | **level-2**]

By default, Level-1 and Level-2 use the computation result of **bandwidth-reference**.

(6) Configure the maximum number of equal-cost paths.

max-ecmp-paths *maximum*

The default maximum number of equal-cost paths is **2**.

(7) Configure the reference bandwidth value for cost computation.

bandwidth-reference *value*

The default reference bandwidth value for cost computation is **100** Mbps.

(8) Configure the metric type.

metric-class { **narrow-metric** [**transition**] | **wide-metric** [**transition**] | **transition** } [**level-1** | **level-2** | **level-1-2**]

The default metric type is Narrow.

(9) Return to the global configuration mode.

exit

(10) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(11) Configure metric of the IS-IS interface.

isis metric-value *metric* [**level-1 | level-2**]

Level-1 and Level-2 use the computation result of bandwidth-reference by default.

(12) Configure the wide metric value of an interface.

isis wide-metric *metric* [**level-1 | level-2**]

The default wide metric value of Level-1 and Level-2 is the computation result of **bandwidth-reference**.

1.13 Configuring the Priority of an IS-IS Device

1.13.1 Overview

Adjusting DIS election priority of a device on an interface can manually affect DIS election result and specify a device to become the DIS.

1.13.2 Restrictions and Guidelines

- A lower DIS priority of an interface indicates a lower priority of being elected as a DIS.
- This function is invalid on a P2P network interface.

1.13.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Configure device priority in DIS election.

isis priority-value *value* [**level-1 | level-2**]

The default priority of a device for Level-1 and Level-2 DIS election is **64**.

1.14 Configuring IS-IS Authentication

1.14.1 Overview

Internet requirements for information security increase. To avoid data theft and tampering, operators apply the IS-IS authentication function on specified areas or interfaces to ensure data security.

- Interface authentication is intended for establishing and maintaining neighbor relationships. A neighbor relationship cannot be established between two IS-IS devices with different interface authentication passwords. This prevents unauthorized or unauthenticated IS-IS devices from joining an IS-IS network that requires authentication. Interface authentication passwords are encapsulated in Hello packets before being sent.
- Area authentication and routing domain authentication in IS-IS are performed to verify LSPs, CSNPs, and PSNPs to prevent unauthorized or unauthenticated routing information from being injected into the LSDB. Authentication passwords are encapsulated in LSPs, CSNPs, and PSNPs before being sent.

1.14.2 Restrictions and Guidelines

- An interface authentication password is encapsulated in a Hello packet before being sent by an interface. When an interface receives a Hello packet, it checks the password in the packet against the existing one.

- Area authentication passwords are encapsulated in Level-1 LSPs, CSNPs, and PSNPs. When an interface receives an LSP, CSNP, or PSNP, it checks the password in the packet against the existing one.
- Routing domain authentication passwords are encapsulated in Level-2 LSPs, CSNPs, and PSNPs. When an interface receives an LSP, CSNP, or PSNP, it checks the password in the packet against the existing one.
- If no particular Level is specified in the command, the default level is Level-1/Level-2, which means that the authentication configuration takes effect to Level-1 and Level-2 concurrently.
- A key chain may contain multiple passwords. A password with a smaller SN is preferentially used for sending a packet. When the packet arrives at the peer device, the device will receive the packet if the password in the packet is consistent with a password in the key chain.
- For plaintext authentication, the *string-text* in the key chain cannot exceed 80 characters; otherwise, the key chain will be invalid.
- Only one key chain can be used at a time. After you configure a new key chain, it will replace the original one.
- Before you deploy IS-IS interfaces and area authentication on all devices in the network or before you change the authentication password or authentication mode, run the **transmit-only** command. The devices will not authenticate received Hello packets to avoid network flapping when IS-IS interface authentication is deployed.

1.14.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a key chain, and enter the key chain configuration mode.

key chain *key-chain-name*

(4) Create a key chain, and enter the key chain configuration mode.

key *key-id*

(5) Configure the key.

key-string [**0** | **7**] *string-text*

(6) Exit the key chain configuration mode.

exit

(7) Return to the global configuration mode.

exit

(8) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.

- **interface** *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(9) Configure Hello packet authentication on an interface.

- Specify the authentication mode as plaintext or MD5.

  isis auth method { **md5** | **text** } [**level-1** | **level-2**]

  The interface authentication mode is disabled by default.

  The priority of the password is higher than that of the password configured using the **isis auth-password** command.

- Configure the password for interface authentication.

  isis auth keychain *key-chain-name* [**level-1** | **level-2**]

  Authentication is not performed if no key chain is configured using the **key chain** command. In addition to the key chain command, you also need to run the **isis auth method** command to make IS-IS key chain authentication take effect.

- (Optional) Configure the password for plaintext authentication of hello packets on an interface.

  isis auth-password [**0** | **7**] *password-string* [**transmit-only**] [**level-1** | **level-2**]

  Plaintext authentication is not enabled by default.

  This command does not take effect if the **isis auth method** command has been run to configure authentication before.

- (Optional) Configure an authentication password in the Hello packets sent. Received Hello packets are not authenticated.

  isis auth transmit-only [**level-1** | **level-2**]

  Packets sent and received on an interface are authenticated by default.

(10) Return to the global configuration mode.

exit

(11) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(12) Configure LSP, CSNP, and PSNP packet authentication in an IS-IS area.

- (Optional) Configure a password for plaintext authentication of a Level-1 area.

  area-auth [**0** | **7**] *password-string* [**transmit-only**]

  The plaintext authentication function of a Level-1 area is disabled by default.

All IS-IS devices in an area must be configured with the same authentication password. This command does not take effect if the **auth method** command has been run to configure authentication before.

- (Optional) Configure a password for plaintext authentication of a Level-2 routing domain.

  domain-auth [**0** | **7**] *password-string* [**transmit-only**]

  The Level-2 area authentication password function is disabled by default.

  All IS-IS devices in Level-2 domain must be configured with the same authentication password. This command does not take effect if the **auth method** command has been run to configure authentication before.

- Specify the IS-IS routing domain authentication mode.

  auth method { **md5** | **text** } [**level-1** | **level-2**]

  The authentication function is disabled by default.

- Specify the key chain for IS-IS authentication.

  auth keychain *name-of-chain* [**level-1** | **level-2**]

  No authentication key chain is configured by default.

  Authentication is not performed if no key chain is configured using the **key chain** command. In addition to the key chain command, you also need to run the **auth method** command to make IS-IS key chain authentication take effect.

- (Optional) Apply IS-IS authentication only to send packets.

  auth transmit-only [**level-1** | **level-2**]

  Packets sent and received are authenticated by default.

1.15 Configuring IS-IS GR

1.15.1 Overview

As long as the network conditions remain unchanged, GR enables IS-IS to be restarted and restored to the pre-restart state without impact on data forwarding. This improves system reliability.

Two roles exist during the GR process: Restarter and Helper. Accordingly, the IS-IS GR function is divided into IS-IS GR Restart and IS-IS GR Help capabilities. A device with the GR Restart capability can send a GR request and execute GR. A device with the GR Help capability can receive a GR request and help its neighbor with GR implementation. The GR process starts when the Restarter sends a GR request. After receiving the GR request, the neighboring device enters Help mode to help the Restarter reestablish its LSDB while maintaining the neighbor relationship with the Restarter. The main GR working mechanism is as follows:

1.15.2 Restrictions and Guidelines

Specification
All products support the IS-IS GR Helper capability.

1.15.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Enable the IS-IS GR Restart capability.

gr

The IS-IS GR Restart capability is enabled by default.

(5) (Optional) Configure the maximum GR interval of a device.

gr grace-period *max-interval*

The maximum GR interval is **300** seconds by default.

(6) Enable the IS-IS GR Help capability.

gr helper cancel

The IS-IS GR Helper function is enabled by default.

This command enables IS-IS to ignore the GR request sent by the device to be restarted.

1.16 Configuring IS-IS NSR

1.16.1 Overview

IS-IS nonstop routing (IS-IS NSR) helps improve system reliability. During the active/standby switchover of devices in distributed or Virtual Switch Unit (VSU) mode, user data traffic keeps being forwarded without interruption. Information that can be backed up includes command configuration, neighbor backup, and LSP DB.

NSR backs up relevant IS-IS information from the master Supervisor Engine to the slave Supervisor Engine of the distributed device, or from the master device to the salve device in VSU mode, so that the device can automatically recover the link state and regenerate a route upon active/standby switchover, without requiring help from neighbor devices during the recovery.

Compared with GR that needs the help of a neighbor, NSR does not need any help from neighbors.

1.16.2 Restrictions and Guidelines

- For the same IS-IS process, either NSP or GR is enabled, because they are exclusive.
- The switchover of distributed devices and VSU devices takes a period of time. If the IS-IS neighbor keepalive duration is less than the switchover duration, IS-IS neighbor relationship with the neighbor device is removed, and the services are interrupted during the switchover. Therefore, it is recommended that the IS-IS neighbor keepalive duration be set not less than the default value. When Fast Hello is enabled, the IS-IS neighbor keepalive duration is less than 1 second and the IS-IS neighbor relationship times out during the switchover, causing NSR failures. Therefore, it is recommended that Fast Hello be disabled when NSR is enabled.

1.16.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Enable the NSR function.

nsr

The NSR function is disabled by default.

1.17 Configuring IS-IS Fast Reroute

1.17.1 Overview

When a link fault occurs, it takes about 10 to 30 seconds for IS-IS to detect the neighbor disconnection, advertise the link fault, recalculate the Shortest Path Tree (SPT), and update the routing table. During this period, there is a traffic interruption due to the absence of valid routes.

To minimize the traffic interruption caused by network failures, administrators can configure IS-IS Fast Reroute (FRR). When FRR is enabled, IS-IS precomputes primary and backup paths for each route during normal route calculation. These paths are updated to the routing table. In the event of a link fault, the device quickly detects the fault on the primary path and switches the traffic to the backup path, eliminating the need for IS-IS to recalculate the routes. This significantly reduces the traffic interruption time. When used with BFD for path detection, IS-IS FRR allows the link interruption time to be reduced from over 10 seconds to about 50 milliseconds. When the device forwards packets over the backup path, IS-IS recalculates the routes based on the changed network topology and updates the routing table. Subsequently, the device uses the newly calculated optimal routes for packet forwarding.

Administrators can use IS-IS automatic calculation of backup paths or directly specify backup paths for eligible routes based on comprehensive network planning.

1.17.2 Restrictions and Guidelines

- IS-IS basic functions must be configured.
- When FRR is enabled for IS-IS, you are advised to enable BFD at the same time so that the device can quickly detect link faults, thereby shortening the forwarding interruption time. If the interface is up or down, to shorten the forwarding interruption time during IS-IS fast reroute, you can configure carrier-delay 0 in interface configuration mode to achieve the fastest switchover speed.
- If an interface has limited remaining bandwidth or may fail simultaneously with the primary interface, it cannot be a backup interface. In this case, the command needs to be enabled in interface configuration mode to exclude the interface from being used as a backup interface. After this command is run, a backup interface will be selected from other interfaces during IS-IS FRR calculation.

1.17.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Enable FRR for IS-IS.

frr { **lfa** [**downstream-paths**] **| route-map** *route-map-name* } { **level-1 | level-2** }

By default, FRR is disabled for IS-IS.

(5) Return to the global configuration mode.

exit

(6) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the tunnel interface configuration mode.

  interface tunnel *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(7) (Optional) Configure LFA protection mode for an IS-IS interface.

isis frr protection { node | link-node | disable }

By default, LFA link protection is enabled.

This command does not take effect if the **fast-rerotue route-map** command is configured.

(8) (Optional) Configure the function of excluding an interface from being a backup.

isis frr no-eligible-backup

By default, IS-IS is enabled and neighboring interfaces can be used as backup interfaces.

This command does not take effect if **frr route-map** command is configured.

1.18 Correlating IS-IS with BFD

1.18.1 Overview

Bidirectional Forwarding Detection (BFD) is used to test connectivity between devices. A link fault can be detected in as short as 150 ms. After IS-IS is correlated with BFD, IS-IS can sense the death of a neighbor in as short as 150 ms once a link is faulty. This accelerates route convergence and prevents traffic interruption.

Normally, BFD sends detection packets at millisecond intervals to detect the link state. When a link exception (such as a disconnected link) occurs, BFD can quickly detect it and instruct IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Then IS-IS recalculates and generates a new route to bypass the abnormal link, thus realizing fast convergence. With the introduction of new techniques such as the Multi-Service Transport Platform (MSTP), link congestion tends to occur during peak hours of data communication. BFD quickly detects the link exception and instructs IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Link switch is performed to bypass the congested link. A Hello packet for IS-IS neighbor detection is sent every 10s and its expiration time is 30s. The Hello packet can still be received normally when BFD detects an exception, and therefore an IS-IS neighbor relationship is reestablished quickly, causing the route to be restored to the congested link. Then BFD detects the abnormal link and link switch is performed again. This process is repeated, which makes the route be switched between the congested link and other links, causing repetitive flapping.

The anti-congestion option is used to avoid routing flapping in case of link congestion. After the option is configured, the IS-IS neighbor state is still kept alive when link congestion occurs, but the neighbor reachability information in LSPs is deleted. The route is switched to a normal link. When the congested link is restored, the neighbor reachability information in LSPs is recovered and the route is switched back, which avoids route flapping.

1.18.2 Restrictions and Guidelines

- You must configure BFD session parameters before you enable IS-IS correlation with BFD.
- When you run the **bfd up-dampening** command on an interface with IS-IS correlation with BFD, you must run the **bfd whole-interfaces [anti-congestion]** command.
- When you run the **bfd whole-interfaces [anti-congestion]** command, you must run the **bfd up-dampening** command on the interface. The two commands must be used together. If you run only one command, the anti-congestion feature may not take effect or other network exceptions may occur.
- The IS-IS BFD TLV enable option takes effect only after it is configured at both ends and BFD-enable TLV information at both ends is consistent.
- IP routing may cause a neighbor's interface for BFD session setup to be inconsistent with the interface for outgoing BFD packets. If this happens, the BFD session cannot be set up.
- If a neighbor's interface for BFD session setup is inconsistent with the interface for outgoing BFD packets, the BFD session cannot be set up.

1.18.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Enable BFD correlation in IS-IS process mode.

bfd whole-interfaces [**anti-congestion | tlv-enable**]

The IS-IS correlation with BFD function is disabled on all interfaces by default.

(5) Return to the global configuration mode.

exit

(6) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(7) Enable IS-IS correlation with BFD on an interface.

isis bfd-enable [**cancel** | **anti-congestion | tlv-enable**]

The IS-IS correlation with BFD function is enabled on an interface by default if the **bfd whole-interfaces** command is run. The IS-IS correlation with BFD function is not enabled on an interface if the **bfd whole-interfaces** command is not run. The anti-congestion option is disabled by default.

1.19 Configuring the IS-IS Overload Bit

1.19.1 Overview

An IS-IS node is forced to configure the overload bit in a non-virtual LSP to instruct its IS-IS neighbors to avoid using the local node as a forwarding device.

1.19.2 Restrictions and Guidelines

- If the **startup** keyword is selected, the IS-IS node automatically enters overload state after restart. If the **startup** keyword is not selected, the IS-IS node enters overload state immediately after restart.

- The overload bit is used in the following three situations:
  - Device overload

    The local IS-IS node has overload issues, such as insufficient memory or full CPU load; as a result, its routing table has incomplete routes or does not have resource forwarding data. You can configure the overload bit in an LSP to instruct the neighbor to avoid using the local node as a forwarding device.

    To configure the overload bit, run the **remain-overload** command without the **startup** keyword. The overload bit can be configured or removed manually. When the local IS-IS node is restored, manually remove the command configuration; otherwise, the node is always in overload state.
  - Instantaneous black hole

    In the scenario described by RFC 3277, the IS-IS convergence speed is faster than the BGP speed; as a result, after an IS-IS node is restarted, a route may be instantaneously unreachable, which is called an instantaneous black hole. You can set the overload bit in an LSP to instruct the neighbor to avoid using the local node as a forwarding device until the specified time has elapsed.

    To set the overload bit, run the **remain-overload** command with the **startup** keyword. The overload bit can be configured or removed automatically by the IS-IS node based on the configuration. After the **startup** keyword is selected, the IS-IS node automatically enters instantaneous black hole state after restart. When a neighbor relationship is established, the IS-IS node sends an LSP with the overload bit to notify the neighbor that the local node enters instantaneous black hole (or overload) state and instruct the neighbor to avoid using the local node as a forwarding device. After the specified time has elapsed, the IS-IS node immediately sends an LSP with the overload bit canceled to notify the neighbor that the local node has exited instantaneous black hole (or overload) state and can work as a forwarding device.
  - Disabling real data forwarding on the local IS-IS node

    If you only need to connect the local IS-IS node to a production network for testing or to meet other functional requirements, but does not require the node to forward real data in the network, you can set the overload bit in an LSP to instruct the neighbor to avoid using the local node as a forwarding device.

    To set the overload bit, run the **remain-overload** command without the **startup** keyword. The overload bit can be configured or removed manually. You can set the **restrain** keyword based on requirements to limit the routing information carried in an LSP in case of overload. For example, internal and external routes can be suppressed, and only the local direct route is advertised. For example, the advertised direct route and the metric value to reach a neighbor are set to the maximum values.

1.19.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

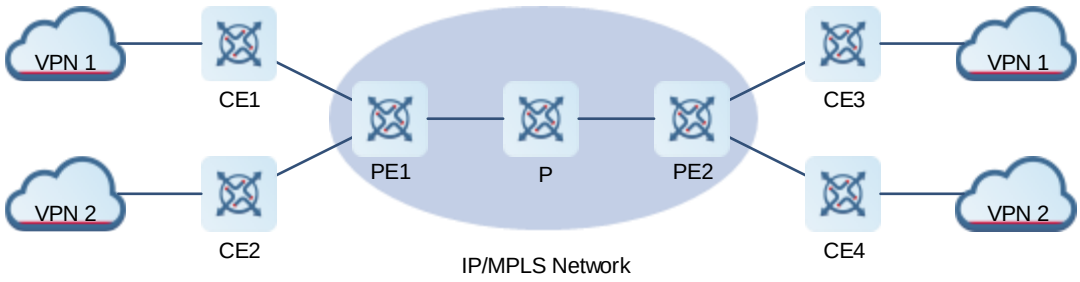
config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Configure the IS-IS overload bit.

remain-overload [**startup** { *overload-time* | **wait-bgp-converge** [*bgp-convergence-time*] }] [**restrain** { **interlevel** | **external** | **max-advertise-metric** } *] [**level-1** | **level-2**]



A neighbor considers the local IS-IS node as a forwarding device to forward data by default.

1.20 Configuring IS-IS VRF

1.20.1 Overview

VPN routing and forwarding (VRF) is mainly used for local routing and packet. It avoids route conflict caused by use of the same prefix by multiple VPNs. IPv4 VPN and IPv6 VPN combine Multiprotocol Label Switching (MPLS) advantages in terms of Quality of Service (QoS) and security assurance, and are the primary solutions for interconnecting the geographically different office branches of an enterprise or industry user.

Figure 1-10 Separation of Different VPNs by VRF Tables Configured on Provider Edge (PE) Devices

As shown in Figure 1-10, configure the two sites (CE1 and CE3) in VPN1 to access each other and the two sites (CE2 and CE4) in VPN2 to access each other, and forbid access between the sites in VPN1 and those in VPN2 because VPN1 and VPN2 belong to different customers or departments and may have identical IP addresses.

The customer edge (CE) devices connect the customer network to the PEs to exchange VPN routing information with the PEs, that is, advertise local routes to the PEs and learn remote routes from the PEs.

Each PE learns routes from directly connected CEs and exchanges the learned VPN routes with the other PEs through the Border Gateway Protocol (BGP). The PEs provide access to the VPN service.

The Provider (P) device in the Service Provider (SP) network-advertise is not directly connected to the CEs. The P device only needs the MPLS forwarding capability and does not maintain VPN information.

The IS-IS protocol running between the PEs and CEs requires the VRF capability to separate routing information between VPN1 and VPN2. That is, IS-IS only learns routes through VRF.

1.20.2 Restrictions and Guidelines

- The IS-IS instances bound with the same VRF table must be configured with different system IDs. The IS-IS instances bound with different VRF tables can be configured with the same system ID.
- One IS-IS instance can be bound with only one VRF table, but one VRF table can be bound to multiple IS-IS instances.
- When the VRF table bound to an IS-IS instance is changed, all IS-IS interfaces associated with the instance will be deleted. That is, the **ip router-protocol isis [tag] interface** configuration and the redistribution configuration in routing configuration mode will be deleted.

1.20.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Configure IS-IS VRF.

vrf *vrf-name*

VRF binding of an IS-IS instance is disabled by default.

1.21 Configuring IS-IS MTR

1.21.1 Overview

The IS-IS MTR technique helps users deploy IPv6 unicast networks without the constraint on consistency between IPv4 and IPv6 unicast topology information.

1.21.2 Restrictions and Guidelines

- Metric-style must be set to **Wide** or **Transition** before you enable this function.
- The MTR feature will be disabled if Metric-style is set to **Narrow** or only one Level is configured to support Wide or Transition mode.

1.21.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Enter the IS-IS IPv6 address family configuration mode.

address-family-mode ipv6 unicast

(5) Configure IS-IS MTR.

ipv6-multitopology [*transition*]

IS-IS is not configured with MTR by default. That is, IS-IS does not support IPv6 unicast topologies. Configure IS-IS SNMP.

1.22 Configuring IS-IS SNMP

1.22.1 Overview

Use the network management software to manage OSPF parameters and monitor the OSPF running status.

1.22.2 Restrictions and Guidelines

- The latest standards stipulate that the MIB operation can be performed on a single instance. By default, the MIB operation is performed on the first displayed IS-IS instance. Because multiple IS-IS instances can be configured, the administrator can use this command to specify the instances on which the MIB operation will be performed.

1.22.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable IS-IS trap globally.

snmp-agent enable traps [*isis*]

The SNMP agent is forbidden to send Trap messages to the NMS by default.

This command must be used with the **snmp-agent host** command in global configuration mode so that trap messages can be sent.

(4) Configure an SNMP host globally.

snmp-agent host { *ipv4-addrress* | **ipv6** *ipv6-address* } [**vrf** *vrf-name*] [**traps**] [**version** { **1** | **2c** | **3** { **auth** | **noauth** | **priv** }] *community-string* [**udp-port** *port-num*] [*notification-type*]

No SNMP host address is configured by default.

(5) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(6) Bind the instances on which the IS-IS MIB operation will be performed.

enable mib-binding

By default, the SNMP operation is performed on the first displayed IS-IS instance.

(7) Allow sending trap messages.

enable traps { **all** | *traps set* }

The IS-IS trap message sending function is disabled by default.

1.23 Enabling Super VLAN for IS-IS

Note

This function is supported by only the S6920-4C, S6520-64CQ, S6510-4C, S6510-32CQ, or S6510-48VS8CQ.

1.23.1 Overview

In normal cases, a super VLAN contains multiple sub VLANs. Multicast packets of a super VLAN are also sent to its sub VLANs. In this case, when IS-IS multicast packets are sent over a super VLAN containing multiple sub VLANs, the IS-IS multicast packets are replicated multiple times, which exceeds the processing capability of the device. As a result, a large number of packets are discarded, causing protocol flapping. In most scenarios, the IS-IS function does not need to be enabled on a super VLAN, and it is disabled by default. In some application

scenarios, the IS-IS function must be run on the super VLAN, but packets only need to be sent to one sub VLAN. In this case, you can decide to send multicast packets to a certain sub VLAN or to all sub VLANs as actually needed using this command. You must be cautious when configuring packet transmission to all sub VLANs, as the large number of sub VLANs may cause a device processing bottleneck, which will lead to the neighbor flapping.

1.23.2 Restrictions and Guidelines

- The IS-IS basic functions must be configured.
- The specified sub VLAN must be connected to neighbors.

1.23.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the SVI configuration mode.

- **interface vlan** *interface-number*

(4) Configure IS-IS to run on a super VLAN.

isis subvlan { **all |** *vlan-id* }

The IS-IS function takes effect in super VLAN only and is disabled by default.

1.24 Configuring IS-IS Two-way Maintenance

1.24.1 Overview

In a large-scale network, a large number of packets are sent and received, which occupies lots of CPU and memory resources, causing some IS-IS packets to be delayed or discarded. If the time required for processing hello packets exceeds the neighbor relationship maintenance time, the corresponding neighbor relationship times out and is removed. If the two-way maintenance function is enabled, in addition to the hello packets, the LSP, CSNP, and PSNP packets from a neighbor can also be used to maintain the bidirectional communication between neighbors when a large number of packets exist in the network. This prevents termination of the adjacency caused by delayed or discarded hello packets.

1.24.2 Restrictions and Guidelines

- The IS-IS basic functions must be configured.
- The neighbor relationship is successfully established.

1.24.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Enable the IS-IS two-way maintenance function.

two-way-maintain

The two-way maintenance function is enabled by default.

1.25 Configuring IS-IS BGP-LS

1.25.1 Overview

BGP-link state (BGP LS) is a new way to collect the network topology. It makes topology collection more simple and efficient. For the IS-IS protocol, network topology information includes information about nodes, links, and route prefixes, which are all carried in LSP packets. When the BGP-LS function is enabled on an IS-IS instance, IS-IS parses out information about nodes, links, and route prefixes from LSP packets, encapsulates the information according to the RFC-7752 standard, and advertises the information to BGP. BGP summarizes information and reports it to the upper level controller, which performs path selection and calculation.

1.25.2 Restrictions and Guidelines

- The IS-IS basic functions must be configured.
- LSP packets must exist in the LSPDB of the corresponding level in the local IS-IS instance. For the LSP configuration, see "Configuring IS-IS LSPs"

1.25.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing process configuration mode.

router-protocol isis [*tag*]

(4) Configure the BGP-LS function on the IS-IS instance.

distribute bgp-ls [**instance-id** *instance-id*] [**level-1** | **level-2**] [**throttle** *delay-time*]

By default, the BGP-LS function is disabled on an IS-IS instance.

1.26 Configuring IS-IS ATT Bit

1.26.1 Overview

An IS-IS Attached (ATT) bit generated by a Level-1-2 router identifies whether a Level-1 area is attached to other areas. The ATT bit is related to Level-1 LSPs only. After a Level-1 router receives the LSPs carrying the ATT bit 1 from the Level-1-2 router, the Level-1 router generates a route with the same destination address as the default route of the Level-1-2 router. Traffic can be forwarded along this route, achieving mutual communication with other areas. To modify the default route generation of routers in a Level-1 area, you can

configure this function. After IS-IS setting ATT bit is configured, IS-IS will modify the ATT bit in Level-1 LSPs based on the configuration, and the default route generation will also change accordingly.

1.26.2 Restrictions and Guidelines

This command takes effect for Level-1-2 routers only.

The ATT bit in Level-1 LSPs identifies whether a Level-1 area is attached to other areas. The default rule is as follows:

- If a Level-1-2 router is attached to a Level-2 backbone area, the Level-1-2 router sets the ATT bit in its generated Level-1 LSP to 1. After a Level-1 router receives the LSPs carrying the ATT bit 1 from the Level-1-2 router, the Level-1 router generates a route with the same destination address as the default route of the Level-1-2 router. Traffic can be forwarded along this route, achieving mutual communication with other areas. To prevent the Level-1 router connected to the Level-1-2 router from advertising the default route when the ATT bit is set to 1, use either of the following methods:
  - Run the **att-bit-ignore** command on the Level-1 router that is connected to the Level-1-2 router.
  - Run the **att-bit-set never** command on the Level-1-2 router to disable the router from sending Level-1 LSPs with the ATT bit 1.
- If the Level-1-2 router is connected to only one area, the Level-1-2 router sends the Level-1 LSPs carrying the ATT bit 0. To enable the ATT bit in Level-1 LSPs remain at 1, run the **att-bit-set always** command.

If multiple topology configurations exist, the ATT bit in the IPv6 unicast topology is set in the MT ID 2 of TLV 229 in Level-1 LSPs. The default rule and the rule for changing the default settings are the same as the ATT bit rule in LSPs.

When this command is configured in IS-IS routing process configuration mode, it applies to the ATT bit in Level-1 LSPs, that is, controlling the calculation of default IPv4 and IPv6 routes in the default topology.

When this command is configured in IS-IS address-family ipv6 configuration mode, it applies to the ATT bit in MT ID 2 of TLV 229 in Level-1 LSPs, that is, controlling the calculation of default routes for IPv6 single-topology in multiple topologies.

1.26.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Configure the **att-bit-set** function on an IS-IS instance.

att-bit-set { **always** | **never** }

By default, an IS-IS Level-1 router sets the ATT bit in LSPs using the default rule.

(5) Configure the **att-bit-ignore** function on an IS-IS instance.

att-bit-ignore

By default, the IS-IS-enabled router advertises the default route when the ATT bit is set to 1.

1.27 Configuring Extended Feature of IS-IS

1.27.1 Overview

IS-IS provides rich extended features that can be configured based on actual needs.

1.27.2 Configuration Tasks

The IS-IS extended feature configuration tasks are as follows and optional. Select tasks for configuration according to the actual condition.

- Configuring the Maximum Metric of a Neighbor
- Configuring the Maximum Number of Area Addresses
- Configuring SPF Calculation Interval
- Canceling Three-Way Handshake of a P2P Network
- Enabling TLV to Be Padded Based on Supported Protocol
- Configuring the Reachable Time of a Suppressed Neighbor
- Suppressing Advertisement of Directly Connected Routes on an Interface

1. Overview

By default, directly connected routes of an interface are advertised in LSPs for route calculation. If you want to exclude the directly connected routes from route calculation on a specific interface, you can configure this function. After this command is configured, the directly connected routes of a specified protocol will not be advertised on an IS-IS interface and the establishment of IS-IS neighbors is still allowed. This function can suppress the interface prefixes carried in LSPs to keep them invisible to external entities, thereby enhancing security and accelerating route convergence.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Enable the function of suppressing the advertisement of directly connected routes on an IS-IS interface.

isis suppress-reachability

By default, the advertisement of directly connected routes is not suppressed on an IS-IS interface.

- Enabling Adjacency Event Output

1.27.3 Configuring the Maximum Metric of a Neighbor

1. Overview

In the Overlay scene where IS-IS is applied to Underlay, the Overlay tunnel may rely on Underlay routing. After the IS-IS neighbor is up, the Underlay route is reachable but the Overlay tunnel may not be created, which may lead to traffic interruption. This function can prevent traffic interruption.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Configure the maximum metric for the directly-connected route after the first neighbor is up.

max-advertise-metric on-neighbor-up *delay-time*

The metric of the directly-connected route is not set to the maximum value by default.

1.27.4 Configuring the Maximum Number of Area Addresses

1. Overview

Generally, an IS-IS process is configured with a NET address. During area reallocation, an IS-IS process can be configured with multiple NET addresses to ensure routing correctness. The system ID of multiple NET addresses must be the same. For Level-1 IS-IS routers, neighbor relationship can be created between the routers only when the maximum numbers of area addresses are the same.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Configure the maximum number of area addresses.

maximum-area-addr *max-area-number*

The maximum number of area addresses is **3** by default.

1.27.5 Configuring SPF Calculation Interval

1. Overview

Increasing the maximum interval for performing SPF calculations can avoid frequent SPF calculations and waste of CPU resources. However, a larger interval also leads to slower responses to route changes.

2. Restrictions and Guidelines

- The first wait time for performing the SPF calculation is *initial-interval*. If the network is unstable, the SPF calculation trigger interval is smaller than *maximum-interval* and the second wait time for performing the SPF calculation is changed to *hold-interval*. A corresponding penalty is added to this interval: The next interval for the SPF calculation doubles the previous interval for the same SPF calculation, until the SPF calculation interval reaches the *maximum interval*. Subsequent SPF calculations are performed at the *maximum interval*. When the network becomes stable, the interval for performing the SPF calculation becomes greater than the *maximum interval*, and the wait time for performing the SPF calculation is restored to the *initial interval*.
- The value of the configured *initial-interval* cannot be greater than that of *maximum-interval*. Otherwise, the value of *initial-interval* is changed to that of *maximum-interval*.
- The value of the configured *hold-interval* cannot be greater than that of *maximum-interval*. Otherwise, the value of *hold-interval* is changed to that of *maximum-interval*.
- The value of the configured *initial-interval* cannot be greater than that of *hold-interval*. Otherwise, the value of *initial-interval* is changed to that of *hold-interval*.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Configure the SPF calculation interval.

spf-throttling-interval [**level-1** | **level-2**] *maximum-interval* [*initial-interval hold-interval*]

By default, the maximum calculation interval of two SPF calculations is **10** seconds, the delay of the first SPF calculation is **50** ms, and the maximum interval for the first and second SPF calculations is **200** ms. Exponential backoff algorithm uses Level-1/Level-2. That is, it takes effect for Level-1 and Level-2 concurrently.

1.27.6 Canceling Three-Way Handshake of a P2P Network

1. Overview

Neighbor establishment in a P2P network requires three-way handshake. The neighbor relationship can be established only after the three-way handshake succeeds. If you want to accelerate neighbor establishment or

there is device that does not support three-way handshake, you can run this command to cancel three-way handshake.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregated sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Cancel three-way handshake of a P2P network.

isis three-way-handshake disable

Three-way handshake is performed by default.

1.27.7 Enabling TLV to Be Padded Based on Supported Protocol

1. Overview

When network devices supporting IPv4 IS-IS, IPv6 IS-IS, and IPv4 IS-IS and IPv6 are configured to establish a neighbor relationship, the calculated routes may be unreachable, resulting in routing black holes. To prevent routing black holes, the TLV (#129) field of device IS-IS protocol is padded based on protocols supported by an instance, that is, IS-IS instances that establish a neighbor relationship need to support the same protocol.

2. Restrictions and Guidelines

The TLV (#129) field of the IS-IS protocol supported by devices of some vendors is padded based on protocols supported by an interface. In single topology mode, a device connects to a device of another vendor, a loopback interface is configured on both devices, both IS-IS IPv4 IS-IS and IPv6 IS-IS are enabled, and only a single protocol stack (IPv4 IS-IS or IPv6 IS-IS) is configured on the interconnected interfaces of the two devices. The

device of the other vendor sends TLV#129 (supporting only a single protocol stack) based on interfaces whereas device sends TLV#129 (supporting dual protocol stacks) based on instances. As a result, the displayed neighbor status on the device of the other vendor is "Init". Devices failed to establish a neighbor relationship with the device of the other vendor. For this, the **interfaces-protocol-compatible** command can be configured to enable devices to establish a neighbor relationship with devices of other vendors.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Configure the TLV field of the IS-IS protocol to be padded based on protocols supported by an interface.

interfaces-protocol-compatible

The TLV field of the IS-IS protocol is padded based on protocols supported by an interface by default.

1.27.8 Configuring the Reachable Time of a Suppressed Neighbor

1. Overview

After the interface neighbor is up, this command prevents the neighbor reachability information from being added to LSP so as to delay the routing calculation. When the timer expires, the neighbor reachability information is added to LSP to start the routing calculation. This function prevents the route calculation from using the old LSP, which may lead to route flapping.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Suppress route calculation after the IS-IS neighbor is up.

isis suppress on-neighbor-up *delay-time*

The route calculation suppression function is disabled by default.

1.27.9 Suppressing Advertisement of Directly Connected Routes on an Interface

1. Overview

By default, directly connected routes of an interface are advertised in LSPs for route calculation. If you want to exclude the directly connected routes from route calculation on a specific interface, you can configure this function. After this command is configured, the directly connected routes of a specified protocol will not be

advertised on an IS-IS interface and the establishment of IS-IS neighbors is still allowed. This function can suppress the interface prefixes carried in LSPs to keep them invisible to external entities, thereby enhancing security and accelerating route convergence.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Enable the function of suppressing the advertisement of directly connected routes on an IS-IS interface.

isis suppress-reachability

By default, the advertisement of directly connected routes is not suppressed on an IS-IS interface.

1.27.10 Enabling Adjacency Event Output

1. Overview

You can run a debugging command to record neighbor state changes of IS-IS, but the command consumes many system resources. You can enable adjacency event output to avoid this issue.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IS-IS routing configuration mode.

router-protocol isis [*tag*]

(4) Enable neighbor relationship event output.

log-adj-changes

The function of recording neighbor state changes of IS-IS is enabled by default without the debugging command.

1.28 Monitoring

Run the display command to check the running status of a configured function to verify the configuration effect.

Run the cleanup command to clear information.

⚠ Caution

Running the **cleanup** command during operation of the device may lose vital information and interrupt services.

Run the debugging command to output debugging information.

Caution

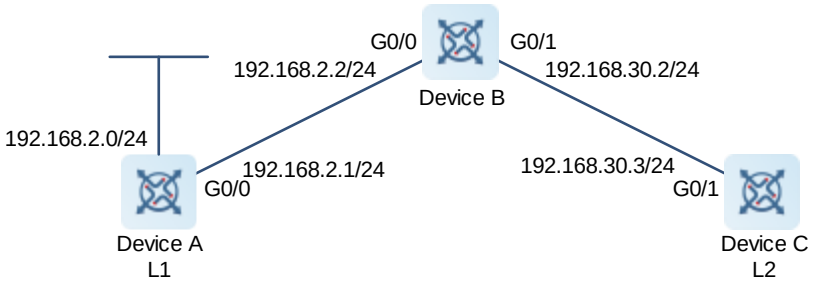
The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-2 Monitoring

Command	Purpose
cleanup clns neighbors-table	Clears all IS-IS neighbor relationship tables.
cleanup isis *	Clears all IS-IS data structures.
cleanup isis [*tag*] **counter**	Clears different statistical information of IS-IS.
cleanup isis [*tag*] **bgp-ls**	Clears BGP-LS information of IS-IS.
display clns [*tag*] **is-neighbors-info** [*interface-type interface-number*] [**detail**]	Displays all IS-IS neighbors and provides device adjacency relationships.
display clns [*tag*] **neighbors-info** [*interface-type interface-number*] [**detail**]	Displays all IS neighbors and provides device information and adjacency relationship information about terminals.
display isis-instance [*tag*] **counter**	Displays different statistical information of IS-IS.
display isis-instance [*tag*] **database** [**detail** | **verbose**] [**l1** | **l2** | **level-1** | **level-2**] [*lspid*]	Displays LSP DB information.
display isis-instance [*tag*] **gr**	Displays the state information related to IS-IS GR.
display isis-instance [*tag*] **hostname**	Displays the relationship between the device name and system ID.
display isis-instance [*tag*] **interface** [*interface-type interface-number*] [*counter*]	Displays the details of an IS-IS interface.
display isis-instance [*tag*] **fully-connected-groups**	Displays the mesh group configuration of different interfaces.
display isis-instance [*tag*] **neighbors** [**detail**]	Displays IS-IS neighbor information.
display isis-instance [*tag*] **nsr**	Displays IS-IS NSR information.
display isis-instance [*tag*] **virtual-neighbors**	Displays the neighbor information of virtual systems in IS-IS.
display isis-instance [*tag*] **protocol**	Displays the protocol information of IS-IS.
display isis-instance [*tag*] **topology-info** [**l1** | **l2** | **level-1** | **level-2**]	Displays the topology of IS-IS device connection.

Command	Purpose
display isis-instance [*tag*] **ipv6 topology-info** [**l1** | **l2** | **level-1** | **level-2**]	Displays IS-IS IPv6 unicast topology information of IS-IS.
display isis-instance [*tag*] **frr**	Displays IS-IS FRR information.
debugging isis { **all** | **auth | events** | **gr** | **ifsm** | **intf** | **lsp** | **mtr** | **nfsm** | **nsm** | **nsr** | **pdu** | **rdnd | segment-routing** [**mpls** | **prefix-sid** [*sid*] | **adjacency-sid** [*sid*] | **srgb** | **srlb**] | **distribute** | **mom** | **mpls | spf** | **warn** }	Enables IS-IS debugging.

1.29 Configuration Examples



1.29.1 Performing Basic Authentication Configuration of IS-IS

1. Requirements

Devices A, B, and C are connected through the Ethernet and run IS-IS. Device A is a Level-1 device, Device B is a Level-1/Level-2 device, and Device C is a Level-2 device. The following configuration requirements exist: Plaintext authentication is applied to the Hello packets between Device A and Device B, as well as Level-1 LSPs and SNPs. MD5 authentication is applied to the Hello packets between Router B and Router C, as well as Level-2 LSPs and SNPs.

2. Topology

Figure 1-11 Configuring Basic Authentication Configuration of IS-IS

3. Notes

- Configure a key string.
- Configure IS-IS area authentication and interface authentication.

4. Procedure

(1) Configure IP addresses for interfaces.

Configure Device A.

```
Device A> privilege
```

```
Device A# config-system terminal
Device A(cfg)# interface gigabitethernet 0/0
Device A(cfg-if-GigabitEthernet 0/0)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/0)# ip address 192.168.20.1 255.255.255.0
Device A(cfg-if)# exit
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# interface gigabitethernet 0/0
Device B(cfg-if-GigabitEthernet 0/0)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/0)# ip address 192.168.20.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/0)# exit
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/1)# ip address 192.168.30.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/1)# exit
```

Configure Device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/1)# ip address 192.168.30.3 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/1)# exit
```

(2) Perform basic configuration of IS-IS.

Configure Device A.

```
Device A(cfg)# router-protocol isis
Device A(cfg-router)# net 49.0001.0000.0000.0001.00
Device A(cfg-router)# is-type level-1
Device A(cfg-router)# exit
Device A(cfg)# interface gigabitethernet 0/0
Device A(cfg-if-GigabitEthernet 0/0)# ip router-protocol isis
```

Configure Device B.

```
Device B(cfg)# router-protocol isis
Device B(cfg-router)# net 49.0001.0000.0000.0002.00
Device B(cfg-router)# exit
Device B(cfg)# interface gigabitethernet 0/0
Device B(cfg-if-GigabitEthernet 0/0# ip router-protocol isis
Device B(cfg-if-GigabitEthernet 0/0)# exit
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip router-protocol isis
Device B(cfg-if-GigabitEthernet 0/1)# exit
```

Configure Device C.

```
Device C(cfg)# router-protocol isis
```

```
Device C(cfg-router)# net 49.0002.0000.0000.0003.00
Device C(cfg-router)# is-type level-2-only
Device C(cfg-router)# exit
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# ip router-protocol isis
Device C(cfg-if-GigabitEthernet 0/1)# exit
```

(3) Enable IS-IS authentication.

Set the area authentication password of Device A to **aa**, and set the interface authentication password of GigabitEthernet 0/0 to **cc**.

```
Device A(cfg)# router-protocol isis
Device A(cfg-router)# area-auth aa
Device A(cfg-router)# exit
Device A(cfg)# interface gigabitethernet 0/0
Device A(cfg-if-GigabitEthernet 0/0)# isis auth-password cc
```

Configure Device B with Level-1 area plaintext authentication and set the key string to **kc1**; configure Level-2 area plaintext authentication and set the key string to kc**2**. Configure Device A with interface plaintext authentication and set the key string to **kc3**. Configure Device C with interface MD5 authentication and set the key string to **kc3**.

```
Device B(cfg)# key chain kc1
Device B(cfg-keychain)# key 1
Device B(cfg-keychain-key)# key-string aa
Device B(cfg-keychain-key)# exit
Device B(cfg-keychain)# exit
Device B(cfg)# key chain kc2
Device B(cfg-keychain)# key 1
Device B(cfg-keychain-key)# key-string bb
Device B(cfg-keychain-key)# exit
Device B(cfg-keychain)# exit
Device B(cfg)# key chain kc3
Device B(cfg-keychain)# key 1
Device B(cfg-keychain-key)# key-string cc
Device B(cfg-keychain-key)# exit
Device B(cfg-keychain)# exit
Device B(cfg)# router-protocol isis
Device B(cfg-router)# auth method text level-1
Device B(cfg-router)# auth keychain kc1 level-1
Device B(cfg-router)# auth method md5 level-2
Device B(cfg-router)# auth keychain kc2 level-2
Device B(cfg-router)# exit
Device B(cfg)# interface gigabitethernet 0/0
Device B(cfg-if-GigabitEthernet 0/0)# isis auth method text
Device B(cfg-if-GigabitEthernet 0/0)# isis auth keychain kc3
Device B(cfg-if-GigabitEthernet 0/0)# exit
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# isis auth method md5
```

```
Device B(cfg-if-GigabitEthernet 0/1)# isis auth keychain kc3
```

Configure Device C with Level-2 area MD5 authentication and set the key string to **kc2**. Configure Device B with interface MD5 authentication and set the key string to **kc3**.

```
Device C(cfg)# key chain kc2
Device C(cfg-keychain)# key 1
Device C(cfg-keychain-key)# key-string bb
Device C(cfg-keychain-key)# exit
Device C(cfg-keychain)# exit
Device C(cfg)# key chain kc3
Device C(cfg-keychain)# key 1
Device C(cfg-keychain-key)# key-string cc
Device C(cfg-keychain-key)# exit
Device C(cfg-keychain)# exit
Device C(cfg)# router-protocol isis
Device C(cfg-router)# auth method md5 level-2
Device C(cfg-router)# auth keychain kc2
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# isis auth method md5
Device C(cfg-if-GigabitEthernet 0/1)# isis auth keychain kc3
```

5. Verification

Check the neighbor information of Device A.

```
Device A# display isis-instance neighbors
Area (null):
System Id          Type   IP Address          State    Holdtime   Circuit              Interface
B                  L1     192.168.20.2        Up       28         A.01                 GigabitEthernet 0/0
```

Check the IS-IS database information of Device A.

```
Device A# display isis-instance database detail
Area (null):
IS-IS Level-1 Link State Database:
LSPID                 LSP Seq Num  LSP Checksum  LSP Holdtime      ATT/P/OL

!
router-protocol isis
 net 49.0002.0000.0000.0003.00
 is-type level-2
 auth method md5 level-2
 auth keychain kc2
!
interface gigabitethernet 0/1
 unset switch-port
 ip address 192.168.30.3 255.255.255.0
 ip router-protocol isis
 isis auth method md5
 isis auth keychain kc3
!
```

7. Common Errors

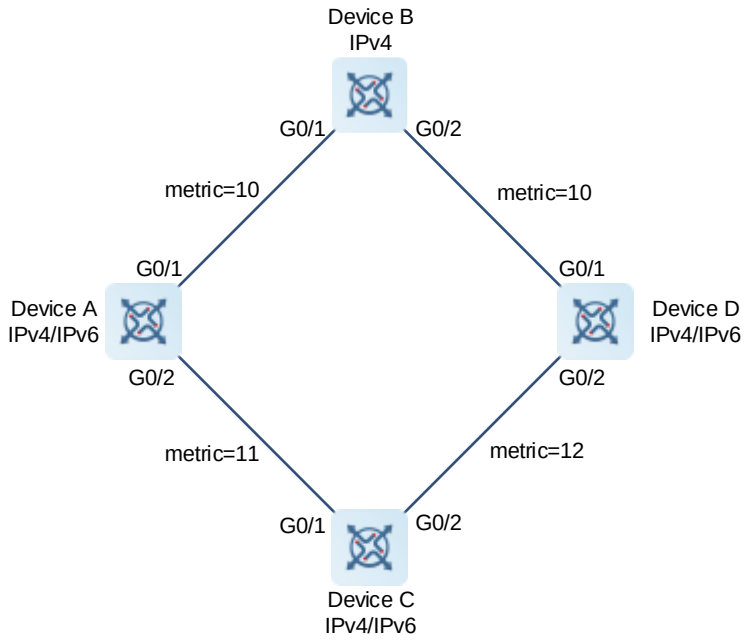
- Different authentication passwords are configured between neighbors.
- Different authentication modes are configured between neighbors.

1.29.2 Configuring IS-IS MTR

1. Requirements

The typical application scenario of MTR is to retain devices that only support IPv4 services in a network where IPv6 service extension will be performed.

As shown in Figure 1-12, Device B only supports the IPv4 protocol stack but does not support the MTR feature; therefore, it can only run IPv4 services. The network capacity needs to be scaled to support IPv6 services in order to meet service extension requirements. (Devices A, C, and D that support the MTR feature will be added.) Device B that supports only one protocol stack must be replaced to maintain the stability of the network running IPv4 and IPv6 dual protocol stacks; otherwise, IPv6 routing black holes may occur.



If you need to retain Device B, you can configure the MTR feature on the new devices. The MTR feature enables Device B to continue to run IPv4 services without interference on the IPv4 and IPv6 services on the new devices. The MTR feature improves networking flexibility, indirectly prolongs the service life of old devices, and meets service extension requirements while maximizing the values of old devices.

The configuration requirements are as follows:

- Retain Device B, which only supports IPv4 services.
- Add devices that support IPv4 and IPv6 dual protocol stacks, and separate IPv4 route calculation and IPv6 route calculation.

2. Topology

Figure 1-12 Configuring IS-IS MTR

3. Notes

- Perform basic configuration of IS-IS.
- Enable the MTR function.

4. Procedure

- Configure Device A.

  Configure IS-IS, set the metric type to Wide, and enable the MTR function.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# router-protocol isis
Device A(cfg-router)# net 49.0001. 0000.0000.0001.00
Device A(cfg-router)# is-type level-1
Device A(cfg-router)# metric-class wide-metric
Device A(cfg-router)# address-family-mode ipv6
Device A(cfg-router-af)# ipv6-multitopology
Device A(cfg-router-af)# exit
Device A(cfg-router)# exit
```

  Configure an IP address for the interface and add the interface to IS-IS.

```
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 enable
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 address 1002::1/112
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 router-protocol isis
Device A(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/1)# ip router-protocol isis
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/2)# ipv6 enable
Device A(cfg-if-GigabitEthernet 0/2)# ipv6 address 1003::1/112
Device A(cfg-if-GigabitEthernet 0/2)# ipv6 router-protocol isis
Device A(cfg-if-GigabitEthernet 0/2)# ip address 192.168.2.1 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/2)# ip router-protocol isis
Device A(cfg-if-GigabitEthernet 0/2)#isis wide-metric 11
```

- Configure Device B.

  Configure IS-IS, set the metric type to Wide, and enable the MTR function.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# router-protocol isis
Device B(cfg-router)# net 49.0001. 0000.0000.0002.00
Device B(cfg-router)# is-type level-1
Device B(cfg-router)# metric-class wide-metric
Device B(cfg-router)# address-family-mode ipv6
Device B(cfg-router-af)# unset adjacency-support-check
```

```
Device B(cfg-router-af)# exit
Device B(cfg-router)# exit
```

Configure an IP address for the interface and add the interface to IS-IS.

```
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/1)# ip router-protocol isis
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface gigabitethernet 0/2
Device B(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/2)# ip address 192.168.3.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/2)# ip router-protocol isis
```

- Configure Device C.

  Configure IS-IS, set the metric type to Wide, and enable the MTR function.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# router-protocol isis
Device C(cfg-router)# net 49.0001. 0000.0000.0003.00
Device C(cfg-router)# is-type level-1
Device C(cfg-router)# metric-class wide-metric
Device C(cfg-router)# address-family-mode ipv6
Device C(cfg-router-af)# ipv6-multitopology
Device C(cfg-router-af)# exit
Device C(cfg-router)# exit
```

Configure an IP address for the interface and add the interface to IS-IS.

```
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/1)# ipv6 enable
Device C(cfg-if-GigabitEthernet 0/1)# ipv6 address 3001::1/112
Device C(cfg-if-GigabitEthernet 0/1)# ipv6 router-protocol isis
Device C(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.3 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/1)# ip router-protocol isis
Device C(cfg-if-GigabitEthernet 0/1)#isis wide-metric 11
Device C(cfg-if-GigabitEthernet 0/1)# exit
Device C(cfg)# interface gigabitethernet 0/2
Device C(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/2)# ipv6 enable
Device C(cfg-if-GigabitEthernet 0/2)# ipv6 address 3004::1/112
Device C(cfg-if-GigabitEthernet 0/2)# ipv6 router-protocol isis
Device C(cfg-if-GigabitEthernet 0/2)# ip address 192.168.4.3 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/2)# ip router-protocol isis
Device C(cfg-if-GigabitEthernet 0/2)# isis wide-metric 12
```

- Configure Device D.

  Configure IS-IS, set the metric type to Wide, and enable the MTR function.

```
Device D> privilege
Device D# config-system terminal
Device D(cfg)# router-protocol isis
Device D(cfg-router)# net 49.0001.0000.0000.0004.00
Device D(cfg-router)# is-type level-1
Device D(cfg-router)# metric-class wide-metric
Device D(cfg-router)# address-family-mode ipv6
Device D(cfg-router-af)# ipv6-multitopology
Device D(cfg-router-af)# exit
Device D(cfg-router)# exit
```

Configure an IP address for the interface and add the interface to IS-IS.

```
Device D(cfg)# interface gigabitethernet 0/1
Device D(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device D(cfg-if-GigabitEthernet 0/1)# ipv6 enable
Device D(cfg-if-GigabitEthernet 0/1)# ipv6 address 4002::1/112
Device D(cfg-if-GigabitEthernet 0/1)# ipv6 router-protocol isis
Device D(cfg-if-GigabitEthernet 0/1)# ip address 192.168.3.4 255.255.255.0
Device D(cfg-if-GigabitEthernet 0/1)# ip router-protocol isis
Device D(cfg-if-GigabitEthernet 0/1)# exit
Device D(cfg)# interface gigabitethernet 0/2
Device D(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device D(cfg-if-GigabitEthernet 0/2)# ipv6 enable
Device D(cfg-if-GigabitEthernet 0/2)# ipv6 address 4003::1/112
Device D(cfg-if-GigabitEthernet 0/2)# ipv6 router-protocol isis
Device D(cfg-if-GigabitEthernet 0/2)# ip address 192.168.4.4 255.255.255.0
Device D(cfg-if-GigabitEthernet 0/2)# ip router-protocol isis
```

5. Verification

Run the display command on Device A to view IPv4 route information and check whether the next hop of the IPv4 route destined for Device D is Device B.

```
Device A# display ip route-config
Codes:   C - connected, S - static, R - RIP, B - BGP
         O - OSPF, IA - OSPF inter area
         N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
         E1 - OSPF external type 1, E2 - OSPF external type 2
         i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
         ia - IS-IS inter area, * - candidate default
Gateway of last resort is no set
C       192.168.1.0/24 is directly connected, GigabitEthernet 0/1
C       192.168.1.1/32 is local host.
C       192.168.2.0/24 is directly connected, GigabitEthernet 0/2
C       192.168.2.1/32 is local host.
i L1 192.168.3.0/24 [115/20] via 192.168.1.2, 00:13:14, GigabitEthernet 0/1
i L1 192.168.4.0/24 [115/23] via 192.168.2.3, 00:02:40, GigabitEthernet 0/2
```

Run the display command on Device A to view IPv6 route information and check whether the next hop of the IPv6 route destined for Device D is Device C.

```
Device A# display ipv6 route
IPv6 routing table name is - Default - 16 entries
Codes: C - Connected, L - Local, S - Static, R - RIP, B - BGP
       I1 - ISIS L1, I2 - ISIS L2, IA - ISIS interarea, IS - ISIS summary
       O - OSPF intra area, OI - OSPF inter area,  OE1 - OSPF external type 1, OE2 - OSPF external type 2
       ON1 - OSPF NSSA external type 1, ON2 - OSPF NSSA external type 2
L      ::1/128 via Loopback, local host
C       1002::/112 via GigabitEthernet 0/1, directly connected
L      1002::1/128 via GigabitEthernet 0/1, local host
C       1003::/112 via GigabitEthernet 0/2, directly connected
L      1003::1/128 via GigabitEthernet 0/2, local host
I1     3001::/112 [115/21] via FE80::C806:5FF:FEE8:38, GigabitEthernet 0/2
I1     3004::/112 [115/21] via FE80::C806:5FF:FEE8:38, GigabitEthernet 0/2
I1     4002::/112 [115/31] via FE80::C806:5FF:FEE8:38, GigabitEthernet 0/2
I1     4003::/112 [115/31] via FE80::C806:5FF:FEE8:38, GigabitEthernet 0/2
L      FE80::/10 via ::1, Null0
C       FE80::/64 via GigabitEthernet 0/2, directly connected
L      FE80::1614:4BFF:FE12:ADFC/128 via GigabitEthernet 0/2, local host
C       FE80::/64 via GigabitEthernet 0/1, directly connected
L      FE80::1614:4BFF:FE12:ADFD/128 via GigabitEthernet 0/1, local host
C       FE80::/64 via Local 0, directly connected
L      FE80::1614:4BFF:FE12:ADFC/128 via Local 0, local host
```

6. Configuration Files

Device A configuration file

```
!
router-protocol isis
 net 49.0001. 0000.0000.0001.00
 is-type level-1
 metric-class wide-metric
 address-family-mode ipv6

```

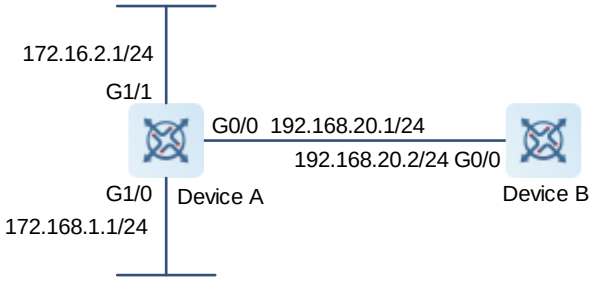
7. Common Errors

- The metric-style is not set to **Wide** or **Transition**.
- The protocol types used by two neighbors do not match; therefore, a neighbor relationship cannot be established.
- The IP addresses of the interfaces connected between neighbors are not in the same network segment.
- The **ip router-protocol isis** command is not executed on interfaces.
- No NET address is configured, or different NET addresses exist at Level-1.
- max-area-addresses is configured differently on both sides.
- metric-style is configured differently on both sides.
- The interface Levels on both sides are different. One side is Level-1, whereas the other side is Level-2.
- One side is configured with the P2P mode, whereas the other side is configured with the broadcast mode.

- One side is enabled with authentication, whereas the other side is not.



1.29.3 Configuring IS-IS Route Summarization

1. Requirements

Device A and Device B are connected through the Ethernet and run IS-IS. Device A is configured to advertise only the 172.16.0.0/22 route instead of the 172.16.1.0/24 and 172.16.2.0/24 routes.

2. Topology

Figure 1-13 Configuring IS-IS Route Summarization

3. Notes

- Configure IS-IS.
- Configure route summarization.

4. Procedure

(1) Configure IS-IS.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# router-protocol isis
Device A(cfg-router)# net 49.0001.0000.0000.0001.00
Device A(cfg-router)# exit
Device A(cfg)# interface gigabitethernet 0/0
Device A(cfg-if-GigabitEthernet 0/0)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/0)# ip address 192.168.20.1 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/0)# ip router-protocol isis
Device A(cfg-if-GigabitEthernet 0/0)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ip address 172.16.1.1 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/1)# ip router-protocol isis
Device A(cfg-if-GigabitEthernet 0/1)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/2)# ip address 172.16.2.1 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/2)# ip router-protocol isis
Device A(cfg-if-GigabitEthernet 0/2)# exit
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# router-protocol isis
Device B(cfg-router)# net 49.0001.0000.0000.0002.00
Device B(cfg-router)# exit
Device B(cfg)# interface gigabitethernet 0/0
Device B(cfg-if-GigabitEthernet 0/0)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/0)# ip address 192.168.20.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/0)# ip router-protocol isis
```

(2) Configure route summarization.

Configure Device A.

```
Device A(cfg)# router-protocol isis
Device A(cfg-router)# summary-address 172.16.0.0/16 level-1-2
```

5. Verification

Run the display ip route-config command on Device B to check whether only one summary route exists.

```
Device B# display ip route-config
i L1      172.16.0.0/16 [115/20]    via 192.168.20.1, FastEthernet0/0
```

6. Configuration Files

- Device A configuration file

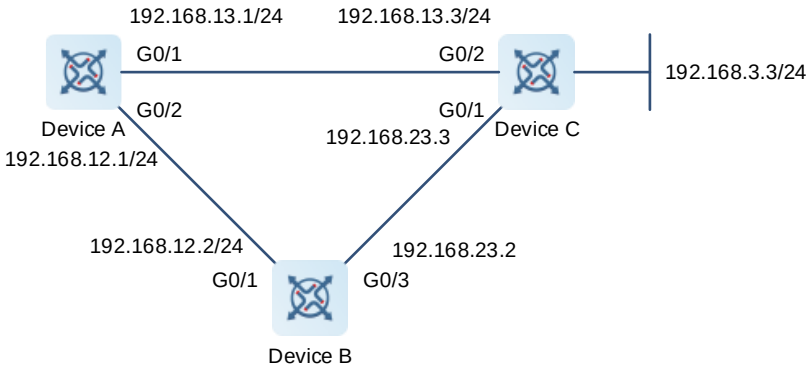
```
!
router-protocol isis
 net 49.0001.0000.0000.0001.00
 summary-address 172.16.0.0/16 level-1-2
!
interface gigabitethernet 0/0
 unset switch-port
 ip address 192.168.20.1 255.255.255.0
 ip router-protocol isis
!
interface gigabitethernet 1/0
 unset switch-port
 ip address 172.16.1.1 255.255.255.0
 ip router-protocol isis
!
interface gigabitethernet 1/1
 unset switch-port
 ip address 172.16.2.1 255.255.255.0
 ip router-protocol isis
!
```

- Device B configuration file

```
!
```

```
router-protocol isis
 net 49.0001.0000.0000.0002.00
!
interface gigabitethernet 0/0
 unset switch-port
 ip address 192.168.20.2 255.255.255.0
 ip router-protocol isis
!
```

1.29.4 Correlating IS-IS with BFD



1. Requirements

Devices A, B, C, and D are interconnected through IS-IS routing protocol. The devices are Level-2 devices.

When a link from Device A to Device C fails, services can be quickly switched to Device B.

2. Topology

Figure 1-14 Correlating IS-IS with BFD

3. Notes

- Configure interface IP addresses for all the devices.
- Configure the basic IS-IS functions on all devices.
- Enable the BFD function in the IS-IS routing process mode.

4. Procedure

(1) Configure interface IP addresses and perform basic configuration of IS-IS.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/2)# ip address 192.168.12.1/24
Device A(cfg-if-GigabitEthernet 0/2)# ip router-protocol isis
```

```
Device A(cfg-if-GigabitEthernet 0/2)# exit
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ip address 192.168.13.1/24
Device A(cfg-if-GigabitEthernet 0/1)# ip router-protocol isis
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# router-protocol isis
Device A(cfg-router)# net 49.0001.0000.0000.0001.00
Device A(cfg-router)# is-type level-2-only
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/1)# ip address 192.168.12.2/24
Device B(cfg-if-GigabitEthernet 0/1)# ip router-protocol isis
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface gigabitethernet 0/3
Device B(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/3)# ip address 192.168.23.2/24
Device B(cfg-if-GigabitEthernet 0/3)# ip router-protocol isis
Device B(cfg-if-GigabitEthernet 0/3)# exit
Device B(cfg)# router-protocol isis
Device B(cfg-router)# net 49.0001.0000.0000.0002.00
Device B(cfg-router)# is-type level-2-only
```

Configure Device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# interface gigabitethernet 0/2
Device C(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/2)# ip address 192.168.13.3/24
Device C(cfg-if-GigabitEthernet 0/2)# ip router-protocol isis
Device C(cfg-if-GigabitEthernet 0/2)# exit
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device C(cfg-if-GigabitEthernet 0/1)# ip address 192.168.23.3/24
Device C(cfg-if-GigabitEthernet 0/1)# ip router-protocol isis
Device C(cfg-if-GigabitEthernet 0/1)# exit
Device C(cfg)# router-protocol isis
Device C(cfg-router)# net 49.0001.0000.0000.0003.00
Device C(cfg-router)# is-type level-2-only
```

(2) Correlate IS-IS with BFD globally.

Configure Device A.

```
Device A(cfg-router)# bfd whole-interfaces
```

Configure Device B.

```
Device B(cfg-router)# bfd whole-interfaces
```

Configure Device C.

```
Device C(cfg-router)# bfd whole-interfaces
```

5. Verification

- Normal network environment

  Check the routing table of Device A.

```
Device A# display ip route-config
I L2    192.168.23.0/24 [115/2] via 192.168.13.3, 00:19:07, GigabitEthernet 0/1
                                [115/2] via 192.168.12.2, 00:19:07, GigabitEthernet 0/2
I L2    192.168.33.0/24 [115/1] via 192.168.13.3, 00:17:40, GigabitEthernet 0/1
```

  Run **traceroute 192.168.3.3** on Device A.

```
Device A# traceroute 192.168.3.3
   < press Ctrl+C to break >
Tracing the route to 192.168.3.3

 1          192.168.3.3        <1 msec       5 msec       9 msec
```

- Link from Device A to Device C fails

  Check the routing table of Device A.

```
Device A# display ip route-config isis
I L2    192.168.23.0/24 [115/2] via 192.168.12.2, 00:00:08, GigabitEthernet 0/2

1 Configuring BGP

Note

The L2VPN EVPN address family mode, EVPN configuration mode, and EVPN-VNI configuration mode of BGP is not supported by the S6980-64QC, S6580-48CQ8QC, or S6580-24DC8QC.

1.1 Introduction

1.1.1 Overview

The Border Gateway Protocol (BGP) is a dynamic routing protocol that automatically exchanges loop-free routing information between autonomous systems (ASs).

A network is divided into multiple ASs to facilitate management. In the early Internet, the Exterior Gateway Protocol (EGP) was used to switch routing information between ASs. This protocol was first mentioned in RFC 187 and then listed into RFC 904 in 1984. EGP was a simple network reachability protocol and applied only to tree networks. Therefore, it could not meet the increasingly complicated network management requirements and finally was replaced by BGP. Unlike EGP, BGP can avoid loops and select better routes, and efficiently transfers routes and supports higher scalability.

The development of BGP has undergone different stages, and BGP-1 (RFC 1105), BGP-2 (RFC 1163), and BGP-3 (RFC 1267) were previously released. The prevailing version is BGP-4 (RFC 4271), which is widely applied between ASs as a standard routing protocol.

BGP has the following features:

- Interior Gateway Protocols (IGPs) such as Open Shortest Path First (OSPF) and Routing Information Protocol (RIP) focus on discovery and route calculation. By contrast, BGP lays emphasis on the control of route spreading and is applicable to networks that carry massive routes.
- BGP uses Transmission Control Protocol (TCP) as the transmission protocol and the destination port is 179. BGP uses the reliable transmission mechanism of TCP to ensure transmission reliability.
- As a distance vector routing protocol, BGP transmits only the locally selected optimal routes to its neighbors.

Note

In this chapter, the term "router" refers to any network device that supports the routing function. These network devices can be Layer-3 (L3) switches, routers, or firewalls.

1.1.2 Concepts

1. BGP speaker

Devices that run BGP and send BGP packets are called BGP speakers.

2. BGP peer

BGP speakers with a BGP session established are BGP peers. Multiple peers constitute a peer group.

3. AS

Devices that manage and share the same routing policies in one organization are an AS. When BGP is enabled on a router, a local AS number must be specified for it. An AS number is a globally unique number allocated by IANA, consisting of two or four bytes.

A traditional AS number consists of 2 bytes, ranging from 1 to 65535. The new 4-byte AS numbers aims to resolve the resource exhaust problem, and their value range is from 1 to 4294967295.

4-byte AS numbers support two expression modes: decimal notation mode and dot mode. The decimal notation mode is the same as the traditional expression mode, that is, the 4 bytes of an AS number are expressed in decimal notation. The conversion relationship between the dot mode and decimal notation mode is as follows: 4-byte decimal AS number = x × 65536 + Y.

For example:

- For an AS number 65534 in decimal mode, it is 65,534 in dot mode. An AS number smaller than 65536 is the same in decimal mode and dot mode.
- For an AS number 65536 in decimal mode, it is 1.0 in dot mode.
- For an AS number 65538 in decimal mode, it is 1.2 in dot mode.

With introduction of 4-byte AS numbers, BGP connections may be established between BGP speakers supporting only 2-byte AS numbers and those supporting 4-byte AS numbers. To communicate with a device that supports 4-byte AS numbers, reserve the AS number 23456 for filling on the device that supports only 2-byte AS numbers.

4. Neighbor type and route type

BGP neighbors are classified into two types:

- Internal BGP (IBGP) neighborship: The neighborship between BGP speakers within an AS is called IBGP neighborship. Routes learned from IBGP neighbors are called IBGP routes. IBGP completes transition of routing information within the AS.
- External BGP (EBGP) neighborship: The neighborship between BGP speakers in different ASs is called EBGP neighborship. Routes learned from EBGP neighbors are called EBGP routes. EBGP is used to exchange routing information between different ASs.

5. BGP message types

BGP runs by sending the following five types of messages:

- OPEN message: for establishing a connection between BGP peers.
- UPDATE message: for exchanging routing information between BGP peers.
- NOTIFICATION message: for closing a BGP connection.
- KEEPALIVE message: for keeping a BGP connection alive.
- ROUTE-REFRESH message: for requesting peers to re-send routing information after the routing strategy is changed. Only BGP-enabled devices that support the route refresh function will send and respond to this message.

The above messages are event-triggered except the KEEPALIVE message, which is sent periodically.

1.1.3 Route Attributes of BGP

When a BGP speaker advertises a route to its neighbors, the BGP speaker also advertises the attributes carried by the route. Common BGP attributes are as follows:

1. Origin attribute

Specifies the origin of a BGP route, which is set to IGP, EGP, or INCOMPLETE.

- IGP: The value is 0, specifying the internal routing information of the originating AS.
- EGP: The value is 1, specifying the routing information obtained from EGP.
- INCOMPLETE: The value is 2, specifying the routing information learned through other means.

2. AS_PATH attribute

Lists the ASs passed by a route reversely. The last AS is placed at the beginning of the list.

The AS_PATH attribute is used for:

- When a router receives routing information with the local AS number in the AS_PATH, the router considers that this route has loop and discards the packet.
- Routing information distribution is controlled by using the AS_PATH-based filtering rules. These filtering rules use regular expressions to parse AS paths.
- According to RFC 1771, BGP does not consider the AS path length when selecting an optimal path. Generally, a shorter AS path means a higher path priority; therefore, devices consider the AS path length when selecting the optimal path. Based on the actual condition, you can determine whether to consider the AS path length when selecting the optimal path.

3. NEXT_HOP attribute

Specifies the IP address of the next hop to be reached by a BGP route.

The change in the NEXT_HOP attribute complies with the following rules:

- When the route forwarded to an IBGP peer is non-local, the device does not change the NEXT_HOP attribute.
- When the route forwarded to an IBGP peer is local, the local interface address that the device uses to establish a BGP neighbor relationship with the peer is the next hop address.
- When the route is forwarded to an EBGP peer, the local interface address that the device uses to establish a BGP neighbor relationship with the peer is the next hop address.

4. MULTI_EXIT_DISC attribute

Distinguishes multiple output or input points for reaching the same neighbor AS. A smaller value means a higher priority. The MULTI_EXIT_DISC attribute is short for MED.

BGP uses the MED value as the basis for comparing priorities of paths learned from EBGP peers. A smaller MED value means a higher path priority.

- The **MED** value is compared only for paths of peers from the same AS during the optimal path selection by default.
- The **MED** value is not compared for paths of peers from other member ASs in an AS alliance during the optimal path selection by default.

- If a path not configured with the MED attribute is received, the MED value of this path is **0** by default. Since a smaller MED value means a higher path priority, the MED value of this path has the highest priority.
- The **MED** value is not compared for paths from different ASs during the optimal path selection by default. Instead, the receiving sequence of the paths is compared.

5. LOCAL_PREF attribute

Distinguishes the priorities of IBGP routes in an AS. A larger value means a higher priority.

When sending routes received from EBGP peers to IBGP peers, a BGP speaker adds the LOCAL_PREF attribute. BGP uses the LOCAL_PREF value as the basis for comparing priorities of paths learned from IBGP peers. A larger LOCAL_PREF value means a higher path priority.

6. ATOMIC_AGGREGATE attribute

This attribute informs the receiver that this route is aggregated.

When the BGP Speaker receives two overlay routes, and the IP address contained in one of them is a subset of the other, the BGP Speaker usually prefers a more-specific route. However, if the BGP Speaker propagates a less-specific route, the propagated route must carry the ATOMIC-AGGREGATE attribute. If a route with the ATOMIC-AGGREGATE attribute is received, it indicates that a more-specific route is lost during propagation.

During route aggregation, the ATOMIC-AGGREGATE attribute will be added to the aggregated route.

7. AGGREGATOR attribute

As a supplement to the ATOMIC_ AGGREGATE attribute, the AGGREGATOR attribute contains the AS number that initiated the route aggregation, and the IP address of the BGP speaker that generated the aggregation route.

During route aggregation, for aggregated route, the AGGREGATOR attribute will be added when the ATOMIC-AGGREGATE attribute is added.

8. COMMUNITY attribute

The COMMUNITY attribute is another method of controlling the distribution of routing information.

A community is a set of destination addresses. The COMMUNITY attribute is intended to facilitate execution of a community-based routing policy so as to simplify the configuration of routing information distribution control on BGP speakers. By using the community attribute, you can control the receiving and distribution of routing information. A destination address can belong to multiple communities. An AS administrator can define the communities, to which a destination address belongs.

BGP pre-defines four common community attribute values:

- **Internet**: Indicates the Internet community. All paths belong to this community.
- **No-export**: Specifies that the path is not advertised to EBGP peers.
- **No-advertise**: Specifies that the path is not advertised to any BGP peer.
- **Local-as**: Indicates that a path is not advertised outside the local AS. When an alliance is configured, the path is not advertised to other ASs or member ASs.

By default, all destination addresses belong to the Internet community and are carried in the COMMUNITY attribute of paths.

BGP speakers can set, add, or modify the community attribute value when learning, advertising, or re-distributing routes. An aggregate path will contain the community attribute values of all aggregated paths.

9. AIGP metric attribute

The AIGP metric attribute can accumulate the IGP metrics of paths that a route passes through. Preferred route selection based on the AIGP attribute value can reflect the path cost more accurately. A smaller AIGP attribute value indicates a higher route priority. Routes carrying the AIGP attribute have a higher priority than those without the AIGP attribute.

If the next hop of a route carrying the AIGP attribute is changed to self or another value during route transmission, the IGP metric value of the route to the original next-hop address needs to be added to the AIGP attribute value.

1.1.4 Route Exchange and Route Selection Policy of BGP

1. Route exchange

By default, the following rules are followed when routing information is exchanged between BGP neighbors:

- BGP receives routing information from all neighbors.
- If the sender of BGP routing information is an IBGP neighbor, BGP will send the routing information to the EBGP neighbor.
- If the sender of BGP routing information is an EBGP neighbor, BGP will send the routing information to all IBGP and EBGP neighbors.
- BGP sends only BGP routes that need to be updated when updating routing information.
- If there are multiple valid routes on the device to the same destination address, BGP will only advertise the optimal route.

BGP cannot automatically discover or learn accessible networks. The accessible network information of a local AS must be imported to BGP so that BGP can advertise this information to neighbors.

Two methods can be used to import network information of the local AS to BGP:

- Manual configuration: Import accessible network information within a specified range to BGP.
- Configuring route re-distribution: Configure route re-distribution to re-distribute accessible network information of IGP to BGP.

BGP offers a robust route management function. By configuring a route exchange policy for a BGP peer, you can actively control routes to be received by and to be advertised to this peer.

Send routing information of other ASs exchanged by BGP to the routing table of a device so that the device can forward packets of other ASs. Import routing information of other ASs exchanged by BGP to IGP so that IGP distributes the information to other IGP devices in the local AS and these devices can forward packets of other ASs.

Generally, BGP speakers serving as IBGP neighbors of each other are not directly connected physically. IGP devices in the link between the BGP speakers may fail to learn routing information same as that on the BGP speakers. When a BGP speaker at the border of an AS forwards packets received from other domains to the next-hop IBGP neighbor, the packets pass an IGP device in the middle. In this case, the packets may be lost due to no routing information on the IGP device. To synchronize BGP with IGP, you must ensure that all routers within an AS learn routing information to be sent to another AS before the routing information is advertised to this AS. BGP and IGP should be synchronized in most cases, except that:

- Routing information passing through this AS is not configured. For example, the AS is a stub AS.
- All routers within the AS run BGP. Full mesh is established among all BGP speakers (neighborship is established between each two BGP speakers).

2. BGP route update group

The BGP route update group function is a technology used to enhance the performance for advertising routes to neighbors.

The BGP route update group technology automatically classifies neighbors using the same policy into the same update group. When sending a route to a neighbor, the device encapsulates the update packet based on the update group, and sends the update packet to all neighbors in the update group. In this way, the update packet is encapsulated only once but sent multiple times, improving the performance of route advertisement to neighbors.

3. Route selection policy

BGP policies for selecting the optimal route are:

(1) Invalid routing entries (entries with the next hop unreachable and flapping entries) are not used for optimal route selection.

(2) Ethernet Virtual Private Network (EVPN) route: When routes share the same route distinguisher (RD), routes with the route target (RT) matched take priority over those with RT filtered.

(3) EVPN routes: A static MAC address route is preferred.

(4) EVPN routes: An anycast MAC route is prior to a local route.

(5) EVPN routes: The sequence numbers of routes from the same VXLAN tunnel end point (VTEP) are compared and a route with a larger sequence number is preferred.

(6) If not, the route generated by the **network-advertise** command is preferred.

(7) Otherwise, a route with the maximum weight is preferred (the default weight value of a route originated locally is **32768**, and the weight value of a router advertised by a neighbor is **0**).

(8) If routes have the same weight, a route with a larger **LOCAL_PREF** value is preferred.

(9) If routes have the same local priority, a local BGP route from the local router is preferred.

(10) The types of local routes are compared, and the route priority is as follows: direct route > static route > aggregate route generated by BGP.

(11) If the local routes have the same type, the Accumulated Interior Gateway Protocol (AIGP) extended route is compared. A route that carries the AIGP attribute is prior to that without the AIGP attribute.

(12) If the AIGP attribute comparison is skipped, the link state (LS) extended attribute is compared:

a A route with the LS attribute is preferred.

b A route with a smaller IGP metric is preferred.

c A route of the wide type has a higher priority than that of the narrow type.

(13) Otherwise, a route with the shortest AS length is selected.

(14) Otherwise, a route with the lowest **ORIGIN Code** attribute value is selected.

(15) Otherwise, a route with the smallest **MED** value is selected.

(16) Otherwise, EBGP routes have a higher priority than IBGP routes and routes in an AS alliance, and the IBGP routes have the same priority as the routes in an AS alliance.

(17) Otherwise, a route with the smallest IGP metric value to the next hop is selected.

(18) Otherwise, an EBGP route that is received first is selected.

(19) Otherwise, a route advertised by a BGP speaker with a smaller router-ID is selected.

(20) Otherwise, a route with a smaller cluster length is selected.

(21) Otherwise, a route with a smaller neighbor address is selected.

1.1.5 Neighbor Connection Establishment

A BGP neighbor is manually configured by a user. Neighbor relationships can be established in two modes: IBGP and EBGP. Users can identify the connection mode between BGP speakers according to the AS carrying the BGP peer and the AS carrying the BGP speaker.

A BGP speaker proactively sends a TCP connection request to a specified BGP peer. After a TCP connection is established successfully, BGP speakers exchange BGP protocol packets to negotiate about connection parameters. The BGP neighbor relationship is successfully established after the negotiation succeeds.

1. Establishing a TCP connection

A BGP speaker initiates a TCP connection request to a neighbor. The destination IP address of the request is the peer IP address specified by the user and the port number is fixed to 179.

The BGP speaker also listens on port 179 of the local TCP connection to receive connection requests from its peers.

2. Negotiating about protocol parameters

After a TCP connection is successfully established, BGP speakers exchange OPEN packets to negotiate about BGP connection parameters. Negotiated parameters include the following:

- **Version**: Indicates the BGP version number. At present, only version 4 is supported.
- **Neighbor AS number**: Determines whether the AS number of a neighbor is consistent with the AS number specified locally. If no, the connection request is denied.
- **Hold time**: Indicates the timeout duration for a BGP connection. The default value is **180** seconds.
- **Neighbor capability**: Negotiates about various extended capabilities supported by the neighbor, including the address family, dynamic route update and GR functions.

3. Maintaining the neighbor relationship

BGP speakers send the Keepalive message to each other periodically. If a new Keepalive packet is not received from a BGP neighbor after the hold time expires, the BGP speaker considers the neighbor unreachable, disconnects the TCP connection from the neighbor, and attempts to reconnect to it. The interval for a BGP speaker to send the Keepalive message is one third of the negotiated hold time and is 60 seconds by default.

The system allows you to manually configure various timers within BGP to meet the neighbor keepalive and route management requirements in different network environments.

- BGP neighbor keepalive timer

  BGP uses the keepalive timer to maintain a valid connection with a peer and the holdtime timer to judge whether the peer is valid. The default value of the keepalive timer is **60** seconds and the default value of the holdtime timer is **180** seconds. When BGP speakers establish a BGP connection, both parties negotiate about the holdtime and the smaller holdtime value is selected. The keepalive timer is set to one third of the negotiated holdtime value or the configured keepalive value, whichever is smaller.

- Neighbor reconnection timer

To reduce the impact of frequent BGP reconnection to a failed neighbor on the network bandwidth, after a BGP speaker detects a neighbor connection failure, it attempts to reconnect to the neighbor after the Connect-Retry timer expires. The default value of the Connect-Retry timer is **15** seconds.

- Route advertisement timer

  To reduce the impact of route update packets on the network bandwidth, after a BGP speaker detects a network topology change, it does not advertise the route update to its neighbors immediately. Instead, the BGP speaker adopts a regular update mechanism to advertise all changed routing information to its neighbors.

1.1.6 Multi-Path Load Balancing of BGP

Multi-path load balancing means that there are multiple paths to the same network and data packets are evenly forwarded by these paths. In this case, one route has multiple next hops in the routing table.

According to the types of equal-cost routes, multi-path load balancing of BGP is classified into the following types:

- EBGP load balancing: Implements load balancing for routes learned from EBGP neighbors.
- IBGP load balancing: Implements load balancing for routes learned from IBGP neighbors.

When there are multiple paths to the same network in the routing table of BGP, BGP calculates a route with the highest priority by default. If there are multiple optimal routes with the same priority, BGP still selects a unique route according to comparison rules, advertises the route to the forwarding plane, and controls the forwarding of data streams. After multi-path load balancing is enabled, in addition to calculating a unique optimal route, BGP lists paths with the same priority as the optimal route as equal-cost routes. Then, BGP advertises the optimal route and equal-cost routes to the forwarding plane to implement load balancing.

Equal-cost routes have the same basic attributes and priority. That is, according to the optimal path selection rules of BGP, paths have the same priorities before router-IDs are compared.

- AS_PATH loose comparison

  Equal-cost routes must have the same AS-PATH attribute by default. Under such strict conditions, load balancing cannot be implemented in certain environments. In this case, you are advised to enable the AS-PATH loose comparison mode. In AS-PATH loose comparison mode, when other conditions for equal-cost routes are met, equal-cost route conditions are met as long as the AS-PATH lengths of routes and the AS-PATH lengths of the member ASs are equal respectively.

- Router-ID multi-path comparison

  Equal-cost routes do not need to come from the same device (that is, the sources of the routes do not need to have the same router ID) by default. After the router-ID multi-path comparison is enabled, only routes with the same router-ID can be equal-cost routes.

- Non-equal-cost load balancing

  Load-balanced routes are equal-cost routes by default. After the non-equal-cost load balancing is enabled, you can configure routes to carry the Link-Bandwidth attribute so that non-equal-cost routes form.

1.1.7 Route Reflector

Route reflectors are a method of reducing IBGP peer connections in an AS.

According to the principle of BGP route advertisement, all BGP speakers in an AS must establish a full mesh of connections (every two BGP speakers need to establish a neighbor relationship). Too many BGP speakers in

an AS will increase their resource cost, ramp up network administrators' configuration workload and complexity, and reduce the network expansion capacity.

You can configure a BGP speaker as a route reflector, which classifies IBGP peers in the AS into two types: clients and non-clients.

The rules for implementing a route reflector in an AS are as follows:

- Configure a route reflector and specify clients for the route reflector. The route reflector and its clients form a cluster. The route reflector will connect to its clients.
- The clients of a route reflector in a cluster cannot connect to BGP speakers outside the cluster.
- Within an AS, a full mesh of connections is established among IBGP peers of non-clients. The IBGP peers of non-clients include the following situations: Multiple route reflectors in a cluster; a route reflector in a cluster and BGP speakers (generally not supporting the route reflector function) not involved in the route reflector function out of the cluster; a route reflector in a cluster and route reflectors in other clusters.

The rules for processing a route received by a route reflector are as follows:

- A route update message received from an EBGP speaker will be sent to all clients and non-clients.
- A route update message received from a client will be sent to other clients and all non-clients.
- A route update message received from an IBGP non-client will be sent to all clients of the route reflector.

1.1.8 BGP Alliance

Alliances are another method of reducing IBGP peer connections in an AS.

You can divide an AS into multiple member ASs and configure a unified alliance ID (namely, alliance AS number) for these member ASs to form an alliance. Outside the alliance, the entire alliance is still considered as an AS and only the AS number of the alliance is visible. Inside the alliance, BGP speakers in a member AS still establish a full mesh of IBGP peer connections, BGP speakers in different member ASs establish EBGP connections. Though EBGP connections are established between BGP speakers in different member ASs, the NEXT_HOP, MED, LOCAL_PREF, and other path attributes keep unchanged during information exchange.

1.1.9 Route Aggregation

The great BGP routing table in a large network brings heavy load to BGP devices. BGP supports classless inter-domain routing (CIDR). Therefore, route aggregation entries can be created to reduce the size of the BGP routing table. BGP aggregation entries can be added to the BGP routing table only when valid paths are configured within the aggregation range. Routes can be manually aggregated on a device. Thus, this function can control whether to reserve AS path information within the aggregation address range, and whether to advertise only aggregated paths.

1.1.10 Route Dampening

If a route changes between the valid state and invalid state, route flapping occurs. Route flapping often causes the transmission of unstable routes in a network, and thereby causes network instability. BGP route dampening is a method of reducing route flapping. It reduces possible route flapping by monitoring routing information from EBGP peers.

Terms involved in BGP route dampening are as follows:

- **Route Flap**: A route changes between the valid sate and invalid state.
- **Penalty**: Once route flapping occurs, a BGP speaker, on which route dampening is enabled, adds a penalty

value to this route. The penalty value accumulates until **Suppress Limit** is reached.

- **Suppress Limit**: When the penalty of a route is greater than this value, the route is suppressed.
- **Half-life-time**: It indicates the time required for the penalty to be halved.
- **Reuse Limit**: When the penalty value of a route is smaller than this value, route suppression is canceled.
- **Max-suppress-time**(Upper limit of penalty time): The maximum penalty value depends on the configured upper limit of penalty time. The penalty value will not increase after reaching the upper limit. Formula: Maximum penalty value = 2 ^ (Max-suppress-time/Half-life-time) x Reuse Limit, and the maximum penalty value cannot be greater than **20000**.

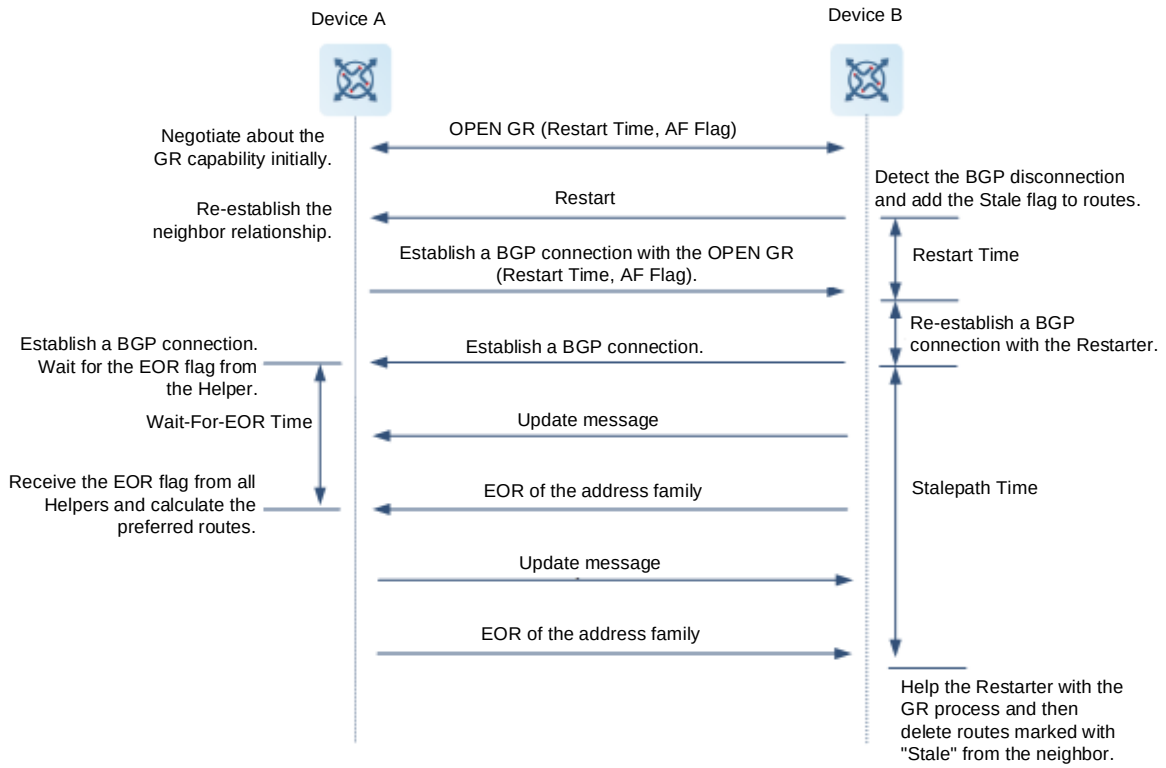
A BGP speaker assigns a route a penalty (accumulated to the penalty value) each time the route flaps. When the penalty value reaches Suppress Limit, the route is suppressed. The penalty does not increase after it reaches a certain value. This value is called the upper limit of penalty. When the penalty value reaches Half-life-time, the penalty is halved. When the penalty value is reduced to Reuse Limit, the route is activated again.

By default, the penalty value increases by 1000 when a route is reactivated and increases by 500 when a route is updated.

1.1.11 BGP Reliability

1. GR

Graceful restart (GR) is intended to ensure that data forwarding is not interrupted during the BGP restart. The GR function keeps the network topology stable, maintains the forwarding table, and ensures that key services are not interrupted during the switching of master and slave supervisor engines.



BGP GR is not an independent process, but is jointly accomplished by the Restarter and Helper.

- The Restarter performs restart and is capable of making the route forwarding plane to keep working when the route control plane is faulty.
- The Helper is the BGP neighbor of the Restarter and helps the Restarter complete GR.

To deliver graceful restart, BGP adds a capability field indicating to neighbors its support for GR to the OPEN message. The capability is called Graceful Restart Capability. During initialization of a BGP connection, both neighbors negotiate about the GR capability.

The End-of-RIB (EOR) flag is added to the update packets of BGP, to indicate that the routing information update to the neighbor is completed.

Figure 1-1 BGP GR Interaction Process

(1) When BGP establishes a neighbor relationship at the beginning, BGP uses the GR capability field in the OPEN message to negotiate about the GR capabilities of both neighbors.

(2) At a moment, the Restarter performs restart, and the BGP session is disconnected. The Helper detects the disconnection, keeps the route of the Restarter valid, but marks the Stale (aged but not updated).

(3) The Restarter completes restart.

(4) The Restarter connects to the Helper again.

(5) The Restarter waits for the route update message and EOR flag from the Helper.

(6) After receiving the EOR flag from all neighbors, the Restarter performs route calculation, updates routing entries, and then sends updated routes to the Helper.

(7) After receiving the updated routes, the Helper cancels their Stale flag. After receiving the EOR flag from the Restarter, the Helper deletes routes with the Stale flag (these routes are not updated), calculates routes calculation, and updates the routing entries. The entire GR process is completed.

BGP GR defines several important extended timers:

- **Restart-Timer**

  The value of this timer is advertised by the GR Restarter to the GR Helper. It indicates the maximum waiting time that the GR Restarter hopes the Helper to wait before a new connection is established between them. You can run the **bgp-instance graceful-restart restart-time** command to change the time value.

- **Wait-For-EOR Timer**

This timer indicates the maximum time for the GR Restarter to wait for the EOR flag from all GR Helpers. After the EOR flag is received from all GR Helpers or the Wait-For-EOR timer expires, the GR Restarter calculates the preferred routes and updates the routing entries. You can run the **bgp-instance advertise-delay** command to change the time value.

- **StalePath Timer**

  The timer indicates the maximum time for the GR-Helper to wait for the EOR flag from the GR Restarter after the connection between them is restored. Within this period, the Helper keeps the original route of the Restarter valid. After receiving the EOR flag or after the StalePath timer expires, the Helper clears the routing entries with the Stale tag. You can run the **bgp-instance graceful-restart staleroute-time** command to change the time value.

2. BGP NSR

None-stop-routing (NSR) is used to ensure uninterrupted routes during protocol restart upon a switchover between the master and slave supervisor engines. During the switchover, the NSR function keeps the network topology stable, maintains the neighbor status and forwarding table, and ensures that key services are not interrupted.

Unlike BGP GR, BGP NSR does not need the assistance of neighbors.

- Connections between BGP neighbors are not interrupted during active/standby switchover.
- Neighbors do not perceive the restart behavior of the peer device. The GR technology is used for restart restoration.

Neighbors with the BGP NSR function enabled do not need to negotiate about the GR capability nor need assistance from the peer. Therefore, no interworking problem arises.

3. Fast rerouting

With the fast development of IP technologies and the application of various complex services, higher requirements are posed for network security and stability. Some real-time services (audios and videos) are sensitive to the network running status and are largely affected by unstable networks. Therefore, network reliability receives more and more attention. In response to this requirement, the IP Fast Reroute (FRR) function appears. This function aims to use a backup link to forward data during route platform convergence after a faulty link is detected so as to ensure that intact packets are forwarded timely.

Thus, BGP FRR can avoid route disconnection due to a link fault before BGP route convergence. If a BGP routing table has multiple paths to the same network, BGP calculates the route with the highest priority by default. After the BGP FRR function is used, BGP selects a backup route for each optimal route. When detecting a fault occurring on the master link by using the BFD fast link detection mechanism, the device switches data to the selected backup link for data forwarding. After route convergence is completed, the device switches data to the re-calculated optimal path for data forwarding.

1.1.12 MP-BGP

Traditional BGP-4 only supports unicast IPv4 routes, and cannot propagate routing information of other network layer protocols (such as IPv6 unicast protocol). MP-BGP (Multi-Protocol BGP) is an extension of BGP-4, which can propagate the routing information of other network layer protocols without changing the original message mechanism and routing mechanism of the BGP protocol.

Compared with BGP, MP-BGP has two additional optional attributes:

- MP_REACH_NLRI (Multiprotocol Reachable NLRI): This attribute is used to carry the reachable route prefix

and the next-hop IP address information of multiple network layer protocols, in order to advertise the route to BGP neighbors.

- MP_UNREACH_NLRI (Multiprotocol Unreachable NLRI): This attribute is used to carry the unreachable route prefix information of multiple network layer protocols, in order to withdraw the route.

If the BGP Speaker does not support MP-BGP, these two attributes will be ignored after an UPDATE message with the above two attributes is received.

MP-BGP supports propagating the routing information for the following protocols:

1. EVPN

The EVPN is an extended layer-2 VPN technology based on the Multi-Protocol BGP (MP-BGP). The MP-BGP expands the EVPN address family to transfer the required layer-2 and layer-3 routing information.

MP-BGP adds not only the EVPN address family, but also the EVPN network layer reachability information, which includes the following:

- Ethernet Auto-discovery Route: Used to automatically discover Ethernet segment (ES) information in a multi-homed network.
- MAC/IP Advertisement Route: Used to advertise the MAC address and host ARP information.
- Inclusive Multicast Ethernet Tag (IMET) Route: Used to automatically discover VXLAN tunnel end points (VTEPs) and create VXLAN tunnels.
- Ethernet Segment Route: Used to advertise ES information and information about connected VTEPs.
- IP Prefix Route: Used to advertise routing information of IP network segments.

The preceding EVPN routing information includes the RD and RT information. The RD is used for EVPN routes of different VNIs and the RT is used for importing EVPN routes between different devices.

1.1.13 BMP

BGP Monitor Protocol (BMP) monitors BGP running on a device. It focuses on the status of BGP peers, peer entry transmission and receiving, and all kinds of BGP peer statistics.

A BGP speaker proactively sends a TCP connection request to a specified BMP server. After a TCP connection is established successfully, the BGP speaker advertises a BMP packet to the BMP server. In the TCP connection request initiated by a BGP speaker to a BMP server, the destination IP address is the IP address of the specified BMP server and the port number is a specified port number.

1.1.14 BGP Neighbor Auto-Discovery

BGP is based on the Transmission Control Protocol/Internet Protocol (TCP/IP) and requires IP addresses to establish BGP connections. In data center scenarios, a large number of IP addresses need to be assigned to devices. To save address resources without affecting BGP connections, you can deploy the BGP neighbor auto-discovery function. This function can save IP address resources, and supports neighbor auto-discovery and connection.

1.1.15 Others

1. Regular expression

A regular expression matches strings based on a rule. It is used to assess text data and return True or False to decide whether the expression can correctly describe the data.

The following table describes special characters involved in regular expressions used in BGP path attributes.

Table 1-1 Description of Special Characters in a Regular Expression

Character	Symbol	Special Meaning
Period	.	Matches any single character.
Asterisk	*	Matches zero or any sequence in a string.
Plus sign	+	Matches one or any sequence in a string.
Question mark	?	Matches zero or one symbol in a string.
Caret	^	Matches the start of a string.
Dollar sign	$	Matches the end of a string.
Underline	_	Matches commas, brackets, start and end of a string, and spaces.
Square brackets	[ ]	Matches a single character within a range.

1.1.16 Protocols and Standards

- RFC 1105: Border Gateway Protocol (BGP)
- RFC 1163: Border Gateway Protocol (BGP)
- RFC 1267: Border Gateway Protocol 3 (BGP-3)
- RFC 1771: A Border Gateway Protocol 4 (BGP-4)
- RFC 2918: Route Refresh Capability for BGP-4
- RFC 4273: Definitions of Managed Objects for BGP-4
- RFC 4360: PrBGP Extended Communities Attribute
- RFC 4364: Proposed Standard: BGP/MPLS IP Virtual Private Networks (VPNs)
- RFC 4486: Proposed Standard: Subcodes for BGP Cease Notification Message
- RFC 4724: Proposed Standard: Graceful Restart Mechanism for BGP
- RFC 4760: Draft Standard: Multiprotocol Extensions for BGP-4
- RFC 4893: BGP Support for Four-octet AS Number Space
- RFC 5396: Textual Representation of Autonomous System (AS) Numbers
- RFC 5492: Draft Standard: Capabilities Advertisement with BGP-4
- RFC 6198: Requirements for the Graceful Shutdown of BGP Sessions
- RFC 7313: Enhanced Route Refresh Capability for BGP-4
- RFC 7311: The Accumulated IGP Metric Attribute for BGP
- RFC 7432: Proposed Standard: BGP MPLS-based Ethernet VPN

1.2 Configuration Task Summary

BGP configuration includes the following tasks:

- Configuring BGP Basic Features
  - Configuring the BGP Version
  - Enabling BGP
  - Configuring a BGP Neighbor
  - (Optional) Configuring a BGP IPv6 Address Family
  - (Optional) Configuring a BGP Peer Group
  - (Optional) Configuring the Dot Mode to Display 4-Byte AS Numbers
  - (Optional) Injecting Network Information of Local AS into BGP
  - (Optional) Obtaining Reachable Networks of Other AS from BGP
  - (Optional) Configuring BGP Capacity Protection
  - (Optional) Shutting Down BGP Connections Gracefully
  - (Optional) Configuring BGP Soft Reset
  - (Optional) Configuring Scope Configuration Mode
  - (Optional) Configuring BGP Route Update Mechanisms
  - (Optional) Configuring BGP Timers
- (Optional) Configuring a Large-Scale BGP Network
  All the following configuration tasks are optional and may be selected as needed.
  - Configuring BGP Route Reflector
  - Configuring BGP AS Alliance
  - Configuring Route Aggregation
  - Configuring Route Dampening
- (Optional) Configuring BGP Route Selection and Load Balancing
  All the following configuration tasks are optional and may be selected as needed.
  - Configuring BGP Multi-Path Load Balancing
  - Configuring BGP Routes to be Recursive Only to Host Routes
  - Configuring Outbound Loop Detection for a BGP Neighborr
  - Configuring BGP ADD-PATH
  - Configuring BGP Advertising Routes with the Lowest Priority upon Device Restart
  - Configuring AS_PATH Attribute
  - Configuring MED
  - Configuring AIGP
  - Configure LOCAL_PREF
  - Configure Extended Community Attribute
  - Configuring BGP Best Path Selection
- (Optional) Configuring BGP Controlling Route Advertisement and Receiving

All the following configuration tasks are optional and may be selected as needed.

- Configuring BGP Filters
- Configuring BGP Route Sending Interval and Count
- Configuring BGP Modifying Propagated Routing Information
- Configuring BGP Processing Received Routing Information
- Configuring BGP Fast Withdrawing Specific Route
- Configuring BGP Delaying Advertising Routing Information

- (Optional) Configuring the BGP Security Features

  All the following configuration tasks are optional and may be selected as needed.
  - Configuring MD5 Authentication
  - Configuring BGP Peer GTSM Security Check

- (Optional) Configuring BGP Reliability

  All the following configuration tasks are optional and may be selected as needed.
  - Configuring BFD for BGP
  - Configuring BGP FRR
  - Configuring EBGP Multi-Path Bypass Protection
  - Configuring BGP GR
  - Configuring BGP NSR
  - Configuring BGP Session Keepalive
  - Configuring EBGP Fast Neighbor Detection
  - Configuring BGP Link-State Group Association

- (Optional) Configuring MP-BGP
  - Configuring an EVI
  - Configuring EVPN

- _(Optional) Configuring BGP Neighbor Auto-Discovery

  All the following configuration tasks are optional and may be selected as needed.
  - Configuring BGP Neighbor Auto-Discovery
  - Configuring Interface Neighbor Auto-Discovery

- (Optional)Configuring BGP Extended Features
  - Configuring BMP Monitoring
  - Configuring BGP Administrative Distance
  - Configuring Enhanced VPN Route Import
  - Configuring BGP Link-State

1.3 Configuring BGP Basic Features

1.3.1 Configuration Tasks

The configuration of BGP basic features includes the following tasks:

- Configuring the BGP Version
- Enabling BGP
- Configuring a BGP Neighbor
- (Optional) Configuring a BGP IPv6 Address Family
- (Optional) Configuring a BGP Peer Group
- (Optional) Configuring the Dot Mode to Display 4-Byte AS Numbers
- (Optional) Injecting Network Information of Local AS into BGP
- (Optional) Obtaining Reachable Networks of Other AS from BGP
- (Optional) Configuring BGP Capacity Protection
- (Optional) Shutting Down BGP Connections Gracefully
- (Optional) Configuring BGP Soft Reset
- (Optional) Configuring Scope Configuration Mode
- (Optional) Configuring BGP Route Update Mechanisms
- (Optional) Configuring BGP Timers

1.3.2 Configuring the BGP Version

1. Overview

After the TCP session is set up, the BGP Speaker will exchange the OPEN packets to negotiate BGP connection parameters, including the BGP version. Only BGP 4 is supported currently.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure the BGP version number for a specified BGP peer.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **version 4**

No BGP version number is configured for a specified BGP peer by default.

1.3.3 Enabling BGP

1. Overview

Before configuring the BGP function, you need to enable the BGP protocol, and configure the AS number.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) (Optional) Configure the device ID of the device running the BGP protocol.

bgp-instance router-id *ipv4-address*

By default, the loopback interface of the device is preferred as the device ID. If no loopback interface is available, the Router-ID of the device is used.

(5) (Optional) Configure the default address family as IPv4 unicast address family.

bgp-instance default-config ipv4-unicast

By default, the default address family is the IPv4 unicast address family.

(6) (Optional) Configure the device to record the BGP status change information without the Debug function.

bgp-instance log-peer-changes

By default, the device records the BGP status change information without the Debug function.

(7) (Optional) Disable the TCP source IP address check function of BGP.

bgp-instance tcp-source-check disable

By default, the TCP source IP address check function is enabled.

1.3.4 Configuring a BGP Neighbor

1. Overview

This section describes how to configure a BGP speaker as a neighbor.

2. Restrictions and Guidelines

- If IBGP neighbors are not directly connected, you need to configure IGP or a static routing protocol to implement reachable routes between the neighbors.
- If EBGP neighbors are not directly connected, you need to configure the **ebgp-multihop** parameter for the neighbors.
- The source interface for establishing a neighbor relationship must be a valid local interface or IP address.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) (Optional) Configure the alarm function when the maximum number of BGP neighbors is exceed.

bgp-instance maximum-peer *maximum-neighbor-numbers* **warning**

By default, the alarm function the maximum number of BGP neighbors is exceed is not configured.

(5) (Optional) Configure the maximum number of sessions that can be established by a BGP peer.

bgp-instance network-peer-number *maximum-session-number*

By default, no maximum number of sessions that can be established by a BGP peer is configured.

(6) (Optional) Enable the BGP peer address family capability detection function.

bgp-instance notify unsupport-capability

By default, the BGP peer address family capability detection function is disabled.

(7) (Optional) Save original routing information sent by all BGP peers under the current BGP instance.

bgp-instance soft-resave inbound

No original routing information sent by all BGP peers under the current BGP instance is saved by default.

(8) (Optional) Set the connect-retry value used during BGP connection establishment.

bgp-instance timer connect-retry *connect-retry*

The connect-retry value used during BGP connection establishment is not configured by default.

(9) (Optional) Use RT attributes advertised by neighbors when RT is not configured for VRF.

bgp-instance keep vrf-route-target

By default, RT attributes advertised by neighbors are not used when RT is not configured for VRF.

(10) (Optional) Enter a required address family configuration mode. If you need to perform configuration for a specific address family, select one of the following tasks to configure.

- Enter the IPv4 unicast configuration mode.

  address-family-mode ipv4 [**unicast**]

- Enter the IPv4 VRF configuration mode.

  address-family-mode ipv4 vrf *vrf-name*

- Enter the IPv6 unicast configuration mode.

  address-family-mode ipv6 [**unicast**]

- Enter the IPv6 VRF configuration mode.

  address-family-mode ipv6 vrf *vrf-name*

- Enter the L2VPN configuration mode.

  address-family-mode l2vpn evpn

  BGP neighbors are not allowed to exchange L2VPN information by default.

- Enter the link-state configuration mode.

  address-family-mode link-state [**unicast**]

(11) Create a BGP neighbor. When the configured AS number is the same as the local AS number, an IBGP neighbor is created. When the configured AS number is different from the local AS number, an EBGP neighbor is created.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

No neighbor is specified for a BGP speaker by default.

(12) (Optional) Configure the description of the specified peer (group).

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **description** *text*

By default, the description of the specified peer (group) is not configured.

(13) (Optional) Configure a source interface or IP address for establishing a TCP connection with the neighbor. A loopback interface is recommended for IBGP neighbors while a directly connected interface is recommended for EBGP neighbors.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **update-source** { *interface-type interface-number* | *address* }

BGP automatically selects the source IP address for a TCP connection based on the IP address of a neighbor by default. The IP address of the outbound interface of local packets is generally used.

(14) (Optional) Configure the time to live (TTL) for TCL packets received from the neighbor. A larger TTL value indicates more hops to the neighbor. When the TTL is **1**, the BGP neighbor must be directly connected to the device.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ebgp-multihop** [*ttl*]

The default TTL values of TCP packets to be sent to IBGP neighbors and EBGP neighbors are **255** and **1** respectively.

(15) (Optional) Configure the mode for BGP to establish a TCP connection with the neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **transport connection-mode** { **active-only** | **both** | **passive-only** }

By default, BGP neighbors support the active and passive modes of establishing TCP connections.

(16) (Optional) Activate the address family capability for the neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **activate**

Only the IPv4 unicast address family capability is activated for neighbors created in BGP configuration mode by default.

(17) (Optional) Configure the maximum number of sessions that can be established by a BGP peer.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* } **session-number** *maximum-session-number*

No maximum number of sessions that can be established by a BGP peer is configured by default.

(18) (Optional) Configure the DSCP value for sending BGP packets.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **dscp** [*dscp*]

The default DSCP value is **48**.

1.3.5 Configuring a BGP IPv6 Address Family

1. Overview

This section describes how to configure BGP to exchange IPv6 routes to implement IPv6 network access between different ASs.

2. Restrictions and Guidelines

- Generally, BGP uses IPv6 addresses to establish neighbor relationships and implement the exchange of IPv6 routes.
- When IPv6 link local address to establish peer connection with a BGP peer, the address is expressed as Linklocal address% interface name, for example, FE80:: 1% Gigabit Ethernet 0/1.
- In special scenarios, for example, the IPv6 provider edge router (6PE) function is configured, BGP supports

the exchange of IPv6 routes with the neighbors using IPv4 addresses.

- Configurations related to BGP IPv6 services must be completed in BGP IPv6 address family mode.
- Neighbors using IPv6 addresses are used to exchange IPv6 routes. When a neighbor is configured in BGP mode, BGP automatically activates the IPv4 unicast address family capability for the neighbor. You are advised to manually disable the IPv4 unicast address family capability.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(5) Configure the BGP IPv4 address family mode.

address-family-mode ipv4 unicast

(6) Disable the IPv4 address family capability for the BGP neighbor.

unset peer { *neighbor-ipv4-address* | *peer-group-name* } **activate**

- The IPv4 address family capability is enabled by default.

(7) Configure the BGP IPv6 address family mode.

address-family-mode ipv6 unicast

(8) Configure the IPv6 address family capability for the BGP neighbor.

peer { *neighbor-ipv6-address* | *peer-group-name* } **activate**

The IPv6 address family capability is disabled by default.

(9) (Optional) Configure BGP to advertise IPv6 routes.

network-advertise *network-ipv6-address/prefix-length* [**route-map** *route-map-name*] [**backdoor-route**]

No network routing information is configured for BGP by default.

(10) (Optional) Configure to use the link local address as the global next-hop IP address with sending IPv6 routing information to the BGP IPv6 link local peer (group).

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **global-nexthop-replace-local**

By default, when sending IPv6 routing information to the BGP IPv6 link-local address peer (group), the global next-hop IP address is not the link-local address.

1.3.6 Configuring a BGP Peer Group

1. Overview

BGP speakers in the same peer group have the same update strategy. Peer groups can simplify configuration and improve the running efficiency.

2. Restrictions and Guidelines

- Members of a peer group inherit all configurations of the peer group. Unified configuration of a peer group can be replaced by separate configuration of each member in the peer group, except the configuration that influences output update, for example, the configuration of **peer route-filtering**, **peer route-map**, and **peer filter-rule-list**.
- You can neither put neighbors belonging to different address families to the same peer group nor put IBGP and EBGP neighbors to the same peer group.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) (Optional) Enter a required address family configuration mode. If you need to perform configuration for a specific address family, select one of the following tasks to configure.

- Enter the IPv4 unicast configuration mode.

  address-family-mode ipv4 [**unicast**]

- Enter the IPv4 VRF configuration mode.

  address-family-mode ipv4 vrf *vrf-name*

- Enter the IPv6 unicast configuration mode.

  address-family-mode ipv6 [**unicast**]

- Enter the IPv6 VRF configuration mode.

  address-family-mode ipv6 vrf *vrf-name*

- Enter the L2VPN configuration mode.

  address-family-mode l2vpn evpn

  BGP neighbors are not allowed to exchange L2VPN information by default.

- Enter the link-state configuration mode.

  address-family-mode link-state [**unicast**]

(5) Create a peer group.

peer *peer-group-name* **peer**-**group**

(6) Specify a BGP speaker as a member of the BGP peer group.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* } **peer-group** *peer-group-name*

1.3.7 Configuring the Dot Mode to Display 4-Byte AS Numbers

1. Overview

The 4-byte AS numbers can be represented in dot mode.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure the dot mode to display 4-byte BGP AS numbers.

bgp-instance as-symbol dot

1.3.8 Injecting Network Information of Local AS into BGP

1. Overview

BGP will not automatically discover or learn reachable networks. The information of reachable networks in local AS must be injected into BGP, so that BGP can propagate the information to BGP peers.

There are two ways to inject network information in local AS into BGP:

- Manual static configuration: inject the information of reachable networks within the specified range into BGP.
- Configure route redistribution: inject the information of reachable networks of IGP protocol into BGP.

2. Restrictions and Guidelines

- You are advised to enable the network information synchronization function. Otherwise, routing black holes may be incurred.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure to redistribute the routing information of other routing protocols to all BGP instances.

router-protocol bgp redistribute-route [**vrf** *vrf-name*] { **ipv4 unicast-af-modifier** | **ipv6 unicast-af-modifier** } *protocol-type* [**metric-value** *metric-value* | **route-map** *map-tag*] *

By default, redistributing the routing information of other routing protocols to all BGP instances is not configured.

(4) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(5) (Optional) Configure the current instance to not apply non-specified instance redistribution.

bgp-instance redistribute-route unspecified instance ignore

By default, a BGP instance applies non-specified instance redistribution.

(6) (Optional) Enter a required address family configuration mode. If you need to perform configuration for a specific address family, select one of the following tasks to configure.

- Enter the IPv4 unicast configuration mode.

address-family-mode ipv4 [**unicast**]

- Enter the IPv4 VRF configuration mode.

  address-family-mode ipv4 vrf *vrf-name*

- Enter the IPv6 unicast configuration mode.

  address-family-mode ipv6 [**unicast**]

- Enter the IPv6 VRF configuration mode.

  address-family-mode ipv6 vrf *vrf-name*

(7) Add static routing entries to a BGP routing table and advertise the routing entries to peers.

network-advertise *network-number* [**mask** *mask*] [**route-map** *route-map-name*] [**backdoor-route**]

No static routing entry is added to a BGP routing table and advertised to peers by default.

(8) (Optional) Configure a device to advertise routing information configured by running the **network-advertise** command after the device synchronizes with the local route.

network-advertise synchronization

By default, a device will advertise routing information configured by running the **network-advertise** command after the device synchronizes with the local route.

(9) Configure route redistribution. All the following configuration commands are optional and can be configured as needed.

(10) Configure to redistribute the routing information of other routing protocols to the BGP instance.

redistribute-route *protocol-type* [**metric-value** *metric-value* | **route-map** *map-tag*] *

By default, redistributing routing information of other routing protocols to a BGP instance is not configured.

(11) Configure to redistribute the routing information of the IS-IS routing protocol to the BGP instance.

redistribute-route isis [*isis-tag*] [{ **level-1** | **level-1-2** | **level-2** } | **metric-value** *metric-value* | **route-map** *map-tag*] *

By default, redistributing routing information of IS-IS routing protocol to a BGP instance is not configured.

(12) Configure to redistribute the routing information of OSPF routing protocol to the BGP instance.

redistribute-route ospf *process-id* [**filter** { { **external-type** | { **external-type 1** | **external-type 2** }* } | **internal-type** | { **nssa-external-type** | { **nssa-external-type 1** | **nssa-external-type 2** } * } } * | **metric-value** *metric-value* | **route-map** *map-tag*] *

By default, redistributing routing information of OSPF routing protocol to a BGP instance is not configured.

(13) Configure to enable to inject multiple next-hop routes of other protocols into the BGP protocol.

bgp-instance src-paths *protocol-type* **all**

By default, injecting multiple next-hop routes is disabled.

(14) (Optional) Configure to use the manually configured metric value when BGP redistributes a route.

default-metric *metric-value*

By default, the metric value of the route is used when the route is redistributed by BGP.

1.3.9 Obtaining Reachable Networks of Other AS from BGP

1. Overview

After the routing information of other ASs obtained by BGP is delivered to the routing table of the device, the device can forward messages sent to these ASs.

By injecting the routing information of other ASs obtained by BGP into the IGP which advertises the routing information to other devices in the local AS, these devices can forward messages sent to these ASs.

2. Restrictions and Guidelines

Generally, BGP Speakers that are IBGP neighbors to each other are not directly connected physically. IGP-enabled devices in the middle may not learn the same routing information as BGP Speakers. When the BGP Speaker at the boundary of the AS domain forwards the packets received from other domains to the next-hop IBGP neighbor, the packets will pass through the intermediate IGP-enabled device, and may be lost because there is no route on the IGP-enabled device. The synchronization of BGP and IGP can prevent such routing black hole. To achieve this, the routing information to be sent to another AS can only be propagated after all routing devices in this AS learn the routing information.

Under the following two cases, you can cancel the synchronization mechanism to ensure fast convergence of routing information:

- There is no route information traversing this AS, which in general, is a stub AS.
- All routers in the AS run the BGP protocol, and a full connection is established among all BGP speakers, that is, BGP speakers establish adjacency relationship in pairs.

3. Prerequisites

A route map must be configured. See *Configuring Routing Policies* for details about configuring a route map.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Control the routing information delivered by BGP to the core routing table.

table-map *route-map-name*

By default, BGP does not modify the attributes of all routing information delivered to the core routing table.

(5) Configure BGP to redistribute routes received from IBGP neighbors to IGP.

bgp-instance redistribute-inner-router

By default, BGP allows routes received from IBGP neighbors to be redistributed to IGP.

(6) (Optional) Enable the BGP and IGP routing information synchronization function.

synchronization

By default, the BGP and IGP routing information synchronization function is disabled.

(7) (Optional) Configure BGP to advertise the redistributed default route.

default-information originate

By default, BGP will not advertise the redistributed default route.

1.3.10 Configuring BGP Capacity Protection

1. Overview

Excessive BGP routing entries can overload the device capacity, especially on devices with a small memory. BGP capacity protection can help avoid non-predictable running status caused by excessive resource consumption of the device. BGP capacity protection includes the following two parts:

- Restricting the number of BGP routing entries
  The number of BGP routing entries can be restricted by configuring the maximum number of routing entries in a BGP address family and the maximum number of routing entries that are learned by a BGP neighbor.
- Enabling BGP to enter the overflow state in case of memory insufficiency
  After BGP enters the OVERFLOW state, it will discard the newly learned routes. This can effectively ensure that the memory will not be further consumed. If the BGP address family enters the OVERFLOW state, the newly learned route may be discarded, which may cause a network-wide routing loop. To reduce the probability of this phenomenon, BGP will generate a default route to the NULL interface, which will always exist in the OVERFLOW state.

  For the newly learned route, if the route is not a specific route which is a non-default route in the current routing table, the system will discard the route so that the memory can maintain at a relatively stable state. The system selectively discards routes to ensure that the overall network does not have routing loops. It is relatively safe for BGP to enter the OVERFLOW state.

2. Restrictions and Guidelines

- You can use the **cleanup bgp-instance** { *addressfamily* | **all** } command to reset a BGP session, and exit the OVERFLOW state of BGP address family.
- If the **unset overflow memory-lack** command is configured, BGP will not enter the OVERFLOW state when the memory is insufficient, which may cause memory resources to continue to be consumed. When the memory consumption exceeds the range allowed by the system, BGP will disconnect all neighbors and delete all learned routes.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure BGP to enter the OVERFLOW state when the memory is insufficient.

overflow memory-lack

BGP enters the overflow state by default when the memory is insufficient.

(5) Enable the function of route entry limit in global configuration mode or for specified VRF instances.

bgp-instance maximum-prefix *maximum-prefix-numbers* [**vrf** *vrf-name*]

The function of route entry limit is disabled in global configuration mode or for specified VRF instances by default.

(6) Configure the maximum number of prefixes received from specified BGP peers.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **maximum-prefix** *maximum-prefix-value* [*maximum-prefixthreshold*] [**restart-time** *restart-time* | **warning** [**suppress**]]

The number of prefixes received from a specified BGP peer is not limited by default.

(7) Enter the corresponding address family configuration mode. Configure only one task.

- Enter the IPv4 unicast configuration mode.
  - **address-family-mode ipv4** [**unicast**]
- Enter the IPv4 VRF configuration mode.
  - **address-family-mode ipv4 vrf** *vrf-name*
- Enter the IPv6 unicast configuration mode.
  - **address-family-mode ipv6** [**unicast**]
- Enter the IPv6 VRF configuration mode.
  - **address-family-mode ipv6 vrf** *vrf-name*
- Enter the L2VPN configuration mode.
  - **address-family-mode l2vpn evpn**

BGP neighbors are not allowed to exchange L2VPN information by default.

(8) Configure the maximum number of prefixes in a BGP routing information base under the address family.

maximum-prefix *maximum-prefix-number*

The number of route prefixes in a BGP routing information base under an address family is not limited by default.

1.3.11 Shutting Down BGP Connections Gracefully

1. Overview

In a network, as a user isolates or upgrades a device, the RFC 6198 defines a function of shutting down BGP connections gracefully. This function demands the device to shut down connections with its neighbors when service traffic is not interrupted or is interrupted for a short time.

This feature adopts the "Make-Before-Break" mode to shut down BGP connections, to ensure that service traffic is not interrupted or is interrupted for a very short period of time in the process from the feature configuration to actual BGP connection shutdown. The steps are as follows:

(1) The feature enables the device to advertise a route with the lowest priority (the value of Local-Pref is **0** or the value of MED is 4,294,967,295), carrying Gshut Community, to a neighbor. Then, the neighbor updates the route and switches traffic to a backup link or other equal-cost links.

(2) The device shuts down the BGP connection with the neighbor after a period of time.

The delay time for BGP connection shutdown can be manually specified or automatically calculated. The automatically calculated delay time is based on 1 second for 1,000 routes.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Shut down all connections in a BGP instance gracefully.

bgp-instance shutdown [**graceful** [**append-community** *community-value*] [**delay** *delay-time*]]

None of the connections in a BGP instance is shut down by default.

(5) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(6) Shut down connections of the BGP neighbor gracefully.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **shutdown** [**graceful** [**append-community** *value*] [**delay** *time*]]

None of the connections of a BGP neighbor is shut down by default.

1.3.12 Configuring BGP Soft Reset

1. Overview

If routing policies (including peer route-filtering, peer route-map, peer prefix-list, and peer filter-rule-list) are modified, an effective method must be available to implement new routing policies. The conventional method is to configure BGP soft reset, which implements a new routing policy without terminating a BGP session connection. When an output routing policy is modified, BGP soft reset will re-advertise all routing information of a BGP speaker to its neighbors.

If an input routing policy is modified, the operation is more complex than that performed when an output routing policy is modified. This is because output routing policies are implemented on the routing table of the local BGP speaker, while the input routing policies are implemented on the routing information received from BGP peers. The local BGP speaker does not retain the original routing information received from BGP peers to reduce memory occupancy. If an input routing policy is modified and a neighbor supports the route update function, you can configure soft reset to send a route update request to the neighbor. After receiving the request, the neighbor re-advertises all routing information. You can also configure the local BGP speaker to store original routing information for each specified BGP peer and the original routing information is used as a basis for judging the modification of input routing policies.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Clear the specified session of the BGP IPv4 unicast address family.

cleanup bgp-instance ipv4 unicast-af-modifier [**vrf** vrf-name] { ***** | *as-number* | *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**soft**] [**inbound** | **outbound**]

(3) Enter the global configuration mode.

config-system terminal

(4) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(5) (Optional) Save the original routing information of a specified BGP peer.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **soft-resave inbound**

No original routing information of a specified BGP peer is saved by default.

1.3.13 Configuring Scope Configuration Mode

1. Overview

BGP can be configured based on VRF by configuring the Scope configuration mode. The commands configured in the Scope configuration mode only take effect in the corresponding VRF.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure to enter the Scope configuration mode, and associate VRF with BGP.

scope vrf *vrf-name*

By default, the Scope address family is not configured.

1.3.14 Configuring BGP Route Update Mechanisms

1. Overview

BGP provides two route update mechanisms: regular scanning update and event triggering update.

- Regular scanning update

  BGP uses an internal timer to start scanning regularly and update the routing table.

- Event triggering update

  When BGP configuration commands are changed due to user configuration or the next hop of a BGP route changes, BGP is triggered to start the scanning mechanism and update the routing table.

  The function of triggering routing table update by the change of the next hop of BGP is a method of reducing the BGP convergence time. This function optimizes the method of monitoring the next hops of routes, to enable BGP to speed up route convergence when the network topology is stable. When BGP establishes a connection with a neighbor, it automatically monitors the next hops of the routes learned from the neighbor. When a next hop changes in the core routing table, BGP receives a next hop change advertisement and updates the BGP routing table. This optimization measure improves the convergence performance of BGP routes by reducing the time for detecting next-hop changes.

2. Restrictions and Guidelines

- Based on address families, this function is configured in the IPv4, IPv6, IPv4 VRF, and IPv6 VRF address family modes.
- If you set the BGP route update mechanism to event-triggering update, you must disable synchronization (by running the **unset synchronization** command) and enable the BGP next-hop triggering update function.
- The **bgp-instance nexthop-scan trigger delay** command and the **bgp-instance scan-interval** command control the same timer. If the BGP route update mechanism is configured as regular scanning update and the timer specified in the **bgp-instance nexthop-scan trigger delay** command is set to greater than 60 seconds, this command does not take effect, because the scanning timer is triggered prior to the delay of the next hop triggering update.
- In an unstable network environment with frequent hop changes, especially with many routes, the configuration of the next hop triggering update causes unnecessary route calculations, and thus consumes more CPU resources. Therefore, you are advised to disable this function in this environment.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure an interval of regular scanning update of BGP.

bgp-instance scan-interval *scan-time*

The default interval of regular scanning update of BGP is **60** seconds.

(5) (Optional) Enter the address family configuration mode. To configure this function for a specific address family, please configure only one task.

- Enter the IPv4 unicast configuration mode.

  address-family-mode ipv4 [**unicast**]

- Enter the IPv4 VRF configuration mode.

  address-family-mode ipv4 vrf *vrf-name*

- Enter the IPv6 unicast configuration mode.

  address-family-mode ipv6 [**unicast**]

- Enter the IPv6 VRF configuration mode.

  address-family-mode ipv6 vrf *vrf-name*

- Enter the L2VPN configuration mode.

  address-family-mode l2vpn evpn

  BGP neighbors are not allowed to exchange L2VPN information by default.

- Enter the link-state configuration mode.

  address-family-mode link-state [**unicast**]

(6) Configure the BGP route update mechanism as event triggering update. Run the following commands in turn:

- Configure the event triggering update mechanism to update the routing table.

  bgp-instance scan-rib disable

  BGP updates the routing table in regular scanning mode by default.

- Enable the next hop triggering update.

  bgp-instance nexthop-scan trigger enable

  The function of next hop triggering update is enabled by default.

- Configure a delay of updating the routing table before the next hop of a BGP route changes.

  bgp-instance nexthop-scan trigger delay *delay-time*

  The default delay of updating the routing table is **5** seconds after the next hop of a BGP route changes.

1.3.15 Configuring BGP Timers

1. Overview

By manually configuring timers in the BGP protocol, you can flexibly meet neighbor keepalive requirements in different network environments.

- Holdtime and Keepalive timers

BGP uses the Keepalive timer to maintain an effective connection with the peer, and uses the Holdtime timer to determine whether the peer is alive. When a BGP connection is established between BGP peers, the peers will negotiate the Holdtime interval and choose the smaller Holdtime value. The Keepalive timer value will be 1/3 of the negotiated Holdtime interval or the configured Keepalive value, whichever is smaller.

- Connect-Retry timer

To reduce the impact of BGP's frequent attempts to reconnect with disconnected neighbors on the network bandwidth, the BGP peer will initiate a Connect-Retry timer after detecting the failure to establish a connection with the neighbor, and try to reconnect after the interval expires.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure the BGP timer interval.

timers-set bgp *keepalive-time holdtime* [*minimum-holdtime*]

By default, the interval for BGP to send keepalive messages is 60 seconds, and the hold time is 180 seconds. The minimum hold-time for neighbor notification is not limited.

(5) Configure the interval of Keepalive, Hold-Time, and Connect-Retry timers when establishing a BGP connection with a specified BGP peer.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **timers-set** { *keepalive-interval holdtime* [*minimum-holdtime*] | **connect** *connect-retry* }

By default, when establishing a BGP connection with a BGP peer, the interval of the Keepalive timer is 60 seconds, that of the Hold-Time timer is 180 seconds, and that of the Connect-Retry timer is 15 seconds.

(6) (Optional) Enable BGP internal timer accurate control function.

bgp-instance timer accuracy-control

By default, the BGP internal timer accurate control function is disabled.

1.4 Configuring a Large-Scale BGP Network

1.4.1 Configuration Tasks

The large BGP network configuration includes the following tasks: All configuration tasks are optional and may be selected as needed.

- Configuring BGP Route Reflector
- Configuring BGP AS Alliance
- Configuring Route Aggregation
- Configuring Route Dampening

1.4.2 Configuring BGP Route Reflector

1. Overview

A route reflector can be configured in an IBGP environment so that routing information is reflected between clients and the number of BGP neighbor connections is reduced.

2. Restrictions and Guidelines

- If you configure a route reflector in an address family, the reflector takes effect only in this address family.
- To facilitate configuration, you need to configure the reflector device. The client devices do not need to be configured as clients.
- When multiple reflection clusters are deployed in one AS domain, different reflection cluster identifiers must be configured for them.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(5) Configure the local device as a route reflector. Then, the BGP neighbor becomes the route reflection client.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **route-reflector-client**

(6) (Optional) Enable the route reflection function between clients of the devices.

bgp-instance client-reflection enable

The route reflection function between clients is enabled by default.

(7) (Optional) Configure a BGP reflection cluster ID.

bgp-instance cluster-id *cluster-id*

A BGP reflection cluster ID is the BGP router-ID by default.

(8) (Optional) Allow the BGP route reflector to modify route attributes.

bgp-instance route-reflector attribute-change

No route reflector is allowed to modify route attributes by default.

According to RFC4456, to prevent route loops, a BGP route reflector cannot modify route attributes when reflecting routes. However, relevant route attributes need to be modified when you re-plan network traffic paths. Users can configure a command to modify route attributes (including Route-map and Nexthop-self) on the route reflector.

1.4.3 Configuring BGP AS Alliance

1. Overview

On a large BGP network, you can configure a BGP alliance to divide an AS into multiple member ASs, to reduce the number of IBGP neighbor connections and facilitate AS management.

2. Restrictions and Guidelines

- You are advised to use private AS numbers for member ASs within an alliance. A private AS number is in the range from 64512 to 65535.
- Within a member AS of an alliance, BGP speakers must be connected in a full mesh manner or configured as reflectors and reflector clients.
- EBGP neighbor relationships must be established between member ASs of an alliance.
- All BGP speakers in an alliance must associate with a member AS of the alliance.
- All member ASs that have established EBGP relationships with the local device must be configured on members of a BGP alliance.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure a BGP alliance ID. The local BGP AS (specified by the **router-protocol bgp** *as-number* command) becomes the private AS inside the alliance and is invisible to other AS domains.

bgp-instance as-confederation id *as-number*

No alliance ID is configured for a BGP speaker by default.

(5) Configure members for the BGP alliance. The specified AS and local AS belong to the same alliance.

bgp-instance as-confederation peers *as-number*

No alliance member is configured for BGP by default.

1.4.4 Configuring Route Aggregation

1. Overview

One or more refined BGP routes are aggregated as a BGP route with a shorter network mask.

2. Restrictions and Guidelines

- By default, BGP advertises path information before and after aggregation. To enable BGP to advertise only path information after aggregation, run the **summary-address summary-only** command.
- When the **summary-address** command is used to configure route aggregation, the aggregated routes take effect immediately as long as any route falls into the configured address range.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure the route aggregation entries of BGP.

summary-address { *ipv4-address mask* | *prefix* } [**advertise-route-map** *route-map-name* | **gen-sys-set** | **attribute-route-map** *route-map-name* | **summary-only** | **suppress-route-map** *route-map-name*] *

No route aggregation entry of BGP is configured by default.

1.4.5 Configuring Route Dampening

1. Overview

BGP route dampening is a method of reducing route flapping. It reduces possible route flapping by monitoring routing information from EBGP peers. The BGP speaker punishes a route once (added to the penalty) route flapping occurs. When the penalty reaches the upper limit, the route is suppressed. When the Half-life-time reaches, the penalty is halved. When the penalty is reduced to the Reuse Limit, the route is reactivated.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Enable the route dampening function and configure dampening parameters.

bgp-instance damp [*half-life* [*reusing suppressing maximun-supress-time*] [**withdrawal-ignore**] | **route-map** *route-map-name*]

The route dampening function is disabled by default.

1.5 Configuring BGP Route Selection and Load Balancing

1.5.1 Configuration Tasks

The configuration of BGP route selection and load balancing includes the following tasks: All configuration tasks are optional and may be selected as needed.

- Configuring BGP Multi-Path Load Balancing
- Configuring BGP Routes to be Recursive Only to Host Routes
- Configuring Outbound Loop Detection for a BGP Neighbor
- Configuring BGP ADD-PATH
- Configuring BGP Advertising Routes with the Lowest Priority upon Device Restart
- Configuring AS_PATH Attribute
- Configuring MED Attribute
- Configuring AIGP Attribute
- Configure LOCAL_PREF Attribute
- Configure Extended Community Attribute
- Configuring BGP Best Path Selection

1.5.2 Configuring BGP Multi-Path Load Balancing

1. Overview

This section describes how to implement multi-path load balancing for IBGP routes.

2. Restrictions and Guidelines

- Routes learned from an IBGP neighbor must have the same priority (the router-ID is not compared).
- This command does not allow IBGP and EBGP routes to form equivalent routes.
- All next hops must carry the Link-Bandwidth attribute so that non-equal-cost routes are generated. Otherwise, non-equal-cost load balancing cannot be implemented.
- Enable the function of sending extended community attributes so that the link bandwidth attribute can be sent to an IBGP neighbor.
- The function of carrying the link bandwidth attribute when a route from a specified neighbor is sent to an IBGP neighbor takes effect only on single-hop EBGP neighbors.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) (Optional) Enter a required address family configuration mode. If you need to perform configuration for a specific address family, select one of the following tasks to configure.

- Enter the IPv4 unicast configuration mode.

  address-family-mode ipv4 [**unicast**]

- Enter the IPv4 VRF configuration mode.

  address-family-mode ipv4 vrf *vrf-name*

- Enter the IPv6 unicast configuration mode.

  address-family-mode ipv6 [**unicast**]

- Enter the IPv6 VRF configuration mode.

  address-family-mode ipv6 vrf *vrf-name*

(5) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(6) Configure BGP load balancing. To configure equal-cost route load balancing by EBGP multiple paths of an alliance or by local inter-VRF imported routes, run the **max-ecmp-paths ebgp** command.

max-ecmp-paths { **ebgp** | **ibgp** } *maximum-paths-number*

BGP load balancing is disabled by default.

(7) (Optional) Enable the function of sending extended community attributes, to ensure that the link bandwidth attribute is transferred between neighbors.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **send-community** [**both** | **standard** | **extended**]

By default, when configuring a BGP peer for L2VPN address families, the extended community attributes will be advertised to this BGP neighbor at the same time. When a BGP peer is configured for other address families, the community attribute will not be advertised to this BGP neighbor.

(8) (Optional) Enable non-equal-cost load balancing. Non-equal-cost routes are generated based on the link bandwidth attribute.

bgp-instance link-bandwidth

Non-equal-cost load balancing is disabled by default.

(9) (Optional) Configure the unit of bandwidth transmission as kbytes.

bgp-instance link-bandwidth-kbytes

The transmission unit in the link bandwidth extended attribute is bytes by default.

(10) (Optional) Set the transmission mode of link bandwidth extended attribute to **non-transitive**.

bgp-instance link-bandwidth-non-transitive

The transmission mode of link bandwidth extended attribute is **transitive** by default.

(11) (Optional) Enable the function of carrying the link bandwidth attribute when a route from a specified neighbor is sent to an IBGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **link-bandwidth**

The function of carrying the link bandwidth attribute in a route from a specified neighbor is disabled by default.

(12) (Optional) Configure link bandwidth attribute to be carried in the specified neighbor's routes sent to other EBGP neighbors.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **link-bandwidth-ebgp**

No link bandwidth attribute is carried in the specified neighbor's routes sent to other EBGP neighbors by default.

(13) (Optional) Configure the link bandwidth extended community attribute received from the specified neighbor to be used for calculating non-equal-cost load balancing and cumulative bandwidth values.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **link-bandwidth-transitive**

The link bandwidth extended community attribute received from the specified neighbor is not configured to calculate non-equal-cost load balancing and cumulative bandwidth values by default.

1.5.3 Configuring BGP Routes to be Recursive Only to Host Routes

1. Overview

BGP routes use optimal matching for route recursion by default. BGP routes may be recursive to default routes or incorrect network segment routes, resulting in an error in the egress or next hop. After the function of making BGP routes recursive only to host routes is enabled, BGP routes are recursive only to 32-bit IPv4 host routes or 128-bit IPv6 host routes. This function is applied to routes learned by IBGP neighbors or multi-hop EBGP neighbors that have established neighbor relationships by using the loopback interface.

After the function of making BGP routes recursive only to host routes is enabled, the device checks the validity of the next-hop addresses of IBGP or multi-hop EBGP routes via exact matching, and conducts route recursion on the IBGP or multi-hop EBGP routes via exact matching when they are written into the forward information database (FIB). For example, the next-hop address of the IBGP route 192.168.2.0/24 is 1.1.1.1. The next-hop address of the IBGP route 192.168.2.0/24 is valid only when the route 1.1.1.1/32 exists, and the egress of the route written into the FIB is the egress of the route 1.1.1.1/32.

2. Restrictions and Guidelines

- This function takes effect only on IBGP or multi-hop EBGP routes. It is unavailable to direct EBGP routes or routes whose next-hop addresses are direct connection addresses.
- IBGP or multi-hop EBGP neighbor relationships of the device need to be established using the address of the loopback interface. Otherwise, this function cannot be enabled.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure BGP routes to be recursive only to host routes.

bgp-instance recursive host-route

BGP routes recurse via optimal matching by default.

1.5.4 Configuring Outbound Loop Detection for a BGP Neighbor

1. Overview

When receiving a BGP route from a neighbor, BGP conducts loop detection on the BGP route by default. If the AS-PATH attribute carried in a BGP route contains the local AS number, BGP filters out the BGP route. The BGP outbound loop detection is to conduct loop detection on routes before the routes are transmitted to a neighbor, so as to filter out loop routes.

When sending a route to an EBGP neighbor, the device judges whether the AS-PATH attribute carried in the BGP route contains the AS number of the neighbor. If yes, the route is looped and the device does not send the route to the EBGP neighbor.

2. Restrictions and Guidelines

This feature is available only to EBGP neighbors.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(5) Configure outbound loop detection for the BGP neighbor

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as-loop-check out**

The outbound loop detection is disabled for a neighbor by default.

1.5.5 Configuring BGP ADD-PATH

1. Overview

The BGP additional paths (ADD-PATH) attribute is used to receive multiple routes with the same prefix from an IBGP neighbor. When receiving routes with the same prefix from the same peer, BGP replaces a previous route with the latest new one by default, that is, BGP regards the routes with the same prefix received from the same neighbor as one entry. After the BGP ADD-PATH function is configured, BGP adds a path-ID field to the route advertised to a neighbor that supports the ADD-PATH capability. The device judges whether routes are the same based on the route prefix and path-ID of a neighbor. When a received route is different from previous

routes, the device adds it as a new entry. In this way, the device can obtain multiple routes with the same prefix from the same neighbor.

2. Restrictions and Guidelines

Run the bgp-instance alternative-paths select command to select ADD-PATH alternative routes of a specific type. If the type of selected ADD-PATH alternative routes is different from that of to-be-advertised ones, the ADD-PATH alternative routes are not advertised but only the optimal routes are advertised.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Enable the ADD-PATH selection function.

bgp-instance alternative-paths select { **all** | **best** *number* | **ecmp** }

(5) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** as-number

(6) The ADD-PATH function is disabled by default. Configure the device to advertise the ADD-PATH alternative routes of a specific type to a peer when the ADD-PATH negotiation is successful.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **advertise alternative-paths** { **all** | **best** *number* | **ecmp** }

BGP does not advertise ADD-PATH alternative routes to its neighbors by default.

(7) Enable the ADD-PATH capability for a specified peer.

peer { *peer-address* | *peer-group-name* } **alternative-paths** { **send [recv] | recv** }

The ADD-PATH capability of a peer is disabled by default.

1.5.6 Configuring BGP Advertising Routes with the Lowest Priority upon Device Restart

1. Overview

By default, after a neighbor relationship is established upon device restart, a BGP peer can advertise routes to its neighbors. However, in certain cases, for example, a device has many neighbors, there are considerable routes during device startup, but writing entries into the hardware is slow. The neighbors have learned the routes and started forwarding traffic, but the local device has not completed the writing of entries into the hardware, causing a traffic forwarding failure. Therefore, it is necessary to adjust the priority of routes advertised by BGP to the lowest priority after the device restart. In this way, routes passing through the local device are not selected while other routes are available.

This function enables BGP to advertise routes with the lowest priority to neighbors after the local device is started and has established a neighbor relationship. For EBGP neighbors, the MED value of routes is adjusted to 4294967295. For IBGP neighbors, the LOCAL_PREF value of routes is adjusted to 0. After confirming that ARP entries have been delivered and forwarding entries have been written into hardware, run the cleanup

bgp-instance advertise lowest-priority startup command to restore the priority of advertised routes. If you do not configure the priority restoration for advertised routes, the device automatically restores the priority of advertised routes after a period of time.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure BGP to adjust the priority of advertised routes to the lowest level upon device restart.

bgp-instance advertise lowest-priority startup [*recover-time*]

BGP does not modify the priority of advertised routes by default.

1.5.7 Configuring AS_PATH Attribute

1. Overview

AS_PATH Lists the ASs passed by a route reversely. Routes are selected based on different AS_PATH attributes.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) (Optional) Enter the address family configuration mode. To configure this function for a specific address family, please configure only one task.

- Enter the IPv4 unicast configuration mode.

  address-family-mode ipv4 [**unicast**]

- Enter the IPv4 VRF configuration mode.

  address-family-mode ipv4 vrf *vrf-name*

- Enter the IPv6 unicast configuration mode.

  address-family-mode ipv6 [**unicast**]

- Enter the IPv6 VRF configuration mode.

  address-family-mode ipv6 vrf *vrf-name*

- Enter the L2VPN configuration mode.

  address-family-mode l2vpn evpn

- Enter the link-state configuration mode.

  address-family-mode link-state [**unicast**]

(5) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(6) (Optional) Configure to check the first AS number in the AS_PATH path field of the UPDATE message.

bgp-instance specify-first-as

By default, the device checks the first AS number in the AS_PATH path field of the UPDATE message.

(7) (Optional) Configure a BGP route to limit the number of AS numbers in the AS_PATH attribute.

bgp-instance max-as-limit *maxas-limit-number*

By default, the number of AS numbers in the AS_PATH attribute is not limited.

(8) (Optional)Configure a local AS number for all BGP peers of the current VRF instance.

bgp-instance local-as *as-number* [**no-prepend** [**change-as** [**dual-as**]]]

By default, no local AS number is configured for all BGP peers of the current VRF instance by default.

When the AS number of the local BGP system changes, there is no need to change the BGP configuration of the peer device. This function is used for AS migration and merging on large-scale networks while ensuring consistent configuration of other devices in interconnected ASs.

(9) Configure the local AS for the BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **local-as** *as-number* [**no-prepend** [**change-as** [**dual-as**]]]

No local AS is configured for any peer by default, and the local AS of a peer is the real AS of BGP.

After the local AS function is configured, when the real AS of the local BGP changes, you do not need to change the BGP configuration on the peer and a BGP connection can be still established. This function is used for AS migration and merging on large networks and ensures that the device configurations in other interconnected ASs are not affected.

(10) (Optional) Configure to delete the private AS number recorded in the AS path attribute of the route propagated to the specified EBGP peer.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **delete-private-as** [**force** [**ignore-remote-as**]] [**change-as**]

By default, the private AS number recorded in the AS path attribute of the route propagated to the specified EBGP peer is not deleted.

1.5.8 Configuring MED Attribute

1. Overview

The MED attribute is used to determine the best path when traffic enters the AS. When BGP Speaker obtains multiple routes with the same destination IP address but different next-hop IP addresses through different EBGP peers, if other conditions are the same, the priority will be given to the route with a smaller MED value when selecting the best path.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Enable BGP to always compare the MED value.

bgp-instance match-med

By default, the always compare MED value is disabled.

(5) (Optional) Configure to preferably compare the MED value of paths from peers of the same AS.

bgp-instance definitive-med

By default, the preferably compare MED value of paths from peers of the same AS is not configured.

1.5.9 Configuring AIGP Attribute

1. Overview

AIGP attribute can accumulate the IGP Metric of paths the route passes through. BGP uses the AIGP attribute for routing optimization. A route with a smaller AIGP attribute value has a higher priority.

By default, BGP route does not carry AIGP attribute. You can run the set-rule aigp-metric command of the route map to configure the AIGP attribute for the route.

2. Prerequisites

The AIGP weight attribute for routes that match the Match rule is configured. See *Configuring Routing Policy* for details.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Enable the AIGP function of BGP neighbors.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **aigp** [**transform med**]

By default, the AIGP function of BGP neighbors is disabled.

1.5.10 Configure LOCAL_PREF Attribute

1. Overview

When a BGP Speaker propagates a route received from the EBGP peer to another IBGP peer, it will add the LOCAL_PREF attribute. BGP will compare the LOCAL_PREF value when selecting the best path. A path with a higher LOCAL_PREF value has a higher priority.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure the default LOCAL_PREF attribute value.

bgp-instance default local-preference *local-preference-value*

By default, the LOCAL_PREF value is 100.

1.5.11 Configure Extended Community Attribute

1. Overview

The extended community attribute is the extension of BGP community attribute for specific services.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure BGP to carry the non-transitive extended community attribute when advertising routes to EBGP neighbors.

bgp-instance advertise non-transitive extcommunity

By default, BGP does not carry the non-transitive extended community attribute when advertising routes to EBGP neighbors.

1.5.12 Configuring BGP Best Path Selection

1. Overview

When BGP selects the best path, it needs to compare some routing attributes. You can use the configuration commands to configure the policy for the system to compare routing attributes.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) The following steps are optional, and can be configured as needed.

- Configure to not compare the AIGP Metric value when selecting the best path.

- **bgp-instance optimal-path aigp ignore**
- By default, the AIGP Metric value is compared when selecting the best path.

- Configure to not compare the AS path length when selecting the best path.
  - **bgp-instance optimal-path as-path ignore**
  - By default, the AS path length is compared when selecting the best path.
- Configure BGP to relax the comparison of the AS_PATH attribute for BGP multipath load balancing.
  - **bgp-instance optimal-path as-path multipath-relax**
  - By default, relax comparison of the AS_PATH attribute for BGP multipath load balancing is not configured.
- Allow BGP to compare the alliance's AS AS_PATH length when selecting the best path.
  - **bgp-instance optimal-path compare-confed-aspath**
  - By default, the AS_PATH attribute value of an EBGP route within the same alliance is not compared when selecting the best path. The best path is selected based on other conditions.
- Configure to compare Router ID of paths when selecting the best path.
  - **bgp-instance optimal-path compare-router-id**
  - By default, when selecting the best path, if all path attributes of two paths received from different EBGP peers are the same, the path received first is considered to be the best path.
- Configure to not compare the serial number of EVPN table entries from the same VTEP when selecting the best path.
  - **bgp-instance optimal-path evpn-seq-relax**
  - By default, when selecting the best path, the device needs to compare the serial number of EVPN table entries from the same VTEP.

Note

This command is not supported by the S6980-64QC, S6580-48CQ8QC, or S6580-24DC8QC.

- Configure not to compare the IGP Metric value of the next hop when selecting the best path.
  - **bgp-instance optimal-path igp-metric ignore**
  - By default, the IGP Metric value of the next hop is compared when selecting the best path.
- Configure to compare the MED of the paths from the peers within the AS alliance when selecting the best path.
  - **bgp-instance optimal-path med confed** [**worst-med**]
  - By default, the MED value of the paths from peers in the AS alliance is not compared when selecting the best path.
- Set the lowest priority for paths without the MED attribute when selecting the best path.
  - **bgp-instance optimal-path med worst-med**
  - By default, when selecting the best path, the priority of paths without the MED attribute is set to the highest.
- Enable the Router ID comparison function for BGP multipath load balancing.

- **bgp-instance optimal-path multipath-compare-routerid**
- By default, the Router ID comparison function for BGP multipath load balancing is disabled.

- Reduce the priority of VTEP EVPN entry capacity comparison for optimal path election.

  bgp-instance optimal-path vtep-compare-delay

  Reducing the priority of VTEP EVPN entry capacity comparison for optimal path election is disabled by default.

1.6 Configuring BGP Controlling Route Advertisement and Receiving

1.6.1 Configuration Tasks

The configuration of route advertisement and receiving control of BGP includes the following tasks: All configuration tasks are optional and may be selected as needed.

- Configuring BGP Filters
- Configuring BGP Route Sending Interval and Count
- Configuring BGP Modifying Propagated Routing Information
- Configuring BGP Processing Received Routing Information
- Configuring BGP Fast Withdrawing Specific Route
- Configuring BGP Delaying Advertising Routing Information

1.6.2 Configuring BGP Filters

1. Overview

You can configure BGP filters to enable the device to advertise or receive only specified routes. BGP supports multiple route filtering policies.

2. Prerequisites

If the command parameter involves a route map, you need to configure the route map first. See *Configuring Routing Policies* for configuring a route map.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure the global routing policy for matching for outbound route advertisement.

bgp-instance advertise-route-map *route-map-name*

By default, the global routing policy is not used for matching when sending outbound routes to BGP neighbors.

(5) Configure to use route matching policy for inbound or outbound routes.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

By default, route matching is not configured for inbound or outbound routes.

(6) Configure to implement routing policies according to ACL when sending and receiving routing information from or to a specified BGP peer.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **route-filtering** { *access-list-name* | *access-list-number* } { **in** | **out** }

By default, the routing policy is not configured according to ACL when sending and receiving routing information from or to the specified BGP peer.

(7) Configure to selectively advertise route information suppressed by route aggregation.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **unsuppress-route-map** *map-tag*

By default, routing information that is suppressed by routing aggregation is not selectively advertised.

(8) Allow BGP Speaker to advertise default routes to peers (groups).

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **default-originate** [**route-map** *map-tag*]

By default, BGP Speaker is not allowed to advertise default routes to peers (groups).

(9) Allow BGP Speaker to receive the UPDATE message containing the AS number of local device.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **allowas-in** [*occurrence-number*]

By default, BGP Speaker is allowed to receive the UPDATE message containing the AS number of local device.

(10) Configure that source-specific routes are not suppressed within the domain group to which the specified BGP peer belongs.

- Configure the domain group to which the specified BGP peer belongs.
  - **peer** { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **domain** *domain-name*
  - By default, the Domain group to which the specified BGP peer belongs is not configured.
- Configure the domain group to which the specified BGP peer belongs to not suppress source-specific routes.
  - **peer** { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **domain-unsuppress**
  - By default, the domain group to which the specified BGP peer belongs does not suppress source-specific routes.

(11) (Optional) Enable the Route-Target filtering function.

bgp-instance default-config routing-target filter

By default, the Route-Target filtering function is enabled.

Note

This command is not supported by the S6980-64QC, or S6580-24DC8QC.

1.6.3 Configuring BGP Route Sending Interval and Count

1. Overview

You can tune the outbound route advertisement speed of the BGP Speaker by configuring the time interval and number of BGP routes advertised.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure the time interval for sending BGP route update messages.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **advertisement-interval** *advertisement-interval*

By default, the time interval for sending BGP route update message is 0 seconds for IBGP connections, and 30 seconds for EBGP connections.

(5) Configure the time interval to advertise the specified peer of the locally originated BGP route.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as-origination-interval** *seconds*

By default, the time interval for advertising the locally originated BGP route to the specified peer is 1 second.

1.6.4 Configuring BGP Modifying Propagated Routing Information

1. Overview

You can use configuration commands to enable BGP to carry the specified information or modify the specified information in the route advertised by BGP.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure the source site attribute values of the BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **soo** *soo-value*

By default, the source site attribute value of the BGP neighbor is not configured.

(5) Configure PE to override the AS number of a site.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as-override**

By default, PE is not configured to override the AS number of a site.

(6) Configure the next hop when distributing routes to a specified BGP peer. The following tasks are mutually exclusive. Configure only one of them.

- Configure to set the next hop of route as this device when distributing routes to a specific BGP peer.
  - **peer** { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **nexthop-local**
  - By default, the next hop is the BGP Speaker when advertising routes to an EBGP peer, and the next hop is not modified when advertising routes to an IBGP peer.
- Configure to not modify the next hop when advertising routes to a peer (group).
  - **peer** { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **nexthop-unaltered**
  - By default, the next hop will be changed to the BGP Speaker when advertising routes to an EBGP peer, and the next hop will not be modified when advertising routes to an IBGP peer.

1.6.5 Configuring BGP Processing Received Routing Information

1. Overview

You can use configuration commands to configure BGP to process the received routing information.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure not to perform private PIC processing on routing information sent to and received by a BGP peer when distributing routes to and receiving routes from the designated BGP peer.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **pic-disable**

By default, the device performs private PIC processing on the routes sent and received by BGP peers.

(5) Configure the weight of the specified BGP peer.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **private-value** *weight-value*

By default, the weight of the specified BGP peer is not configured. The initial weight of routes learned from the neighbor is 0, and that of locally generated routes is 32768.

1.6.6 Configuring BGP Fast Withdrawing Specific Route

1. Overview

With the rapid development of IP technologies and the application of various complex services, higher requirements are posed for the network. Customers may need fast convergence of specific routes. This function can meet customers' requirements for preferential withdrawal of specific routes.

The route withdrawal sequence is calculated based on the routes in the routing table by default. This function adds routes that meet conditions to a high-priority queue for preferential processing, so as to achieve the purpose of rapidly withdrawing specified routes.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) (Optional) Enter the address family configuration mode. To configure this function for a specific address family, please configure only one task.

- Enter the IPv4 unicast configuration mode.

  address-family-mode ipv4 [**unicast**]

- Enter the IPv4 VRF configuration mode.

  address-family-mode ipv4 vrf *vrf-name*

- Enter the IPv6 unicast configuration mode.

  address-family-mode ipv6 [**unicast**]

- Enter the IPv6 VRF configuration mode.

  address-family-mode ipv6 vrf *vrf-name*

(5) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(6) Configure BGP to rapidly withdraw specified routes.

bgp-instance fast-withdraw { **access-control-list** { *access-list-number* | *access-list-name* } | **prefix-list** *prefix-list-name* | **route-map** *route-map-name* }

The rapid withdrawal of specified routes is disabled by default.

(7) Allow BGP Speaker to fast withdraw default routes to peers (groups).

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **default-fast-withdraw**

By default, BGP Speaker does not fast withdraw the default route to peers (groups).

1.6.7 Configuring BGP Delaying Advertising Routing Information

1. Overview

- Delayed advertisement upon system restart

  After the system is restarted and a neighbor relationship is established, a BGP peer can advertise routes to its neighbors. However, in certain cases, for example, a device has many neighbors or routes and the device is restarted. So, the device is slow in writing entries to hardware. As a result, the neighbors have learned the routes and started forwarding traffic, but the local device hardware has not completed writing of entries, causing a traffic forwarding failure.

  The BGP delayed advertisement upon system restart enables the device not to immediately advertise routes to its neighbors but wait for a period of time after the system is restarted and the BGP neighbor relationships are established. This function does not affect other behaviors of neighbors such as route

receiving. If some routes need to be kept from impact of the system delay, you can configure a prefix-list policy to match these routes, providing a flexible route advertisement method.

Delay-time specifies the waiting time before routes are advertised to neighbors and startup-time specifies the startup-time. Within the startup-time, BGP sends received routing information to the neighbors at an interval specified by delay-time. After the startup-time ends, the default route advertisement behavior recovers.

- Delayed first route advertisement

  Once the neighbors of BGP negotiate to reach the established status, they send update packets each other. If delayed first route advertisement of BGP is configured on the local device, the local device will send the route received from the specified neighbor to other neighbors after the delayed period.

2. Restrictions and Guidelines

- If delayed advertisement of BGP upon system restart and delayed first route advertisement of BGP are enabled at the same time, delayed advertisement of BGP upon system restart takes precedence over delayed first route advertisement for first routes of BGP.
- BGP GR is not affected by either delayed advertisement of BGP upon system restart or delayed first route advertisement of BGP, that is, the BGP GR route advertisement is not affected by the delay time.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Enable the function of delayed advertisement of BGP upon system restart.

bgp-instance initial-advertise-delay { *delay-time* [*startup-time*] [**wait-for-controller**] | **prefix-list** *prefix-list-name* }

The function of delayed advertisement of BGP upon system restart is disabled by default.

(5) Configure the maximum delay time for the BGP speaker to first send update messages.

bgp-instance advertise-delay *delay-time*

The default maximum delay time for the BGP speaker to first send update messages is **120** seconds.

1.7 Configuring the BGP Security Features

1.7.1 Overview

The configuration of the BGP security function includes the following tasks: All configurations are optional and may be selected as needed.

- Configuring MD5 Authentication
- Configuring BGP Peer GTSM Security Check

1.7.2 Configuring MD5 Authentication

1. Overview

Message-digest algorithm 5 (MD5) authentication passwords are used when BGP speakers establish a TCP connection. If the authentication fails, no TCP connection will be established.

2. Restrictions and Guidelines

- The same password must be set for the BGP speakers that need to establish a BGP connection. Otherwise, no neighbor relationship can be established between them.
- After the MD5 authentication command is configured, BGP speakers re-establishes a BGP connection.
- Only one authentication password can be configured for one neighbor.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) (Optional) Enter the address family configuration mode. To configure this function for a specific address family, please configure only one task.

- Enter the IPv4 unicast configuration mode.

  address-family-mode ipv4 [**unicast**]

- Enter the IPv4 VRF configuration mode.

  address-family-mode ipv4 vrf *vrf-name*

- Enter the IPv6 unicast configuration mode.

  address-family-mode ipv6 [**unicast**]

- Enter the IPv6 VRF configuration mode.

  address-family-mode ipv6 vrf *vrf-name*

- Enter the L2VPN configuration mode.

  address-family-mode l2vpn evpn

  BGP neighbors are not allowed to exchange L2VPN information by default.

- Enter the link-state configuration mode.

  address-family-mode link-state [**unicast**]

(5) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(6) Configure MD5 encryption for a TCP connection to be established with the BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **password** [**0** | **7**] *password-string*

By default, a BGP connection is not encrypted through MD5.

1.7.3 Configuring BGP Peer GTSM Security Check

1. Overview

Network devices consume CPU resources when processing IP packets on the control plane. An attacker continuously sends false BGP packets to a device. If the device finds the packets sent to the local device upon receipt of them and forwards the packets to the control plane for processing without identification, the device consumes many CPU resources, because it needs to process these packets.

Configuring BGP GTSM security check can protect devices from CPU type attacks. GTSM security check determines whether the TTL value in IP packet headers is within the specified range. If not, the packets are invalid and directly discarded.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure the function of GTSM security check for BGP neighbors.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ttl-safety hops** *hop-count*

The function of GTSM security check is not enabled by default.

1.8 Configuring BGP Reliability

1.8.1 Configuration Tasks

BGP reliability configuration includes the following tasks: All configurations are optional and may be selected as needed.

- Configuring BFD for BGP
- Configuring BGP FRR
- Configuring EBGP Multi-Path Bypass Protection
- Configuring BGP GR
- Configuring BGP NSR
- Configuring BGP Session
- Configuring EBGP Fast Neighbor Detection
- Configuring BGP Link-State Group Association

1.8.2 Notes

This section describes the precautions for configuring the BGP reliability function.

Whether the BGP reliability function is supported depends on devices.

Table 1-2 Products Supporting the BGP Reliability Function

Function	Device Supporting the Function
Configuring BGP NSR	S6520-64CQ, S6510-32CQ, S6510-48VS8CQ, S6510-4C, and S6250-48XS8CQ

1.8.3 Configuring BFD for BGP

1. Overview

You can configure bidirectional forwarding detection (BFD) for BGP to rapidly detect a network failure and switch data to a backup link, thereby improving the network use experience.

2. Restrictions and Guidelines

You need to configure BGP peer-specific BFD detection parameters for multi-hop BFD only. Single-hop BFD can use BGP peer-specific BFD detection parameters or BFD detection parameters configured on an interface. Peer-specific BFD detection parameters take precedence over the parameters configured on an interface.

3. Prerequisites

Before configuring BFD for BGP, make sure that GP peer-specific BFD session parameters have been configured. Peer-specific BFD detection parameters take precedence over the parameters configured on an interface. The REUP link-state group is configured. See *Configuring BFD* for details.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) (Optional) Enter the address family configuration mode. To configure this function for a specific address family, please configure only one task.

- Enter the IPv4 unicast configuration mode.

  address-family-mode ipv4 [**unicast**]

- Enter the IPv4 VRF configuration mode.

  address-family-mode ipv4 vrf *vrf-name*

- Enter the IPv6 unicast configuration mode.

  address-family-mode ipv6 [**unicast**]

- Enter the IPv6 VRF configuration mode.

  address-family-mode ipv6 vrf *vrf-name*

(5) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(6) Configure BFD for BGP to detect the neighbor changes.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **fall-over bfd** [**single-hop-prefer**] [**compatible**]

The BFD function is disabled by default.

(7) (Optional) Configure BFD detection parameters for the specified BGP peer (group).

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **fall-over bfd-detect interval** *interval-number* **min-rx** *min-rx-number* **multiplier** *multiplier-number*

No BFD detection parameters are configured for the specified BGP peer (group) by default.

1.8.4 Configuring BGP FRR

1. Overview

This section describes how to use a backup route to replace a failed route to rectify the fault locally.

2. Prerequisites

Configure a BFD session for a neighbor to implement fast link fault detection.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) (Optional) Enter the address family configuration mode. To configure this function for a specific address family, please configure only one task.

- Enter the IPv4 unicast configuration mode.

  address-family-mode ipv4 [**unicast**]

- Enter the IPv4 VRF configuration mode.

  address-family-mode ipv4 vrf *vrf-name*

- Enter the IPv6 unicast configuration mode.

  address-family-mode ipv6 [**unicast**]

- Enter the IPv6 VRF configuration mode.

  address-family-mode ipv6 vrf *vrf-name*

(5) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(6) Configure BGP FRR.

bgp-instance auto-frr

The FRR function is disabled by default.

1.8.5 Configuring EBGP Multi-Path Bypass Protection

1. Overview

After EBGP multi-path bypass protection is configured, when all ECMP routes fail, the bypass route becomes the primary route for data forwarding.

BGP FRR supports only 1:1 protection. After the equal-cost multi-path routing (ECMP) function is enabled, FRR becomes unavailable. The multi-path bypass protection enables BGP to support 1:N protection. Users can configure BGP multi-path bypass protection to enable the system to select a backup bypass path even if ECMP is configured. When all ECMP routes fail, the bypass route becomes the primary route for forwarding.

When there are multiple paths to the same network in the routing table of BGP, BGP calculates a route with the highest priority by default. After the BGP multi-path bypass protection function is enabled, BGP selects a preferred backup route even if ECMP routes exist. After the fast link detection mechanism of BFD detects that the master link is faulty, the system switches data to the originally calculated backup link for forwarding. After route convergence is completed, the device switches data to the re-calculated optimal path for data forwarding.

2. Restrictions and Guidelines

You can configure a neighbor BFD session to implement fast link fault detection.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure BGP multi-path bypass protection.

bgp-instance install standby-path

Multi-path bypass protection is disabled by default.

(5) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(6) Create a BFD session for the BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **fall-over bfd**

No BFD session is configured for a BGP neighbor by default.

1.8.6 Configuring BGP GR

1. Overview

This section describes how to configure BGP GR to ensure that data transmission is not interrupted during protocol restart and implement the deployment of highly reliable networks.

2. Restrictions and Guidelines

- To successfully deploy the BGP GR function, you need to configure a neighbor as the GR Helper.

- IGP GR also needs to be configured in an IBGP environment.
- After BGP GR is enabled, you need to reset a BGP neighbor connection to make BGP GR take effect.
- After the GR function is enabled in BGP configuration mode, the GR function will be enabled in all address families.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(5) Configure BGP GR.

bgp-instance graceful-restart

The GR function is enabled by default.

(6) Configure the BGP GR restart timer.

bgp-instance graceful-restart restart-time *restart-time*

The default timer value is **120** seconds.

(7) (Optional) Configure the BGP GR routing aging timer.

bgp-instance graceful-restart staleroute-time *time*

The default value of the aging timer is **360** seconds.

(8) (Optional) Configure the maximum wait time for EOR flags of BGP GR of all neighbors.

bgp-instance advertise-delay *delay*

The default maximum waiting time of EOR flags is **120** seconds.

(9) (Optional) Disable the GR function of BGP specified address family.

bgp-instance graceful-restart disable

By default, when the global BGP GR function is enabled, the GR function under each BGP address family is also enabled.

(10) (Optional) Configure the restart time of BGP long-lived GR.

bgp-instance graceful-restart long-lived-restart-time *time*

BGP long-lived GR is disabled by default.

(11) (Optional) Configure GR restart time for BGP peers.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **restart-time** *time* [**strictly**]

No GR restart time is configured for BGP peers by default.

1.8.7 Configuring BGP NSR

Note

This function is supported by only the S6520-64CQ, S6510-32CQ, S6510-4C, S6510-48VS8CQ, and S6250-48XS8CQ.

1. Overview

During switchover between master and slave supervisor engines, the NSR function keeps the network topology stable, maintains neighbor status and forwarding table, and ensures that key services are not interrupted.

2. Restrictions and Guidelines

- To deploy the BGP NSR function, rely on the device to support the function of dual engine redundancy.
- After the BGP NSR function is enabled, connections to the BGP neighbors will be reset for the function to take effect.
- The neighbor based NSR command is equivalent to the **bgp-instance nsr** command. This function enables the NSR function for all neighbors.
- You are not advised to use the neighbor-based NSR command as it is to be abandoned.
- When the BGP NSR function is enabled for a neighbor, the connection to the neighbor will be reset and the TCP none-stop-service (NSS) will be enabled for the neighbor. Then, relevant neighbor and routing information will be backed up to the slave supervisor engine. In this case, if the NSR function is enabled after a BGP speaker is in the established state, the neighbor relationship will be re-established, causing neighbor flapping. You are advised to enable NSR before a neighbor relationship is established between peers.
- The NSR function does not take effect on a neighbor that fails to establish a BGP connection. That is, if the BGP connection of a neighbor is not in the established state, the neighbor will not execute the NSR operation. Only a neighbor in the established state will perform NSR-related backup operations.
- Supporting the BGP NSR function does not mean that the device can perform switchovers between the active and standby management boards. To perform such switchovers, you must depend on the device hardware. NSR devices must support the function of dual engine redundancy.
- If the BGP or TCP backup is not complete, the current BGP NSR switchover may fail. When a NSR switchover failure occurs, routes can be still recovered through BGP GR. Therefore, you are advised to enable both BGP NSR and BGP GR.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure the NSR function of BGP.

bgp-instance nsr [stable-mode]

By default, the NSR function is disabled.

(5) (Optional) Enable the NSR function of the specified BGP peer (group).

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ha-mode nsr** [**stable-mode**]

By default, the NSR function of BGP peer (group) is disabled.

1.8.8 Configuring BGP Session Keepalive

1. Overview

For devices that support BGP, routing errors in an address family will affect route stability in other address families: When a device receives an update packet from a neighbor and an error on the multi-protocol routing attribute is detected, the device will disconnect the BGP session. As a result, flapping occurs on routes in all address families of this neighbor.

After the BGP session retention function is enabled, if an error occurs in the routing attribute of an address family, only the routing information related to the neighbor in this address family is deleted. The BGP session and other address families are not affected, which enhances the stability of BGP.

Recovery-time specifies the waiting time for automatic route recovery. A neighbor must support the route-refresh capability so that the time can be set. After the recovery-time elapses, BGP sends the route-refresh message of the address family to the neighbor and re-advertises all routing information in the address family to this neighbor.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure BGP to retain BGP sessions when it detects a multiprotocol path error.

bgp-instance mp-error-handle session-retain [**refresh-timer** *refresh-timer*]

BGP terminates BGP sessions by default when it detects a multiprotocol route error.

1.8.9 Configuring EBGP Fast Neighbor Detection

1. Overview

After the EBGP neighbor fast detection is configured, the device will quickly close the BGP session connection when the network interface for directly connecting the EBGP neighbor fails.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Enable the EBGP neighbor fast link detection function.

bgp-instance ebgp-interface-fallover

By default, the EBGP neighbor fast link detection function is enabled.

1.8.10 Configuring BGP Link-State Group Association

1. Overview

Rapid Ethernet Uplink Protection (REUP) is a fast uplink protection function. In the dual-uplink networking mode, REUP is used to ensure normal communication of links, block redundant links, avoid link loops, acting as a fast backup. REUP binds the link state of multiple downlink interfaces to the interface state of multiple uplinks by configuring the downlink and uplink interfaces of the link-state group. When all uplink links in the group fail, all downlink interfaces in the group are forced to be down. However, in the actual scenario, the state of the uplink interface may be normal, but the BGP connection established through the uplink interface is disconnected. In this case, REUP will not close the downlink, and the device still needs to handle the downlink traffic. Since the BGP connection has been disconnected and there is no corresponding routing table entry on the device, the device will discard this part of traffic. If the device can automatically close the downlink interface when it detects that the BGP connection is disconnected, the device will not need to process the downlink traffic.

After the BGP link-state group association function is configured, if all BGP neighbors associated with this link-state group are disconnected, the device will automatically close all the downlink interfaces in the link-state group to avoid wasting device resources for processing traffic.

2. Prerequisites

The link-state group of REUP must be configured. See *Configuring REUP* for details.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Associate a BGP peer (group) with a link-state group.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **link-state group** *link-state-group-number*

By default, a BGP peer (group) is not associated with a link-state group.

(5) (Optional) Configure the delay time for disassociating the BGP neighbor with the link-state group due to link failure.

bgp-instance link-state-group up-delay *delay-time*

By default, the delay time for disassociating the BGP neighbor with the link-state group due to link failure is 5 seconds.

1.9 Configuring MP-BGP

1.9.1 Configuration Tasks

1. EVPN

The configuration tasks of BGP EVPN function are as follows:

- Configuring an EVI
- Configuring EVPN

1.9.2 Configuring an EVI

1. Overview

This section describes how to configure an EVPN instance (EVI).

2. Restrictions and Guidelines

- When the number of configured VNIs exceeds the capacity or some VNI instances are being deleted, the configuration fails.
- The RD values of different VNI instances must be different. Therefore, VNI instances must be configured in batches by running only the **rd auto** command.
- If an EVI is defined and an RD value has been configured for it, the RD value cannot be modified. To modify the RD value, delete the EVI and then configure a new RD. One EVI instance can have only one RD value.
- RD values automatically generated are in the format of ipv4-address:nn. In the format, "ipv4-address" indicates the BGP router-ID and *nn* is the index value allocated by the BGP software. The value generated by the **rd auto** command keeps unchanged after generation, and it remains unchanged even if the BGP router-ID changes.
- An EVI instance can be configured with multiple imported and exported RT values.
- The automatically generated RT value is in the format of AS2:nn. In the format, "AS2" indicates the 2-byte AS number. If a 4-byte AS number is used, it is truncated to two bytes and then placed in the RT value; "nn" indicates the VNI-ID, which occupies four bytes and can fully accommodate the complete the VNI-ID value.
- If the BGP AS number changes, the automatically generated RT value also changes.
- If the manually configured RT value is the same as the automatically generated RT value, both values are displayed.
- Automatically generated RT values cannot be deleted even if you configure an RT value deletion command. Instead, you need to run the **unset route-target auto** command to delete the configuration.
- The routing policy in an EVI supports only one **route-map**, and the new configuration will overwrite the earlier configuration if multiple route maps are configured.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the EVPN function and enter the EVPN configuration mode.

evpn

The EVPN function is disabled by default.

(4) Enter the EVI configuration mode. Configure one of the following tasks.

- Create an EVI.
  - **vni** *vni-id*
  - No EVI is configured by default.
- Create EVIs in batches.
  - **vni range** *vni-id-list*

(5) Configure an RD.

rd { **auto** | *rd-value* }

No RD is configured for an EVI by default.

(6) Configure an RT.

routing-target { **both** | **import** | **export** } { **auto** | *rt-value* }

No RT value is configured for an EVI instance by default.

(7) (Optional) Configure a routing policy for the EVI. Configure one of the following tasks.

- Configure policy rules for extended community attributes of EVPN routes distributed from the local end to the remote end.
  - **export map** *route-map-name*
  - No policy rule is configured by default for extended community attributes of EVPN routes distributed from the local end to the remote end.
- Filter out remote EVPN routes that are imported to the local VNI instance, or modify the attribute of the remote EVPN routes to be imported to the local VNI instance.
  - **import map** *route-map-name*
  - No routing policy rule is configured for importing remote EVPN routes to the local VNI by default.

(8) (Optional) Configure the EVPN Type 5 route mode.

ip-prefix model { **interface-less** | **interface-full** { **sbd-irb** | **unnumber-sbd-irb** } }

By default, EVPN Type 5 routes support the Interface-Less mode.

1.9.3 Configuring EVPN

1. Overview

This section describes how to configure a policy related to the L2VPN EVPN address family.

2. Restrictions and Guidelines

- Mobility may occur on one MAC address many times. When a provider edge router (PE) detects an MAC address mobility event through local learning, it will start a timer of *mac-mobility-interval* (the default value is **180** seconds). If the number of detected MAC address mobility events exceeds the value of *mac-mobility-threshold* (the default value is **5**) before the timer times out, it is considered that a MAC address conflict occurs. After a MAC address conflict occurs, the EVPN route corresponding to the MAC address is not advertised to a neighbor and a delay recovery timer with the value of *retry-timer* (**180** seconds by default) is started. When the timer expires, the MAC address conflict is deleted and the EVPN route

corresponding to the MAC address is advertised again.

- Generally, the inner MAC address of an EVPN packet is the router MAC address of the egress gateway. You can also modify attributes to configure the anycast MAC address as the inner MAC address of EVPN packets.
- If the VNI instance, to which an EVPN route belongs, has no corresponding VNI instance on the local device, the modified attributes do not take effect.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Create a BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

(5) Configure the L2VPN EVPN address family mode.

address-family-mode l2vpn evpn

BGP neighbors are not allowed to exchange L2VPN information by default.

(6) Activate the EVPN capability for the BGP neighbor.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **activate**

The EVPN address family is disabled by default.

(7) (Optional)Configure MAC mobility detection parameters.

bgp-instance mac-mobility *mac-mobility-interval mac-mobility-threshold* [*retry-timer*]

By default, the timer time of MAC address move detection is set to **180** seconds, the detection times is **5**, and the delayed timer time of MAC conflict restoration is **180** seconds.

(8) (Optional)Set the router MAC attribute of EVPN routing information to the router MAC address or anycast MAC address of the local device for EVPN VXLAN scenarios across data centers.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **router-mac-self**

The router MAC attribute of EVPN routes is not modified when the routes are distributed to a specified BGP peer by default.

(9) (Optional) Configure to advertise only VNI Mapping table entries to a specified peer.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **send-mapping-only**

By default, advertising only VNI Mapping table entries to a specified peer is not configured.

Note

This command is not supported by the S6980-64QC, S6920-4C, or S6580-24DC8QC switch.

(10) (Optional) Configure to redistribute IPv4 unicast route.

advertise ipv4 unicast-af-modifier

Redistributing IPv4 unicast route is not configured by default.

(11) Configure to redistribute IPv6 unicast route.

advertise ipv6 unicast-af-modifier

Redistributing IPv6 unicast route is not configured by default.

1.10 Configuring BGP Neighbor Auto-Discovery

1.10.1 Configuration Tasks

The BGP neighbor auto-discovery configuration includes the following tasks:

- Configuring BGP Neighbor Auto-Discovery
- Configuring Interface Neighbor Auto-Discovery

1.10.2 Configuring BGP Neighbor Auto-Discovery

1. Overview

This section describes how to configure BGP neighbor auto-discovery.

2. Restrictions and Guidelines

- If an auto-discovered neighbor conflicts with a common neighbor or network segment neighbor, retain the neighbor based on the priority. Priorities: Common neighbor > auto-discovered neighbor > network segment neighbor.
- The **peer update-source** command cannot be configured for neighbor groups used by interfaces.
- Interfaces with BGP neighbor auto-discovery enabled send BGP hello packets and learn peer routes through negotiation. The **distance** command is used to change the administrative distance of routes discovered by the BGP auto-discovery mechanism.
- You can run **exit**-**auto-discovery** command to exit the BGP neighbor auto-discovery configuration mode.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Create a BGP neighbor group.

peer *peer-group-name* **peer-group**

The neighbor group is used when a neighbor is created for an interface.

(5) Enable the neighbor auto-discovery function and enter the neighbor auto-discovery configuration mode.

auto-discovery

The neighbor auto-discovery function is disabled by default.

(6) (Optional) Configure the remote neighbor AS number list acceptable by BGP neighbor auto-discovery.

accept-as-list *as-list*

By default, there is no restriction on the remote neighbor AS number list acceptable by BGP neighbor auto-discovery.

(7) (Optional) Configure the administrative distance for routes learned through auto-discovery.

distance *distance*

The default administrative distance of a route learned through auto-discovery is **18**.

1.10.3 Configuring Interface Neighbor Auto-Discovery

1. Overview

This section describes how to configure interface neighbor auto-discovery.

2. Restrictions and Guidelines

- Neighbor auto-discovery can be configured only on the L3 interfaces and cannot be configured on loopback interfaces.
- Neighbor auto-discovery can take effect on an interface only after an IPv4/IPv6 address or the **ipv6 enable** command is configured for the interface.
- *as-number* must be the same as the AS number of a BGP instance.
- The **peer update-source** command cannot be configured on a specified peer group of an interface.
- IBGP and EBGP neighbors need to use different peer groups.
- The value of *hello-interval* cannot be greater than 1/3 of the value of *hold-time*.
- When *hold-time* of hello packets is up, the BGP auto-discovered peer disconnects the session.
- When **source-interface** is set to a loopback interface, the IPv6 address sent to the peer for establishing a session uses the smallest IPv6 address configured for the loopback interface. After a large IPv6 address has been configured for the loopback interface and the peer has used the address to establish a BGP session, if a small IPv6 address is configured for the loopback interface, the auto-discovery mechanism sends the small IPv6 address to the peer. Then, the peer uses the small IPv6 address to establish a BGP session and deletes the previously auto-discovered neighbor.
- When **source-interface** is set to **source-self**, the IPv6 address sent to the peer for establishing sessions is the IPv6 LinkLocal address of the interface to establish sessions with the peer.
- When *source-interface* is set to a loopback interface and the loopback interface uses an IPv4 address, the layer 3 interface needs to use the IPv4 address or the IPv6 address (**ipv6 enable** *and* **ip l3protocol default-up**)

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure a local AS number for the BGP auto-discovered peer.

bgp-instance auto-discovery local-as *as-number*

No local AS number is configured for BGP auto-discovered peers by default.

(5) Configure the source interface and peer group to be used for establishing a BGP connection with a peer.

bgp-instance auto-discovery source-interface { *interface-type interface-number* | **source-self** } **peer-group** *peer-group-name* [**ipv4** | **ipv6**]

By default, no source interface or peer group is specified for establishing a BGP connection with a peer.

(6) (Optional) Configure the timer duration of the BGP neighbor auto-discovery.

bgp-instance auto-discovery hello-period *hello-interval* **hold-time** *hold-time*

The default interval for BGP to send hello messages is **15** seconds and the default hold time is **180** seconds.

1.11 Configuring BGP Extended Features

1.11.1 Configuration Tasks

The configuration of BGP extended functions includes the following tasks: All configuration tasks are optional and may be selected as needed.

- Configuring BMP Monitoring
- Configuring BGP Administrative Distance
- Configuring Enhanced VPN
- Configuring BGP Link-State

1.11.2 Configuring BMP Monitoring

1. Overview

After BMP monitoring is configured, BMP is monitored by the BMP server, which focuses on the status of BGP peers, peer entry transmission and receiving, and all kinds of peer statistics.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure neighbor to be monitored by the specified BMP server.

peer { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **bmp-active** { **all** | **server** *server-number*&<1-8> }

BGP peers are not monitored by the BMP server by default.

3. Configure BMP server instances.

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a BMP server instance.

bmp server *server-number*

(4) Configure the address and port number of the BMP server.

address [*bmp-server-ipv4-address* | *bmp-server-ipv6-address*] **port** *port-number*

The address and port number of the BMP server are not configured in BMP mode by default.

(5) Configure the MD5 authentication password for establishing a TCP connection with the BGP server.

password [**0** | **7**] *string*

By default, the MD5 authentication password for TCP connections to the BGP server is not configured.

(6) Configure an outbound interface for establishing a TCP connection with the BMP server.

update-source *interface-type interface-number*

The system automatically selects the outbound interface for a TCP connection based on the IP address of the BMP server by default. The outbound interface of local packets is generally used.

(7) Configure the VRF instance, to which a TCP connection to the BMP server belongs.

vrf *vrf-name*

A TCP connection is established with the BMP server in the default VRF instance by default.

(8) (Optional) Configure the interval for re-establishing a TCP connection with the BMP server.

bmp-reconnect-delay *time*

The interval for reconnecting to the BMP server gradually increases from the initial **30** seconds by default.

(9) (Optional) Configure a description for the BMP server instance.

description *text*

No description is configured for a BMP server instance by default.

(10) Configure the BMP server to monitor routes that are received from peers and have a routing policy applied.

adj-rib-in post-policy

The BMP server does not monitor routes that are received from a BGP peer and have a routing policy applied by default.

(11) Configure the BMP server to monitor routes that are received from a peer and are not renamed.

adj-rib-in pre-policy

The BMP server does not monitor routes that are received from a BGP peer and are not renamed by default.

(12) Configure the BMP server to monitor routes that are sent to a peer and have a routing policy applied.

adj-rib-out post-policy

The BMP server does not monitor routes that are sent to a BGP peer and have a routing policy applied by default.

(13) Configure the BMP server to monitor routes that are sent to a peer before a routing policy is applied.

adj-rib-out pre-policy

The BMP server does not monitor routes that are sent to a BGP peer before a routing policy is applied by default.

(14) Configure the monitoring of local-rib routes for IPv4 or IPv6.

local-rib { **ipv4** | **ipv6** } **unicast-af-modifier** [**vrf** *vrf-name*] [**add-paths**] [**route-map** *map-tag*]

The BMP server does not monitor local-rib routes for IPv4 or IPv6 by default.

(15) Enable the packet mirroring function of BGP.

route mirroring

The BMP server does not send route mirroring packets by default.

(16) Configure the interval for BMP server to send status statistics.

stats-reporting-period *time*

When status statistics of a monitored peer are changed, BMP delays a period of time in sending the status statistics to the BMP server by default.

(17) (Optional) Configure the maximum number of cached packet bytes of a BMP instance.

buffer-size *buffer-size-maximum* [**warning**]

1.11.3 Configuring BGP Administrative Distance

1. Overview

The administrative distance is used to evaluate the reliability of various route sources. A smaller administrative distance indicates a better route.

- Administrative distance of BGP

  The administrative distance indicates the reliability of a route source. The value range is from 1 to 255. A larger administrative distance indicates a lower route reliability. BGP sets different administrative distances for sources, from which routing information is learned. Administrative distances are classified into external-distances, internal-distances, and local-distances.

  - External-distance: Indicates the administrative distances of routes learned from EBGP peers.
  - Internal-distance: Indicates the administrative distances of routes learned from IBGP peers.
  - Local-distance: Indicates the administrative distances of routes learned from peers but it is considered that better routes can be learned from IGP. Generally, these routes can be indicated by the **network-advertise backdoor-route** command.

- Backdoor route

  If you prefer an IGP route without using this EBGP route, you can configure this EBGP route as the backdoor route. The default administrative distance of routes learned from a BGP speaker that has established an EBGP connection is **20**. You can run the **network-advertise backdoor-route** command to set the administrative distance of EBGP routes to 200 so that routes learned from IGP have a higher priority. Routes learned from IGP are considered as backdoor routes and are not advertised externally.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable BGP to enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Configure the administrative distance of a BGP route.

distance bgp *external-distance internal-distance local-distance*

The default administrative distance of a route learned by BGP from an EBGP peer is **20** and that of a route learned by BGP from an IBGP peer is **200**.

(5) Configure a backdoor route.

network-advertise *network-number* [**mask** *mask*] [**route-map** *map-tag*] **backdoor-route**

No backdoor route is configured by default.

1.11.4 Configuring Enhanced VPN Route Import

1. Overview

By default, when VRF routes are imported into each other, L3VPN remote routes are imported into VRF, or EVPN routes are imported into the IP routing table, only the routes with a preferred next hop are imported. If the enhanced VPN route importing function is configured, all next-hop routes or equal-cost next-hop routes can be imported. The imported routes can realize ECMP multi-path load sharing.

2. Restrictions and Guidelines

- IBGP routes and EBGP routes cannot be equal-cost routes.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) (Optional) Enter the corresponding address family configuration mode. Configure one of the items below for a specific address family.

(5) Enter the IPv4 unicast configuration mode.

address-family-mode ipv4 [**unicast**]

(6) Enter the IPv4 VRF configuration mode.

address-family-mode ipv4 vrf *vrf-name*

(7) Enter the IPv6 unicast configuration mode.

address-family-mode ipv6 [**unicast**]

(8) Enter the IPv6 VRF configuration mode.

address-family-mode ipv6 vrf *vrf-name*

(9) Configure the route import policy.

import route strategy { **all** | **optimal-path** | **multipath** }

By default, only preferred routes are imported.

1.11.5 Configuring BGP Link-State

1. Overview

BGP Link-State can collect link state information and summarize it to the controller.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the BGP protocol, and enter the BGP configuration mode.

router-protocol bgp *as-number*

(4) Allow BGP neighbors to interact routing information with each other, and enter the Link-State address family configuration mode.

address-family-mode link-state [**unicast**]

By default, the Link-State address family is not configured.

(5) Configure the AS field and Router ID field in the LS table entries advertised by BGP.

domain-distinguisher *ipv4-address:nn*

By default, the AS field and Router ID field in the LS table entries advertised by BGP are the current AS number and Router ID of BGP.

1.12 Monitoring

Run the display commands to check the running status of a configured function to verify the configuration effect.

Run the cleanup commands to clear information.

⚠ Caution

Run the **cleanup** command during operation of the device may lose vital information and interrupt services.

Run the debugging commands to output debugging information.

⚠ Caution

The output debugging information occupies system resources. Therefore, disable the debugging switch immediately after use.

Table 1-3 Monitoring

Command	Purpose
cleanup bgp-instance all [*as-number*] [**soft**] [**inbound** | **outbound**]	Restores the priority of the route advertised by BGP to the neighbor to the priority before it is adjusted to the lowest priority.
cleanup bgp-instance all peer-group *peer-group-name* [**soft**] [**inbound** | **outbound**]	Clears all address families of BGP.
cleanup bgp-instance all peer-group *peer-group-name* [**soft**] [**inbound** | **outbound**]	Clears a specified peer group in BGP.
cleanup bgp-instance all update-group-info [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**soft**] [**inbound** | **outbound**]	Clears sessions of all members in the update group.
cleanup bgp-instance ipv4 unicast-af-modifier [**vrf** vrf-name] { ***** | *as-number* | *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**soft**] [**inbound** | **outbound**] **cleanup ip bgp-instance** [**vrf** *vrf-name*] { ***** | *as-number* | *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**soft**] [**inbound** | **outbound**]	Clears specified sessions of BGP IPv4 unicast address family.
cleanup bgp-instance ipv4 unicast-af-modifier [**vrf** *vrf-name*] **damp** [*ipv4-address* [*mask*] **cleanup ip bgp-instance** [**vrf** *vrf-name*] **damp** [*ipv4-address* [*mask*]	Clears IPv4 unicast address family damping information and route suppression.
cleanup bgp-instance ipv4 unicast-af-modifier [**vrf** *vrf-name*] **external** [**soft**] [**inbound** | **outbound**] **cleanup ip bgp-instance** [**vrf** *vrf-name*] **external** [**soft**] [**inbound** | **outbound**]	Clears EBGP connections of all IPv4 unicast address families.
cleanup bgp-instance ipv4 unicast-af-modifier [**vrf** *vrf-name*] **flap-statistics** [ipv4-*address* [*mask*] **cleanup ip bgp-instance** [**vrf** *vrf-name*] **flap-statistics** [*ipv4-address* [*mask*]	Clears routing flap statistics of the IPv4 unicast address family.
cleanup bgp-instance ipv4 unicast-af-modifier [**vrf** *vrf-name*] **peer-group** *peer-group-name* [**soft**] [**inbound** | **outbound**] **cleanup ip bgp-instance** [**vrf** *vrf-name*] **peer-group** *peer-group-name* [**soft**] [**inbound** | **outbound**]	Clears sessions of all members in the IPv4 unicast address family peer group.

cleanup bgp-instance ipv4 unicast-af-modifier [**vrf** *vrf-name*] **table-map** **cleanup ip bgp-instance** [**vrf** *vrf-name*] **table-map**	Clears and updates the Table-map settings of BGP IPv4 unicast address family.
cleanup bgp-instance ipv4 unicast-af-modifier [**vrf** *vrf-name*] **update-group** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**soft**] [**inbound** | **outbound**] **cleanup ip bgp-instance** [**vrf** *vrf-name*] **update-group-info** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**soft**]] [**inbound** | **outbound**]	Clears sessions of all members in the update group of the IPv4 unicast address family.
cleanup bgp-instance ipv6 unicast-af-modifier [**vrf** *vrf-name*] { ***** | *as-number* | *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**soft**] [**inbound** | **outbound**]	Clears specified sessions of BGP IPv6 unicast address family.
cleanup bgp-instance ipv6 unicast-af-modifier [**vrf** *vrf-name*] **damp** [*ipv6-address/prefix-length*]	Clears IPv6 unicast address family damping information and route suppression.
cleanup bgp-instance ipv6 unicast-af-modifier [**vrf** *vrf-name*] **external** [**soft**] [**inbound** | **outbound**]	Clears EBGP connections of all IPv6 unicast address families.
cleanup bgp-instance ipv6 unicast-af-modifier [**vrf** *vrf-name*] **flap-statistics** [*ipv6-address/prefix-length*]	Clears routing flap statistics of the IPv6 unicast address family.
cleanup bgp-instance ipv6 unicast-af-modifier [**vrf** *vrf-name*] **peer-group** *peer-group-name* [**soft**] [**inbound** | **outbound**]	Clears sessions of all members in the IPv6 unicast address family peer group.
cleanup bgp-instance ipv6 unicast-af-modifier [**vrf** *vrf-name*] **table-map**	Clears and updates the Table-map settings of BGP IPv6 unicast address family.
cleanup bgp-instance ipv6 unicast-af-modifier [**vrf** *vrf-name*] **update-group** [*neighbor-ipv4-address* | *neighbor-ipv6-addres* | *update-group-index*] [**soft**] [**inbound** | **outbound**]	Clears sessions of all members in the update group of the IPv6 unicast address family.
cleanup bgp-instance l2vpn evpn-af-modifier { ***** | *as-number* | *neighbor-ipv4-address* | *neighbor-ipv6-addres* } [**soft**] [**inbound** | **outbound**]	Clears specified sessions of L2VPN EVPN address family.
cleanup bgp-instance l2vpn evpn-af-modifier damp	Clears L2VPN EVPN address family damping information and route suppression.
cleanup bgp-instance l2vpn evpn-af-modifier external [**soft**] [**inbound** | **outbound**]	Clears EBGP connections of all L2VPN EVPN address families.

cleanup bgp-instance l2vpn evpn-af-modifier flap-statistics	Clears routing flap statistics of the L2VPN EVPN address family.
cleanup bgp-instance l2vpn evpn-af-modifier peer-group *peer-group-name* [**soft**] [**inbound** | **outbound**]	Clears sessions of all members in the L2VPN EVPN address family peer group.
cleanup bgp-instance l2vpn evpn-af-modifier update-group [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**soft**] [**inbound** | **outbound**]	Clears sessions of all members in the update group of the L2VPN EVPN address family.
cleanup evpn conflict mac [*vni-id*]	Clears EVPN conflict MAC address information.
cleanup bgp-instance link-state unicast-af-modifier { ***** | *as-number* | *neighbor-ipv4-address* | *neighbor-ipv6-addres* } [**soft**] [**inbound** | **outbound**]	Clears specified sessions of the Link-State address family.
cleanup bgp-instance link-state unicast-af-modifier external-type [**soft**] [**inbound** | **outbound**]	Clears EBGP connections of all Link-State address families.
cleanup bgp-instance link-state unicast-af-modifier ls-srv	Clears LS server connections of the Link-State address family.
cleanup bgp-instance link-state unicast-af-modifier peer-group *peer-group-name* [**soft**] [**inbound** | **outbound**]	Clears sessions of all members in the Link-State address family peer group.
cleanup bgp-instance link-state unicast-af-modifier update-group [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**soft**] [**inbound** | **outbound**]	Clears sessions of all members in the update group of the Link-State address family.
cleanup bmp { **all** | **server** *server-number* }	Clears BMP protocol.

display bgp-instance all [**aggregate** | **community** [*community-number*&<1-n> [**match**]] | **comm-type-list** *community-name* [**match**] | **extend-comm-list** *extcommunity-name* [**match**] | **filter-rule-list** *path-list-number* | **inconsistent-as** | **quoted-regular-expression** *regexp* | **regexp** *regexp*] **display bgp-instance all damp** { **damp-paths** | **flap-statistics** | **arguments** } **display bgp-instance all peers**[{ *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**advertised-routes** [**check**] | **ha-mode** [**adj-in** [**detail**] | **adj-out**] | **hide-info** | **policy-based** [**detail**] | **received-routes** | **routes**]] **display bgp-instance all paths** **display bgp-instance all status** **display bgp-instance all update-group** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**ha-mod adj-out** | **status**]	Displays all BGP routing information.
display bgp-instance auto-discovery [**interface** *interface-type interface-number*]	Displays BGP neighbor auto-discovery information.
display bgp-instance bmp { **peer** | **server** [*server-number*] [**detail**] | **status** }	Displays BMP server information.
display bgp-instance develop { **attr** { **color-nexthop** | **prefix-sid** } | **bgp-instance** | **cap** | **connected** | **evi-rd-hash** | **ifx-link-group** | **interface nd** [*ifx-number* [*mac-address*]] | **io-process** [**log-info** | **log-warn** | **master** | **memory** | **peer** [*neighbor-ipv4-address* [*vrf-name*] | *neighbor-ipv6-address* [*vrf-name*] | *peer-id*]] | **link-state-group** | **mom** | **peer-as** | **pic-info** | **route-shake** | **segment-routing policy** [**color** *color-number*] [**endpoint** *endpoint-address*] | **segment-routing ipv6 local-sid** [**sid** *sid-address*] | **segment-routing ipv6 local-sid-retry** | **thread** | **unspec-instance-redist-conf** | **vr** | **vrf-rd-hash** }	Displays BGP development information.
display bgp-instance evpn-af-modifier [**evi** [*vni-id*] | **evi-hash** | **local-mac** [*vni-id*] [**detail**] | **remote-mac** [*vni-id*] [**detail**] | **route-list** { **ethernet-ad** | **ethernet-segment** | **inclusive-multicast** } [*vni-id*] | **share-ip** [*vni-id*] [**detail**] | **status** | **vtep-nbr** [*vni-id*]]	Displays EVPN related information.
display bgp-instance grst { **bfd** | **evi** | **label** | **label-set** | **mdc** | **peer-info** | **status** }	Displays GR related information.
display bgp-instance hash-peer	Displays Hash tables of all neighbors.

display bgp-instance link-state unicast-af-modifier damp { **damp-paths** | **flap-statistics** | **arguments** } **display bgp-instance link-state unicast-af-modifier** [**detail** [*prefix-string*] | **ls-client** | **status**] **display bgp-instance link-state unicast-af-modifier peers**[{ *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**advertised-routes** [**check**] | **ha-mode** { **adj-in** [**detail**] | **adj-out** } | **hide-info** | **policy** [**detail**] | **received-routes** | **routes**]] **display bgp-instance link-state unicast-af-modifier update-group** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**ha-mod adj-out** | **status**]	Displays specific routes of BGP Link-State address family.
display bgp-instance log-info	Displays BGP logs.
display bgp-instance log-warn	Displays BGP alarms.
display bgp-instance memory	Displays BGP memory.
display bgp-instance nsr [**info** | **sock-cb** [*sock-cb-id*] | **sock-list** | **status**]	Displays NSR related information.
display bgp-instance route-block	Displays black-hole route statistics.
display bgp-instance rpi { **acl** [**detail** [*acl-name*]] | **as-access-list** | **comm-type-list** | **extend-comm--list** | **ip-prefix-list** | **ipv6-prefix-list** | **route-map** }	Displays RPI policy related information.
display bgp-instance statistics [**vrf** *vrf-name*]	Displays BGP statistics.
display evpn [*vni-id]* [**detail**]	Displays configured EVI instances.

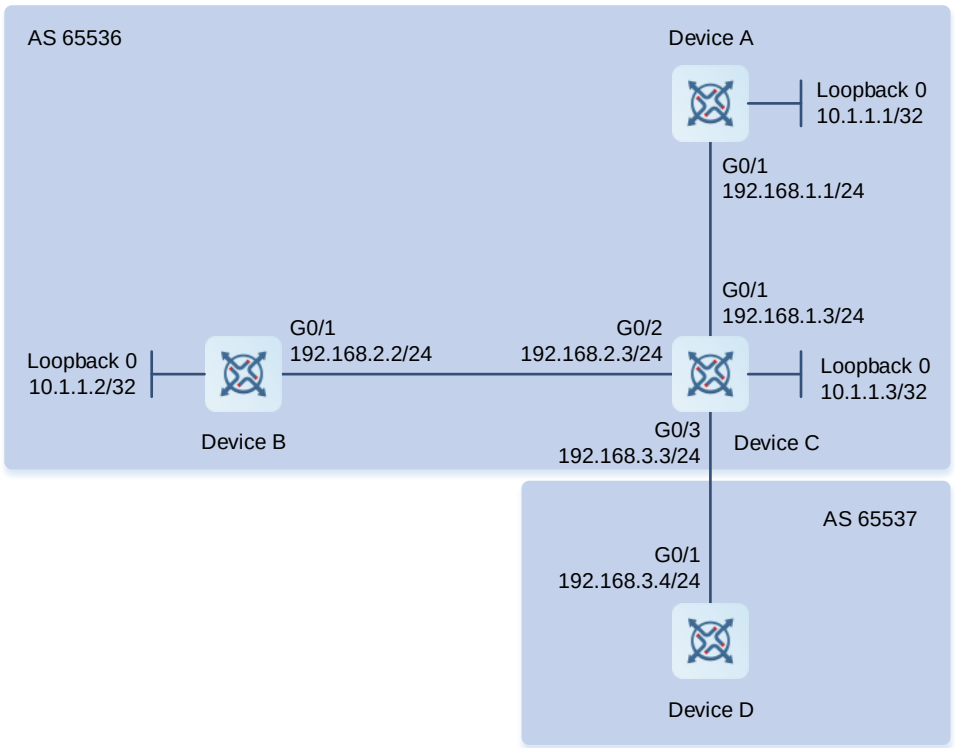
display evpn mac { **conflict** | **mobility** } [*vni-id*]	Displays MAC addresses mobility and conflicts.
display ip bgp-instance [*prefix-ipv4-address* [*network-mask* [**longer-prefixes**]] | **aggregate** | **cidr-only** | **community** [*community-number*&<1-n> [**match**]] | **comm-type-list** *community-name* [**match**] | **extend-comm-list** *extcommunity-name* [**match**] | **filter-rule-list** *path-list-number* | **global-vrf detail** | **inconsistent-as** | **labels** | **prefix-list** *ip-prefix-list-name* | **quoted-regular-expression** *regexp* | **regexp** *regexp* | **route-map** *map-tag*] **display ip bgp-instance vrf** *vrf-name* [*prefix-ipv4-address* [*network-mask* [**longer-prefixes**]] | **aggregate** | **cidr-only** | **community** [*community-number*&<1-n> [**match**]] | **comm-type-list** *community-name* [**match**] | **detail** [**all**] | **extend-comm-list** *extcommunity-name* [**match**] | **filter-rule-list** *path-list-number* | **inconsistent-as** | **prefix-list** *ip-prefix-list-name* | **quoted-regular-expression** *regexp* | **regexp** *regexp* | **route-map** *map-tag*]] **display ip bgp-instance** [**vrf** *vrf-name*] **damp** { **damp-paths** | **flap-statistics** | **arguments** } **display ip bgp-instance** [**vrf** *vrf-name*] **neighbors** [{ *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**advertised-routes** [**check**] | **ha-mode** [**adj-in** [**detail**] | **adj-out**] | **hide-info** | **policy** [**detail**] | **received-routes** | **routes**]] **display ip bgp-instance** [**vrf** *vrf-name*] **paths** **display ip bgp-instance** [**vrf** *vrf-name*] **status** **display ip bgp-instance** [**vrf** *vrf-name*] **update-group** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**ha-mod adj-out** | **status**] **display ip bgp-instance scan** [**detail**]	Displays routes in BGP IPv4 unicast address family.
display bgp key-chain [*keychain-name*]	Displays BGP Key-chain information.
debugging ip bgp all	Debugs BGP.
debugging ip bgp auto-discovery	Debugs BGP neighbor auto-discovery.
debugging ip bgp bmp	Debugs BGP BMP.
debugging ip bgp damp	Debugs BGP route dampening.

debugging ip bgp event-info **debugging ip bgp event-infoagg** **debugging ip bgp event-infofrr** **debugging ip bgp event-infogrst** **debugging ip bgp event-infois** **debugging ip bgp event-infomsg** **debugging ip bgp event-infonexthop** **debugging ip bgp event-infoscan** **debugging ip bgp event-infothread**	Debugs BGP even handling.
debugging ip bgp filters	Debugs BGP route filtering.
debugging ip bgp fsm	Debugs BGP state machine.
debugging ip bgp keepalives	Debugs BGP neighbor keepalive.
debugging ip bgp mpls	Debugs BGP MPLS processing.
debugging ip bgp nsm	Debugs BGP core route processing.
debugging ip bgp update-info **debugging ip bgp update-infoin** **debugging ip bgp update-infoout**	Debugs BGP UPDATE message.
debugging ip bgp evpn	Debugs BGP EVPN.
debugging ip bgp vxlan	Debugs BGP VXLAN interaction.
debugging ip bgp update-group-info	Debugs BGP UPDATE-GROUP debugging switch.
debugging ip bgp alternative-paths	Debugs BGP ADD-PATH.
debugging ip bgp mbgp	Debugs MBGP routes sent by BGP to NSM.
debugging ip bgp CLI	Debugs BGP CLI commands.

debugging ip bgp debug address-family-mode link-state link-state **debugging ip bgp debug address-family-mode l2vpn evpn** **debugging ip bgp debug address-family-mode vpnv4 unicast-af-modifier** **debugging ip bgp debug address-family-mode vpnv6 unicast-af-modifier** **debugging ip bgp-instance info-filter address-family-mode ipv6 unicast-af-modifier** **debugging ip bgpdebug address-family-mode ipv4 unicast-af-modifier** **debugging ip bgp debug as** *as-number* **debugging ip bgp debug update-group-info** *update-group-index* **debugging ip bgp debug route-map** *map-tag* **debugging ip bgp debug srp-prefix** *srp-prefix* **debugging ip bgp idebug ls-prefix** *ls-prefix* **debugging ip bgp debug prefix** *prefix-address* **debugging ip bgp debug peer** [*neighbor-ipv4-address* | *neighbor-ipv6-address*] **debugging ip bgp info-filter ifx**	Debugs information filtering of BGP.
debugging ip bgp segment-routing	Debugs BGP SR.
debugging ip bgp sr-policy	Debugs BGP SR policies.
debugging ip bgp monitor	Debugs the BGP monitor.
debugging ip bgp ipc-msg	Debugs BGP IPC information.
debugging ip bgp pic	Debugs BGP PIC information.
debugging ip bgp bmp-fsm	Debugs BGP BMP state machine.
debugging ip bgp time-stat	Debugs the BGP timer.
debugging ip bgp dump-file	Debugs BGP and saves information to a file.
debugging ip bgp warn	Debugs BGP alarms.
debugging ip bgp fsm-trace	Debugs state machine stack information of BGP.

debugging ip bgp link-state-af **debugging ip bgp link-state-af srv6-sid-info** **debugging ip bgp link-state-af prefix-info** **debugging ip bgp link-state-af link-info** **debugging ip bgp link-state-af node-info**	Debugs link-state address family information of BGP.
debugging ip bgp rpi	Debugs BGP RPI.
debugging ip bgp show	Debugs BGP show information.
debugging ip bgp sock-cb warn **debugging ip bgp sock-cb event**	Debugs BGP SOCK-CB.

1.13 Configuration Examples



1.13.1 Configuring BGP Basic Networking

1. Requirements

BGP speakers need to establish IBGP neighbor relationships and EBGP neighbor relationships to implement basic networking.

2. Topology

Figure 1-2 Configuring BGP Basic Networking

3. Notes

- Enable BGP on all devices and set AS numbers for the devices as shown in Figure 1-2 (omitted).
- Configure a loopback interface on each of Devices A, B, and C, which establish IBGP neighbor relationships through the loopback interfaces.
- Configure Devices C and D to establish an EBGP neighbor relationship through directly connected interfaces.
- Create an IBGP peer group on Device C.

4. Procedure

(1) Configure loopback interfaces and IP addresses for the interfaces.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# interface loopback 0
Device A(cfg-if-Loopback 0)# ip address 10.1.1.1 255.255.255.255
Device A(cfg-if-Loopback 0)# exit
Device A(cfg)# interface GigabitEthernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/1)# exit
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# interface loopback 0
Device B(cfg-if-Loopback 0)# ip address 10.1.1.2 255.255.255.255
Device B(cfg-if-Loopback 0)# exit
Device B(cfg)# interface GigabitEthernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/1)# exit
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# interface loopback 0
Device C(cfg-if-Loopback 0)# ip address 10.1.1.3 255.255.255.255
Device C(cfg-if-Loopback 0)# exit
Device C(cfg)# interface GigabitEthernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.3 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/1)# exit
Device C(cfg)# interface GigabitEthernet 0/2
Device C(cfg-if-GigabitEthernet 0/2)# ip address 192.168.2.3 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/2)# exit
Device C(cfg)# interface GigabitEthernet 0/3
Device C(cfg-if-GigabitEthernet 0/3)# ip address 192.168.3.3 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/3)# exit
```

Configure Device D.

```
Device D# config-system terminal
Device D(cfg)# interface GigabitEthernet 0/1
```

```
Device D(cfg-if-GigabitEthernet 0/1)# ip address 192.168.3.4 255.255.255.0
Device D(cfg-if-GigabitEthernet 0/1)# exit
```

(2) Enable BGP and configure the loopback interfaces as neighbor interfaces.

Configure Device A.

```
Device A(cfg)# router-protocol bgp 65536
Device A(cfg-router)# peer 10.1.1.3 remote-as 65536
Device A(cfg-router)# peer 10.1.1.3 update-source loopback 0
```

Configure Device B.

```
Device B(cfg)# router-protocol bgp 65536
Device B(cfg-router)# peer 10.1.1.3 remote-as 65536
Device B(cfg-router)# peer 10.1.1.3 update-source loopback 0
```

Configure Device C.

```
Device C(cfg)# router-protocol bgp 65536
Device C(cfg-router)# peer ibgp-group peer-group
Device C(cfg-router)# peer ibgp-group remote-as 65536
Device C(cfg-router)# peer ibgp-group update-source loopback 0
Device C(cfg-router)# peer 10.1.1.1 peer-group ibgp-group
Device C(cfg-router)# peer 10.1.1.2 peer-group ibgp-group
Device C(cfg-router)# peer 192.168.3.4 remote-as 65537
```

Configure Device D.

```
Device D(cfg)# router-protocol bgp 65537
Device D(cfg-router)# peer 192.168.3.3 remote-as 65536
```

5. Verification

On Device A, run the **display ip bgp-instance peer** command to display the BGP neighbor status. By viewing the BGP neighbor status displayed in the BGP state in the corresponding neighbor table, you can verify whether the device has successfully established a BGP connection with the neighbor. The value Established indicates that the connection has been successfully established, and the value Active indicates that the neighbor has been activated but a connection has not yet been established.

```
Device A# display ip bgp-instance peer
BGP peer is 10.1.1.3, remote AS 65536, local AS 65536, internal link
  BGP version 4, remote router ID 10.1.1.3
  BGP state = Established, up for 00:00:05
  Last read          00:00:04, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received (old and new)
    Four-octets ASN Capability: advertised and received
    Address family IPv4 Unicast: advertised and received
  Received 2 messages, 0 notifications, 0 in queue
    open message:1 update message:0 keepalive message:1
    refresh message:0 dynamic cap:0 notifications:0
  Sent 2 messages, 0 notifications, 0 in queue
    open message:1 update message:0 keepalive message:1
    refresh message:0 dynamic cap:0 notifications:0
```

```
  Route refresh request: received 0, sent 0
  Minimum time between advertisement runs is 0 seconds
  Update source is Loopback 0

 For address family: IPv4 Unicast
  BGP table version 1, peer version 1
  Index 0, Offset 0, Mask 0x1
  0 accepted prefixes
  0 announced prefixes

 Connections established 1; dropped 0
Local host: 10.1.1.1, Local port: 1039
Foreign host: 10.1.1.3, Foreign port: 179
Nexthop: 10.1.1.1
Nexthop global: ::
Nexthop local: ::
BGP connection: non shared network
Last Reset:             00:00:09, due to BGP Notification received
Notification Error Message: (Cease/Other Configuration Change.)
```

On Device B, run the **display** command to display the BGP neighbor status.

```
Device B# display ip bgp-instance peer
BGP peer is 10.1.1.3, remote AS 65536, local AS 65536, internal link
  BGP version 4, remote router ID 10.1.1.3
  BGP state = Established, up for 00:00:07
  Last read             00:00:05, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received (old and new)
    Four-octets ASN Capability: advertised and received
    Address family IPv4 Unicast: advertised and received
  Received 2 messages, 0 notifications, 0 in queue
    open message:1 update message:0 keepalive message:1
    refresh message:0 dynamic cap:0 notifications:0
  Sent 2 messages, 0 notifications, 0 in queue
    open message:1 update message:0 keepalive message:1
    refresh message:0 dynamic cap:0 notifications:0
  Route refresh request: received 0, sent 0
  Minimum time between advertisement runs is 0 seconds
  Update source is Loopback 0

 For address family: IPv4 Unicast
  BGP table version 1, peer version 1
  Index 0, Offset 0, Mask 0x1
  0 accepted prefixes
  0 announced prefixes

 Connections established 1; dropped 0
```

```
Local host: 10.1.1.2, Local port: 1041

```

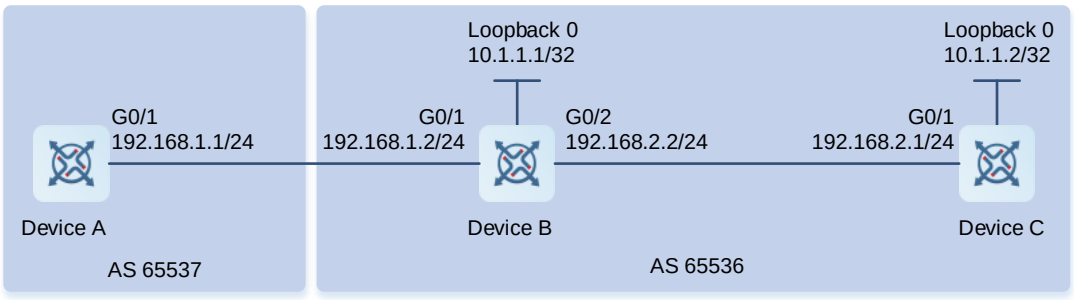
7. Common Errors

- IGP is disabled and the local loopback address and the loopback address of an IBGP neighbor cannot interwork with each other, resulting in the failure to establish a neighbor relationship.
- When EBGP neighbors are not directly connected, **ebgp-multihop** is not configured, causing the failure to establish a TCP connection.



1.13.2 Configuring BGP MD5 Authentication

1. Requirements

The establishment of a TCP connection needs MD5 encryption to ensure data transmission security.

2. Topology

Figure 1-3 Configuring BGP MD5 Authentication

3. Notes

- Enable BGP on all devices and set AS numbers for the devices as shown in Figure 1-3 (omitted).
- Configure a loopback interface on each of Devices B and C, which establish an IBGP neighbor relationship through the loopback interfaces (omitted).
- Configure Devices A and B to establish an EBGP neighbor relationship through directly connected interfaces.
- On Devices A, B, and C, configure passwords for their neighbors.

4. Procedure

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65537
Device A(cfg-router)# peer 192.168.1.2 remote-as 65536
Device A(cfg-router)# peer 192.168.1.2 password 7 ebgpneighbor
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 65536
Device B(cfg-router)# peer 10.1.1.2 remote-as 65536
Device B(cfg-router)# peer 10.1.1.2 update-source loopback 0
Device B(cfg-router)# peer 10.1.1.2 password ibgpneighbor
Device B(cfg-router)# peer 192.168.1.1 remote-as 65537
Device B(cfg-router)# peer 192.168.1.1 password 7 ebgpneighbor
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# router-protocol bgp 65536
Device C(cfg-router)# peer 10.1.1.1 remote-as 65536
Device C(cfg-router)# peer 10.1.1.1 update-source loopback 0
Device C(cfg-router)# peer 10.1.1.1 password ibgpneighbor
```

5. Verification

On Device A, run the **display ip bgp-instance peers** command to display the BGP neighbor status.

```
Device A# display ip bgp-instance peers
BGP peer is 192.168.1.2, remote AS 65536, local AS 65537, external link
  BGP version 4, remote router ID 10.1.1.1
  BGP state = Established, up for 00:04:54
  Last read               , hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received (old and new)
    Four-octets ASN Capability: advertised and received
    Address family IPv4 Unicast: advertised and received
  Received 7 messages, 0 notifications, 0 in queue
    open message:1 update message:0 keepalive message:6
    refresh message:0 dynamic cap:0 notifications:0
  Sent 7 messages, 0 notifications, 0 in queue
    open message:1 update message:0 keepalive message:6
    refresh message:0 dynamic cap:0 notifications:0
  Route refresh request: received 0, sent 0
  Minimum time between advertisement runs is 30 seconds

6. Configuration Files

- Device A configuration file

```
!
router-protocol bgp 65537
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 192.168.1.2 remote-as 65536
 peer 192.168.1.2 password 7 ebgpneighbor
 address-family-mode ipv4
  peer 192.168.1.2 activate
  exit-address-family-mode
!
```

- Device B configuration file

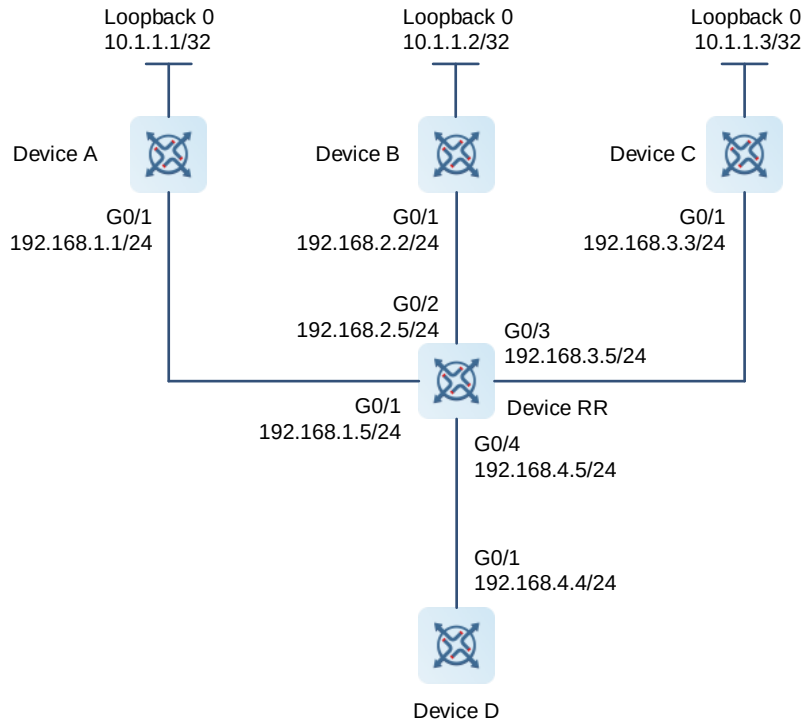
```
!
router-protocol bgp 65536
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 10.1.1.2 remote-as 65536
 peer 10.1.1.2 update-source Loopback 0
 peer 10.1.1.2 password ibgpneighbor
 peer 192.168.1.1 remote-as 65537
 peer 192.168.1.1 password 7 ebgpneighbor
 address-family-mode ipv4
  peer 10.1.1.2 activate
  peer 192.168.1.1 activate
  exit-address-family-mode
!
```

- Device C configuration file

```
!
router-protocol bgp 65536
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 10.1.1.1 remote-as 65536
 peer 10.1.1.1 update-source Loopback 0
 peer 10.1.1.1 password ibgpneighbor
 address-family-mode ipv4
  peer 10.1.1.1 activate
  exit-address-family-mode
!
```

7. Common Errors

- The passwords for MD5 authentication are different on both sides of a BGP neighbor relationship.



1.13.3 Configuring a BGP Route Reflector

1. Requirements

In a network involving many BGP speakers, a route reflector needs to be configured to simplify the management and synchronization of routing information and make routing more efficient.

2. Topology

Figure 1-4 Configuring a BGP Route Reflector

3. Notes

- Enable BGP on all devices and set AS numbers for the devices as shown in Figure 1-4 (omitted).
- Configure a loopback interface on each device and configure the devices to establish IBGP neighbor relationships through the loopback interfaces according to connection lines shown in the figure above (omitted).
- Configure route reflection on device RR and specify Devices A, B, C, and D as reflection clients.

4. Procedure

(1) Configure BGP neighbors to advertise network information.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65536
Device A(cfg-router)# peer 10.1.1.5 remote-as 65536
Device A(cfg-router)# peer 10.1.1.5 update-source loopback 0
Device A(cfg-router)# network-advertise 192.168.1.0 mask 255.255.255.0
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 65536
Device B(cfg-router)# peer 10.1.1.5 remote-as 65536
Device B(cfg-router)# peer 10.1.1.5 update-source loopback 0
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# router-protocol bgp 65536
Device C(cfg-router)# peer 10.1.1.5 remote-as 65536
Device C(cfg-router)# peer 10.1.1.5 update-source loopback 0
```

Configure Device D.

```
Device D# config-system terminal
Device D(cfg)# router-protocol bgp 65536
Device D(cfg-router)# peer 10.1.1.5 remote-as 65536
Device D(cfg-router)# peer 10.1.1.5 update-source loopback 0
```

(2) Configure a route reflector.

Configure Device RR.

```
Device RR# config-system terminal
Device RR(cfg)# router-protocol bgp 65536
Device RR(cfg-router)# peer 10.1.1.1 remote-as 65536
Device RR(cfg-router)# peer 10.1.1.1 update-source loopback 0
Device RR(cfg-router)# peer 10.1.1.1 route-reflector-client
Device RR(cfg-router)# peer 10.1.1.2 remote-as 65536
Device RR(cfg-router)# peer 10.1.1.2 update-source loopback 0
Device RR(cfg-router)# peer 10.1.1.2 route-reflector-client
Device RR(cfg-router)# peer 10.1.1.3 remote-as 65536
Device RR(cfg-router)# peer 10.1.1.3 update-source loopback 0
Device RR(cfg-router)# peer 10.1.1.3 route-reflector-client
```

```
Device RR(cfg-router)# peer 10.1.1.4 remote-as 65536
Device RR(cfg-router)# peer 10.1.1.4 update-source loopback 0
Device RR(cfg-router)# peer 10.1.1.4 route-reflector-client
```

5. Verification

On Device RR, check the BGP neighbor status.

```
Device RR# display ip bgp-instance status
BGP router identifier 10.1.1.5, local AS number 65536
BGP table version is 1
0 BGP AS-PATH entries
0 BGP Community entries
1 BGP Prefix entries (Maximum-prefix:4294967295)

Neighbor        V           AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down   State/PfxRcd
10.1.1.1        4        65536       8       9        1    0    0 00:05:11        1
10.1.1.2        4        65536       9       9        1    0    0 00:05:24        0
10.1.1.3        4        65536       8       7        1    0    0 00:05:10        0
10.1.1.4        4        65536       9       8        1    0    0 00:05:14        0

Device RR# display ip bgp-instance
BGP table version is 1, local router ID is 10.1.1.5

1.13.4 Configuring a BGP Alliance

1. Requirements

A BGP alliance needs to be configured to solve the problem of too many maintenance resources due to excessive IBGP connections in the network.

2. Topology

Figure 1-5 Configuring a BGP Alliance

3. Notes

- Configure IP addresses for device interfaces (omitted).
- On Devices A and B, configure BGP, set the member AS number to **65536**, and configure an IBGP neighbor relationship.
- On Devices C and D, configure BGP, set the member AS number to **65537**, and configure an IBGP neighbor relationship.
- On Devices BR1 and E, configure BGP, set the member AS number to **65538**, and configure an IBGP neighbor relationship.
- On Devices A, B, C, D, E, and BR1, set the Alliance ID to **100**.
- On Device A, configure 65537 as the alliance number, configure device C as an EBGP neighbor, and set the peer AS number to **65537**.
- On Device C, set the alliance member numbers to **65536** and **65538**, configure device A as an EBGP neighbor and set the peer AS number to **65536**, configure device BR1 as an EBGP neighbor and set the peer AS number to **65538**.
- On Device BR1, set the alliance member number to **65537**, configure device C as an EBGP neighbor and set the peer AS number to **65537**, configure device BR2 as an EBGP neighbor and set the peer AS number

to **200**.

- On Device BR2, configure BGP, set the AS number to **200**, configure device BR1 an EBGP neighbor, and set the peer AS number to **100**.

4. Procedure

(1) Configure IBGP neighbors and EBGP neighbors to advertise network information.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65536
Device A(cfg-router)# peer 10.1.1.2 remote-as 65536
Device A(cfg-router)# peer 10.1.1.2 update-source loopback 0
Device A(cfg-router)# peer 10.1.1.3 remote-as 65537
Device A(cfg-router)# peer 10.1.1.3 ebgp-multihop 2
Device A(cfg-router)# peer 10.1.1.3 update-source loopback 0
Device A(cfg-router)# network-advertise 192.168.1.0 mask 255.255.255.0
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 65536
Device B(cfg-router)# peer 10.1.1.1 remote-as 65536
Device B(cfg-router)# peer 10.1.1.1 update-source loopback 0
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# router-protocol bgp 65537
Device C(cfg-router)# peer 10.1.1.1 remote-as 65536
Device C(cfg-router)# peer 10.1.1.1 update-source loopback 0
Device C(cfg-router)# peer 10.1.1.1 ebgp-multihop 2
Device C(cfg-router)# peer 10.1.1.4 remote-as 65537
Device C(cfg-router)# peer 10.1.1.4 update-source loopback 0
Device C(cfg-router)# peer 10.1.1.5 remote-as 65538
Device C(cfg-router)# peer 10.1.1.5 update-source loopback 0
Device C(cfg-router)# peer 10.1.1.5 ebgp-multihop 2
```

Configure Device D.

```
Device D# config-system terminal
Device D(cfg)# router-protocol bgp 65537
Device D(cfg-router)# peer 10.1.1.3 remote-as 65537
Device D(cfg-router)# peer 10.1.1.3 update-source loopback 0
```

Configure Device E.

```
Device E# config-system terminal
Device E(cfg)# router-protocol bgp 65538
Device E(cfg-router)# peer 10.1.1.5 remote-as 65538
Device E(cfg-router)# peer 10.1.1.5 update-source loopback 0
```

Configure Device BR1.

```
Device BR1# config-system terminal
```

```
Device BR1(cfg)# router-protocol bgp 65538
Device BR1(cfg-router)# peer 10.1.1.3 remote-as 65537
Device BR1(cfg-router)# peer 10.1.1.3 update-source loopback 0
Device BR1(cfg-router)# peer 10.1.1.3 ebgp-multihop 2
Device BR1(cfg-router)# peer 10.1.1.6 remote-as 65538
Device BR1(cfg-router)# peer 10.1.1.6 update-source loopback 0
Device BR1(cfg-router)# peer 192.168.6.7 remote-as 200
```

Configure Device BR2.

```
Device BR2# config-system terminal
Device BR2(cfg)# router-protocol bgp 200
Device BR2(cfg-router)# peer 192.168.6.5 remote-as 100
Device BR2(cfg-router)# network-advertise 192.168.6.0 mask 255.255.255.0
```

(2) Configuring alliance members.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65536
Device A(cfg-router)# bgp-instance as-confederation id 100
Device A(cfg-router)# bgp-instance as-confederation peers 65537
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# router-protocol bgp 65537
Device C(cfg-router)# bgp-instance as-confederation id 100
Device C(cfg-router)# bgp-instance as-confederation peers 65536 65538
```

Configure Device BR1.

```
Device BR1# config-system terminal
Device BR1(cfg)# router-protocol bgp 65538
Device BR1(cfg-router)# bgp-instance as-confederation id 100
Device BR1(cfg-router)# bgp-instance as-confederation peers 65537
```

5. Verification

On Device A, check BGP information.

```
Device A# display ip bgp-instance status
BGP router identifier 10.1.1.1, local AS number 65536
BGP table version is 1
1 BGP AS-PATH entries
0 BGP Community entries
1 BGP Prefix entries (Maximum-prefix:4294967295)

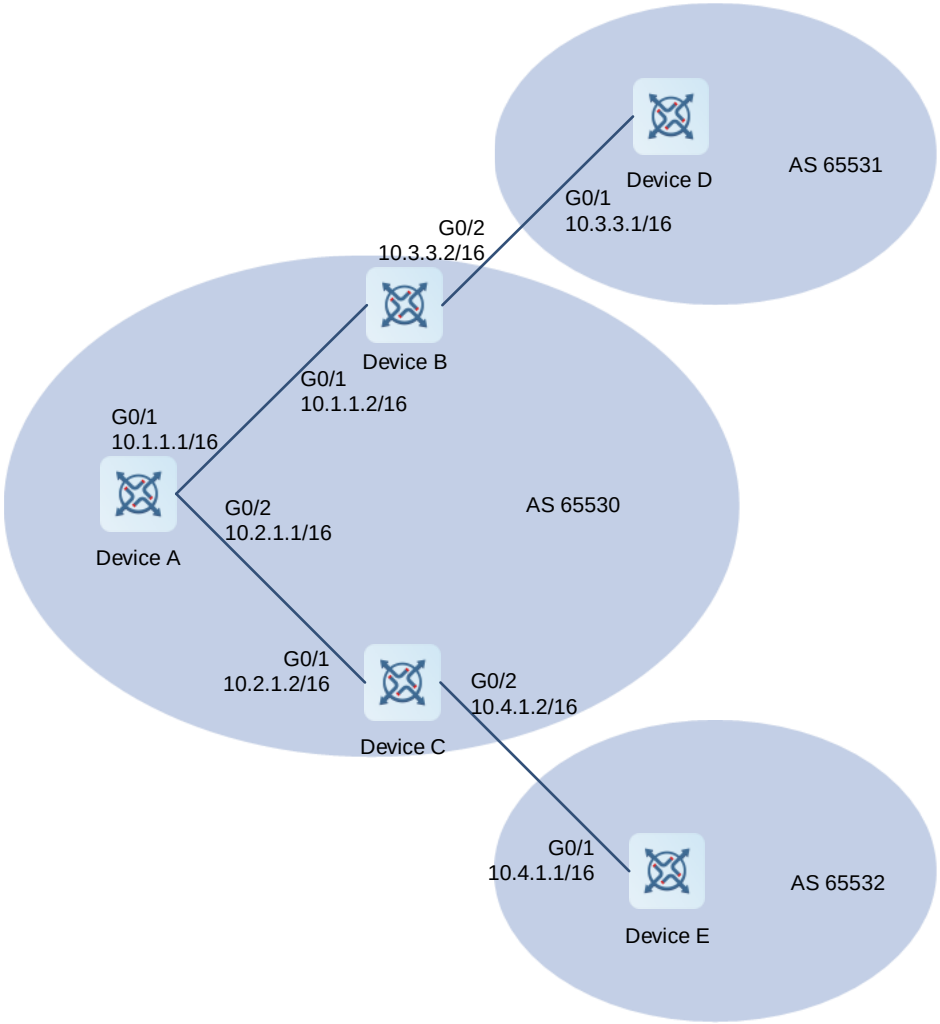
7. Common Errors

- No BGP alliance neighbor is configured.
- A full mesh of connections is not deployed within member ASs of an alliance.



1.13.5 Configuring IBGP Multi-Path Load Balancing

1. Requirements

When there are two routes to the same destination network segment, load balancing needs to be configured to fully utilize network bandwidth resources.

2. Topology

Figure 1-6 Configuring IBGP Multi-Path Load Balancing

3. Notes

- Enable BGP on all devices and set AS numbers for the devices as shown in Figure 1-6 (omitted).
- Configure devices A and B and devices A and C to establish IBGP neighbor relationships through directly connected interfaces (omitted).
- Configure devices B and D and devices C and E to establish EBGP neighbor relationships through directly connected interfaces (omitted).
- Import the same routes to devices D and E.
- On device A, configure IBGP load balancing and enable the AS-PATH loose comparison mode.

4. Procedure

(1) Configure routing information on device A, and re-advertise directly connected route information on devices D and E.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# ip route-config 10.3.0.0 255.255.0.0 10.1.1.2
Device A(cfg)# ip route-config 10.4.0.0 255.255.0.0 10.2.1.2
```

Configure Device D.

```
Device D# config-system terminal
Device D(cfg)# router-protocol bgp 65531
Device D(cfg-router)# redistribute-route connected
```

Configure Device E.

```
Device E# config-system terminal
Device E(cfg)# router-protocol bgp 65532
Device E(cfg-router)# redistribute-route connected
```

(2) On Device A, configure load balancing in AS-PATH loose comparison mode.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65530
Device A(cfg-router)# max-ecmp-paths ibgp 2
Device A(cfg-router)# bgp-instance optimal-path as-path multipath-relax
```

5. Verification

On Device A, check BGP information.

```
Device A# display ip bgp-instance status
BGP router identifier 10.2.1.1, local AS number 65530
BGP table version is 9
2 BGP AS-PATH entries
0 BGP Community entries
3 BGP Prefix entries (Maximum-prefix:4294967295)

Neighbor        V    AS         MsgRcvd    MsgSent    TblVer    InQ    OutQ    Up/Down

```

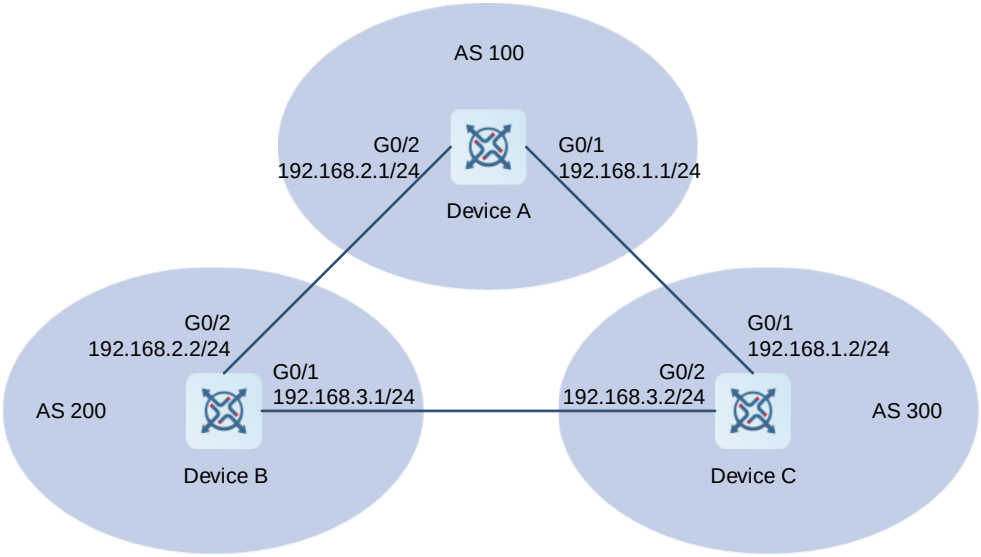
7. Common Errors

The priorities of multi-hop BGP paths are different, which causes a load balancing failure.



1.13.6 Configuring EBGP FRR

1. Requirements

The FRR function needs to be configured to back up and forward routing information and reduce the delay in service switching.

2. Topology

Figure 1-7 Configuring EBGP FRR

3. Notes

- Enable BGP on all devices (omitted).
- Configure addresses for directly connected interfaces on Devices A, B, and C, and configure them to establish EBGP neighbor relationships (omitted).
- Configure a BFD session for the EBGP neighbor relationship between Devices B and C.
- Configure FRR on Device C.

4. Procedure

(1) Configure interface addresses and interface BFD parameters on devices B and C.

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# interface GigabitEthernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip address 192.168.3.1 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/1)# bfd min_tx_interval 200 min_rx_interval 200 multiplier 5
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface GigabitEthernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# ip address 192.168.2.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/2)# exit
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# interface GigabitEthernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/1)# exit
Device C(cfg)# interface GigabitEthernet 0/2
Device C(cfg-if-GigabitEthernet 0/2)# ip address 192.168.3.2 255.255.255.0
```

```
Device C(cfg-if-GigabitEthernet 0/2)# bfd min_tx_interval 200 min_rx_interval 200 multiplier 5
Device C(cfg-if-GigabitEthernet 0/2)# exit
```

(2) Configure BFD for BGP and BGP FRR.

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 200
Device B(cfg-router)# peer 192.168.3.2 remote-as 300
Device B(cfg-router)# peer 192.168.3.2 fall-over bfd
Device B(cfg-router)# peer 192.168.2.1 remote-as 100
Device B(cfg-router)# redistribute-route connect
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# router-protocol bgp 300
Device C(cfg-router)# peer 192.168.1.1 remote-as 100
Device C(cfg-router)# peer 192.168.3.1 remote-as 200
Device C(cfg-router)# peer 192.168.3.1 fall-over bfd
Device C(cfg-router)# address-family-mode ipv4 unicast
Device C(cfg-router-af)# bgp-instance auto-frr
Device C(cfg-router-af)# redistribute-route connect
```

5. Verification

On Device C, check BGP information.

```
Device C# display ip bgp-instance status
BGP router identifier 10.10.10.10, local AS number 300
BGP table version is 12
4 BGP AS-PATH entries
0 BGP Community entries

1.13.7 Configuring BGP to Rapidly Withdraw Specified Routes

1. Requirements

Specified routing information needs to be withdrawn.

2. Topology

Figure 1-8 Configuring Fast Withdrawal of Specified Routes

3. Notes

- Enable BGP on all devices (omitted).
- Configure devices A and B to establish a BGP neighbor relationship (omitted).
- Configure an ACL on device A.
- Configure fast withdrawal of specified routes on device A.

4. Procedure

(1) Configure an ACL to permit the address 1.1.1.1.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# ip access-control-list standard 1
Device A(cfg-stdacl)# permit 1.1.1.1 0.0.0.0
Device A(cfg-stdacl)# exit
```

(2) Configure fast withdrawal of the specified route 1.1.1.1.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65530
Device A(cfg-router)# peer 192.168.1.2 remote-as 65531
Device A(cfg-router)# bgp-instance fast-withdraw access-control-list 1
```

5. Verification

On Device A, check BGP routing information.

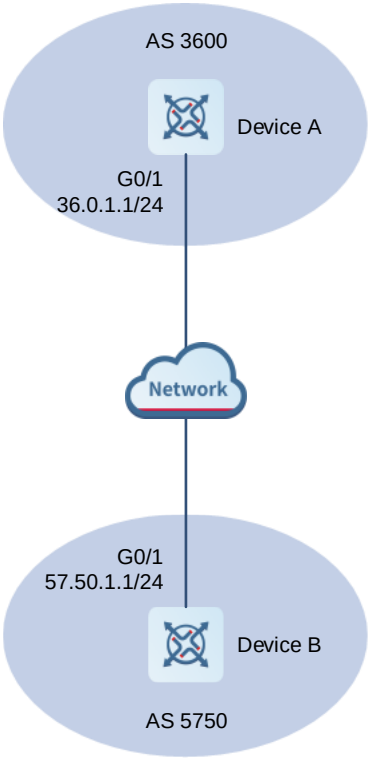
```
Device A# display current-config router-protocol bgp
router-protocol bgp 65530
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 192.168.1.2 remote-as 65531
```

```
 address-family-mode ipv4
   bgp-instance fast-withdraw access-control-list 1
   peer 192.168.1.2 activate
 exit-address-family-mode
```

6. Configuration Files

- Device A configuration file

```
!
ip access-control-list standard 1
  10 permit host-route 1.1.1.1
!
router-protocol bgp 65530
  bgp-instance log-peer-changes
  bgp-instance graceful-restart restart-time 120
  bgp-instance graceful-restart staleroute-time 360
  bgp-instance graceful-restart
  peer 192.168.1.2 remote-as 65531
  address-family-mode ipv4
    bgp-instance fast-withdraw access-control-list 1
    peer 192.168.1.2 activate
    exit-address-family-mode
!
```



1.13.8 Configuring the BGP Local AS

1. Requirements

When the real AS of the local BGP changes, a new virtual AS 23 can be configured between peers so that the BGP configurations on peers do not need to be configured.

2. Topology

Figure 1-9 Configuring BGP Local AS

3. Notes

- Establish an EBGP neighbor relationship between devices A and B and set the local AS number of the EBGP neighbor to 23.
- Establish an EBGP neighbor relationship with devices A on B.

4. Procedure

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 3600
Device A(cfg-router)# peer 57.50.1.1 remote-as 5750
Device A(cfg-router)# peer 57.50.1.1 update-source loopback 0
Device A(cfg-router)# peer 57.50.1.1 ebgp-multihop 255
Device A(cfg-router)# peer 57.50.1.1 local-as 23 no-prepend change-as dual-as
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 5750
Device B(cfg-router)# peer 36.0.1.1 remote-as 23
Device B(cfg-router)# peer 36.0.1.1 update-source loopback 0
Device B(cfg-router)# peer 36.0.1.1 ebgp-multihop 255
```

5. Verification

On Device A, check the BGP neighbor status.

```
Device A# display ip bgp-instance peers 57.50.1.1
BGP peer is 57.50.1.1, remote AS 5750, local AS 23(using Peer's Local AS, no-prepend, change-as,
dual-as), external link
  BGP version 4, remote router ID 0.0.0.0
  BGP state = Idle
  Last read, hold time is 180, keepalive interval is 60 seconds
  Received 0 messages, 0 notifications, 0 in queue
    open message:0 update message:0 keepalive message:0
    refresh message:0 dynamic cap:0 notifications:0
  Sent 0 messages, 0 notifications, 0 in queue
```

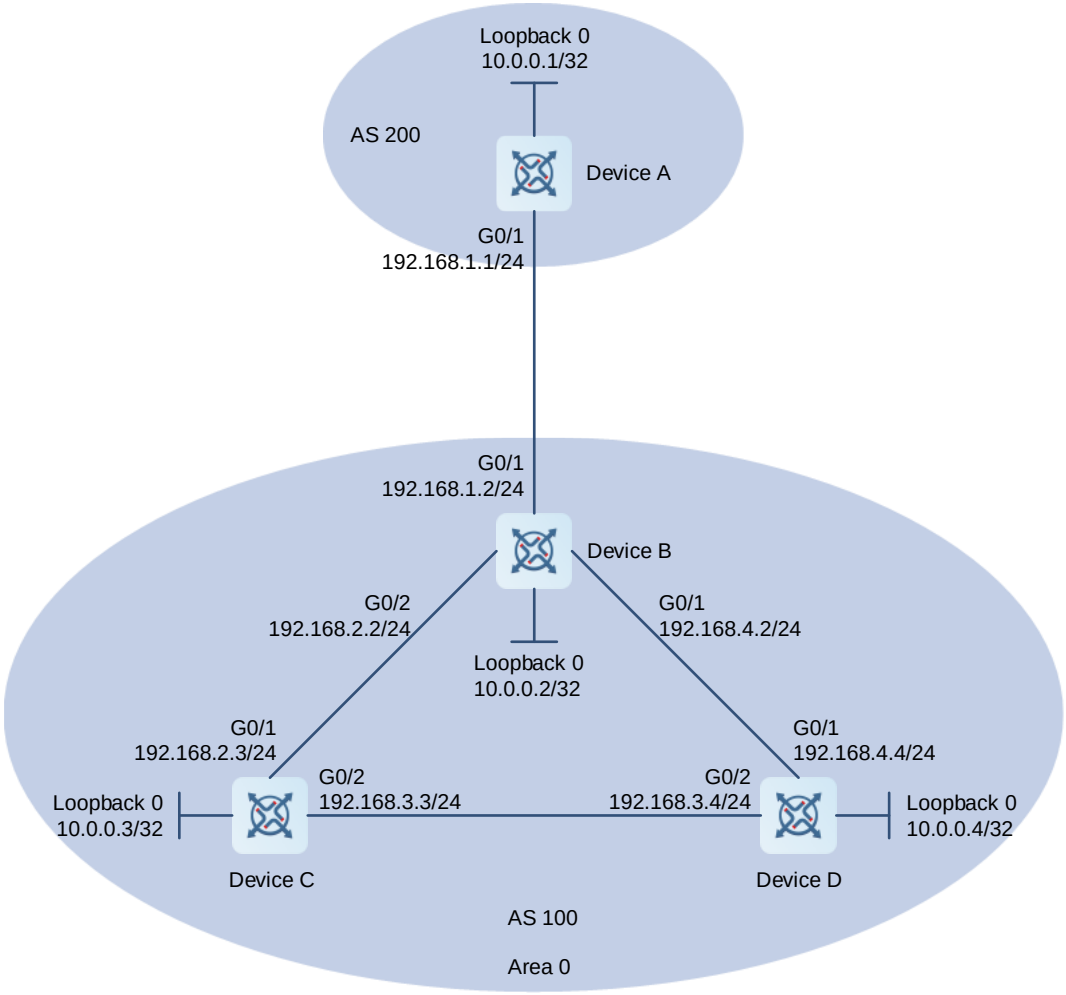
6. Configuration Files

- Device A configuration file

```
!
router-protocol bgp 3600
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 57.50.1.1 remote-as 5750
 peer 57.50.1.1 local-as 23 no-prepend change-as dual-as
 peer 57.50.1.1 ebgp-multihop 255
 peer 57.50.1.1 update-source Loopback 0
 address-family-mode ipv4
  peer 57.50.1.1 activate
  exit-address-family-mode
!
```

- Device B configuration file

```
!
router-protocol bgp 5750
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 36.0.1.1 remote-as 23
 peer 36.0.1.1 ebgp-multihop 255
 peer 36.0.1.1 update-source Loopback 0
 address-family-mode ipv4
  peer 36.0.1.1 activate
  exit-address-family-mode
!
```



1.13.9 Configuring BGP GR

1. Requirements

Data forwarding should not be interrupted during the protocol restart.

2. Topology

Figure 1-10 Configuring BGP GR

3. Notes

- Enable BGP on all devices and set AS numbers for the devices as shown in Figure 1-10 (omitted).
- Configure a loopback interface on each of Devices B, C, and D and configure the devices to establish IBGP neighbor relationships through the loopback interfaces (omitted).
- Configure Devices A and B to establish an EBGP neighbor relationship through directly connected interfaces (omitted).
- On Devices A, B, C, and D, and enable the BGP GR function.

4. Procedure

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol ospf 1
Device A(cfg-router)# gr
Device A(cfg-router)# exit
Device A(cfg)# router-protocol bgp 200
```

```
Device A(cfg-router)# bgp-instance graceful-restart
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol ospf 1
Device B(cfg-router)# gr
Device B(cfg-router)# exit
Device B(cfg)# router-protocol bgp 100
Device B(cfg-router)# bgp-instance graceful-restart
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# router-protocol ospf 1
Device C(cfg-router)# graceful-restart
Device C(cfg-router)# exit
Device C(cfg)# router-protocol bgp 100
Device C(cfg-router)# bgp-instance graceful-restart
```

Configure Device D.

```
Device D# config-system terminal
Device D(cfg)# router-protocol ospf 1
Device D(cfg-router)# gr
Device D(cfg-router)# exit
Device D(cfg)# router-protocol bgp 100
Device D(cfg-router)# bgp-instance graceful-restart
```

5. Verification

On Device B, run the **display ip ospf-instance** command to display the OSPF routing status.

```
Device B# display ip ospf-instance
Routing Process "ospf 1" with ID 10.0.0.2
Process uptime is 4 minutes
Process bound to VRF default
Conforms to RFC2328, and RFC1583Compatibility flag isenabled
Supports only single TOS(TOS0) routes
Supports opaque LSA
This router is an ASBR (injecting external routing information)
SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
LsaGroupPacing: 240 secs
Number of incomming current DD exchange neighbors 0/5
Number of outgoing current DD exchange neighbors 0/5
Number of external LSA 4. Checksum 0x0278E0
Number of opaque AS LSA 0. Checksum 0x000000
Number of non-default external LSA 4
External LSA database is unlimited.
Number of LSA originated 6
Number of LSA received 2
Log Neighbor Adjency Changes : Enabled
Graceful-restart enabled
```

```
Graceful-restart helper support enabled
Number of areas attached to this router: 1
Area 0 (BACKBONE)
```

On Device B, run the **display ip bgp-instance peers** command to display the BGP neighbor status.

```
Device B# display ip bgp-instance neighbors
BGP peer is 192.168.195.183, remote AS 200, local AS 100, external link
Using BFD to detect fast fallover - BFD session state up
  BGP version 4, remote router ID 10.0.0.1
  BGP state = Established, up for 00:06:37
  Last read 00:06:37, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received (old and new)
Address family IPv4 Unicast: advertised and received
Graceful restart: advertised and received
  Remote Restart timer is 120 seconds
  Address families preserved by peer:
    None
```

6. Configuration Files

- Device A configuration file

```
router-protocol bgp 200
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 address-family-mode ipv4
  exit-address-family-mode
!
router-protocol ospf 1
 gr
!
```

- Device B configuration file

```
router-protocol bgp 100
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 address-family-mode ipv4
  exit-address-family-mode

!
```

- Device C configuration file

```
router-protocol bgp 100
```

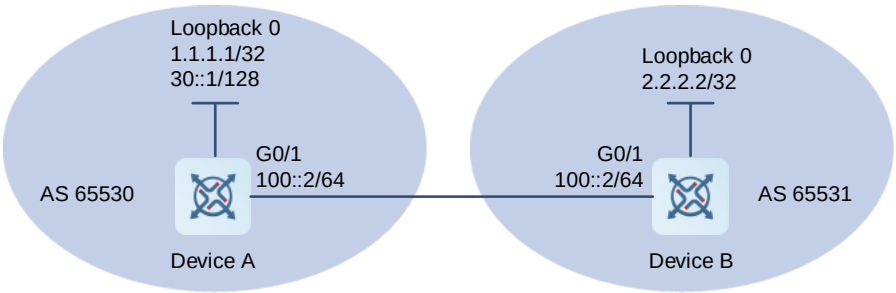
```
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 address-family-mode ipv4
  exit-address-family-mode
!
router-protocol ospf 1
 gr
!
```

- Device D configuration file

```
router-protocol bgp 100
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 address-family-mode ipv4
  exit-address-family-mode
!
router-protocol ospf 1
 gr
!
```

7. Common Errors

- GR is not enabled for IGP.
- GR is not enabled for a BGP neighbor.



1.13.10 Configuring IPv6 Route Exchange Across ASs

1. Requirements

IPv6 routing information needs to be exchanged across different ASs.

2. Topology

Figure 1-11 Configuring IPv6 Route Exchange Across ASs

3. Notes

- Enable BGP on all devices and set AS numbers for the devices as shown in Figure 1-11 (omitted).

- Configure BGP neighbors, disable the IPv4 address family capability for the neighbors, and activate the IPv6 address family capability.
- Configure BGP to advertise IPv6 routes.

4. Procedure

(1) Configure BGP and activate the IPv6 address family.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65530
Device A(cfg-router)# peer 100::1 remote-as 65531
Device A(cfg-router)# address-family-mode ipv4
Device A(cfg-router-af)# unset peer 100::1 activate
Device A(cfg-router-af)# exit-address-family-mode
Device A(cfg-router)# address-family-mode ipv6
Device A(cfg-router-af)# peer 100::1 activate
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 65531
Device B(cfg-router)# peer 100::2 remote-as 65530
Device B(cfg-router)# address-family-mode ipv4
Device B(cfg-router-af)# unset peer 100::2 activate
Device B(cfg-router-af)# exit-address-family-mode
Device B(cfg-router)# address-family-mode ipv6
Device B(cfg-router-af)# peer 100::2 activate
```

(2) Configure the advertisement of IPv6 network information.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65530
Device A(cfg-router)# address-family-mode ipv6
Device A(cfg-router-af)# network-advertise 30::1/128
```

5. Verification

On Device A, check the BGP neighbor status.

```
Device A# display bgp-instance ipv6 unicast-af-modifier status
BGP router identifier 1.1.1.1, local AS number 65530
BGP table version is 1
1 BGP AS-PATH entries
0 BGP Community entries
1 BGP Prefix entries (Maximum-prefix:4294967295)

Neighbor        V           AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down       State/PfxRcd
100::1          4        65531       4       6        1    0    0 00:01:49            0

Total number of neighbors 1
```

On Device B, check the BGP neighbor status.

```
Device B# display bgp-instance ipv6 unicast-af-modifier
BGP table version is 4, local router ID is 2.2.2.2
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
                    S Stale, b - backup entry
Origin codes: i - IGP, e - EGP, ? - incomplete

    Network            Next Hop              Metric       LocPrf       Weight Path
*> 30::1/128          100::2                  0                              0 65530 i

Total number of prefixes 1
```

6. Configuration Files

- Device A configuration file

```
!
router-protocol bgp 65530
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 100::1 remote-as 65531
 address-family-mode ipv4
  unset peer 100::1 activate
  exit-address-family-mode
 address-family-mode ipv6
  network-advertise 30::1/128
  peer 100::1 activate
  exit-address-family-mode
!
```

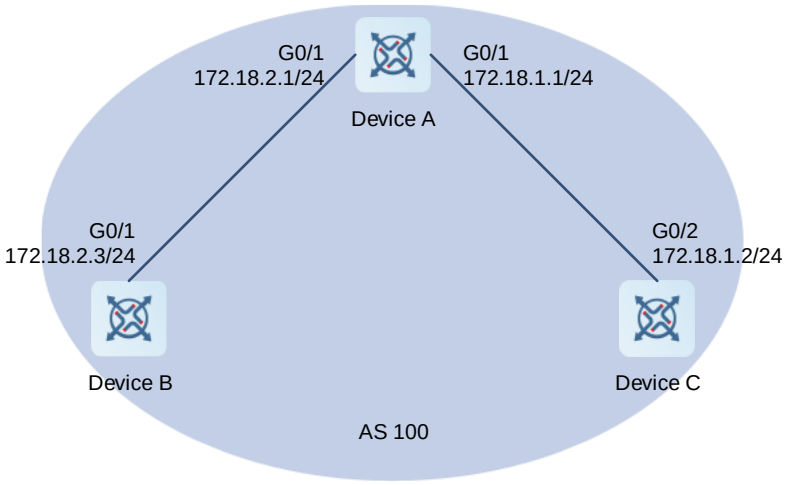
- Device B configuration file

```
!
router-protocol bgp 65531
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 100::2 remote-as 65530
 address-family-mode ipv4
  unset peer 100::2 activate
  exit-address-family-mode
 address-family-mode ipv6
  peer 100::2 activate
  exit-address-family-mode
!
```

7. Common Errors

- The IPv6 address family capability is not activated for BGP neighbors.

- In non-6PE scenarios, IPv4 addresses are used to establish a neighbor relationship to exchange IPv6 routes.



1.13.11 Configuring the BGP EVPN

1. Requirements

The L2VPN EVPN address family needs to be configured.

2. Topology

Figure 1-12 Configuring the BGP EVPN

3. Notes

- Enable BGP on all devices and set AS numbers for the devices as shown in Figure 1-12 (omitted).
- Configure BGP neighbors as shown in the figure (omitted).
- Configure device A as a BGP route reflector.
- Activate the L2VPN EVPN address family capability for the BGP neighbors.

4. Procedure

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 100
Device A(cfg-router)# peer 172.18.2.3 remote-as 100
Device A(cfg-router)# peer 172.18.1.2 remote-as 100
Device A(cfg-router)# address-family-mode l2vpn evpn
Device A(cfg-router-af)# peer 172.18.2.3 activate
Device A(cfg-router-af)# peer 172.18.1.2 activate
Device A(cfg-router-af)# peer 172.18.2.3 route-reflector-client
Device A(cfg-router-af)# peer 172.18.1.2 route-reflector-client
Device A(cfg-router-af)# exit-address-family-mode
```

Configure Device B.

```
Device B# config terminal
```

```
Device B(cfg)# evpn
Device B(cfg-evpn)# vni 100
Device B(cfg-evpn-vni)# rd auto
Device B(cfg-evpn-vni)# route-target both auto
Device B(cfg-evpn-vni)# exit
Device B(cfg-evpn)# exit
Device B(cfg)# router-protocol bgp 100
Device B(cfg-router)# peer 172.18.2.1 remote-as 100
Device B(cfg-router)# address-family-mode l2vpn evpn
Device B(cfg-router-af)# peer 172.18.2.1 activate
Device B(cfg-router-af)# exit-address-family-mode
```

Configure Device C.

```
Device C # config terminal
Device C(cfg)# evpn
Device C(cfg-evpn)# vni 100
Device C(cfg-evpn-vni)# rd auto
Device C(cfg-evpn-vni)# route-target both auto
Device C(cfg-evpn-vni)# exit
Device C(cfg-evpn)# exit
Device C(cfg)# router-protocol bgp 100
Device C(cfg-router)# peer 172.18.1.1 remote-as 100
Device C(cfg-router)# address-family-mode l2vpn evpn
Device C(cfg-router-af)# peer 172.18.1.1 activate
Device C(cfg-router-af)# exit-address-family-mode
```

5. Verification

On Device A, check L2VPN EVPN information.

```
Device A# display bgp-instance l2vpn evpn-af-modifier all status
For address family: L2VPN EVPN
BGP router identifier 3.3.3.3, local AS number 100

```

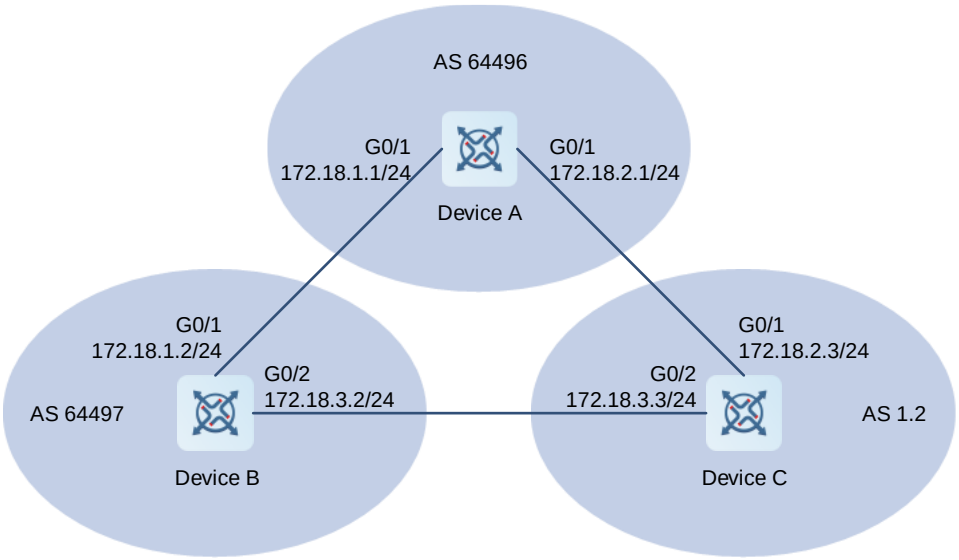
7. Common Errors

- No neighbor is configured for the L2VPN EVPN address family.
- The EVPN address family capability of a BGP neighbor is not activated.



1.13.12 Configuring Compatibility Between BGP Devices Supporting 4-Byte AS Numbers and Those Supporting 2-Byte AS Numbers

1. Requirements

- Routers supporting 2-byte AS numbers and those supporting 4-byte AS numbers (using 2-byte AS numbers) can establish BGP connections.
- Routers supporting 2-byte AS numbers and those supporting 4-byte AS numbers (using 4-byte AS numbers) can establish BGP connections.
- Two routers supporting 4-byte AS numbers can establish a BGP connection, with one using a 2-byte AS number and the other using a 4-byte AS number.

2. Topology

Figure 1-13 Configuring Compatibility Between BGP Devices Supporting 4-Byte AS Numbers and Those Supporting 2-Byte AS Numbers

3. Notes

- Enable BGP on all devices and set AS numbers for the devices as shown in Figure 1-13 (omitted).
- Configure BGP neighbors.

4. Procedure

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 64496
Device A(cfg-router)# peer 172.18.1.2 remote-as 64497
Device A(cfg-router)# peer 172.18.2.3 remote-as 23456
Device A(cfg-router)# end
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 64497
Device B(cfg-router)# peer 172.18.1.1 remote-as 64496
Device B(cfg-router)# peer 172.18.3.3 remote-as 1.2
Device B(cfg-router)# bgp-instance as-symbol dot
Device B(cfg-router)# end
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# router-protocol bgp 1.2
Device C(cfg-router)# peer 172.18.2.1 remote-as 64496
Device C(cfg-router)# peer 172.18.3.2 remote-as 64497
Device C(cfg-router)# end
```

5. Verification

On Device A, check the BGP neighbor status.

```
Device A# display ip bgp-instance status

BGP router identifier 172.18.1.1, local AS number 64496
BGP table version is 1, main routing table version 1

Neighbor        V    AS        MsgRcvd    MsgSent    TblVer    InQ    OutQ    Up/Down      Statd
172.18.1.2      4    64497     7          7          1         0      0       00:03:04     0
172.18.2.3      4    23456     4          4          1         0      0       00:00:15     0
```

On Device B, check the BGP neighbor status.

```
Device B# display ip bgp-instance status

BGP router identifier 172.18.3.2, local AS number 64497
BGP table version is 1, main routing table version 1

Neighbor        V    AS        MsgRcvd    MsgSent    TblVer    InQ    OutQ    Up/Down      Statd
172.18.1.1      4    64496     7          7          1         0      0       00:00:04     0
172.18.3.2      4    1.2       4          4          1         0      0       00:00:16     0
```

6. Configuration Files

- Device A configuration file

```
!
router-protocol bgp 64496

 address-family-mode ipv4
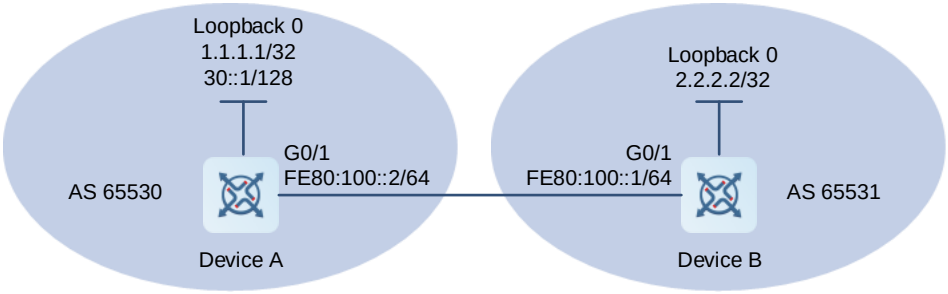
  peer 172.18.2.1 activate
  peer 172.18.3.2 activate
  exit-address-family-mode
!
```



1.13.13 Configuring an IPv6 Local Link Address

1. Requirements

An IPv6 local link address needs to be configured as a neighbor update address.

2. Topology

Figure 1-14 Configuring IPv6 Local Link Address

3. Notes

- Enable BGP on all devices, configure IPv6 local link addresses for interfaces, and set the AS numbers for the devices as shown in Figure 1-14 (omitted).
- Configure BGP neighbors, disable the IPv4 address family capability for the neighbors, and activate the IPv6 address family capability.
- Configure BGP to advertise IPv6 routes.

4. Procedure

(1) Enable the IPv6 address family capability and disable the IPv4 address family capability.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65530
Device A(cfg-router)# peer fe80:100::1%Gi0/1 remote-as 65531
Device A(cfg-router)# address-family-mode ipv4
Device A(cfg-router-af)# unset peer fe80:100::1%Gi0/1 activate
Device A(cfg-router-af)# exit-address-family-mode
Device A(cfg-router)# address-family-mode ipv6
Device A(cfg-router-af)# peer fe80:100::1%Gi0/1 activate
Device A(cfg-router-af)# network-advertise 30::1/128
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 65531
Device B(cfg-router)# peer fe80:100::2%Gi0/1 remote-as 65530
Device B(cfg-router)# address-family-mode ipv4
Device B(cfg-router-af)# unset peer fe80:100::2%Gi0/1 activate
Device B(cfg-router-af)# exit-address-family-mode
Device B(cfg-router)# address-family-mode ipv6
Device B(cfg-router-af)# peer fe80:100::2%Gi0/1 activate
```

(2) Configure BGP to advertise IPv6 addresses.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65530
Device A(cfg-router)# address-family-mode ipv6
Device A(cfg-router-af)# network-advertise 30::1/128
```

5. Verification

On Device A, check the BGP neighbor status.

```
Device A# display bgp-instance ipv6 unicast-af-modifier status
BGP router identifier 1.1.1.1, local AS number 65530
BGP table version is 1
1 BGP AS-PATH entries
0 BGP Community entries
1 BGP Prefix entries (Maximum-prefix:4294967295)

Neighbor                V           AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down
State/PfxRcd
fe80:100::1%Gi0/1       4        65531       4       6        1    0    0 00:01:49
0

Total number of neighbors 1
```

On Device B, check the BGP neighbor status.

```
Device B# display bgp-instance ipv6 unicast-af-modifier
```

```
BGP table version is 4, local router ID is 2.2.2.2
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
                    S Stale, b - backup entry
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network          Next Hop            Metric     LocPrf     Weight Path
*> 30::1/128        fe80:100::2         0                     0 65530 i

Total number of prefixes 1
```

6. Configuration Files

- Device A configuration file

```
!
router-protocol bgp 65530
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer fe80:100::1%Gi0/1 remote-as 65531
 address-family-mode ipv4
  unset peer fe80:100::1%Gi0/1 activate
  exit-address-family-mode
 address-family-mode ipv6
  network-advertise 30::1/128
  peer fe80:100::1%Gi0/1 activate
  exit-address-family-mode
!
```

- Device B configuration file

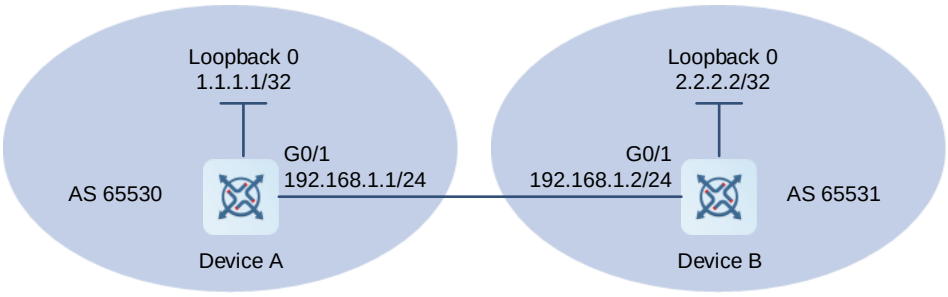
```
!
router-protocol bgp 65531
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer fe80:100::2%Gi0/1 remote-as 65530
 address-family-mode ipv4
  unset peer fe80:100::2%Gi0/1 activate
  exit-address-family-mode
 address-family-mode ipv6
  peer fe80:100::2%Gi0/1 activate
  exit-address-family-mode
!
```

7. Common Errors

- An IPv6 local link address is used to establish a neighbor relationship during neighbor configuration, but the interface, on which the IPv6 local link address is configured, is not configured as the update source during

local configuration.

- Only one end uses an IPv6 local link address for establishing a neighbor relationship.



1.13.14 Configuring BGP NSR

1. Requirements

NSR can be configured to ensure that data switching and forwarding are not interrupted.

2. Topology

Figure 1-15 Configuring BGP NSR

3. Notes

- Enable BGP on all devices and set AS numbers for the devices as shown in Figure 1-15 (omitted).
- Configure devices A and B to establish an EBGP neighbor relationship through directly connected interfaces.
- Enable the BGP NSR function on device A.

4. Procedure

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65530
Device A(cfg-router)# peer 192.168.1.2 remote-as 65530
Device A(cfg-router)# peer 192.168.1.2 ha-mode nsr
```

5. Verification

On device A, check the BGP neighbor status.

```
Device A# display ip bgp-instance peers
BGP peer is 192.168.1.2, remote AS 65530, local AS 65531, external link
Using BFD to detect fast fallover - BFD session state up
  BGP version 4, remote router ID 2.2.2.2
  BGP state = Established, up for 00:06:37
  Last read 00:06:37, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received (old and new)
Address family IPv4 Unicast: advertised and received
Graceful restart: advertised and received
  Remote Restart timer is 120 seconds
```

```
  Address families preserved by peer:
    None
```

On device B, check the BGP neighbor status.

```
Device B# display ip bgp-instance peers
BGP peer is 192.168.1.1, remote AS 65530, local AS 65531, external link
Using BFD to detect fast fallover - BFD session state up
  BGP version 4, remote router ID 1.1.1.1
  BGP state = Established, up for 00:06:37
  Last read 00:06:37, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received (old and new)
Address family IPv4 Unicast: advertised and received
Graceful restart: advertised and received
  Remote Restart timer is 120 seconds
  Address families preserved by peer:
    None
```

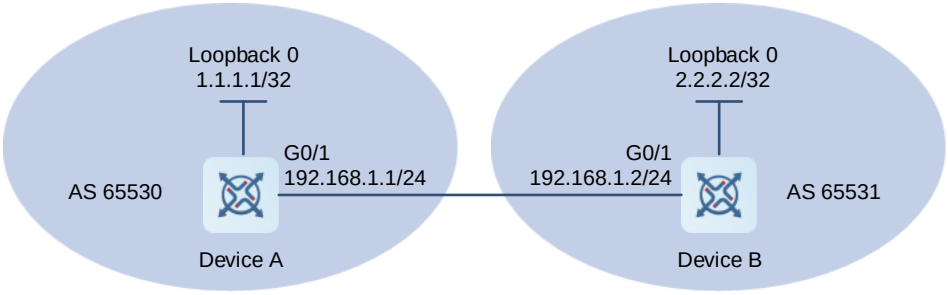
6. Configuration Files

- Device A configuration file

```
!
router-protocol bgp 65530
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 bgp-instance nsr
 peer 192.168.1.2 remote-as 65530
 address-family-mode ipv4
  peer 192.168.1.2 activate
  exit-address-family-mode
!
```

7. Common Errors

- IGP is not configured.
- The NSR function is not enabled for BGP neighbors.



1.13.15 Configuring BGP Routes to Be Recursive Only to Host Routes

1. Requirements

Non-direct BGP routes need to be recursive to host routes.

2. Topology

Figure 1-16 Configuring BGP Routes to Be Recursive Only to Host Routes

3. Notes

- Enable BGP on all devices and set the AS numbers as shown in the figure above (omitted).
- Configure devices A and B to establish an EBGP neighbor relationship through loopback interfaces (omitted).
- On devices A and B, enable the function of making BGP routes recursive only to host routes.

4. Procedure

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65530
Device A(cfg-router)# bgp-instance recursive host-route
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 65531
Device B(cfg-router)# bgp-instance recursive host-route
```

5. Configuration Files

- Device A configuration file

```
!
router-protocol bgp 65530
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 address-family-mode ipv4
  bgp-instance recursive host-route
  exit-address-family-mode
!
```

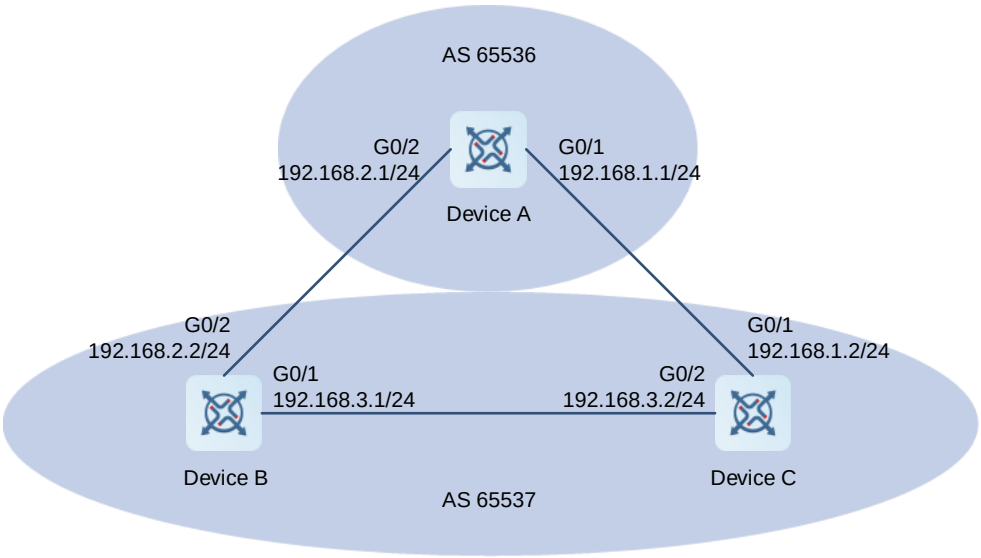
- Device B configuration file

```
!
router-protocol bgp 65531
 bgp-instance log-peer-changes
```

```
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 address-family-mode ipv4
  bgp-instance recursive host-route
  exit-address-family-mode
!
```

6. Common Errors

If an IBGP or multi-hop EBGP neighbor relationship is established not using loopback addresses, after the function is enabled, BGP cannot to find host routes matching the next-hop addresses. As a result, the next hops of BGP routes are invalid and routes cannot be preferentially selected.



1.13.16 Configuring Outbound Loop Detection for a BGP Neighbor

1. Requirements

Outbound loop detection needs to be configured for a BGP neighbor to prevent the receiving of routing information carrying the AS number of the neighbor in the AS-PATH attribute.

2. Topology

Figure 1-17 Configuring Outbound Loop Detection for a BGP Neighbor

3. Notes

- Enable BGP on all devices and set AS numbers for the devices as shown in Figure 1-17 (omitted).
- Configure devices A and C and devices B and C to establish EBGP neighbor relationships (omitted).
- On device C, enable outbound loop detection for its neighbors: devices A and B.

4. Procedure

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65536
```

```
Device A(cfg-router)# peer 192.168.1.2 remote-as 65537
Device A(cfg-router)# peer 192.168.1.2 as-loop-check out
Device A(cfg-router)# peer 192.168.2.2 remote-as 65537
Device A(cfg-router)# peer 192.168.2.2 as-loop-check out
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 65537
Device B(cfg-router)# peer 192.168.2.1 remote-as 65536
Device B(cfg-router)# peer 192.168.3.2 remote-as 65537
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# router-protocol bgp 65537
Device C(cfg-router)# peer 192.168.1.1 remote-as 65536
Device C(cfg-router)# peer 192.168.3.1 remote-as 65537
```

5. Verification

On Device A, check the BGP neighbor status.

```
Device A# display ip bgp-instance peers 192.168.2.2
BGP peer is 192.168.2.2, remote AS 65537, local AS 65536, external link
Using as path loop detection in announcing route
  BGP version 4, remote router ID 192.168.2.2
  BGP state = Established, up for 00:06:37
  Last read 00:06:37, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received (old and new)
Address family IPv4 Unicast: advertised and received
Graceful restart: advertised and received
  Remote Restart timer is 120 seconds
  Address families preserved by peer:
    None
……
```

```

1.13.17 Shutting Down BGP Connections Gracefully

1. Requirements

Graceful shutdown of BGP connections needs to be configured on a device. Then, after a certain period of time (automatically calculated based on the number of advertised routes or specified by *delay time*), the device disconnects BGP connections from its neighbors to reduce the impact on the network.

2. Topology

Figure 1-18 Configuring Graceful Shutdown of BGP Connections

3. Notes

- Enable BGP on all devices and set AS numbers for the devices as shown in Figure 1-18 (omitted).
- Configure devices A and C and devices B and C to establish EBGP neighbor relationships (omitted).
- On device A, configure the graceful shutdown of all connections in the BGP instance.

4. Procedure

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65536
Device A(cfg-router)# peer 192.168.1.2 remote-as 65537
Device A(cfg-router)# peer 192.168.1.2 as-loop-check out
Device A(cfg-router)# peer 192.168.2.2 remote-as 65537
Device A(cfg-router)# peer 192.168.2.2 as-loop-check out
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 65537
Device B(cfg-router)# peer 192.168.2.1 remote-as 65536
Device B(cfg-router)# peer 192.168.3.2 remote-as 65537
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# router-protocol bgp 65537
Device C(cfg-router)# peer 192.168.1.1 remote-as 65536
Device C(cfg-router)# peer 192.168.3.1 remote-as 65537
Device C(cfg-router)# bgp-instance shutdown graceful
```

5. Verification

On Device C, check the BGP neighbor status.

```
Device C(cfg)#display ip bgp-instance peer 192.168.1.1
For address family: IPv4 Unicast
BGP peer is 192.168.1.1, remote AS 65536, local AS 65537, external link
 Administratively graceful shut down
  BGP version 4, remote router ID 0.0.0.0
  BGP state = Idle
  Last read               , hold time is 30, keepalive interval is 1 seconds
  Configured hold time is 30, keepalive interval is 1 seconds
  Received 0 messages, 0 notifications, 0 in queue
    open message:0 update message:0 keepalive message:0
    refresh message:0 dynamic cap:0 notifications:0
  Sent 0 messages, 0 notifications, 0 in queue
    open message:0 update message:0 keepalive message:0
    refresh message:0 dynamic cap:0 notifications:0
  Route refresh request: received 0, sent 0
  Minimum time between advertisement runs is 30 seconds
  Update source is Loopback 0

 For address family: IPv4 Unicast
  BGP table version 1, peer version 0
  Index 1, Offset 0, Mask 0x2
  0 accepted prefixes
  0 announced prefixes

 Connections established 0; dropped 0
  BGP peer may be up to 255 hops away.
Sock_fd: -1
Last Reset:               , due to BGP Notification received
Notification Error Message: (Cease/Other Configuration Change.)
```

6. Configuration Files

- Device A configuration file

```
!
router-protocol bgp 65536
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 192.168.1.2 remote-as 65537
 peer 192.168.2.2 remote-as 65537
 address-family-mode ipv4
  peer 192.168.1.2 activate
  peer 192.168.1.2 as-loop-check out
```

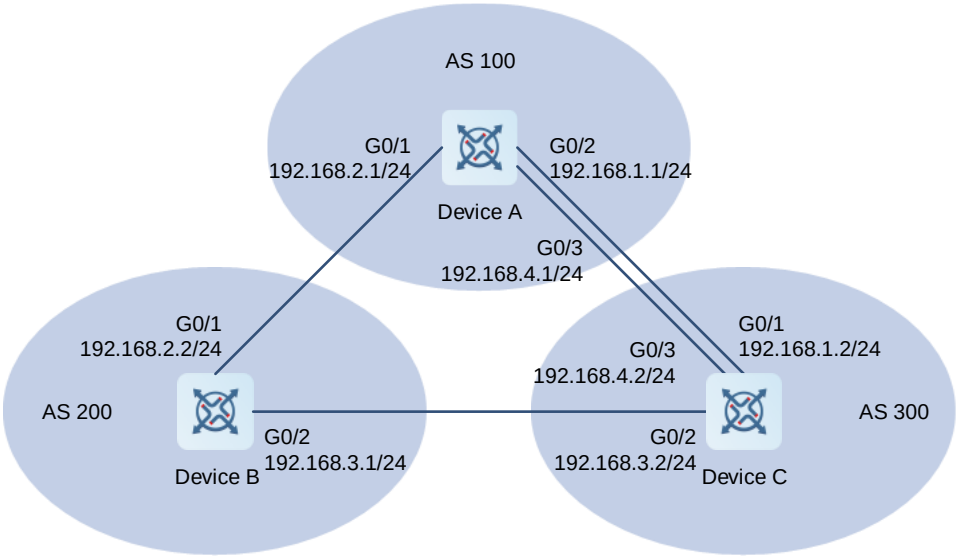
```
  peer 192.168.2.2 activate
  peer 192.168.2.2 as-loop-check out
  exit-address-family-mode
!
```

- Device B configuration file

```
!
router-protocol bgp 65537
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 192.168.2.1 remote-as 65536
 peer 192.168.3.2 remote-as 65537
 address-family-mode ipv4
  peer 192.168.2.1 activate
  peer 192.168.3.2 activate
  exit-address-family-mode
!
```

- Device C configuration file

```
!
router-protocol bgp 65537
 bgp-instance shutdown graceful
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 192.168.1.1 remote-as 65536
 peer 192.168.3.1 remote-as 65537
 address-family-mode ipv4
  peer 192.168.1.1 activate
  peer 192.168.3.1 activate
  exit-address-family-mode
!
```



1.13.18 Configuring BGP Multi-Path Bypass Protection

1. Requirements

Multi-path bypass protection needs to be configured to enhance routing reliability.

2. Topology

Figure 1-19 Configuring BGP Multi-Path Bypass Protection

3. Notes

- Enable BGP on all devices (omitted).
- Configure addresses for directly connected interfaces on devices A, B, and C, and configure them to establish EBGP neighbor relationships (omitted).
- Configure a BFD session for the EBGP neighbor relationship between devices A and C (omitted).
- On device C, configure BGP multi-path bypass protection and ECMP.

4. Procedure

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 100
Device A(cfg-router)# peer 192.168.1.2 remote-as 300
Device A(cfg-router)# peer 192.168.4.2 remote-as 300
Device A(cfg-router)# peer 192.168.2.2 remote-as 200
Device A(cfg-router)# max-ecmp-paths ebgp 2
Device A(cfg-router)# redistribute-route connected
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 200
Device B(cfg-router)# peer 192.168.3.2 remote-as 300
Device B(cfg-router)# peer 192.168.3.2 fall-over bfd
Device B(cfg-router)# peer 192.168.2.1 remote-as 100
Device B(cfg-router)# redistribute-route connected
```

Configure Device C.

```
Device C# config-system terminal
```

```
Device C(cfg)# router-protocol bgp 300
Device C(cfg-router)# peer 192.168.1.1 remote-as 100
Device C(cfg-router)# peer 192.168.4.1 remote-as 100
Device C(cfg-router)# peer 192.168.3.1 remote-as 200
Device C(cfg-router)# peer 192.168.1.1 fall-over bfd
Device C(cfg-router)# peer 192.168.4.1 fall-over bfd
Device C(cfg-router)# max-ecmp-paths ebgp 2
Device C(cfg-router)# address-family-mode ipv4 unicast
Device C(cfg-router-af)# bgp-instance install standby-path
Device C(cfg-router-af)# redistribute-route connected
```

5. Verification

On Device C, check BGP information.

```
Device C# display ip bgp-instance status
BGP router identifier 192.168.4.2, local AS number 300
BGP table version is 12
4 BGP AS-PATH entries
0 BGP Community entries
4 BGP Prefix entries (Maximum-prefix:4294967295)

Neighbor        V           AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down       State/PfxRcd

1.13.19 Configuring Multi-Path Route Import Between VRF Instances

1. Requirements

Device A is connected with two networks through the interfaces of two VRF instances (vpn1 and vpn2) so that cross-VRF access is implemented through device A.

2. Topology

Figure 1-20 Configuring Multi-Path Route Import Between VRF Instances

3. Notes

- Configure VRF instances and VRF static routes.
- Configure a VRF address family.
- Import VRF static routes to BGP.
- Enable the function of importing multi-path static routes to BGP.
- Configure BGP ECMP.
- Configure the import of all path routes between VRF instances.

4. Procedure

(1) Configure VRF instances and VRF static routes.

Configure Device A.

```
Device A# config-system terminal
```

```
Device A(cfg)# ip vrf vpn1
Device A(cfg-vrf)# rd 200:1
Device A(cfg-vrf)# route-target both 100:100
Device A(cfg-vrf)# exit
Device A(cfg)# ip vrf vpn2
Device A(cfg-vrf)# rd 300:1
Device A(cfg-vrf)# route-target both 100:100
Device A(cfg-vrf)# exit
Device A(cfg)# interface GigabitEthernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# ip vrf bindingvpn1
Device A(cfg-if-GigabitEthernet 0/1)# ip address 44.1.1.2 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# interface GigabitEthernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# ip vrf bindingvpn1
Device A(cfg-if-GigabitEthernet 0/2)# ip address 45.1.1.2 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/2)# exit
Device A(cfg)# interface GigabitEthernet 0/3
Device A(cfg-if-GigabitEthernet 0/3)# ip vrf bindingvpn2
Device A(cfg-if-GigabitEthernet 0/3)# ip address 46.1.1.2 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/3)# exit
Device A(cfg)# interface GigabitEthernet 0/4
Device A(cfg-if-GigabitEthernet 0/4)# ip vrf bindingvpn2
Device A(cfg-if-GigabitEthernet 0/4)# ip address 47.1.1.2 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/4)# exit
Device A(cfg)# ip route-config vrf vpn1 100.1.1.1 255.255.255.255 44.1.1.1
Device A(cfg)# ip route-config vrf vpn1 100.1.1.1 255.255.255.255 45.1.1.1
Device A(cfg)# ip route-config vrf vpn2 200.1.1.1 255.255.255.255 46.1.1.1
Device A(cfg)# ip route-config vrf vpn2 200.1.1.1 255.255.255.255 47.1.1.1
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# ip vrf vpn1
Device B(cfg-vrf)# rd 200:1
Device B(cfg-vrf)# route-target both 100:100
Device B(cfg-vrf)# exit
Device B(cfg)# interface GigabitEthernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip vrf bindingvpn1
Device B(cfg-if-GigabitEthernet 0/1)# ip address 44.1.1.1 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface GigabitEthernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# ip vrf bindingvpn1
Device B(cfg-if-GigabitEthernet 0/2)# ip address 45.1.1.1 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/2)# exit
Device B(cfg)# ip route-config vrf vpn1 100.1.1.2 255.255.255.255 44.1.1.2
Device B(cfg)# ip route-config vrf vpn1 100.1.1.2 255.255.255.255 45.1.1.2
```

Configure Device C.

```
Device C# config-system terminal
Device C(cfg)# ip vrf vpn2
Device C(cfg-vrf)# rd 300:1
Device C(cfg-vrf)# route-target both 100:100
Device C(cfg-vrf)# exit
Device C(cfg)# interface GigabitEthernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# ip vrf bindingvpn2
Device C(cfg-if-GigabitEthernet 0/1)# ip address 46.1.1.1 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/1)# exit
Device C(cfg)# interface GigabitEthernet 0/2
Device C(cfg-if-GigabitEthernet 0/2)# ip vrf bindingvpn2
Device C(cfg-if-GigabitEthernet 0/2)# ip address 47.1.1.1 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/2)# exit
Device C(cfg)# ip route-config vrf vpn2 200.1.1.2 255.255.255.255 46.1.1.2
Device C(cfg)# ip route-config vrf vpn2 200.1.1.2 255.255.255.255 47.1.1.2
```

(2) Configure the function of importing multi-path static routes to BGP to implement inter-VRF route import.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 100
Device A(cfg-router)# address-family-mode ipv4 vrf vpn1
Device A(cfg-router-af)# redistribute-route static
Device A(cfg-router-af)# max-ecmp-paths ebgp 32
Device A(cfg-router-af)# bgp-instance src-paths static all
Device A(cfg-router-af)# import route strategy all
Device A(cfg-router-af)# exit-address-family-mode
Device A(cfg-router)# address-family-mode ipv4 vrf vpn2
Device A(cfg-router-af)# redistribute-route static
Device A(cfg-router-af)# max-ecmp-paths ebgp 32
Device A(cfg-router-af)# bgp-instance src-paths static all
Device A(cfg-router-af)# import route strategy all
Device A(cfg-router-af)# exit-address-family-mode
```

5. Verification

On Device A, check VRF routes.

```
Device A# display ip route-config vrf-info vpn1
Routing Table: vpn1

Codes:   C - Connected, L - Local, S - Static
         R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
         N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
         E1 - OSPF external type 1, E2 - OSPF external type 2
         SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
         IA - Inter area, EV - BGP EVPN, A - Arp to host-route
         * - candidate reset

Gateway of last resort is unset set
```

```
C       44.1.1.0/24 is directly connected, GigabitEthernet 0/1
C       44.1.1.2/32 is local host-route.
C       45.1.1.0/24 is directly connected, GigabitEthernet 0/2
C       45.1.1.2/32 is local host-route.
S       100.1.1.1/32 [1/0] via 44.1.1.1
                           [1/0] via 45.1.1.1
B       200.1.1.1/32 [20/0] via 47.1.1.1, 02:32:01
                           [20/0] via 46.1.1.1, 02:32:01

Device A# display ip route-config vrf-info vpn2
Routing Table: vpn2

Codes:   C - Connected, L - Local, S - Static
         R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
         N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
         E1 - OSPF external type 1, E2 - OSPF external type 2
         SU - IS-IS status, L1 - IS-IS level-1, L2 - IS-IS level-2
         IA - Inter area, EV - BGP EVPN, A - Arp to host-route
         * - candidate reset

Gateway of last resort is unset set
C       46.1.1.0/24 is directly connected, GigabitEthernet 0/3
C       46.1.1.2/32 is local host-route.
C       47.1.1.0/24 is directly connected, GigabitEthernet 0/4
C       47.1.1.2/32 is local host-route.
B       100.1.1.1/32 [20/0] via 45.1.1.1, 03:27:07
                           [20/0] via 44.1.1.1, 03:27:07
S       200.1.1.1/32 [1/0] via 46.1.1.1
                           [1/0] via 47.1.1.1
```

1.13.20 Configuring BMP Monitoring

1. Requirements

The BGP connections established between devices A and B need to be monitored by the BMP server.

2. Topology

Figure 1-21 Configuring BMP Monitoring

3. Notes

- Configure BGP basic features (omitted).
- Configure information relevant to a BMP server instance (address, port number, type of monitored routes, and MD5 authentication password for TCP connection).
- Configure the BMP server to monitor BGP peers.

4. Procedure

(1) Configure information related to a BMP server instance.

Configure device A.

```
Device A# config-system terminal
Device A(cfg)# bmp server 1
Device A(cfg-bmpsrvr)# address 11.1.1.2 port 12345
Device A(cfg-bmpsrvr)# update-source gigabitEthernet 0/1
Device A(cfg-bmpsrvr)# adj-rib-in post-policy
Device A(cfg-bmpsrvr)# password Red-Giant
```

(2) Configure the BMP server to monitor BGP peers.

Configure device A.

```
Device A(cfg)# router-protocol bgp 100
Device A(cfg-router)# peer 10.1.1.2 remote-as 100
Device A(cfg-router)# peer 10.1.1.2 bmp-active server 1
```

5. Verification

On device A, check BGP information.

```
Device A# display bgp-instance all status
For address family: IPv4 Unicast
BGP router identifier 11.1.1.1, local AS number 100
BGP table version is 1
1 BGP AS-PATH entries
0 BGP Community entries
25 BGP Prefix entries (Maximum-prefix:262144)

Neighbor        V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down   State/PfxRcd
10.1.1.2        4        100       0       0        0    0    0 05:36:32        23

Device A# display bgp-instance bmp peer

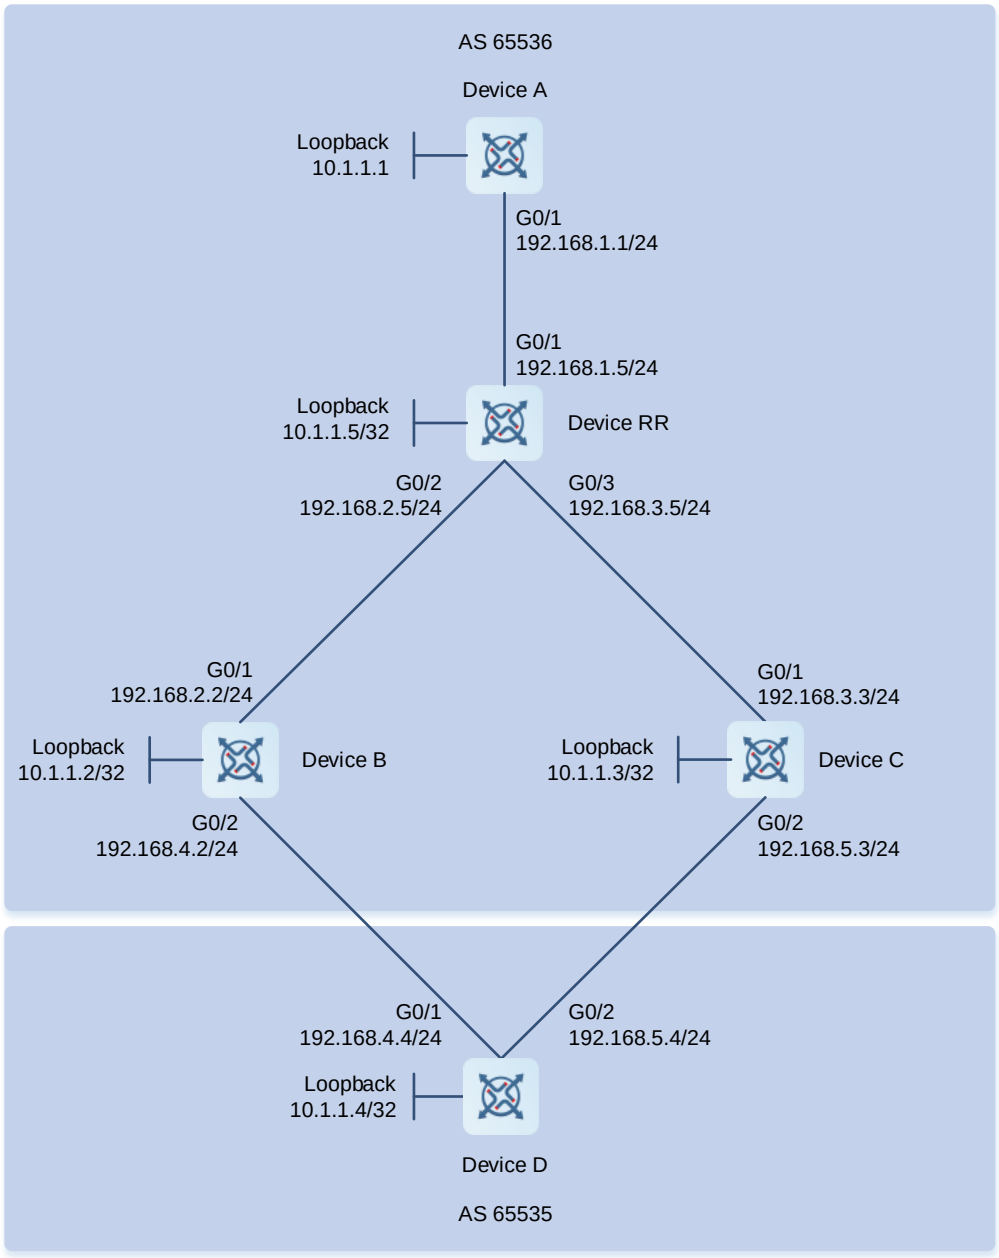
Neighbor        CfgSvr#         ActSvr#
10.1.1.2        1               1

Device A# display bgp-instance bmp status
ID   Host                 Port      State        Time        NBRs
1    11.1.1.2             12345     Established  05:36:12    1
```

6. Configuration Files

- Device A configuration file

```
!
router-protocol bgp 100
 bgp-instance log-peer-changes
 bgp-instance graceful-restart restart-time 120
 bgp-instance graceful-restart staleroute-time 360
 bgp-instance graceful-restart
 peer 10.1.1.2 remote-as 100
 peer 10.1.1.2 bmp-active server 1
 address-family-mode ipv4
  peer 10.1.1.2 activate
  exit-address-family-mode
!
bmp server 1
 address 11.1.1.2 port 12345
 update-source GigabitEthernet 0/1
 adj-rib-in post-policy
 password Red-Giant
!
```



1.13.21 Configuring BGP ADD-PATH

1. Requirements

When the device is allowed to advertise multiple routes with the same prefix to a neighbor, you can define ADD-PATH to enable multiple links to implement load sharing or backup, thereby increasing the network link reliability.

2. Topology

Figure 1-22 Configuring BGP ADD-PATH

3. Notes

- As shown in Figure 1-22, configure interconnection addresses for devices A, B, C, D, and RR, configure devices A, B, C, and RR to establish IBGP neighbor relationships, configure device RR as a BGP route reflector, and configure devices B and D and devices C and D to establish EBGP neighbor relationships.
- Configure a loopback address on device D and advertise it to BGP.
- Configure the ADD-PATH advertisement capability on device RR and the ADD-PATH receiving capability on device A.

4. Procedure

(1) Configure BGP basic features and interface IP addresses on devices A, B, C, and D.

Configure device A.

```
Device A# config-system terminal
Device A(cfg)# interface GigabitEthernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# router-protocol bgp 65536
Device A(cfg-router)# peer 192.168.1.5 remote-as 65536
Device A(cfg-router)# peer 192.168.1.5 alternative-paths recv
```

Configure device B.

```
Device B# config-system terminal
Device B(cfg)# interface GigabitEthernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface GigabitEthernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# ip address 192.168.4.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/2)# exit
Device B(cfg)# router-protocol bgp 65536
Device B(cfg-router)# peer 192.168.2.5 remote-as 65536
Device B(cfg-router)# peer 192.168.4.4 remote-as 65535
```

Configure device C.

```
Device C# config-system terminal
Device C(cfg)# interface GigabitEthernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# ip address 192.168.3.3 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/1)# exit
Device C(cfg)# interface GigabitEthernet 0/2
Device C(cfg-if-GigabitEthernet 0/2)# ip address 192.168.5.3 255.255.255.0
Device C(cfg-if-GigabitEthernet 0/2)# exit
Device C(cfg)# router-protocol bgp 65536
Device C(cfg-router)# peer 192.168.3.5 remote-as 65536
Device C(cfg-router)# peer 192.168.5.4 remote-as 65535
```

Configure device D.

```
Device D# config-system terminal
Device D(cfg)# interface loopback 0
Device D(cfg-if-Loopback 0)# ip address 10.1.1.4 255.255.255.255
Device D(cfg-if-Loopback 0)# exit
Device D(cfg)# interface GigabitEthernet 0/1
Device D(cfg-if-GigabitEthernet 0/1)# ip address 192.168.4.4 255.255.255.0
Device D(cfg-if-GigabitEthernet 0/1)# exit
Device D(cfg)# interface GigabitEthernet 0/1
Device D(cfg-if-GigabitEthernet 0/1)# ip address 192.168.5.4 255.255.255.0
Device D(cfg-if-GigabitEthernet 0/1)# exit
Device D(cfg)# router-protocol bgp 65535
```

```
Device D(cfg-router)# peer 192.168.4.2 remote-as 65536
Device D(cfg-router)# peer 192.168.5.3 remote-as 65536
Device D(cfg-router)# network-advertise 10.1.1.4 mask 255.255.255.255
```

Configure device RR.

```
Device RR# config-system terminal
Device RR(cfg)# interface loopback 0
Device RR(cfg-if-Loopback 0)# ip address 10.1.1.5 255.255.255.255
Device RR(cfg-if-Loopback 0)# exit
Device RR(cfg)# interface GigabitEthernet 0/1
Device RR(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.5 255.255.255.0
Device RR(cfg-if-GigabitEthernet 0/1)# exit
Device RR(cfg)# interface GigabitEthernet 0/2
Device RR(cfg-if-GigabitEthernet 0/2)# ip address 192.168.2.5 255.255.255.0
Device RR(cfg-if-GigabitEthernet 0/2)# exit
Device RR(cfg)# interface GigabitEthernet 0/3
Device RR(cfg-if-GigabitEthernet 0/3)# ip address 192.168.3.5 255.255.255.0
Device RR(cfg-if-GigabitEthernet 0/3)# exit
Device RR(cfg)#ip route-config 192.168.4.0 255.255.255.0 192.168.2.2
Device RR(cfg)#ip route-config 192.168.5.0 255.255.255.0 192.168.3.3
Device RR(cfg)# router-protocol bgp 65536
Device RR(cfg-router)# peer 192.168.1.1 remote-as 65536
Device RR(cfg-router)# peer 192.168.1.1 route-reflector-client
Device RR(cfg-router)# peer 192.168.2.2 remote-as 65536
Device RR(cfg-router)# peer 192.168.2.2 route-reflector-client
Device RR(cfg-router)# peer 192.168.3.3 remote-as 65536
```

(2) Configure the ADD-PATH rules for the route reflector RR.

Configure device RR.

```
Device RR# config-system terminal
Device RR(cfg)# router-protocol bgp 65536
Device RR(cfg-router)# bgp-instance alternative-paths select best 2
Device RR(cfg-router)# peer 192.168.1.1 advertise alternative-paths best 2
Device RR(cfg-router)# peer 192.168.1.1 alternative-paths send
```

5. Verification

On device RR, check the BGP neighbor status.

```
Device RR# display ip bgp-instance
BGP table version is 3, local router ID is 10.1.1.5
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
                    S Stale, b - backup entry, a additional-path
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network            Next Hop              Metric     LocPrf     Weight Path
* ia10.1.1.4/32      192.168.4.4                0        100          0 65535 i
*>i                   192.168.5.4                0        100          0 65535 i
Total number of prefixes 2
```

On device A, run the **display** command to display the BGP neighbor status.

```
Device A# display ip bgp-instance
BGP table version is 2, local router ID is 192.168.1.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
                    S Stale, b - backup entry, a additional-path
Origin codes: i - IGP, e - EGP, ? - incomplete

    Network          Next Hop            Metric     LocPrf     Weight Path
* i 10.1.1.4/32     192.168.5.4              0      100          0 65535 i
* i                  192.168.4.4              0      100          0 65535 i
Total number of prefixes 2
```

6. Configuration Files

1.13.22 Configuring BGP Neighbor Auto-Discovery

1. Requirements

A BGP session is automatically established over a specific interface.

2. Topology

Figure 1-23 Configuring BGP Neighbor Auto-Discovery

3. Notes

- Enable BGP on all devices.
- Configure peer groups and enable the IPv4 and IPv6 address families on all devices.
- Enable BGP neighbor auto-discovery on all devices.
- Configure the **ipv6 enable** command on the interface between device A and device B.
- Configure BGP neighbor auto-discovery on the interface between device A and device B.

4. Procedure

(1) Configure the BGP peer groups, enable the IPv4 and IPv6 address families, and enable BGP neighbor auto-discovery.

Configure device A.

```
Device A# config-system terminal
Device A(cfg)# router-protocol bgp 65530
Device A(cfg-router)# peer ad peer-group
Device A(cfg-router)# address-family-mode ipv4
Device A(cfg-router-af)# peer ad activate
Device A(cfg-router-af)# exit-address-family-mode
Device A(cfg-router)# address-family-mode ipv6
Device A(cfg-router-af)# peer ad activate
Device A(cfg-router-af)# exit-address-family-mode
Device A(cfg-router)# auto-discovery
Device A(cfg-router-ad)# exit-auto-discovery
Device A(cfg-router)# exit
```

Configure device B.

```
Device B# config-system terminal
Device B(cfg)# router-protocol bgp 65531
Device B(cfg-router)# peer ad peer-group
Device B(cfg-router)# address-family-mode ipv4
Device B(cfg-router-af)# peer ad activate
Device B(cfg-router-af)# exit-address-family-mode
Device B(cfg-router)# address-family-mode ipv6
```

```
Device B(cfg-router-af)# peer ad activate
Device B(cfg-router-af)# exit-address-family-mode
Device B(cfg-router)# auto-discovery
Device B(cfg-router-ad)# exit-auto-discovery
Device B(cfg-router)# exit
```

(2) Configure on the **ipv6 enable** command and BGP neighbor auto-discovery on the interface.

Configure device A.

```
Device A# config-system terminal
Device A(cfg)# interface GigabitEthernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ipv6 enable
Device A(cfg-if-GigabitEthernet 0/1)# bgp-instance auto-discovery local-as 65530
Device A(cfg-if-GigabitEthernet 0/1)# bgp-instance auto-discovery source-interface source-self peer-group ad
```

Configure device B.

```
Device B# config-system terminal
Device B(cfg)# interface GigabitEthernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/1)# ipv6 enable
Device B(cfg-if-GigabitEthernet 0/1)# bgp-instance auto-discovery local-as 65531
Device B(cfg-if-GigabitEthernet 0/1)# bgp-instance auto-discovery source-interface source-self peer-group ad
```

5. Verification

On device A, check the BGP neighbor information.

```
Device A# display bgp-instance all peers

For address family: IPv4 Unicast

1 Configuring VRF

1.1 Introduction

1.1.1 Overview

VPN Routing and Forwarding Table (VRF) is used to resolve local routing conflicts caused by the same IP address space between different Virtual Private Networks (VPNs). One VPN corresponds to one VRF. Each VRF is equivalent to a "virtual router" that receives or advertises VPN routing information. Each VRF includes:

- An independent routing table;
- A set of interfaces belonging to this VRF;
- A set of routing protocols used for this VRF only.

Multiple routing tables on the device that provides the VPN service including a public network routing table and one or more VRFs. The public network routing table is used to forward public network packets, and the VRF is used to forward VPN packets. Routes in the public network routing table are separated from those in VRFs, and routes are separated between VRFs.

Note

- A VPN is a private dedicated network built in the public network. "Virtual" means that the VPN is logically exclusive, but not physically exclusive.
- The private dedicated network is called “private network” for short.

1.1.2 Principles

1. VPN Instance

A VPN instance is used to provide the VPN service. On a device that provides the VPN service, a VPN instance includes the VRFs, interfaces, routing protocol processes, and configurations that belong to the same VPN. Generally, the VRF represents a VPN instance.

2. VPN Route

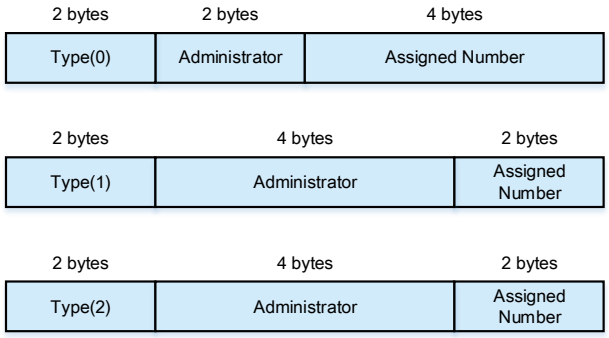
A VPN route is only used to forward VPN packets. It comes from:

- Direct route and host route generated after an interface is added to the VRF;
- Direct route and host route imported from an interface that is not added to the VRF;
- Static and dynamic routes (RIP, RIPng, OSPFv2, OSPFv3, ISIS, and BGP) in the configured VPN instance.

Note

- For configuration of the static route in a VPN instance, see *Configuring IP Route Basics*.
- For configuration of RIP in a VPN instance, see *Configuring RIP*.
- For configuration of RIPng in a VPN instance, see *Configuring RIPng*.
- For configuration of OSPFv2 in a VPN instance, see *Configuring OSPFv2*.
- For configuration of OSPFv3 in a VPN instance, see *Configuring OSPFv3*.
- For configuration of ISIS in a VPN instance, see *Configuring ISIS*.

- For configuration of BGP in a VPN instance, see *Configuring BGP*.



3. VPN Route Attribute

A VPN route has two attributes: Route Distinguisher (RD) and Route Target (RT).

- The RD is used to resolve routing conflicts when the Border Gateway Protocol (BGP) advertises routes. If different VPNs have the same network addresses, the BGP only selects an optimum route from these addresses and advertises this route. As a result, some VPNs cannot receive the routing information. To resolve this problem, you can add different RDs to the same addresses. Based on the different RDs carried in VPN information, the BGP can distinguish the same network addresses, and therefore each VPN can receive its own routing information.

  Generally, a unique RD value is specified for each VPN. A VPN route carries only one RD value. An RD consists of a **Type** field, an **Administrator** field, and an **Assigned Number** field. As shown in Figure 1-1, based on the value of the **Type** field, the RD is encoded in three formats:

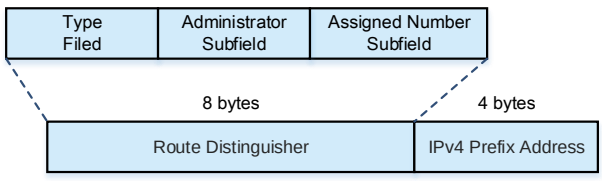


Figure 1-1 RD structure

  - When **Type** is set to **0**, the **Administrator** field has two bytes and is set to an Autonomous System (AS) number, which must be a public AS number; the **Assigned Number** field has four bytes and is managed by the service provider (SP).
  - When **Type** is set to **1**, the **Administrator** field has four bytes and is set to an IPv4, which must be a global IP address; the **Assigned Number** field has two bytes and is managed by the SP.
  - When **Type** is set to **2**, the **Administrator** field has four bytes and is set to a 4-byte AS number; the **Assigned Number** field has two bytes and is managed by the SP.

  An IPv4 address with the RD is called VPN-IPv4 address, as shown in Figure 1-2. After receiving an IPv4 route, the BGP converts it into a globally unique VPN-IPv4 route, and advertises this route in the public network.

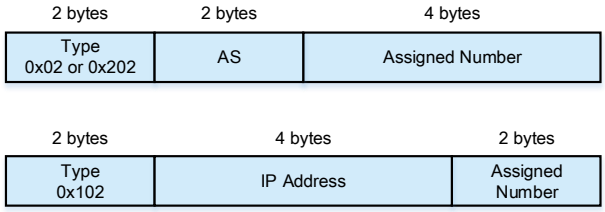

Figure 1-2 VPN-IPv4 address structure

- RT is used to control the advertising and installation policies of VPN routes. The RT attribute falls into the following two types:
  - **Import**: When a device receives the advertised VPN-IPv4 route, the device checks the **Export** attribute of this route. If the **Import** attribute of a specified VPN instance on the device matches the **Export** attribute, the device adds the route to the VPN instance.
  - **Export**: After the local device learns an IPv4 route, it converts this route into a VPN-IPv4 route. The **Export** attribute is set for this route and advertised as the BGP extended community attribute to other devices together with the route.

  The BGP extended community attribute defines the RT structure, as shown in Figure 1-3.

Figure 1-3 RT structure

The RT value and the RD value are similarly defined. When **Type** is set to **0x02** or **0x202**, the AS number must be public. When **Type** is set to **0x102**, the IPv4 address must be a global IP address.

1.1.3 Protocols and Standards

- RFC 4364: BGP/MPLS IP Virtual Private Networks (VPNs)

1.2 Restrictions and Guidelines

- You can configure only one type of VRF: single-protocol VRF or Multi-protocol VRF.
- Single-protocol VRFs only support IPv4, whereas Multi-protocol VRFs support both IPv4 and IPv6.

1.3 Configuration Task Summary

The configuration tasks below are mutually exclusive. Please configure only one task.

- Configuring a Single-protocol VRF
  - Creating a Single-protocol VRF
  - (Optional)Configuring the RD for a Single-protocol VRF
  - (Optional)Configuring the RT for a Single-protocol VRF
  - (Optional)Configuring the Label Allocation Mode for a Single-protocol VRF
  - (Optional)Configuring an Export Policy Associated with a Single-protocol VRF
  - (Optional)Configuring an Import Policy Associated with a Single-protocol VRF
  - Adding an Interface to a Single-protocol VRF
  - (Optional)Importing Routes of an Interface to a Single-protocol VRF

- (Optional)Configuring Maximum Number of Routes for a Single-protocol VRF

- Configuring a Multi-protocol VRF
  - Creating a Multi-protocol VRF
  - (Optional) Configuring the Address Family for a Multi-protocol VRF
  - (Optional)Configuring the RD for a Multi-protocol VRF
  - (Optional)Configuring the RT for a Multi-protocol VRF
  - (Optional)Configuring the Label Allocation Mode for a Multi-protocol VRF
  - (Optional)Configuring an Export Policy Associated with a Multi-protocol VRF
  - (Optional)Configuring an Import Policy Associated with a Multi-protocol VRF
  - Adding an Interface to a Multi-protocol VRF
  - (Optional)Importing Routes of an Interface to a Multi-protocol VRF
  - (Optional)Configuring Maximum Number of Routes for a Multi-protocol VRF
- VRF Configuring a Global VRF
  - Configuring the Address Family for a Global VRF
  - (Optional)Configuring the RD for a Global VRF
  - (Optional)Configuring the RT for a Global VRF
  - (Optional)Configuring the Label Allocation Mode for a Global VRF
  - (Optional)Configuring an Export Policy Associated with a Global VRF
  - (Optional)Configuring an Import Policy Associated with a Global VRF
  - (Optional)Configuring Maximum Number of Routes for a Global VRF

1.4 Configuring a Single-protocol VRF

1.4.1 Overview

A single-protocol VRF is configured to manage VPN routes.

1.4.2 Restrictions and Guidelines

- If a device forwards only packets of a specified VPN or only public network packets, you do not need to configure a single-protocol VRF.
- If the device needs to forward both the public network packets and VPN packets or forward packets from multiple VPNs, VRFs must be created to separate routes.
- You need to add static or dynamic routes (RIP, OSPF, ISIS, and BGP) to a VRF.
- Only IPv4 is supported.
- When a Layer 3 interface joins or exits a single-protocol VRF, the IPv4 address, related routing protocols and Layer 3 attributes of the interface will be deleted as well.
- If a Layer 3 interface has been added to a single-protocol VRF, the IPv4 address, related routing protocols, and Layer 3 attributes of the interface will be deleted when the VRF is deleted.

1.4.3 Configuration Tasks

The configuration of a single-protocol VRF includes the following tasks:

- Creating a Single-protocol VRF
- (Optional)Configuring the RD for a Single-protocol VRF
- (Optional)Configuring the RT for a Single-protocol VRF
- (Optional)Configuring the Label Allocation Mode for a Single-protocol VRF
- (Optional)Configuring an Export Policy Associated with a Single-protocol VRF
- (Optional)Configuring an Import Policy Associated with a Single-protocol VRF
- Adding an Interface to a Single-protocol VRF
- (Optional)Importing Routes of an Interface to a Single-protocol VRF
- (Optional)Configuring Maximum Number of Routes for a Single-protocol VRF

1.4.4 Creating a Single-protocol VRF

1. Overview

This section describes how to create a single-protocol VRF for each VPN.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a single-protocol VRF, and enter the VRF configuration mode.

ip vrf *vrf-name*

No single-protocol VRF is configured by default.

(4) (Optional) Configure a description for single-protocol VRF.

description *description*

No description is configured for single-protocol VRF by default.

1.4.5 Configuring the RD for a Single-protocol VRF

1. Overview

This section describes how to configure the RD to resolve routing conflicts when the BGP advertises routes.

2. Restrictions and Guidelines

- Configure the RD command in single-protocol VRF configuration mode.
- If you have configured a VRF value and its RD value and want to modify the RD value, you must first delete the VRF, reconfigure the VRF, and then configure the RD value.
- You can configure only one RD value for a VRF.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the single-protocol VRF configuration mode.

ip vrf *vrf-name*

(4) Configure the RD.

rd *rd-value*

No RD value is configured by default.

1.4.6 Configuring the RT for a Single-protocol VRF

1. Overview

This section describes how to configure the RT value to control advertisement of VPN routes.

2. Restrictions and Guidelines

- Configure the RT value in single-protocol VRF configuration mode.
- You can configure multiple **Import** or **Export** values for each VRF.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the single-protocol VRF configuration mode.

ip vrf *vrf-name*

(4) Configure the RT.

route-target { **both** | **export** | **import** } *route-value*

No RT is configured by default.

1.4.7 Configuring the Label Allocation Mode for a Single-protocol VRF

1. Overview

This section describes how to configure the label allocation mode for a single-protocol VRF.

2. Restrictions and Guidelines

- Route-based label allocation mode: One route corresponds to one label. The advantage is that the system can look up the ILM table based on the label value and quickly forward packets to the next hop. The disadvantage is that the capacity of the ILM table must be large.
- VRF-based label allocation mode: One VRF corresponds to one label. The advantage is that all routes in the VRF share this label, which reduces the capacity of the ILM table. The disadvantage is that packet

forwarding is slower than that in route-based label allocation mode. This is because the system needs to look up the table twice in the forwarding process. It first looks up the ILM table to find the VRF where the packet is located, and then forwards the packet based on the destination IP address in the routing table of the VRF.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the single-protocol VRF configuration mode.

ip vrf *vrf-name*

(4) Configure the label allocation mode.

alloc-label { **per-route** | **per-vrf** }

No label allocation mode is configured by default.

1.4.8 Configuring an Export Policy Associated with a Single-protocol VRF

1. Overview

This section describes how to configure a policy for exporting the extended community attributes of VPN routes from the local VRF to a remote device.

2. Restrictions and Guidelines

- To more precisely control the extended community attributes of exported routes, you can define a precise rule as needed in the associated route map.
- You can run this command to add or modify the extended community attributes defined by the **route-target export** command.
- You can only run the **match ip address** and **set extcommunity** commands to configure rules for a route map associated by this command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the single-protocol VRF configuration mode.

ip vrf *vrf-name*

(4) Configure the associated export policy.

export map *route-map-name*

No export policy associated with the VRF is configured by default.

1.4.9 Configuring an Import Policy Associated with a Single-protocol VRF

1. Overview

This section describes how to configure a policy for importing VPN routes from a remote device to the local VRF.

2. Restrictions and Guidelines

- To more precisely filter routes imported to the local VRF, you can define a precise rule as needed in the associated route map.
- The rule defined by the **import map** command takes effect after the **Import** extended community attributes defined in the VRF. That is, only after the route matches the extended community attributes defined by the **route-target import** command in the VRF, can the VPN routes received from the remote device be filtered again by rules defined by the **import map** command.
- You can only run the **match ip address** and **match extcommunity** commands to configure rules for a route map associated by the **import map** command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the single-protocol VRF configuration mode.

ip vrf *vrf-name*

(4) Configure the associated import policy.

import map *route-map-name*

No import policy associated with the VRF is configured by default.

1.4.10 Adding an Interface to a Single-protocol VRF

1. Overview

This section describes how to add an interface to a specified VRF. This VRF is used to forward incoming packets of the interface.

2. Restrictions and Guidelines

You must add the interface to the single-protocol VRF before configuring the IPv4 address. If you configure the IPv4 address for an interface and then add the interface to the single-protocol VRF, the configuration of the IPv4 address fails, but the configuration of the IPv6 address is retained.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Add the interface to the single-protocol VRF.

ip vrf binding *vrf-name*

By default, an interface does not belong to any VRF.

1.4.11 Importing Routes of an Interface to a Single-protocol VRF

1. Overview

This section describes how to import the host route and direct route of an interface to a specified VRF.

2. Restrictions and Guidelines

- If you need to use policy-based routing (PBR) to select the VRF, configure the **ip vrf receive** command on the interface to which PBR is applied, and import the direct route and host route on the interface to each VRF available for choice.
- If you need to import the host route and direct route of an interface to multiple VRFs, run this command multiple times.
- The **ip vrf binding** and **ip vrf receive** commands are mutually exclusive on a specified interface. Unlike the **ip vrf binding** command, the **ip vrf receive** command does not add the interface to the VRF, and the interface does not belong to any VRF.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Import the host route and direct route of the interface to a specified VRF.

ip vrf receive *vrf-name*

The direct route and host route of an interface are not imported to any specified VRF by default.

1.4.12 Configuring Maximum Number of Routes for a Single-protocol VRF

1. Overview

You can limit the maximum number of routing entries in a single-protocol VRF by performing this configuration.

2. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Enter the single-protocol VRF configuration mode.
ip vrf *vrf-name*

(4) Configure the maximum number of routes in a single-protocol VRF.
maximum routes-number *limit* { **warning** | *warning-threshold* }

The maximum number of routes in the single-protocol VRF is not limited by default.

1.5 Configuring a Multi-protocol VRF

1.5.1 Overview

This section describes how to configure a Multi-protocol VRF to manage VPN routes. You can configure the address family to support IPv4 and IPv6. The BGP helps you to flexibly isolate VPNs or allow inter-VPN access, or provide the VPN service in an IP/MPLS backbone network.

1.5.2 Restrictions and Guidelines

- If a device forwards only packets of a specified VPN or only public network packets, you do not need to configure a Multi-protocol VRF.
- If the device needs to forward both the public network packets and VPN packets or forward packets from multiple VPNs, VRFs must be created to separate routes.
- You need to add static or dynamic routes (RIP, OSPF, ISIS, and BGP) to a VRF.
- When a Layer 3 interface joins or exits a multi-protocol VRF, the IPv4 address, related routing protocols and Layer 3 attributes of the interface will be deleted as well.
- If a Layer 3 interface has been added to a multi-protocol VRF, the IPv4 address, related routing protocols, and Layer 3 attributes of the interface will be deleted when the VRF is deleted.

1.5.3 Configuration Tasks

The configuration of a Multi-protocol VRF includes the following tasks:

- Creating a Multi-protocol VRF
- (Optional) Configuring the Address Family for a Multi-protocol VRF
- (Optional)Configuring the RD for a Multi-protocol VRF
- (Optional)Configuring the RT for a Multi-protocol VRF
- (Optional)Configuring the Label Allocation Mode for a Multi-protocol VRF
- (Optional)Configuring an Export Policy Associated with a Multi-protocol VRF
- (Optional)Configuring an Import Policy Associated with a Multi-protocol VRF
- Adding an Interface to a Multi-protocol VRF
- (Optional)Importing Routes of an Interface to a Multi-protocol VRF
- (Optional)Configuring Maximum Number of Routes for a Multi-protocol VRF

1.5.4 Creating a Multi-protocol VRF

1. Overview

This section describes how to create a Multi-protocol VRF for each VPN.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a Multi-protocol VRF, and enter the Multi-protocol VRF configuration mode.

vrf definition *vrf-name*

No Multi-protocol VRF exists by default.

(4) (Optional) Configure a description for multi-protocol VRF.

description *description*

No description is configured for multi-protocol VRF by default.

1.5.5 Configuring the Address Family for a Multi-protocol VRF

1. Overview

This section describes how to enable the IPv4/IPv6 address family for a Multi-protocol VRF, and enter the configuration mode.

2. Restrictions and Guidelines

You can configure the address family for each created VRF.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Multi-protocol VRF configuration mode.

vrf definition *vrf-name*

(4) Configure the address family. Configure at least one of the following tasks.

- Configure the IPv4 address family, and enter the VRF IPv4 address family submode.

  address-family ipv4

- Configure the IPv6 address family, and enter the VRF IPv6 address family submode.

  address-family ipv6

No address family is configured for a Multi-protocol VRF by default.

1.5.6 Configuring the RD for a Multi-protocol VRF

1. Overview

This section describes how to configure the RD to resolve routing conflicts when the BGP advertises routes.

2. Restrictions and Guidelines

- Configure the RD command in Multi-protocol VRF configuration mode.
- If you have configured a VRF value and its RD value and want to modify the RD value, you must first delete the VRF, reconfigure the VRF, and then configure the RD value.
- You can configure only one RD value for a VRF.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Multi-protocol VRF configuration mode.

vrf definition *vrf-name*

(4) Configure the RD.

rd *rd-value*

No RD value is configured by default.

1.5.7 Configuring the RT for a Multi-protocol VRF

1. Overview

This section describes how to configure the RT group to control advertisement of VPN routes.

2. Restrictions and Guidelines

- Configure the RT value in Multi-protocol VRF mode or Multi-protocol VRF address family mode.
- You can configure multiple **Import** or **Export** values for each VRF.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Multi-protocol VRF configuration mode.

vrf definition *vrf-name*

- (Optional) Enter the Multi-Protocol VRF address family configuration mode.

  address-family { **ipv4** | **ipv6** }

(4) Configure the RT.

- **route-target** { **both** | **export** | **import** } *route-value*

By default, the RT is not configured.

1.5.8 Configuring the Label Allocation Mode for a Multi-protocol VRF

1. Overview

This section describes how to configure the label allocation mode for a Multi-protocol VRF.

2. Restrictions and Guidelines

- Route-based label allocation mode: One route corresponds to one label. The advantage is that the system can look up the ILM table based on the label value and quickly forward packets to the next hop. The

disadvantage is that the capacity of the ILM table must be large.

- VRF-based label allocation mode: One VRF corresponds to one label. The advantage is that all routes in the VRF share this label, which reduces the capacity of the ILM table. The disadvantage is that packet forwarding is slower than that in route-based label allocation mode. This is because the system needs to look up the table twice in the forwarding process. It first looks up the ILM table to find the VRF where the packet is located, and then forwards the packet based on the destination IP address in the routing table of the VRF.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the multi-protocol VRF configuration mode.

vrf definition *vrf-name*

- Enter the Multi-Protocol VRF address family configuration mode.

  address-family { **ipv4** | **ipv6** }

(4) Configure the label allocation mode.

alloc-label { **per-route** | **per-vrf** }

By default, the label allocation mode is not configured.

1.5.9 Configuring an Export Policy Associated with a Multi-protocol VRF

1. Overview

This section describes how to configure a policy for exporting the extended community attributes of VPN routes from the local VRF to the remote device

2. Restrictions and Guidelines

- To more precisely control the extended community attributes of exported routes, you can define a precise rule as needed in the associated route map.
- You can run this command to add or modify the extended community attributes defined by the **route-target export** command.
- You can only run the **match ip address** and **set extcommunity** commands to configure rules for a route map associated by this command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Multi-protocol VRF configuration mode.

vrf definition *vrf-name*

- Enter the Multi-protocol VRF address family configuration mode.
  - **address-family { ipv4 | ipv6 }**

(4) Configure the associated export policy.

export map *route-map-name*

No export policy associated with the VRF is configured by default.

1.5.10 Configuring an Import Policy Associated with a Multi-protocol VRF

1. Overview

This section describes how to configure a policy for importing VPN routes from a remote device to the local VRF.

2. Restrictions and Guidelines

- To more precisely filter routes imported to the local VRF, you can define a precise rule as needed in the associated route map.
- The rule defined by the **import map** command takes effect after the **Import** extended community attributes defined in the VRF. That is, only after these routes match the extended community attributes defined by the **route-target import** command in the VRF, can the VPN routes received from the remote device be filtered again by rules defined the **import map** command.
- You can only run the **match ip address** and **match extcommunity** commands to configure rules for a route map associated by the import map command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Multi-protocol VRF configuration mode.

vrf definition *vrf-name*

- Enter the Multi-Protocol VRF address family configuration mode.

  address-family { **ipv4** | **ipv6** }

(4) Configure the associated import policy.

import map *route-map-name*

No import policy associated with the VRF is configured by default.

1.5.11 Adding an Interface to a Multi-protocol VRF

1. Overview

This section describes how to add an interface to a specified VRF. This VRF is used to forward incoming packets of the interface.

2. Restrictions and Guidelines

- After this command is executed, the direct route and host route on the interface are automatically imported

to the VRF.

- Before you add an interface to a Multi-protocol VRF, enable the address family for the table. If the IPv4 address family is disabled when you add an interface to a Multi-protocol VRF, you are not allowed to configure the IPv4 and VRRP IPv4 addresses on this interface. If the IPv6 address family is disabled when you add an interface to a Multi-protocol VRF, you are not allowed to configure the IPv6 and VRRP IPv6 addresses on this interface.
- You must add an interface to the Multi-protocol VRF before configuring the IPv4/IPv6 or VRRP IPv4/IPv6 addresses on the interface. When you add an interface to a Multi-protocol VRF, existing IPv4/IPv6 or VRRP IPv4/IPv6 addresses on the interface are deleted, and the IPv6 protocol is disabled on the interface.
- If the IPv4 address family is deleted from the Multi-protocol VRF, the IPv4 and VRRP IPv4 addresses of all interfaces added to this VRF are deleted, and the IPv4 static routes in the VRF or the IPv4 static routes with this VRF as their next-hop VRF are also deleted.
- If the IPv6 address family is deleted from the Multi-protocol VRF, the IPv6 and VRRP IPv6 addresses of all interfaces added to the VRF are deleted, the IPv6 protocol is disabled on the interface, and the IPv6 static routes in the VRF or the IPv6 static routes with this VRF as their next-hop VRF are also deleted.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.
  - **interface overlayrouter** *interface-number*

(4) Add the interface to the Multi-protocol VRF.

vrf binding *vrf-name*

By default, an interface does not belong to any VRF.

1.5.12 Importing Routes of an Interface to a Multi-protocol VRF

1. Overview

This section describes how to import the host route and direct route of an interface to a specified VRF.

2. Restrictions and Guidelines

- If you need to use PBR to select the VRF, configure the **vrf receive** command on the interface to which PBR is applied to import the direct route and host route on the interface to each VRF available for choice.
- If you need to import the host route and direct route of an interface to multiple VRFs, run this command multiple times.
- The **vrf binding** and **vrf receive** commands are mutually exclusive on a specified interface. Unlike the **vrf binding** command, the **vrf receive** command does not add an interface to the specified VRF, and the interface does not belong to any VRF.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the Layer 3 Ethernet sub-interface configuration mode.
  - **interface** *ethernet-type interface-number.subnumber*
- Enter the Layer 3 aggregate sub-interface configuration mode.
  - **interface aggregateport** *interface-number.subnumber*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the tunnel interface configuration mode.
  - **interface tunnel** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*
- Enter the VXLAN routed interface configuration mode.

- **interface overlayrouter** *interface-number*

(4) Import the host route and direct route of the interface to a specified VRF.

vrf receive *vrf-name*

By default, the host route and direct route of the interface are not imported to a specified VRF.

1.5.13 Configuring Maximum Number of Routes for a Multi-protocol VRF

1. Overview

You can limit the maximum number of routing entries in a multi-protocol VRF by performing this configuration.

2. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Enter the multi-protocol VRF configuration mode.
vrf definition *vrf-name*

(4) Enter the multi-protocol VRF address family configuration mode.
address-family { **ipv4** | **ipv6** }

(5) Configure the maximum number of routes in a multi-protocol VRF.
maximum routes *limit* { **warning** | *warning-threshold* }

The maximum number of routes in the multi-protocol VRF is not limited by default.

1.6 VRF Configuring a Global VRF

1.6.1 Overview

This section describes how to configure a global VRF to manage VPN routes. Global VRF exists by default.

1.6.2 Restrictions and Guidelines

- If a device forwards only packets of a specified VPN or only public network packets, you do not need to configure a VRF.
- If the device needs to forward both the public network packets and VPN packets or forward packets from multiple VPNs, VRFs must be created to separate routes.
- You need to add static or dynamic routes (RIP, OSPF, ISIS, and BGP) to a VRF.

1.6.3 Configuration Tasks

The configuration of a Multi-protocol VRF includes the following tasks:

- Configuring the Address Family for a Global VRF
- (Optional)Configuring the RD for a Global VRF
- (Optional)Configuring the RT for a Global VRF
- (Optional)Configuring the Label Allocation Mode for a Global VRF
- (Optional)Configuring an Export Policy Associated with a Global VRF
- (Optional)Configuring an Import Policy Associated with a Global VRF
- (Optional)Configuring Maximum Number of Routes for a Global VRF

1.6.4 Configuring the Address Family for a Global VRF

1. Overview

This section describes how to enable the IPv4/IPv6 address family for a Multi-protocol VRF, and enter the configuration mode.

2. Restrictions and Guidelines

You can configure the address family for each created VRF.

3. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Enter the global VRF configuration mode.
vrf global-vrf

(4) (Optional) Configure a description for global VRF.
description *description*

No description is configured for global VRF by default.

(5) Configure the address family. Configure at least one of the following tasks.

- Configure the IPv4 address family, and enter the VRF IPv4 address family submode.
  address-family ipv4
- Configure the IPv6 address family, and enter the VRF IPv6 address family submode.
  address-family ipv6

By default, IPv4 and IPv6 address families are enabled.

1.6.5 Configuring the RD for a Global VRF

1. Overview

This section describes how to configure the RD to resolve routing conflicts when the BGP advertises routes.

2. Restrictions and Guidelines

- Configure the RD command in global VRF configuration mode.
- If you have configured a VRF value and its RD value and want to modify the RD value, you must first delete the VRF, reconfigure the VRF, and then configure the RD value.
- You can configure only one RD value for a VRF.

3. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Enter the global VRF configuration mode.
vrf global-vrf

(4) Configure the RD.
rd *rd-value*

No RD value is configured by default.

1.6.6 Configuring the RT for a Global VRF

1. Overview

This section describes how to configure the RT group to control advertisement of VPN routes.

2. Restrictions and Guidelines

- Configure the RT value in global VRF mode or global VRF address family mode.
- You can configure multiple **Import** or **Export** values for each VRF.

3. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Enter the global VRF configuration mode.
vrf global-vrf

(4) (Optional) Enter the global VRF address family configuration mode.
address-family { **ipv4** | **ipv6** }

(5) Configure the RT.
route-target { **both** | **export** | **import** } *route-value*

By default, the RT is not configured.

1.6.7 Configuring the Label Allocation Mode for a Global VRF

1. Overview

This section describes how to configure the label allocation mode for a global VRF.

2. Restrictions and Guidelines

- Route-based label allocation mode: One route corresponds to one label. The advantage is that the system can look up the ILM table based on the label value and quickly forward packets to the next hop. The disadvantage is that the capacity of the ILM table must be large.
- VRF-based label allocation mode: One VRF corresponds to one label. The advantage is that all routes in the VRF share this label, which reduces the capacity of the ILM table. The disadvantage is that packet forwarding is slower than that in route-based label allocation mode. This is because the system needs to look up the table twice in the forwarding process. It first looks up the ILM table to find the VRF where the packet is located, and then forwards the packet based on the destination IP address in the routing table of the VRF.

3. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Enter the global VRF configuration mode.
vrf global-vrf

(4) Enter the global VRF address family configuration mode.
address-family { **ipv4** | **ipv6** }

(5) Configure the label allocation mode.
alloc-label { **per-route** | **per-vrf** }

By default, the label allocation mode is not configured.

1.6.8 Configuring an Export Policy Associated with a Global VRF

1. Overview

This section describes how to configure a policy for exporting the extended community attributes of VPN routes from the local VRF to the remote device

2. Restrictions and Guidelines

- To more precisely control the extended community attributes of exported routes, you can define a precise rule as needed in the associated route map.
- You can run this command to add or modify the extended community attributes defined by the **route-target export** command.
- You can only run the **match ip address** and **set extcommunity** commands to configure rules for a route map associated by this command.

3. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Enter the global VRF configuration mode.
vrf global-vrf

(4) Enter the global VRF address family configuration mode.
address-family { **ipv4** | **ipv6** }

(5) Configure the associated export policy.
export map *route-map-name*

No export policy associated with the VRF is configured by default.

1.6.9 Configuring an Import Policy Associated with a Global VRF

1. Overview

This section describes how to configure a policy for importing VPN routes from a remote device to the local VRF.

2. Restrictions and Guidelines

- To more precisely filter routes imported to the local VRF, you can define a precise rule as needed in the associated route map.
- The rule defined by the **import map** command takes effect after the import extended community attributes defined in the VRF. That is, only after these routes match the extended community attributes defined by the **route-target import** command in the VRF, can the VPN routes received from the remote device be filtered again by rules defined the **import map** command.
- You can only run the **match ip address** and **match extcommunity** commands to configure rules for a route map associated by the import map command.

3. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Enter the global VRF configuration mode.
vrf global-vrf

(4) Enter the global VRF address family configuration mode.
address-family { **ipv4** | **ipv6** }

(5) Configure the associated import policy.
import map *route-map-name*

No import policy associated with the VRF is configured by default.

1.6.10 Configuring Maximum Number of Routes for a Global VRF

1. Overview

You can limit the maximum number of routing entries in a global VRF by performing this configuration.

2. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Enter the global VRF configuration mode.
vrf global-vrf

(4) Enter the global VRF address family configuration mode.
address-family { **ipv4** | **ipv6** }

(5) Configure the maximum number of routes in a global VRF.
maximum routes *limit* { **warning** | *warning-threshold* }

The maximum number of routes in the global VRF is not limited by default.

1.7 Monitoring

Run the **display** command to check the running status of a configured function and verify the configuration effect.

Run the **cleanup** commands to clear information.

⚠ Caution

Running the **cleanup** commands may interrupt services due to loss of vital information.

Run the **debugging** command to output debugging information.

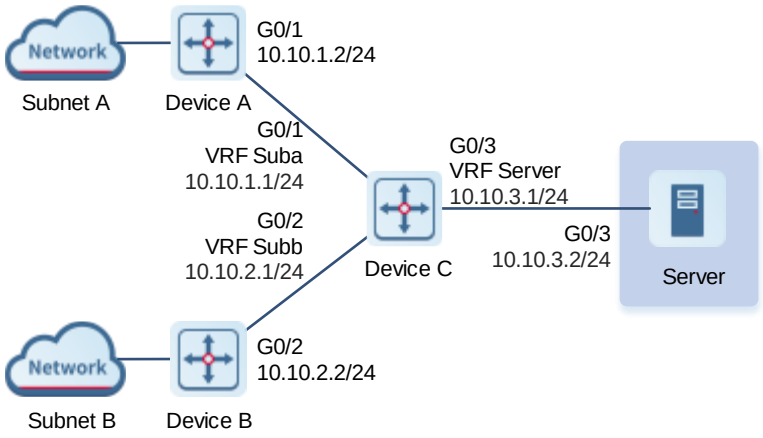
⚠ Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 VRF Monitoring

Command	Purpose
display ip vrf-info [**brief | count | detail | interfaces**] [*vrf-name*]	Displays a single-protocol VRF.
display global-vrf [**brief** | **detail** | **ipv4** | **ipv6**]	Displays a global VRF.
display vrf [**brief | count | detail | ipv4 | ipv6**] [*vrf-name*]	Displays a Multi-protocol VRF.
cleanup ip mrouting-table [**vrf** *vid*] **statistics** { * | *group-address* [*source-address*] }	Clears the multicast route statistics.
cleanup ip pim dense-mode [**vrf** *vid*] **track**	Clears the PIM-DM packet statistics.
cleanup ip route-config vrf *vrf-name*	Clears the routes in a specified VRF.
debugging vrf	Displays the debugging information when a VRF is created, an address family is enabled, and an interface is added to the VRF.
debugging vrf interface	Displays the debugging information of interface-related VRF operations.

1.8 Configuration Examples



1.8.1 Enabling Local Inter-VPN Access

1. Requirements

Subnet A, Subnet B, and Server are three VPNs that have separate address spaces. Subnet A runs RIP, Subnet B runs OSPF, and Servers is a network segment directly connected to Device C. Routes in Subnet A are separated from those in Subnet B, but both Subnet A and Subnet B can access Server.

2. Topology

Figure 1-4 Configuring Local Inter-VPN Access

3. Notes

- On Device C, create a VRF named **Suba**, add the interface directly connected to Device A to the VRF **Suba**. Associate the VRF **Suba** of Device C with Device A by using RIP.
- On Device C, create a VRF named **Subb**, add the interface directly connected to Device B to the VRF **Subb**. Associate the VRF **Subb** of Device C with Device B by using OSPF.
- On Device C, create a VRF named **Server**, add the interface directly connected to Server to the VRF **Server**.
- On Device C, configure RTs for three VRFs, including **Suba**, **Subb**, and **Server**. Import the routes of **Suba** and **Subb** to **Server**, and the routes of **Server** to **Suba** and **Subb**.
- On Device C, configure the BGP, and import the RIP routes to the IPv4 VRF **Suba**, the OSPF routes to the IPv4 VRF **Subb**, and the direct routes to the IPv4 VRF **Server**.

4. Procedure

(1) (Omitted) Configure the IP address for the device.

(2) Create VRFs on Device C.

Create a VRF named **Suba**, add the interface G0/1 directly connected to Device A to the VRF **Suba**.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ip vrf Suba
DeviceC(cfg-vrf)# rd 100:1
DeviceC(cfg-vrf)# route-target import 100:3
DeviceC(cfg-vrf)# route-target export 100:1
DeviceC(cfg-vrf)# exit
DeviceC(cfg)# interface gigabitethernet 0/1
DeviceC(cfg-GigabitEthernet 0/1)# ip vrf binding Suba
DeviceC(cfg-GigabitEthernet 0/1)# ip address 10.10.1.1 255.255.255.0
DeviceC(cfg-GigabitEthernet 0/1)# exit
```

Create a VRF named **Subb**, add the interface G0/2 directly connected to Device B to the VRF **Subb**.

```
DeviceC(cfg)# ip vrf Subb
DeviceC(cfg-vrf)# rd 100:2
DeviceC(cfg-vrf)# route-target import 100:3
DeviceC(cfg-vrf)# route-target export 100:2
DeviceC(cfg-vrf)# exit
DeviceC(cfg)# interface gigabitethernet 0/2
DeviceC(cfg-GigabitEthernet 0/2)# ip vrf binding Subb
DeviceC(cfg-GigabitEthernet 0/2)# ip address 10.10.2.1 255.255.255.0
DeviceC(cfg-GigabitEthernet 0/2)# exit
```

Create a VRF named **Server**, add the interface G0/3 directly connected to Server to the VRF **Server**.

```
DeviceC(cfg)# ip vrf Server
DeviceC(cfg-vrf)# rd 100:3
DeviceC(cfg-vrf)# route-target import 100:1
DeviceC(cfg-vrf)# route-target import 100:2
DeviceC(cfg-vrf)# route-target export 100:3
DeviceC(cfg-vrf)# exit
DeviceC(cfg)# interface gigabitethernet 0/3
DeviceC(cfg-GigabitEthernet 0/3)# ip vrf binding Server
DeviceC(cfg-GigabitEthernet 0/3)# ip address 10.10.3.1 255.255.255.0
DeviceC(cfg-GigabitEthernet 0/3)# exit
```

(3) Enable the routing protocol.

Enable the routing protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# router-protocol rip
DeviceA(cfg-router)# version 2
DeviceA(cfg-router)# unset auto-summary
DeviceA(cfg-router)# network-advertise 10.10.1.0 0.0.0.255
```

Enable the routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# router-protocol ospf 1
DeviceB(cfg-router)# network-advertise 10.10.2.0 0.0.0.255 area 0
```

Enable the routing protocol on Device C.

```
DeviceC(cfg)# router-protocol rip
DeviceC(cfg-router)# address-family-mode ipv4 vrf Suba
DeviceC(cfg-router-af)# version 2
DeviceC(cfg-router-af)# unset auto-summary
DeviceC(cfg-router-af)# network-advertise 10.10.1.0 0.0.0.255
DeviceC(cfg-router-af)# exit-address-family-mode
DeviceC(cfg-router)# exit
DeviceC(cfg)# router-protocol ospf 2 vrf Subb
DeviceC(cfg-router)# network-advertise 10.10.2.0 0.0.0.255 area 0
```

```
DeviceC(cfg-router)# exit
```

(4) Import routes to VRFs.

Import routes to VRFs on Device C.

```
DeviceC(cfg)# router-protocol bgp 200
DeviceC(cfg-router)# address-family-mode ipv4 vrf Suba
DeviceC(cfg-router-af)# redistribute-route rip
DeviceC(cfg-router-af)# exit-address-family-mode
DeviceC(cfg-router)# address-family-mode ipv4 vrf Subb
DeviceC(cfg-router-af)# redistribute-route ospf 2
DeviceC(cfg-router-af)# exit-address-family-mode
DeviceC(cfg-router)# address-family-mode ipv4 vrf Server
DeviceC(cfg-router-af)# redistribute-route connected
DeviceC(cfg-router-af)# exit-address-family-mode
```

5. Verification

Verify the information of interfaces added to VRFs on Device C.

```
DeviceC# display ip vrf interfaces
Interface                IP-Address    VRF         Protocol
GigabitEthernet 0/1      10.10.1.1     Suba        up
GigabitEthernet 0/2      10.10.2.1     Subb        up
GigabitEthernet 0/3      10.10.3.1     Server      up
```

Verify that the routes in **Suba** are separated from those in **Subb**, and routes of **Server** are shared on Device C.

```
DeviceC# display ip route-config vrf Suba
Routing Table: Suba

Codes:   C - connected, S - static, R - RIP, B - BGP
         O - OSPF, IA - OSPF inter area
         N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
         E1 - OSPF external type 1, E2 - OSPF external type 2
         i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
         ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
C       10.10.1.0/24 is directly connected, GigabitEthernet 0/1
C       10.10.1.1/32 is local host.
B       10.10.3.0/24 [20/0] via 0.0.0.0, 00:01:21, GigabitEthernet 0/3

DeviceC# display ip route-config vrf Subb
Routing Table: Subb

Codes:   C - connected, S - static, R - RIP, B - BGP
         O - OSPF, IA - OSPF inter area
         N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
         E1 - OSPF external type 1, E2 - OSPF external type 2
         i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
```

```
            ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
C       10.10.2.0/24 is directly connected, GigabitEthernet 0/2
C       10.10.2.1/32 is local host.
B       10.10.3.0/24 [20/0] via 0.0.0.0, 00:04:03, GigabitEthernet 0/3

DeviceC# display ip route-config vrf Server
Routing Table: Server

Codes:    C - connected, S - static, R - RIP, B - BGP
            O - OSPF, IA - OSPF inter area
            N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
            E1 - OSPF external type 1, E2 - OSPF external type 2
            i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
            ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
B       10.10.1.0/24 [20/1] via 0.0.0.0, 03:00:15, GigabitEthernet 0/1
B       10.10.2.0/24 [20/1] via 0.0.0.0, 00:00:14, GigabitEthernet 0/2
C       10.10.3.0/24 is directly connected, GigabitEthernet 0/3
C       10.10.3.1/32 is local host.
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 unset switch-port
 ip address 10.10.1.2 255.255.255.0
!
router-protocol rip
 version 2
 network-advertise 10.10.1.0 0.0.0.255
 unset auto-aggregation
!
```

Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/2
 unset switch-port
 ip address 10.10.2.2 255.255.255.0
!
router-protocol ospf 2
 network-advertise 10.10.2.0 0.0.0.255 area 0
```

```
!
```

Device C configuration file

```
hostname DeviceC
!
ip vrf Server
 rd 100:3
 route-target export 100:3
 route-target import 100:2
 route-target import 100:1
!
ip vrf Suba
 rd 100:1
 route-target export 100:1
 route-target import 100:3
!
ip vrf Subb
 rd 100:2
 route-target export 100:2
 route-target import 100:3
!
interface GigabitEthernet 0/1
 unset switch-port
 ip vrf binding Suba
 ip address 10.10.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
 unset switch-port
 ip vrf binding Subb
 ip address 10.10.2.1 255.255.255.0
!
interface GigabitEthernet 0/3
 unset switch-port
 ip vrf binding Server
 ip address 10.10.3.1 255.255.255.0
!
router-protocol bgp 200
 address-family-mode ipv4 vrf Suba
  redistribute-route rip
  exit-address-family-mode
 !
 address-family-mode ipv4 vrf Subb
  redistribute-route ospf 2 match-rule internal-route
  exit-address-family-mode
 !
 address-family-mode ipv4 vrf Server
  redistribute-route connected
```

```
   exit-address-family-mode
!
router-protocol ospf 2 vrf Subb
 network-advertise 10.10.2.0 0.0.0.255 area 0
!
Router-protocol rip
 address-family-mode ipv4 vrf Suba
   version 2
   network-advertise 10.10.1.0 0.0.0.255
   unset auto-summary
   exit-address-family-mode
!
```

Server configuration file

```
hostname Server
!
interface GigabitEthernet 0/3
 unset switch-port
 ip address 10.10.3.2 255.255.255.0
!
```

7. Common Errors

- An interface is added to a VRF after the IP address of the interface is configured. In this case, the IP address of the interface is deleted.
- When a physical link is shared by multiple VPNs, the physical interface is added to a VRF.
- VPN routes are not introduced to BGP.

1 Configuring Routing Policies

1.1 Introduction

1.1.1 Overview

Routing policies are a policy set for changing the packet forwarding path or routing information, and are often implemented by a filter list and a route map. Routing policies provide services for different routing protocols, and completes the policy-based control of routing information based on a specified policy set. Policy-based routing (PBR) refers to policy-based routing and forwarding. It can forward packets based on the source address, destination address, packet length, and port, and these matching policies can be provided by routing policies.

Routing policies are flexibly and widely applied in the following ways:

- A filter list is used in a routing protocol to filter or modify routing information.
- A route map is used in a routing protocol to filter or modify routing information. The route map can further use a filter list.
- A route map is used in PBR to control packet forwarding or modify packet fields.

Note

In this chapter, the term "router" refers to any network device that supports the routing function. These network devices can be Layer-3 switches, routers, or firewalls.

1.1.2 Principles

Filter list: It is a group of lists defined based on a routing attribute and can be used by a routing protocol for route filtering.

Route map: It defines a policy that "if certain conditions are matched, processing actions are performed accordingly."

1. Filter list

A filter list is a group of lists defined based on a routing attribute and is a filtering tool of routing policies. To achieve the effect of route filtering, filter lists must be used in a routing protocol or route map. Five types of filter lists are available currently: access control list (ACL), prefix list, autonomous system (AS) path list, community list, and extended community (extcommunity) list.

- ACL

  ACLs include IPv4 and IPv6 ACLs. When defining an ACL, you can specify IPv4/IPv6 addresses and masks to match the destination network segment or next-hop addresses of routing information.

- Prefix list

Similar to ACLs, prefix lists, including IPv4 prefix lists and IPv6 prefix lists, are used to match destination network segments or next hops of routing information.

When configuring a prefix list as the filter list, you can define the prefix address, mask length, and mask range. The prefix address and mask length are used to specify the prefix of the routing information. The mask range specifies the mask range of the routing information to be filtered. That is, a prefix list can be defined to directly filter the subnet segment under a specified prefix network segment without calculating the prefix of the subnet segment in advance. Therefore, prefix lists are more flexible than ACLs.

- AS-path list

  AS-path lists are applicable only to Border Gateway Protocol (BGP). They define filtering rules based on the AS path information. When configuring an AS-path list, you can specify an AS path by using a regular expression to match the AS path.

- Community list

Community lists are applicable only to BGP. They define filtering rules based on the community attributes of routes. When configuring a community list, you can specify a community ID or a regular expression to match the community attribute.

- Extcommunity list

Extcommunity lists are applicable only to BGP. They define filtering rules based on the extended community attributes of routes. When configuring an extcommunity list, you can specify an extended community ID or a regular expression to match the extended community attribute.

2. Route Map

A policy in a route map is a match and set statement, which indicates that if certain conditions are matched, some processing actions will be performed accordingly.

- Main application scenarios of route maps
  - Route filtering: A filter list is used in a routing protocol to filter the routing information sent or received by the protocol.
  - Route redistribution: A route map is used in a routing protocol to filter or modify routing information and redistribute Routing Information Protocol (RIP) routes to Open Shortest Path First (OSPF). Only RIP routes with the hop count of 4 can be redistributed.
  - PBR: A route map is used in PBR to control packet forwarding or modify packet fields and specify optimum outbound interfaces for packets from different subnets.
- Policy execution

  A route map contains multiple policies. Each policy has a corresponding sequence number. A smaller sequence number means a higher priority. You can execute policies by sequence number. Once the matching condition of a policy is met, the processing action of this policy is performed and the route map exits. If no matching condition of any policy is met, no processing action is performed.

- Working modes of policies

  Policies support two working modes:

- **permit**: When the matching condition of a policy is met, the processing action for this policy is performed and the system exits the route map.
- **deny**: When the matching condition of a policy is met, the processing action for this policy is not performed and the system exits the route map.

- Matching conditions of policies

  The matching condition of a policy may contain zero, one, or more match rules.

  - If the matching condition contain zero match rules, all packets match the policy.
  - If the matching condition contains one or more match rules, the matching condition is met only when all the rules are matched.

- Processing action for a policy

  The processing action of a policy may contain zero, one, or more set rules.

  - If the processing action contains zero set rules, no processing action is performed and the system directly exits the route map.
  - If the processing action contains one or more set rules, all processing actions are performed and then the system exits the route map.

1.2 Configuration Task Summary

The configuration of a routing policy includes the following tasks.

(1) Configuring a Filter List
- Defining AS Path Filtering Rules
- Defining a Community List
- Defining an Extcommunity List
- Creating a Prefix List
- Adding a Description for a Prefix List
- Enabling the Sorting Function for a Prefix List
- Creating an IPv6 Prefix List
- Adding a Description for an IPv6 Prefix List
- Enabling the Sorting Function for an IPv6 Prefix List

(2) Configuring a Route Map
- Creating a Policy
- Configuring the Matching Conditions of a Rule
- Configuring the Processing Actions of a Policy
- (Optional) Configuring the Policy Statement

1.3 Configuring a Filter List

1.3.1 Overview

This section describes how to define a set of route filtering rules for a routing protocol.

1.3.2 Restrictions and Guidelines

A configured filter list can take effect only after it is associated with a routing protocol.

1.3.3 Configuration Tasks

The filter list configuration includes the following tasks, which are optional. Select the configuration tasks as required.

- Defining AS Path Filtering Rules
- Defining a Community List
- Defining an Extcommunity List
- Creating a Prefix List
- Adding a Description for a Prefix List
- Enabling the Sorting Function for a Prefix List
- Creating an IPv6 Prefix List
- Adding a Description for an IPv6 Prefix List
- Enabling the Sorting Function for an IPv6 Prefix List

1.3.4 Defining AS Path Filtering Rules

1. Overview

An AS path filter list defines AS path filtering rules by using regular expressions. AS-path is a BGP attribute. Therefore, AS path filtering rules are only applied to a BGP network.

2. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Define AS path filtering rules.
ip as-path access-control-list *path-list-number* { **permit** | **deny** } *regular-expression*

By default, no AS path filtering rule is configured.

1.3.5 Defining a Community List

1. Overview

A community list is a set of routes with the same attributes. Community list is a BGP attribute, and can help reduce the difficulties in BGP route management and maintenance. Similar to an ACL, you can define multiple entries in a community list, and entries are matched based on their sequence numbers. As long as a route matches one entry, the route is permitted by the community list and no further matching is performed.

2. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Define a standard community list.
ip comm-type-list { *community-list-number* | **standard-type** *community-list-name* } { **deny** | **permit** } [*community-list-number* | **gshut** | **internet** | **llgr-stale** | **local-as** | **no-advertise** | **no-export** | **no-llgr**] *

By default, no standard community list is defined.

(4) Define an expanded community list.
ip comm-type-list { *community-list-number* | **expanded** *community-list-name* } { **deny** | **permit** } [*regular-expression*]

By default, no expanded community list is defined.

1.3.6 Defining an Extcommunity List

1. Overview

An extcommunity list is a set of routes with the same attributes. Extcommunity list is a BGP attribute, and can help reduce the difficulties in BGP route management and maintenance. Similar to an ACL, you can define multiple entries in an extcommunity list, and entries are matched based on their sequence numbers. As long as a route matches one entry, the route is permitted by the extcommunity list and no further matching is performed.

2. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Define a standard extcommunity list.
ip extend-comm-list { *standard-list* | **standard-type** *list-name* } { **deny** | **permit** } [**rt** *rt-value* | **soo** *soo-value*] [**color** *color-value* [**only** { 00 | 01 | 10 | 11 }]]

By default, no standard extcommunity list is defined.

(4) Define an expanded extcommunity list.

ip extend-comm-list { *expanded-list* | **expanded** *list-name* } { **deny** | **permit** } [*regular-expression*]

By default, no expanded extcommunity list is defined.

1.3.7 Creating a Prefix List

1. Overview

A prefix list can be directly used by protocols, or used together with a route map as a matching condition of the route map. Similar to an ACL, you can define multiple entries in a prefix list, and entries are matched based on their sequence numbers. As long as a route matches one entry, the route is permitted by the prefix list and no further matching is performed. If a route does not match any entry, it is considered that the route is denied by the prefix list.

2. Restrictions and Guidelines

This command is not a routing policy command, and will not be applied to any routing protocol.

3. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Create a prefix list.
ip prefix-list-info *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv4-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*]

By default, no prefix list is configured.

1.3.8 Adding a Description for a Prefix List

1. Overview

You can add a text description for a prefix list, for example, to describe the purpose of the prefix list. Adding descriptions for prefix lists can facilitate maintenance and tracking.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Add a text description for the IPv4 prefix list.

ip prefix-list-info *prefix-list-name* **description** *description-text*

By default, no text description is configured for the prefix list.

1.3.9 Enabling the Sorting Function for a Prefix List

1. Overview

When you run the **display ip prefix-list-info** command, the sequence numbers of entries in a prefix list are not displayed by default. If these sequence numbers are displayed, you can conveniently add or remove an entry to or from the prefix list.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the function of displaying sequence numbers in the prefix list.

ip prefix-list-info sequence-number

The function of displaying sequence numbers in a prefix list is disabled by default.

1.3.10 Creating an IPv6 Prefix List

1. Overview

An IPv6 prefix list can be directly used by protocols, or used together with a route map as a matching condition of the route map. Similar to an ACL, you can define multiple entries in an IPv6 prefix list, and entries are matched based on their sequence numbers. As long as a route matches one entry, the route is permitted by the prefix list and no further matching is performed. If a route does not match any entry, it is considered that the route is denied by the IPv6 prefix list.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an IPv6 prefix list.

ipv6 prefix-list-info *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv6-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*]

By default, no IPv6 prefix list is configured.

1.3.11 Adding a Description for an IPv6 Prefix List

1. Overview

You can add a text description for a prefix list, for example, to describe the purpose of the prefix list. Adding descriptions for prefix lists can facilitate maintenance and tracking.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Add a description for the IPv6 prefix list.

ipv6 prefix-list-info *prefix-list-name* **description** *description-text*

By default, no description is configured for an IPv6 prefix list.

1.3.12 Enabling the Sorting Function for an IPv6 Prefix List

1. Overview

When you run the **display ipv6 prefix-list-info** command, the sequence numbers of entries in a prefix list are not displayed by default. If these sequence numbers are displayed, you can conveniently add or remove an entry to or from the prefix list.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the function of displaying sequence numbers in the IPv6 prefix list.

ipv6 prefix-list-info sequence-number

The function of displaying sequence numbers in an IPv6 prefix list is displayed by default.

1.4 Configuring a Route Map

1.4.1 Overview

This section describes how to define a set of routing policies to be used by routing protocols or PBR.

1.4.2 Configuration Tasks

The route map configuration includes the following tasks:

(1) Creating a Policy

(2) Configuring the Matching Conditions of a Rule

(3) Configuring the Processing Actions of a Policy

(4) (Optional) Configuring the Policy Statement

1.4.3 Creating a Policy

1. Overview

You can create a route map to control route attributes.

2. Restrictions and Guidelines

- If the route map is unavailable, this command will create a route map and add a policy to the route map.
- If the route map is available, this command will add a policy to the route map.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a route map and enter the route map configuration mode.

route-map *route-map-name* [{ **permit** | **deny** } *sequence-number*]

1.4.4 Configuring the Matching Conditions of a Rule

1. Overview

In a route map, you can configure match rules based on the route attributes. If multiple match rules are configured, all the rules must be matched.

2. Restrictions and Guidelines

- If you use an ACL in a **match** command to define packet matching conditions, you must configure this ACL.
- The following table lists the **match** commands that cannot be configured at the same time:

Table 1-1 Match Commands That Cannot Be Configured at the Same Time

match Command	Exclusive match Command
match-rule ip address	**match-rule ip prefix-list-info**
match-rule ipv6 address	**match-rule ipv6 prefix-list-info**
match-rule ip next-hop	**match-rule ip next-hop prefix-list-info**
match-rule ipv6 next-hop	**match-rule ipv6 next-hop prefix-list-info**
match-rule ip route-source	**match-rule ip route-source prefix-list-info**
match-rule ipv6 route-source	**match-rule ipv6 route-source prefix-list-info**

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the route map configuration mode.

route-map *route-map-name* [{ **permit** | **deny** } *sequence-number*]

(4) Configure a next-hop outbound interface matching rule.

match-rule interface { *interface-type interface-number* }&<1-4>

No next-hop outbound interface matching rule is configured by default.

You can use an IPv4 filter list in the route map to match attributes. The following configurations are optional. You can configure multiple match rules, and all of which must be matched if multiple match rules are configured.

- Configure an AS path filtering rule for path matching.

  match-rule as-path *as-path-acl-list-number*&<1-10>

  By default, no AS-path list is configured for packet matching.

- Configure a community list for packet matching.

  match-rule comm { *community-list-number* [**exact-match**] | *community-list-name* [**exact-match**] } &<1-6>

  By default, no community list is configured for packet matching.

- Configure an extcommunity list for packet matching.

  match-rule extend-comm *extcommunity-list*

  By default, no extcommunity list is configured for packet matching.

- Configure a rule to match the target network routes that are permitted in the ACL or prefix list.
  match-rule ip address { { *acl-name* | *acl-number* }&<1-6> | **prefix-list-info** *prefix-list-name*&<1-6> }

  By default, no ACL or prefix list used for packet matching is configured.

- Configure a rule to match the target network routes whose next-hop IPv4 addresses meet rules in the ACL or prefix list.

  match-rule ip next-hop { { *acl-name* | *acl-number* }&<1-6> | **prefix-list-info** *prefix-list-name*&<1-6> }

  No next-hop IPv4 address matching rule is configured by default.

- Configure a rule to match the target network routes whose source IPv4 addresses meet rules in the ACL or prefix list.

  match-rule ip route-source { { *acl-name* | *acl-number* }&<1-6> | **prefix-list-info** *prefix-list-name*&<1-6> }

  No IPv4 source address matching rule is configured by default.

(5) You can use an IPv6 filter list in the route map to match attributes.

- Configure a rule to match the target IPv6 network routes that are permitted in the ACL or prefix list.
  match-rule ipv6 address { *acl-name* | **prefix-list-info** *prefix-list-name* }

  By default, no IPv6 ACL or IPv6 prefix list is configured.
- Configure a rule to match the target network routes whose next-hop IPv6 addresses meet rules in the ACL or prefix list.

  match ipv6 address { *acl-name* | **prefix-list-info** *prefix-list-name* }

  No next-hop IPv6 address matching rule is configured by default.
- Configure a rule to match the target network routes whose source IPv6 addresses meet rules in the ACL or prefix list.

  match ipv6 route-source { *acl-name* | **prefix-list-info** *prefix-list-name* }

  No IPv6 source address matching rule is configured by default.

(6) Configure a MAC address rule for route matching.

match-rule mac-address *mac-address*

No MAC address-based route matching rule is configured by default.

(7) Configure a rule to match the routes with a fixed metric.

match-rule metric *metric*

By default, the metric values of routes are not matched.

(8) Configure a rule to match the route type.

- Configure a rule for matching the source type of BGP routes.

  match-rule origin { **egp** | **igp** | **incomplete** }

  By default, no rule is configured to match the source type of BGP routes.
- Configure a rule to match the route type.
  match-rule route-type { **connect** | **evpn-type-1** | **evpn-type-2** | **evpn-type-3** | **evpn-type-4** | **evpn-type-5** | **external-route** [**type-1** | **type-2**] | **internal-route** | **level-1** | **level-2** | **local** | **nssa-external-type-route** [**type-1** | **type-2**] | **rip** | **static** } *

  By default, no rule is configured to match any route type.

(9) Configure a rule to match the routes with a specified tag.

match-rule tag *tag*&<1-4>

By default, no rule to match the routes with a specified tag is configured.

1.4.5 Configuring the Processing Actions of a Policy

1. Overview

Processing actions are configured for traffic that matches the rules. The device provides abundant **set** commands for configuring flexible processing actions.

2. Restrictions and Guidelines

- If no set rule is configured, no processing action will be performed.
- If multiple set rules are configured, all set rules must be executed. If the set rules have different priorities, only the set rule with the highest priority takes effect.
- The following table lists the **set-rule** commands that cannot be configured at the same time.

Table 1-2 set-rule Commands That Cannot Be Configured at the Same Time

set Command	Exclusive set Command
set-rule ip-address next-hop	**set-rule ip-address next-hop verify-availability**
set-rule ip-address dscp	**set-rule ip-address tos**
set-rule ip-address dscp	**set-rule ip-address precedence**

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the route map configuration mode.

route-map *route-map-name* [{ **permit** | **deny** } *sequence-number*]

(4) Configure a rule to adjust the BGP attributes.

- Configure the AS number for BGP.

  set-rule aggregator as *as-number ipv4-address*

  By default, no AS number of the aggregator is specified.

- Configure the Accumulated Interior Gateway Protocol (AIGP) metric attribute for Exterior Gateway Protocol (EGP).

  set-rule aigp-metric { *metric-number* | **igp-metric** }

  By default, no AIGP metric attribute is configured for routes.

- Configure a rule to add the specified AS_PATH values.

  set-rule as-path prepend *as-number*&<1-10>

  By default, no rule is configured to configure AS_PATH values for routes.

- Configure a rule to replace the AS_PATH attributes of routes.

  set-rule as-path replace *as-number*&<1-10>

By default, the AS_PATH values of matched routes will not be replaced.

- Configure the atomic-aggregate attribute for routes.

  set-rule atomic-aggregate

  By default, no atomic-aggregate attribute is configured for routes.

- Configure a rule to delete all the community values from BGP routes matching the rules according to the community list.

  set-rule comm-list { *community-list-number* | *community-list-name* } **delete**

  By default, no rule is configured to delete all the community values from routes matching the rules according to the community list.

- Configure the community value for BGP routes.

  set-rule comm { { *community-number*&<1-32> | **internet** | **llgr-stale** | **local-AS** | **no-advertise** | **no-export** | **no-llgr** | **none** } * [**additive**] }

  By default, no community value is specified for a route.

- Configure the flapping parameters for BGP routes.

  set-rule dampening *half-life reuse suppress max-suppress-time*

  By default, when the half-life period is 15 minutes, and the penalty value of a route is lower than 750, route suppression is canceled. When the penalty value of a route exceeds 2000, the route is suppressed. A route can be suppressed for a maximum of 60 minutes.

- Configure a rule to delete the extended community attribute of BGP routes.

  set-rule extcomm-list { *extcommunity-list-number* | *extcommunity-list-name* } **delete**

- Configure the extended community attribute of BGP routes.

  set-rule extend-comm { **rt** *extend-community-value* [**additive**] | **soo** *extend-community-value* }

- Specify the extended community value of **color** for routes that match rules.
  set-rule extend-comm color *color-value* [**only** { 00 | 01 | 10 | 11 }] [**additive**]

(5) Configure the backup outbound interface and backup next hop for fast reroute (FRR).

- Configure the backup outbound interface and backup next hop for FRR.

  set-rule frr backup-interface *interface-type interface-number* **backup-nexthop** *ipv4-address*

  By default, no backup outbound interface and backup next hop of FRR are specified for matched routes.

(6) Configure the next hop.

- Configure the default next-hop IPv4 address for routes.

  set-rule ip-address [**global** | **vrf** *vrf-name*] **default next-hop** { *ipv4-address* [*weight*] }&<1-32>

  By default, no default next-hop IPv4 address is specified for matched routes.

  Note
  This command is not supported by the S6980-64QC, S6920-4C, S6580-48CQ8QC, or S6580-24DC8QC.

- Configure the next-hop IPv4 address for IPv4 packets.

set-rule ip-address [**global vrf** | *vrf-name*] **next-hop** { *ipv4-address* [*weight*] }&<1-32>

By default, no next-hop IPv4 address is specified for matched packets.

- Configure the next-hop IPv4 address for routes.
  set-rule next-hop *ipv4-address*

  By default, no next-hop IPv4 address is specified for matched routes.

- Configure the default next-hop IPv6 address for an IPv6 packet.
  set-rule ipv6-address [**global** | **vrf** *vrf-name*] **default next-hop** { *ipv6-address* [*weight*] }&<1-32>

  By default, no default next-hop IPv6 address is specified for matched IPv6 routes.

  Note

  This command is not supported by the S6980-64QC, S6920-4C, S6580-48CQ8QC, or S6580-24DC8QC.

- Configure the next-hop IPv6 address for an IPv6 packet.
  set-rule ipv6-address [**global** | **vrf** *vrf-name*] **next-hop** { *ipv6-address* [*weight*] }&<1-32>

- Set the next hops of routes to the device itself.
  set-rule ip-address next-hop self

  By default, the next hop is not set to the device itself for matched packets.

- Configure the next hop of a BGP IPv4 route to keep unchanged.
  set-rule ip-address next-hop unchanged

  By default, the next hop is not set to keep unchanged for matched packets.

- Configure the recursive next-hop IP address for packets.
  set-rule ip-address [**vrf** *vrf-name* | **global**] **next-hop recursive** *ipv4-address*

  By default, no recursive next-hop IPv4 address is specified for matched packets.

- Configure the next hop of BGP IPv4 and IPv6 routes to the device itself.
  set-rule next-hop self

  By default, the next hop is not set to the device itself for matched routes.

- Configure the next hop of the routes to keep unchanged.
  set-rule next-hop unchanged

  By default, the next hop is not set to keep unchanged for matched routes.

- Configure the recursive next-hop IPv6 address.
  set-rule ipv6-address [**vrf** *vrf-name* | **global**] **next-hop recursive** *ipv6-address*

  By default, no recursive next-hop IPv6 address is specified for matched IPv6 packets.

- Configure the next hop of the route to the device itself.
  set-rule ipv6-address next-hop self

  By default, the next hop address is not set to the device itself for matched IPv6 packets.

- Set the next hop of the specified IPv6 route to keep unchanged.
  set-rule ipv6-address next-hop unchanged

  By default, the next hop is not set to keep unchanged for matched IPv6 packets.

- Set the L3 VPN next hop to the local virtual routing and forwarding (VRF) instance.

set-rule l3vpn nexthop local-vrf

By default, the L3 VPN next hop is not set to the local VRF instance for routes matching the rules.

- Verify availability of the next-hop IPv4 address.
  set-rule ip-address [**vrf** *vrf-name* | **global**] **next-hop verify-accessibility** *ipv4-address* [*weight*] {**track** *track-obj-number* | **bfd** *interface-type interface-number gateway* }

  By default, availability of the next-hop IPv4 address is not verified for matched packets.

- Verify availability of the next-hop IPv6 address.
  set-rule ipv6-address [**vrf** *vrf-name* | **global**] **next-hop verify-accessibility** *ipv6-address* [*weight*] **bfd** *interface-type interface-number gateway*

  By default, availability of the next-hop IPv6 address is not verified for matched packets.

(7) Configure the flow control parameters.

- Configure the IPv4 header priority.
  set-rule ip-address precedence { *precedence* | **critical** | **flash** | **flash-override** | **immediate** | **internet** | **network** | **priority** | **routine** }

  By default, no IPv4 header priority is configured for matched packets.

- Configure the IPv6 header priority.
  set-rule ipv6-address precedence { *precedence-number* | **critical** | **flash** | **flash-override** | **immediate** | **internet** | **network** | **priority** | **routine** }

  By default, no IPv6 header priority is configured for matched packets.

- Configure the type of service (ToS) for the IPv4 header of a packet.
  set-rule ip-address tos { *tos-number* | **max-reliability** | **max-throughput** | **min-delay** | **min -cost** | **normal** }

  By default, no ToS is configured for the IP header of a matched packet.

- Configure the Differentiated Services Code Point (DSCP) in an IPv4 packet.
  set-rule ip-address dscp *dscp_value*

  By default, no DSCP is configured in an IPv4 packet for matched routes.

- Configure the quality of service (QoS) ID for a route.
  set-rule qos-id *qos-id*

  By default, no QoS ID is specified for matched routes.

- Configure the LOCAL_PREFERENCE parameter.
  set-rule local-preference *precedence-number*

  By default, no LOCAL_PREFERENCE value is configured for matched routes.

(8) Configure redistribution-related information.

- Configure the type of the destination area to which redistributed routes are to be advertised.
  set-rule level { backbone | **level-1 | level-1-2 | level-2** | **stub-area** }

  By default, the type of the destination area is not specified for matched routes.

- Configure the redistributed route tag.
  set-rule tag *tag*

By default, no route tag is configured for matched routes.

(9) Configure the weight, metric, and metric type.

- Configure the metric for routes.
  set-rule metric { **+** *metric-value* | **-** *metric-value* | *metric-value* }

  By default, the metric of a matched route is not modified.

- Configure the metric type for routes.
  set-rule metric-type { **external** | **internal** | **type-1** | **type-2** }

- Configure the weight for BGP routes.
  set-rule weight *weight-number*

  By default, no weight is configured for matched routes.

(10) Configure the route source information.

- Configure the route source attribute.
  set-rule origin { **egp** | **igp** | **incomplete** }

  By default, no route source is specified for matched routes.

- Configure the route originator address.
  set-rule originator-inf *ipv4-address*

  By default, no route originator address is configured for matched routes.

(11) Configure the route management distance.

set-rule distance distance-*number*

By default, no management distance is modified for matched routes.

1.4.6 Configuring the Policy Statement

1. Overview

Similar to the description of a prefix list, you can configure a statement to describe a route map.

2. Restrictions and Guidelines

- This command is not a routing policy command, and will not be applied to any routing protocol.
- This command takes effect only in OPENCONF YANG, and is used to record the statement name of a route map.
- If this command is not configured, the sequence number of a route map is used as the default statement name of the route map. Therefore, the range from 0 to 65535 is reserved for the **statement-name** command as the default configuration range. Within this range, all the sequence numbers except the sequence number of a route map configured with **statement-name** cannot be used because they are reserved for the sub-route maps with the same name as the route map and used as the default statement content.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the route map configuration mode.

route-map *route-map-name* [{ **permit** | **deny** } *sequence-number*]

(4) Configure the statement name for the route map.

statement-name [*name*]

By default, the statement name is the sequence number of the route map.

1.5 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

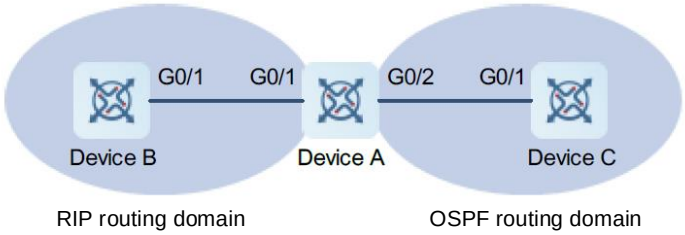
Table 1-3 Routing Policy Monitoring

Command	Purpose
display route-map [*route-map-name*]	Displays the configurations of a route map.
display access-control-lists [*acl-id* | *name*]	Displays the configurations of an ACL.
display ip prefix-list-info [*prefix-name*]	Displays the configurations of an IPv4 prefix list.
display ip protocols [**vrf** *vrf-name*] [**bgp** | **isis** | **ospf** | **rip**]	Displays the status of the IPv4 routing protocols that are currently running.
display ipv6 prefix-list-info [*prefix-name*]	Displays the configurations of an IPv6 prefix list.
display ip as-access-control-list [*as-path-access-list-number*]	Displays the configurations of an AS-path list.
display ip comm-type-list [*community-list-number* | *community-list-name*]	Displays the configurations of a community list.
display ip extend-comm-list [*extcommunity-list-number* | *extcommunity-list-name*]	Displays the configurations of an extcommunity list.

1.6 Configuration Examples

1.6.1 Applying Rules Configured in a Route Map During Route Redistribution

1. Requirements



The RIP routing domain needs to exchange routes with the OSPF routing domain to realize the network-wide interworking.

When RIP routes are redistributed to OSPF, the routes with too many hops are considered unreliable. Therefore, it is required that only RIP routes with the hop count of 4 be redistributed. In the OSPF routing domain, if a route is a Type-1 external route, the tag value of the route is set to 40.

When OSPF routes are redistributed to RIP, only OSPF routes with the tag value of 10 are redistributed. In the RIP routing domain, the initial metric of the routes redistributed to RIP is set to 10.

2. Topology

Figure 1-1 Applying Rules Configured in a Route Map During Route Redistribution

3. Notes

- Configure the route map **redrip** as follows: Configure a rule to match routes with the hop count of 4, set the initial metric of the routes to **40**, set the route type to the external route **type-1**, and set the tag of the routes to **40**.
- Configure the route map **redospf** as follows: Configure a rule to match routes with the tag of **10** and set the initial metric of the routes to **10**.
- Apply the route map **redrip** when RIP routes are redistributed to OSPF.
- Apply the route map **redospf** when OSPF routes are redistributed to RIP.

4. Procedure

(1) Configure IP addresses of the interfaces, and complete the basic OSPF and RIP configuration. (Omitted)

(2) Configure a route redistribution policy for OSPF. In the policy, configure a rule to match routes with the hop count of 4, set the route type to **Type-1** and the tag to **40**.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# route-map redrip permit 10
```

```
Device A(cfg-routemap)# match-rule metric 4
Device A(cfg-routemap)# set-rule metric-type type-1
Device A(cfg-routemap)# set-rule tag 40
Device A(cfg-routemap)# exit
```

(3) Configure a route redistribution policy for RIP. In the policy, configure a rule to match routes with the route tag of **10** and set the metric to **10**.

```
Device A(cfg)# route-map redospf permit 10
Device A(cfg-routemap)# match-rule tag 10
Device A(cfg-routemap)# set-rule metric 10
Device A(cfg-routemap)# exit
```

(4) Configure redistribution of RIP routes to OSPF, and use the route map **redrip** for routing control.

```
Device A(cfg)# router-protocol ospf 1
Device A(cfg-router)# redistribute-route rip subnets route-map redrip
Device A(cfg-router)# exit
```

(5) Configure the redistribution of OSPF routes to RIP, and use the route map **redospf** for routing control.

```
Device A(cfg)# router-protocol rip
Device A(cfg-router)# redistribute-route ospf 1 route-map redospf
Device A(cfg-router)# exit
```

5. Verification

Check the route map configurations on device A to verify the policy rules.

```
Device A# display route-map
route-map redrip, permit, sequence 10
  Match clauses:
    metric 4
  Set clauses:
    metric 40
    metric-type type-1
    tag 40
route-map redospf, permit, sequence 10
  Match clauses:
    tag 10
  Set clauses:
metric 10
```

Check the OSPF routing information library on device A to verify that the routes matching the policy rules are redistributed.

```
Device A# display ip ospf database-info external-route

                OSPF Router with ID (192.100.1.9) (Process ID 1)
```

```
                AS External Link States

  LS age: 5
  Options: 0x2 (-|-|-|-|-|-|E|-)
  LS Type: AS-external-LSA
  Link State ID: 192.168.199.0 (External Network Number)
  Advertising Router: 192.100.1.9
  LS Seq Number: 80000001
  Checksum: 0x554d
  Length: 36
  Network Mask: /24
        Metric Type: 1
        TOS: 0
        Metric: 4
        Forward Address: 0.0.0.0
        External Route Tag: 40
```

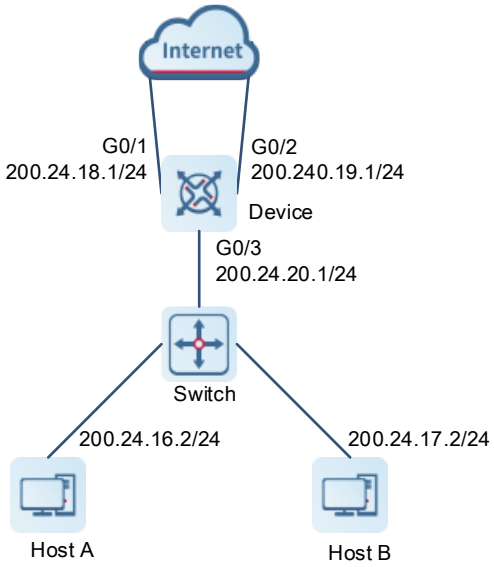
6. Configuration Files

Device A configuration file

```
!
route-map redrip permit 10
 match-rule metric 4
 set-rule metric-type type-1
 set-rule tag 40
!
route-map redospf permit 10
 match-rule tag 10
 set-rule metric 10
!
router-protocol ospf 1
redistribute-route rip route-map redrip subnets
!
router-protocol rip
redistribute-route ospf 1 route-map redospf
!
```

1.6.2 Applying a Route Map in PBR

1. Requirements



Configure PBR on the devices to achieve the following purposes:

- Packets from subnet 1 (200.24.16.0/24) are sent from GE0/1 first.
- Packets from subnet 2 (200.24.17.0/24) are sent from GE0/2 first.

The two egress links work in mutual backup mode.

2. Topology

Figure 1-2 Applying a Route Map in PBR

3. Notes

- Configure two different ACLs to match packets from subnets 1 and 2 respectively.
- Configure the route map RM_FOR_PBR: Configure policy 10 to ensure that "packets from host A are sent from GigabitEthernet 0/1 first"; configure policy 20 to ensure that "packets from host B are sent from GigabitEthernet 0/2 first".
- Configure PBR and apply the route map RM_FOR_PBR to packets received from GigabitEthernet 0/3.
- Configure a PBR to implement redundant backup among multiple next hops.

4. Procedure

(1) Configure the IP addresses of interfaces to implement interworking between networks. (Omitted)

(2) Configure ACLs for subnets 200.24.16.0/24 and 200.24.17.0/24, respectively.

```
Device> privilege
Device# config-system terminal
Device(cfg)# access-control-list 1 permit 200.24.16.0 0.0.0.255
Device(cfg)# access-control-list 2 permit 200.24.17.0 0.0.0.255
```

(3) Configure the routing map **RM_FOR_PBR**, set the next hop of 200.24.16.0 to 200.24.18.1 and its backup next hop to 200.24.19.1, and set the next hop of 200.24.17.0 to 200.24.19.1 and its backup next hop to 200.24.18.1.

```
Device(cfg)# route-map RM_FOR_PBR 10
```

```
Device(cfg-routemap)# match-rule ip address 1
Device(cfg-routemap)# set-rule ip-address next-hop 200.24.18.1
Device(cfg-routemap)# set-rule ip-address next-hop 200.24.19.1
Device(cfg-routemap)# exit
Device(cfg)# route-map RM_FOR_PBR 20
Device(cfg-routemap)# match-rule ip address 2
Device(cfg-routemap)# set-rule ip-address next-hop 200.24.19.1
Device(cfg-routemap)# set-rule ip-address next-hop 200.24.18.1
Device(cfg-routemap)# exit
```

(4) Apply the route map **RM_FOR_PBR** to the interface GigabitEthernet 0/3, and enable load balancing.

```
Device(cfg)# interface GigabitEthernet 0/3
Device(cfg-if-GigabitEthernet 0/3)# ip policy-based route-map RM_FOR_PBR
Device(cfg-if-GigabitEthernet 0/3)# exit
Device(cfg)# ip policy-based redundance
```

5. Verification

Check the PBR configurations to verify that the route map is applied to the interface.

```
Device# display ip policy-based
Balance mode: redundance
Interface                          Route map
GigabitEthernet 0/3                RM_FOR_PBR
```

Check the configurations of the route map to verify the policy rules.

```
Device# display route-map
route-map RM_FOR_PBR, permit, sequence 10
   Match clauses:
      ip address 1
   Set clauses:
      ip next-hop 200.24.18.1
      ip next-hop 200.24.19.1
route-map RM_FOR_PBR, permit, sequence 20
   Match clauses:
      ip address 2
   Set clauses:
      ip next-hop 200.24.19.1
      ip next-hop 200.24.18.1
```

Check the ACL configurations to verify the packet filtering rules.

```
Device# display access-control-lists
ip access-control-list standard-type 1
  10 permit 200.24.16.0 0.0.0.255
  10 permit 200.24.16.0 0.0.0.255
ip access-control-list standard-type 2
```

```
10 permit 200.24.17.0 0.0.0.255
```

6. Configuration Files

Device configuration file

```
!
ip policy-based redundance

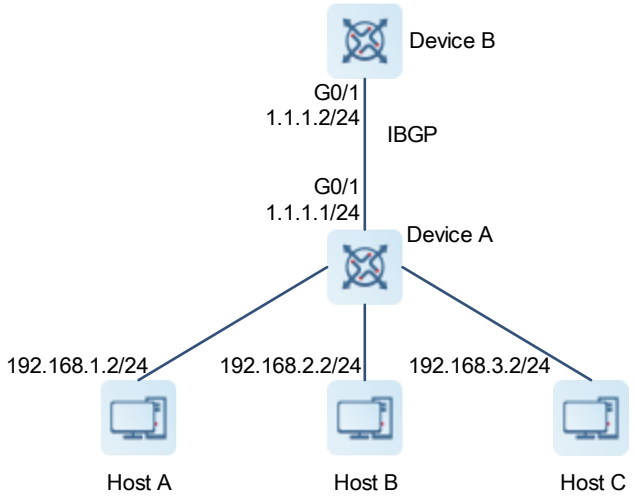
7. Common Errors

- After a policy that uses ACLs and prefix-lists for matching is configured, the corresponding ACLs and prefix lists are not defined.



1.6.3 Configuring a Prefix List

1. Requirements

Device A and device B are Interior Border Gateway Protocol (IBGP) neighbors. Device A performs routing control, and only advertises 192.168.1.0/24 network segment of the route to neighbor Device B.

2. Topology

Figure 1-3 Configuring a Prefix List

3. Notes

- Configure Device A and Device B as IBGP neighbors and advertise routes to the connected three subnets.
- Configure a prefix list.
- Associate the prefix list with device A to filter sent routes.

4. Procedure

(1) Configure the IP addresses of interfaces, and configure device A and device B to advertise routes and become IBGP neighbors. (Omitted)

(2) Configure a prefix list to match the traffic of 192.168.1.0/24.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# ip prefix-list-info pre1 permit 192.168.1.0/24
```

(3) Specify the neighbor 1.1.1.2 in BGP, and apply the prefix list **pre1** to filter sent routes.

```
Device A(cfg)# router-protocol bgp 100
Device A(cfg-router)# peer 1.1.1.2 prefix-list-info pre1 out
```

5. Verification

Check the prefix list.

```
Device A> privilege
Device A# display ip prefix-list-info
ip prefix-list-info pre1: 1 entries
```

```
        seq 5 permit 192.168.1.0/24

Device A# display ip bgp-instance
BGP table version is 2, local router ID is 1.1.1.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,

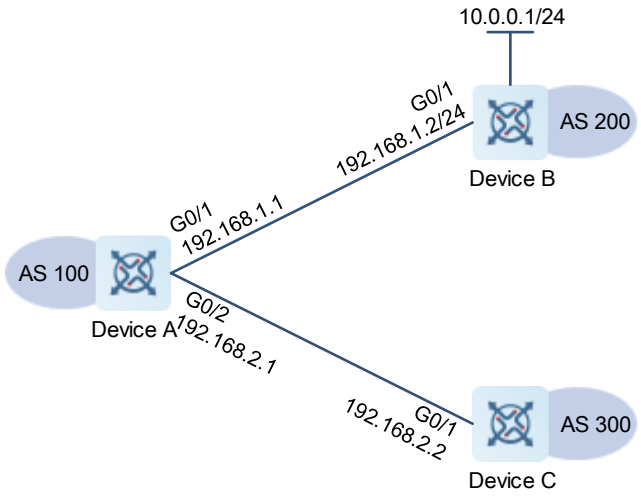
1.6.4 Configuring an AS-Path List



1. Requirements

Device A, Device B and Device C are EBGP neighbors.

Device A filters only the route information containing AS 200 from Device B and Device C.

2. Topology

Figure 1-4 Configuring an AS-Path List

3. Notes

- Create an AS-path filtering rule to match path information containing only the AS number of 200.
- On device A, establish the EBGP neighborship with device B and device C.
- Associate an AS-path list with device A to filter the routes received from device B and device C.

4. Procedure

(1) Configure IP addresses of the interfaces, and complete the basic EBGP configuration. (Omitted)

(2) Configure an AS-path list to match routes with the AS number of 200.

```
Device A(cfg)# ip as-path access-control-list 123 permit ^200$
```

(3) On device A, specify the BGP neighbors, and use the AS path list **123** to filter routes.

```
Device A(cfg)# router-protocol bgp 100
Device A(cfg-router)# peer 192.168.1.2 filter-rule-list 123 in
Device A(cfg-router)# peer 192.168.2.2 filter-rule-list 123 in
```

5. Verification

Check the AS-path list.

```
Device A> privilege
Device A# display ip as-access-control-list
AS path access list 123
permit ^200$
```

Before associating the AS-path list, check the BGP routing table to verify that all routes are learned.

```
Device A# display ip bgp-instance
BGP table version is 1, local router ID is 1.1.1.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
              S Stale, b - backup entry
Origin codes: i - IGP, e - EGP, ? - incomplete

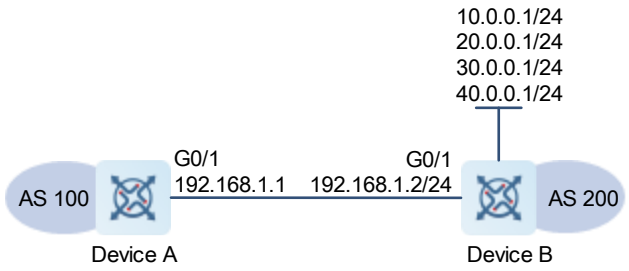
peer 192.168.2.2 filter-rule-list 123 in
!
```

1.6.5 Configuring a Community List



1. Requirements

Device A and Device B, are EBGP neighbors.

The routes received from Device B on Device A will be filtered, and only routes with the community attribute of 100:20 will be received.

2. Topology

Figure 1-5 Configuring a Community List

3. Notes

- Define a standard community list to match routes with the community attribute of **100:20**.
- Establish the EBGP neighborship between device A and device B.
- Configure device B to advertise routes with the community attribute.
- Associate the community list on device A (BGP can be applied only through a route map) to filter routes received from device B.

4. Procedure

(1) Configure IP addresses of the interfaces, and complete the related basic configuration. (Omitted)

(2) Configure a route map on device B, and configure the community attribute.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# route-map comm1
Device B(cfg-routemap)# set-rule comm 100:20 200:20
Device B(cfg-routemap)# exit
Device B(cfg)# route-map comm2
Device B(cfg-routemap)# set-rule comm 100:20
Device B(cfg-routemap)# exit
Device B(cfg)# route-map comm3
Device B(cfg-routemap)# set-rule comm 200:20
Device B(cfg-routemap)# exit
```

(3) Configure device B to advertise routes with the community attribute.

```
Device B(cfg)# router-protocol bgp 200
Device B(cfg-router)# peer 192.168.1.1 send-community
Device B(cfg-router)# network-advertise 10.0.0.0 mask 255.255.255.0 route-map comm1
Device B(cfg-router)# network-advertise 20.0.0.0 mask 255.255.255.0 route-map comm2
Device B(cfg-router)# network-advertise 30.0.0.0 mask 255.255.255.0 route-map comm3
```

```
Device B(cfg-router)# network-advertise 40.0.0.0 mask 255.255.255.0
```

(4) On device A, configure a community list and route map to match routes with the community attribute of **100:20**.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# ip comm-type-list standard-type test permit 100:20
Device A(cfg)# route-map COM
Device A(cfg-routemap)# match-rule comm test
Device A(cfg-routemap)# exit
```

(5) On device A, specify the neighbor 192.168.1.2, and use the route map **COM** to filter routes received from the neighbor.

```
Device A(cfg)# router-protocol bgp 100
Device A(cfg-router)# peer 192.168.1.2 route-map COM in
```

5. Verification

Check the community list of device A.

```
Device A> privilege
Device A# display ip comm-type-list
Named Community standard-type list test
permit 100:20
```

Before associating the community list with device A, check the BGP routing table.

```
Device A# display ip bgp-instance
BGP table version is 1, local router ID is 192.168.1.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
                    S Stale, b - backup entry
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network          Next Hop            Metric     LocPrf     Weight Path
*> 10.0.0.0/24      192.168.1.2              0                    0 200 i
*> 20.0.0.0/24      192.168.1.2              0                    0 200 i
*> 30.0.0.0/24      192.168.1.2              0                    0 200 i
*> 40.0.0.0/24      192.168.1.2              0                    0 200 i

1.7.1 Configuring PBR to Implement Multi-Exit High Availability 16

1.7.2 Selecting an Output Link based on Source Addresses of Packets 20

1 Configuring PBR

1.1 Introduction

1.1.1 Overview

You can apply a route map containing policies to interfaces and devices to implement Policy-Based Routing (PBR).

Similar to static routing, PBR is manually configured and does not automatically update with network changes. It is effective only for packets from local interfaces and devices. PBR is more flexible than static and dynamic routing. Static and dynamic routing forwards packets only based on destination addresses. PBR forwards packets based on the source IP address, destination IP address, packet length, and ingress port.

1.1.2 Principles

1. PBR-Procedure

To implement PBR, perform the following steps:

(1) Define a policy: Use the route map to define matching rules for traffic characteristics and set processing actions.

(2) Apply the policy: Apply the policy to interfaces or local devices.

2. Packet Processing Flow

After the device identifies packets, it processes packets as follows:

(1) Identify the source of traffic to determine the traffic is forwarded or is local, and check whether any policy is applied.

(2) Forward the packets based on the defined policy.

(3) If no next hop is matched or the next hop is unreachable, forward the packets based on the routing table.

(4) If the routing table does not contain any route to the destination address, discard the packets.

3. Definition of a Policy

A policy is a "**match-rule**..., **set-rule**..." statement, which indicates that "if certain conditions are matched, you can perform some processing actions"

Note

For details about the policies, see *Configuring Routing Policies*.

- Executing a policy

  A route map contains multiple policies. Each policy has a sequence number. A smaller sequence number means a higher priority. You can execute policies by sequence number. Once the matching condition of a policy

is met, the processing action of this policy is performed and the route map exits. If no matching condition of any policy is met, no processing is performed.

Policies support two working modes:

- permit: When the matching condition of a policy is met, perform the processing action of this policy and exit the route map.
- deny: When the matching condition of a policy is met, do not perform the processing action of this policy, but exit the route map.

- Matching conditions of policies

  The matching condition of a policy may contain zero, one, or more match rules.

  - If the matching condition contains 0 matching rule, no packet is matched.
  - If the matching condition contains one or more match rules, the matching condition is met only when all the rules are matched.

  In the route map mode, run the **match-rule** command to set matching rules. One **match-rule** command corresponds to one matching rule.

- Processing action for a policy

  The processing action of a policy contains 0, 1 or more set rules.

  - If the processing action contains 0 set rule, no processing action is performed and the route map directly exits.
  - If the processing action contains one or more set rules, all processing actions are performed and then the route map exits.

⚠ Caution

If set rules have different priorities, only the set rule with the highest priority takes effect.

4. Application of a Policy

Apply a route map including policies to interfaces or devices to implement PBR.

- If a route map is applied to an interface, packets received by the interface are routed based on the policy.

  The PBR is often used to control user packets received by a device. It is effective only for forwarded packets, but not for locally initiated packets.

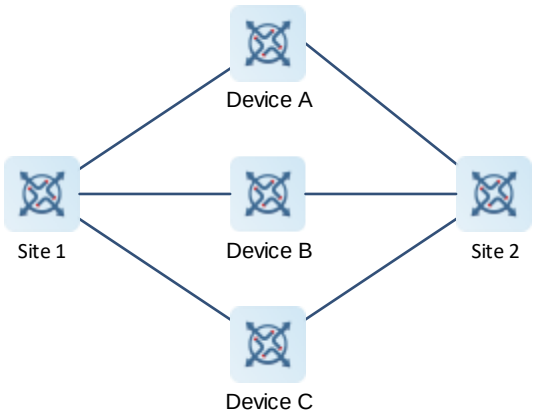
- If a route map is applied to a device, locally initiated packets are routed based on the policy.

  The PBR is often used to control protocol packets exchanged between devices (such as ping packets sent locally). It is effective only for locally initiated packets, but not for forwarded packets.

5. Enhanced Reliability of PBR

- Redundant backup or load balancing

You can set multiple next hops in a policy. Either redundant backup or load balancing can be implemented among multiple next hops. Redundant backup is implemented by default.



- Redundant backup

  As shown in Figure 1-1, the configuration sequence of the next hop from Site 1 to Site 2 is as follows: Device A > Device B > Device C, and the first accessible next hop takes effect. When the currently effective next hop (Device A) is faulty, the traffic automatically switches to the next accessible next hop (Device B). When Device A becomes accessible again, the traffic automatically switches back to Device A.

  A new next hop stays at the end of the sequence. If the original sequence is Device A > Device B > Device C, and if Device A is added after it is deleted, the current sequence becomes Device B > Device C > Device A.

  If no next hop is accessible, packets are discarded.

Figure 1-1 Redundant backup function

- Load balancing

  When multiple accessible next hops take effect concurrently, the Weighted Cost Multiple Path (WCMP) and Equal Cost Multiple Path (ECMP) are supported. After an accessible next hop fails, traffic will be balanced among the other accessible next hops.

- Correlation with BFD

  Correlation between PBR and BFD helps the PBR to better perceive network environment changes. When BFD finds the current next hop unaccessible, the BFD immediately notifies the PBR of switching the traffic to another accessible next hop (to implement redundant backup) or all the other accessible next hops (to implement load balancing).

- Correlation with Track

  Correlation between PBR and Track helps the PBR to better perceive network environment changes. When Track finds the current next hop unaccessible, the Track immediately notifies the PBR of switching the traffic to another accessible next hop (to implement redundant backup) or all the other accessible next hops (to implement load balancing).

6. PBR and VRF

If this feature is selected for VRF based on PBR, an interface to which PBR is applied can filter received IP packets by using the matching rules. If the packets are matched, the interface specifies a VRF instance for route selection in the set rules. The matching rules include the packet length and ACL (IP access list). Since the matching rules are flexible, you can allocate different traffic to different VRF instances based on actual requirements.

Generally, packets received on a VRF interface are forwarded from this VRF interface, and packets received on a global interface are forwarded based on a global routing table. PBR can break this limit and enable packets to be forwarded between a VRF instance and a global route map as follows:

- From a global routing table to a VRF instance: Packets received from a global interface jump to a specified VRF instance for forwarding.
- From a VRF instance to another VRF instance: Packets received from a VRF interface jump to another VRF interface for forwarding.
- From a VRF instance to a global routing table: Packets received from a VRF interface jump to the global routing table for forwarding.

7. Source-address-based PBR

If the source-address-based PBR is generated, you do not need to configure a route map.

- If only the source IPv4 address or source IPv6 address of packets forwarded by the interface needs to be matched, you can run the command of the source-address-based PBR. This command is more simply configured than that of interface-based PBR.
- If the source-address-based PBR is applied to a specified interface, packets received on this interface are routed according to the source addresses.

The PBR is often used to control user packets received by a device. It is effective only for forwarded packets, but not for locally initiated packets.

Note

The source-address-based PBR has a lower priority than the interface-based PBR. If the source-address-based PBR and the interface-based PBR are applied to the same interface, only the interface-based PBR takes effect.

8. PBR-based Traffic Diversion in Layer 3 Authentication

Divert traffic based on PBR for Layer 3 authentication.

1.2 Configuration Task Summary

The PBR configuration includes the following tasks:

(1) Configuring Basic Functions of PBR

- Applying PBR to an Interface

- Applying PBR to a Local Device

(2) (Optional) Configuring Redundant Backup or Load Balancing

(3) (Optional) Configuring Source-Address-Based PBR

1.3 Configuring Basic Functions of PBR

1.3.1 Overview

This section describes how to perform personalized routing management of user data streams by preparing flexible policies.

1.3.2 Restrictions and Guidelines

- A route map must be used when PBR is configured. Therefore, you must configure a route map on a device.
- If an ACL is used when the route map is configured, you must configure the ACL on the device.
- If the route map used in PBR does not exist, the PBR does not take effect.
- If PBR fails to be installed due to hardware resource insufficiency, run the **ip policy-sync all** or the **ipv6 policy-sync all** command to synchronize software entries to hardware when hardware resource is sufficient.
- Usage restrictions of PBR on matching rules in a route map:
  - IPv4 PBR uses IP standard or extended ACLs to define the source (and destination) IP address ranges of packets.
  - IPv6 PBR uses IPv6 extended IP ACLs to define the source (and destination) IPv6 address ranges of packets.
  - If PBR references an ACL but the ACL does not exist, this route submap is not used for packet matching, and packet matching continues from the next route submap. If a packet does not match any route submap, it is forwarded through the common route. If only an ACL is configured but no ACE is configured, PBR forwards packets just as it does when no ACL exists.
  - On switches, interface-based IPv4 PBR supports expert ACLs and MAC ACLs, while local PBR does not support expert ACLs and MAC ACLs.
  - On non-switches, both interface-based PBR and local PBR do not support expert ACLs and MAC ACLs.
  - On switches, if a route submap of PBR references multiple ACLs, only the first ACL is used for matching and subsequent ACLs are not used for matching.

Table 1-1 Matching Rules Supported by PBR

	Command	Description
IPv4 PBR	**match-rule ip address**	The source (and destination) IPv4 addresses are used as the matching condition. Multiple **match-rule ip address** commands are allowed in one policy.

IPv4 PBR	**match-rule length**	The match condition is the IPv4 packet length. One policy can be configured with only one **match-rule length** command.
IPv6 PBR	**match-rule ipv6 address**	The source (and destination) IPv6 addresses are used as the matching condition. Only one **match-rule ipv6 address** command is allowed in one policy.
IPv6 PBR	**match-rule ip policy**	The match conditions are the source IPv4 address (and destination IPv4 address) and the Layer 3 authentication traffic diversion domain type. One policy can be configured with only one **match-rule ip policy** command.

- Usage restrictions of PBR on set rules in a route map:
  - Priorities: **set-rule vrf > set-rule ip-address next-hop** > **set-rule ip-address next-hop recursive** > **set-rule interface** > common route > **set-rule ip-address default next-hop** > **set-rule default interface** > default route. The set commands can be configured at the same time but only the command with the highest priority takes effect.
  - Priorities: **set-rule vrf** > **set-rule ipv6-address next-hop** > **set-rule ipv6-address next-hop recursive** > common route > **set-rule ipv6-address default next-hop** > default route. The **set-rule** commands can be configured at the same time but only the command with the highest priority takes effect.
  - For switches, the **set-rule ipv6-address default next-hop** command does not take effect on IPv6 addresses with the mask length exceeding 64 bits.

Table 1-2 Set Rules Supported by PBR

	Command	Description
IPv4 PBR	**set-rule ip-address tos**	Changes the ToS field of IPv4 packets. This command cannot be configured together with the **set-rule ip-address dscp** command.
	set-rule ip-address precedence	Changes the precedence field of IPv4 packets. This command cannot be configured together with the **set-rule ip-address dscp** command.

	set-rule ip-address dscp	Changes the DSCP field of IPv4 packets. This command cannot be configured together with the **set-rule ip-address tos** and **set-rule ip-address precedence** commands.
	set-rule vrf	Sends IPv4 packets to a certain VRF for forwarding. The packets matching the Match rules are routed by the VRF specified in the **set-rule vrf** command, no matter whether the interface receiving the packets belongs to this VRF. This command cannot be used together with **set-rule interface** or **set-rule default interface** command**.**
	set-rule ip-address next-hop	Configures the next hop for IPv4 packet forwarding. The next hop must be directly connected. Otherwise, the command is invalid. Packets matching a matching rule are first forwarded to the next hop specified by the **set-rule ip-address next-hop** command regardless of whether the actual routing result of the packets in the routing table is the same as the next hop specified by PBR. On the switch, the outbound interface of the next hop supported by PBR can be an SVI, an L3 Ethernet interface, or an L3 aggregate interface.

	set-rule ip-address next-hop recursive	Configures the recursive next hop for IPv4 packet forwarding. The next hop can be directly connected or not. For routes with the next hop not directly connected, static or dynamic routes in the routing table are queried. This command supports recursion to multiple ECMP next hops of static or dynamic routes. A maximum of 32 next hops are supported. If a recursive route is a static recursive route, the next hop of only one static recursive route can be queried. The redundant backup or load balancing mode for recursively searching for multiple next hops is determined by the **ip policy-based** { **redundance** | **load-balance** } command. Packets matching a matching rule are first forwarded to the recursive next hop specified by the **set-rule ip-address next-hop recursive** command regardless of whether the actual routing result of the packets in the routing table is the same as the next hop specified by PBR. The recursive next hop of PBR takes effect only when a static or dynamic route with an egress and a next-hop IP address is queried.
	set-rule ip-address next-hop verify-accessibility	Verifies availability of the next-hop IPv4 address.
	set-rule interface	Specifies the outbound interface for IPv4 packet forwarding. The packets matching the Match rules are forwarded through the outbound interface specified in **set-rule interface** command, no matter whether the route of the packets specified in the routing table is the same as the next hop specified by PBR. This command cannot be used together with **set-rule vrf** command**.**
	set-rule ip-address default next-hop	Configures the default next hop for IPv4 packet forwarding. For IPv4 packets matching a matching rule, if the routing fails or a default route is selected in the routing table, the packets are forwarded to the default next hop specified by the command.

	set-rule ip-address default interface	Specifies the default outbound interface for IPv4 packets. If the routing of the packets matching the Match rules fails or a default route is selected, the packets are forwarded through the outbound interface specified in this command. This command cannot be used together with **set-rule vrf** command**.**
	set-rule ip-address policy l3-auth	Configures Layer 3 authentication for IPv4 packets. Layer 3 authentication will be performed for the packets matching the Match rules. This command is valid for the packets forwarded by interfaces, but invalid for the locally sent packets.
	set-rule ip-address policy load-balance	Configures the load balancing mode for IPv4 packets. If global load balancing mode is enabled, PBR selects an outbound interface for the packets matching the Match rules according to the configured load balancing mode This command is valid for the packets forwarded by interfaces, but invalid for the locally sent packets.
	set-rule ip-address policy no-ttl-decrease	Keeps the TTL of IPv4 packets not decreasing. The TTL in the headers of IPv4 packets that match the Match rules is not decreased by 1 during PBR-based forwarding. This command is applied to Layer 3 authentication traffic diversion. This command is valid for the packets forwarded by interfaces, but invalid for the locally sent packets.
IPv6 PBR	**set-rule ipv6-address precedence**	Changes the precedence field of IPv6 packets. IPv6 PBR does not support the **set-rule ipv6-address tos** and **set-rule ipv6-address dscp** commands.
	set-rule ipv6-address next-hop	Configures the next hop for IPv6 packet forwarding. IPv6 packets matching a matching rule are first forwarded to the next hop specified by the **set-rule ipv6-address next-hop** command regardless of whether the actual routing result of the IPv6 packets in the routing table is the same as the next hop specified by PBR. The next hop must be directly connected. Otherwise, the command is invalid.

	set-rule ipv6-address next-hop recursive	Configures the recursive next hop for IPv6 packet forwarding. The next hop can be directly connected or not. For routes with the next hop not directly connected, static or dynamic routes in the routing table are queried. This command supports recursion to multiple ECMP next hops of static or dynamic routes. A maximum of 32 next hops are supported. If a recursive route is a static recursive route, the next hop of only one static recursive route can be queried. The redundant backup or load balancing mode for recursively searching for multiple next hops is determined by the **ipv6 policy-based** { **redundance** | **load-balance** } command. Packets matching a matching rule are first forwarded to the recursive next hop specified by the **set-rule ipv6-address next-hop recursive** command regardless of whether the actual routing result of the packets in the routing table is the same as the next hop specified by PBR. The recursive next hop of PBR takes effect only when a static or dynamic route with an egress and a next-hop IPv6 address is queried.
	set-rule ipv6-address next-hop verify-availability	Verifies availability of the next-hop IPv6 address.
	set-rule ipv6-address reset next-hop	Configures the default next hop for IPv6 packet forwarding. For IPv6 packets matching a matching rule, if the routing fails or a default route is selected in the routing table, the packets are forwarded to the next hop specified by the command. The next hop must be directly connected. Otherwise, the command is invalid.

1.3.3 Configuration Tasks

The configuration of PBR basic functions includes the following tasks:

- Applying PBR to an Interface
- Applying PBR to a Local Device

1.3.4 Applying PBR to an Interface

1. Overview

This section describes how to apply PBR to an interface to implement personalized routing management on user data streams passing a device.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

- Enter the VXLAN routed interface configuration mode.

  interface overlayrouter *interface-number*

(4) Apply PBR to IPv4 packets received by an interface.

ip policy-based route-map *route-map-name*

By default, no PBR is configured on an interface.

(5) Apply PBR to IPv6 packets received by an interface.

ipv6 policy-based route-map *route-map-name*

By default, no IPv6 PBR is configured on an interface.

1.3.5 Applying PBR to a Local Device

1. Overview

This section describes how to apply PBR to a local device to implement personalized management on packets initiated by the local device. A device has only one IPv4 PBR and one IPv6 PBR.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Apply PBR to IPv4 packets initiated by the local device.

ip local policy-based route-map *route-map-name*

By default, no IPv4 PBR is applied to the local device.

(4) Apply PBR to IPv6 packets initiated by the local device.

ipv6 local policy-based route-map *route-map-name*

By default, no IPv6 PBR is applied to the local device.

1.4 Configuring Redundant Backup or Load Balancing

1.4.1 Overview

Multiple next hops in the mutual backup mode can enhance the network reliability.

Load balancing mode among multiple next hops can expand the network bandwidth.

1.4.2 Restrictions and Guidelines

- If redundant backup is selected, the first next hop takes effect based on the configuration sequence.
- If load balancing is selected, all next hops take effect at the same time and share traffic by weight.
- This configuration applies to all PBRs configured on a device.
- The basic functions of PBR must be configured.
- Redundant backup and load balancing are effective only for the next hops set by the following **set-rule** commands, and only among multiple next hops set by the same **set-rule** command.

Table 1-3 set-rule commands for configuring the next hop

Command	Description
set-rule ip-address next-hop	Configures the next hop of IPv4 packets. This command carries the **weight** parameter to set the weight of the WCMP. The default value is **1**.
set-rule ip-address default next-hop	Configures the default next hop of IPv4 packets. This command carries the **weight** parameter to set the weight of the WCMP. The default value is 1.

Command	Description
set-rule ipv6-address next-hop	Configures the next hop of IPv6 packets. This command carries the **weight** parameter to set the weight of the WCMP. The default value is **1**.
set-rule ipv6-address default next-hop	Configures the default next hop of IPv6 packets. This command carries the **weight** parameter to set the weight of the WCMP. The default value is **1**.
set-rule ip-address next-hop recursive	Configures the recursive next hop of IPv4 packets. Only one command is configured for a route map, and packets can recur to multiple next hops (up to 32 next hops) of a static or dynamic ECMP route. The redundant backup or load balancing mode for recurring to multiple next hops is also determined by the **ip policy** { **redundance** | **load-balance** } command.
set-rule ipv6-address next-hop recursive	Configures the recursive next hop of IPv6 packets. Only one command is configured for a route map, and packets can recur to multiple next hops (up to 32 next hops) of a static or dynamic ECMP route. The redundant backup or load balancing mode for recurring to multiple next hops is also determined by the **ipv6 policy** { **redundance** | **load-balance** } command.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an IPv4 PBR to implement redundant backup or load balancing among multiple next hops.

ip policy { **redundance** | **load-balance** }

By default, multiple next hops of the PBR adopt the redundant backup mode.

(4) Configure an **IPv6** PBR to implement redundant backup or load balancing among multiple next hops.

ipv6 policy { **redundance** | **load-balance** }

By default, multiple next hops of the IPv6 PBR adopt the redundant backup mode.

1.5 Configuring Source-Address-Based PBR

1.5.1 Overview

This section describes how to perform personalized routing management for IPv4 or IPv6 addresses of user data streams by preparing flexible policies.

1.5.2 Restrictions and Guidelines

- Source-address-based PBR has a higher priority than interface-based PBR. When they are applied to an interface at the same time, interface-based PBR takes effect whereas source-address-based PBR does not take effect.
- The global configuration takes effect on the input interface of specified user data streams.
- You can specify multiple source-address-based PBRs for the same interface. The sequence numbers of source-address-based PBRs must be different. A smaller sequence number indicates a higher priority of the source-address-based PBR.

  If the sequence number is the same, the priorities of next hop types are as follows:

  vrf *vrf-name* **next-hop** *ipv4-address* > **interface** *out-interface-type* > **default next-hop** *ipv4-address*> **default interface** *out-interface-type*

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure applying source address policy routing for IPv4 packets received by the interface.

ip policy-source in-interface *interface-type interface-number sequence* { *source-address mask* | *source-address/mask* } { [**default**] **next-hop** { *ipv4-address* [*weight*] }&<1-4> | [**default**] **interface** { *out-interface-type out-interface-number* } &<1-4>| **vrf** *vrf-name* }

By default, no source-address-based PBR takes effect on an interface.

(4) Apply a source-address-based PBR for IPv6 packets received by an interface.

ipv6 policy-source in-interface *interface-type interface-number sequence source-address/prefix-length* { [**default**] **next-hop** [*ipv6-address* [*weight*]]&<1-4> [**default**] **interface** *out-interface-type*&<1-4>| **vrf** *vrf-name* }

By default, no source-address-based IPv6 PBR takes effect on an interface.

1.6 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

You can run the **cleanup** commands to clear information.

⚠ Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

You can run the **debugging** command to output debugging information.

⚠ Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-4 Monitoring of the PBR

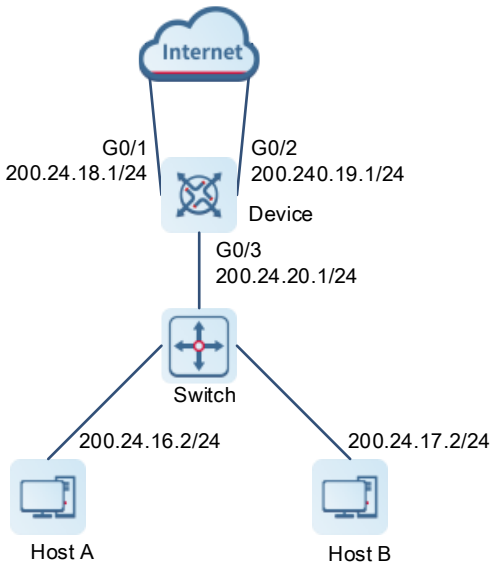
Command	Purpose
display ip policy-based [*route-map-name*]	Displays the configurations of the IPv4 PBR.
display ipv6 policy-based	Displays the configurations of the IPv6 PBR.
display route-map [*name*]	Displays the configurations of a route map.
display access-control-list	Displays the configurations of an ACL.
display ip pbr bfd	Displays the correlation between the IPv4 PBR and BFD.
display ipv6 pbr bfd	Displays the correlation between the IPv6 PBR and BFD.
display ip pbr recursive	Displays routing information of IPv4 PBR after next-hop recursion.
display ipv6 pbr recursive	Displays routing information of IPv6 PBR after next-hop recursion.
display ip pbr route [**interface** *interface-type interface-number* | **local**]	Displays the routing information of the IPv4 PBR.
display ipv6 pbr route [**interface** *interface-type interface-number* | **local**]	Displays the routing information of the IPv6 PBR.
display ip pbr route-map *rmap-name*	Displays a route map used by the IPv4 PBR.

Command	Purpose
display ipv6 pbr route-map *rmap-name*	Displays a route map used by the IPv6 PBR.
display ip pbr source-routing [**interface** *interface-type interface-number*]	Displays the routing information of source-address-based IPv4 PBR.
display ipv6 pbr source-routing [**interface** *interface-type interface-number*]	Displays the routing information of source-address-based IPv6 PBR.
display ip pbr track	Displays the correlation between PBR and tracking.
debugging pbr error	Debugs PBR errors.
debugging pbr events	Debugs PBR events.
debugging pbr ms	Debugs multiple service cards supported by PBR.
debugging pbr msg	Debugs PBR message communication.
debugging pbr nsm	Debugs interaction between PBR and NSM.
debugging pbr packet	Debugs packet forwarding of PBR.
debugging pbr restart	Debugs PBR GR.

1.7 Configuration Examples

1.7.1 Configuring PBR to Implement Multi-Egress High Availability

1. Requirements



Configure PBR on the devices to achieve the following purposes:

- Packets from Host A (200.24.16.2/24) are sent from GigabitEthernet 0/1 first.
- Packets from Host B (200.24.17.2/24) are sent from GigabitEthernet 0/2 first.

The two output links work in mutual backup mode, and are correlated with Track. Thus, when one link is faulty, traffic is quickly switched over to the other link.

2. Topology

Figure 1-2 Configuring PBR to Implement Multi-Egress High Availability

3. Notes

- Configure two different ACLs to match packets in the Host A and Host B network segment respectively.
- Configure the route map RM_FOR_PBR: policy 10 is used to ensure that "packets in the Host A network segment are sent from GigabitEthernet 0/1first"; policy 20 is used to ensure that "packets in the Host B network segment are sent from GigabitEthernet 0/2 first".
- Configure a PBR to implement redundant backup among multiple next hops.
- Configure the track rules and correlation between PBR and Track.
- Configure PBR and apply the route map RM_FOR_PBR to packets received from GigabitEthernet 0/3.

4. Procedure

(1) Configure the IP addresses of interfaces to implement interworking between networks. (Omitted)

(2) Configure ACLs for subnets 200.24.16.0/24 and 200.24.17.0/24, respectively.

```
Device> privilege
Device# config-system terminal
Device(cfg)# access-control-list 1 permit 200.24.16.0 0.0.0.255
Device(cfg)# access-control-list 2 permit 200.24.17.0 0.0.0.255
```

(3) Configure the track rules.

```
Device(cfg)# ip rns 1
Device(cfg-ip-rns)# icmp-echo 200.24.18.1
```

```
Device(cfg-ip-rns)# exit
Device(cfg)# ip rns schedule 1 start-time now life forever
Device(cfg)# track 1 rns 1
Device(cfg)# ip rns 2
Device(cfg-ip-rns)# icmp-echo 200.24.19.1
Device(cfg-ip-rns)# exit
Device(cfg)# ip rns schedule 2 start-time now life forever
Device(cfg)# track 2 rns 2
```

(4) Configure the PBR **RM_FOR_PBR**, set the next hop of 200.24.16.0 to **200.24.18.1** and its backup next hop to **200.24.19.1**, and set the next hop of 200.24.17.0 to **200.24.19.1** and its backup next hop to **200.24.18.1**.

```
Device(cfg)# route-map RM_FOR_PBR 10
Device(cfg-routemap)# match-rule ip address 1
Device(cfg-routemap)# set-rule ip-address next-hop verify-accessibility 200.24.18.1 track 1
Device(cfg-routemap)# set-rule ip-address next-hop verify-accessibility 200.24.19.1 track 2
Device(cfg-routemap)# exit
Device(cfg)# route-map RM_FOR_PBR 20
Device(cfg-routemap)# match ip address 2
Device(cfg-routemap)# set-rule ip-address next-hop verify-accessibility 200.24.19.1 track 2
Device(cfg-routemap)# set-rule ip-address next-hop verify-accessibility 200.24.18.1 track 1
Device(cfg-routemap)# exit
```

(5) Apply the route map RM_FOR_PBR to GigabitEthernet 0/3, and enable load balancing.

```
Device(cfg)# interface GigabitEthernet 0/3
Device(cfg-if-GigabitEthernet 0/3)# ip policy-based route-map RM_FOR_PBR
Device(cfg-if-GigabitEthernet 0/3)# exit
Device(cfg)# ip policy redundance
```

5. Verification

Check the PBR configurations to verify that the route map is applied to the interface.

```
Device# display ip policy-based
Balance mode: redundance
Interface                    Route map                    state
local                        test                         ok
GigabitEthernet 0/3          test                         ok
```

Check the configurations of the route map to verify the policy rules.

```
Device# display route-map
route-map RM_FOR_PBR, permit, sequence 10
  Match clauses:
    ip address 1
  Set clauses:
    ip next-hop 200.24.18.1
```

```
    ip next-hop 200.24.19.1
route-map RM_FOR_PBR, permit, sequence 20
  Match clauses:
    ip address 2
  Set clauses:
    ip next-hop 200.24.19.1
    ip next-hop 200.24.18.1
```

Check the ACL configurations to verify the packet filtering rules.

```
Device# display access-lists
ip access-control-list standard 1
 10 permit 200.24.16.0 0.0.0.255
 10 permit 200.24.16.0 0.0.0.255
ip access-control-list standard 2
 10 permit 200.24.17.0 0.0.0.255
```

Check whether the track objects are up.

```
Device#display track
Track 1
  Reliable Network Service 1
  The state is Up
    1 change, current state last: 120 secs
  Delay up 30 secs, down 50 secs
Track 2
  Reliable Network Service 2
  The state is Up
    1 change, current state last: 130 secs
  Delay up 30 secs, down 50 secs
```

6. Configuration Files

Device configuration file

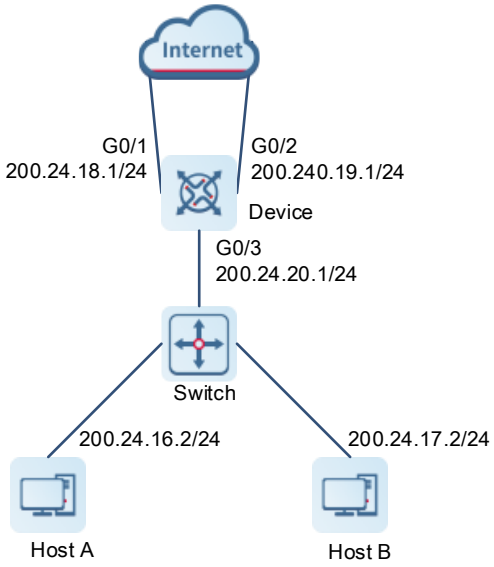
```
!
ip policy redundance
!
access-control-list 1 permit 200.24.16.0 0.0.0.255
access-control-list 2 permit 200.24.17.0 0.0.0.255
!
route-map RM_FOR_PBR 10
 match-rule ip address 1
 set-rule ip-address next-hop verify-accessibility 200.24.18.1 track 1
 set-rule ip-address next-hop verify-accessibility 200.24.19.1 track 2
!
route-map RM_FOR_PBR 20
```

```
 match-rule ip address 2
 set-rule ip-address next-hop verify-accessibility 200.24.19.1 track 2
 set-rule ip-address next-hop verify-accessibility 200.24.18.1 track 1
!
ip rns 1
 icmp-echo 200.24.18.1
!
ip rns 2
 icmp-echo 200.24.19.1
!
ip rns schedule 1 start-time now life forever
ip rns schedule 2 start-time now life forever
!
track 1 rns 1
!
track 2 rns 2
!
interface GigabitEthernet 0/3
 ip policy-based route-map RM_FOR_PBR
!
```

7. Common Errors

- After matching of ACLs and prefix-lists is configured, the corresponding ACLs and prefix lists are not defined.

1.7.2 Selecting an Output Link based on Source Addresses of Packets



1. Requirements

This LAN has two output interfaces for connecting the Internet. The requirements are as follows:

- Route the Internet access data streams from Host A to GigabitEthernet 0/1.
- Route the Internet access data streams from Host B to GigabitEthernet 0/2.
- If the link on GigabitEthernet 0/1 is disconnected, switch over the data streams from GigabitEthernet 0/1 to GigabitEthernet 0/2. Vice versa.

2. Topology

Figure 1-3 Selecting an Output Link based on Source Addresses of Packets

3. Notes

- Configure a source-address-based PBR, and set the next hops for packets from the GigabitEthernet 0/3 of Host A to **GigabitEthernet 0/1** and **GigabitEthernet 0/2**. (Note the configuration sequence.)
- Configure a source-address-based PBR, and set the next hops for packets from the GigabitEthernet 0/3 of Host B to **GigabitEthernet 0/2** and **GigabitEthernet 0/1**. (Note the configuration sequence.)
- Configure a PBR to implement redundant backup among multiple next hops. (The default setting is redundant backup.)

4. Procedure

(1) Configure basic networks, such as the interface IP address.

(2) Select an output link based on source addresses of packets.

```
Device> privilege
Device# config-system terminal
Device (cfg)# ip policy-source in-interface gigabitEthernet 0/3 1 200.24.16.0/24 next-hop 200.24.18.1
200.24.19.1
Device (cfg)# ip policy-source in-interface gigabitEthernet 0/3 2 200.24.17.0/24 next-hop 200.24.19.1
200.24.18.1
Device (cfg)# ip policy redundance
```

5. Verification

Check the configurations of the source-address-based IPv4 PBR.

```
Device # display ip pbr source-routing
PBR IPv4 Source Route
Interface              : GigabitEthernet 0/3
   Sequence            : 1
   Source address : 200.24.16.0/24
   VRF ID              : 0
   Route Flags       :
     Route Type       : PBR
     Direct             : Permit
     Priority          : High

1 Configuring Keys

1.1 Introduction

1.1.1 Overview

Keys are a kind of parameters that are used in algorithms for conversion from plaintext to ciphertext or from ciphertext to plaintext.

To allow packet authentication in a routing protocol to support plaintext authentication and ciphertext authentication, you must use keys.

Note

- Keys are used only for RIP, OSPF, and ISIS packet authentication.
- In this chapter, the term "router" refers to any network device that supports the routing function. These network devices can be Layer-3 switches, routers, or firewalls.

1.1.2 Principles

The key chain provides a tool for the authentication mechanism in a routing protocol.

1. Key Chain

A key chain contains the TCP authentication configuration, authentication algorithm ID, and multiple different keys. Each key has the following attributes:

- Key ID: Identifies a key. In the current key chain, each key corresponds to one ID.
- Authentication string: Specifies a set of key characters used for verifying the consistency of authentication strings in a routing protocol.
- Lifetime: Specifies the lifetime of the current key for sending or receiving packets. Different authentication keys can be used in different periods.
- Authentication algorithm: It is used by keys to authenticate routing protocols.

1.2 Configuring a Key Chain

1.2.1 Overview

This section defines a key chain to be used by a routing protocol.

1.2.2 Restrictions and Guidelines

A key chain can take effect only after it is associated with a routing protocol.

1.2.3 Configuration Tasks

The key configuration includes the following tasks:

(1) Creating a Key Chain

(2) Configuring a Key ID

(3) Configuring a Key String

(4) (Optional) Configuring the Send-Lifetime

(5) (Optional) Configuring the Accept-Lifetime

1.2.4 Creating a Key Chain

1. Overview

In the global configuration mode, you can run the **key chain** *key-chain-name* command to define a key chain and enter the key chain configuration mode.

2. Restrictions and Guidelines

- This configuration is mandatory if a key chain needs to be used.
- If there is no special requirement, you should perform this configuration on all routers that need to authenticate routing protocols.
- To make a key chain take effect, you must configure at least one key.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a key chain, and enter the key chain configuration mode.

key chain *key-chain-name*

No key chain is configured by default.

1.2.5 Configuring a Key ID

1. Overview

In the key chain configuration mode, you can run the **key** *key-id* command to define a key and enter the key chain key configuration mode.

2. Restrictions and Guidelines

- This configuration is mandatory if a key chain needs to be used.

- If there is no special requirement, you should perform this configuration on all devices that need to authenticate routing protocols.
- After the key is configured, it must meet two conditions before it takes effect: (1) the key-string is configured; (2) the key is in the lifetime (send-lifetime and accept-lifetime). If the lifetime is not configured, the key is considered effective permanently once the key-string is configured. Two effective states are defined: effective on the sending end and effective on the receiving end. The two states correspond to send-lifetime and accept-lifetime respectively.
- If there is no special demand, you can configure a key by incrementing the key-id to avoid the authentication state oscillation caused by the possible changes of effective keys. If multiple effective keys exist, each routing protocol uses the key with the smallest key-id.
- In the TCP enhanced authentication scenario, the key-id ranges from 0 to 63.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the key chain configuration mode.

key chain *key-chain-name*

(4) Create a key ID, and enter the key configuration mode of the key chain.

key *key-id*

No key is configured by default.

1.2.6 Configuring a Key String

1. Overview

In the key configuration mode of the key chain, you can specify a key string in plaintext or cyphertext. To ensure security, you are advised to use cyphertext. If you run the **service password-encryption-storage** command to enable the encryption service, you can forcibly convert a plaintext key string into a ciphertext string.

2. Restrictions and Guidelines

- This configuration is mandatory if a key chain needs to be used.
- If there is no special requirement, you should perform this configuration on all routers that need to authenticate routing protocols.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the key chain configuration mode.

key chain *key-chain-name*

(4) Enter the key configuration mode of the key chain.

key *key-id*

(5) Configure a key string.

key-string [**0 | 7**] *string-text*

No key string is configured by default.

1.2.7 Configuring the Send-Lifetime

1. Overview

This section defines the lifetime of a key in the sending direction.

2. Restrictions and Guidelines

If the send-lifetime is not configured, the key chain is always effective.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the key chain configuration mode.

key chain *key-chain-name*

(4) Enter the key configuration mode of the key chain.

key *key-id*

(5) Configure the send-lifetime.

accept-lifetime *start-time* { *end-time* | **duration** *duration-time* | **infinite** }

By default, the accept-lifetime of a key chain is disabled.

1.2.8 Configuring the Accept-Lifetime

1. Overview

This section defines the lifetime of a key in the receiving direction.

2. Restrictions and Guidelines

If the accept-lifetime is not configured, the key chain is always effective.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the key chain configuration mode.

key chain *key-chain-name*

(4) Enter the key configuration mode of the key chain.

key *key-id*

(5) Configure the accept-lifetime.

send-lifetime *start-time* { *end-time* | **duration** *duration-time* | **infinite** }

By default, the send-lifetime of a key chain is disabled.

1.3 Monitoring

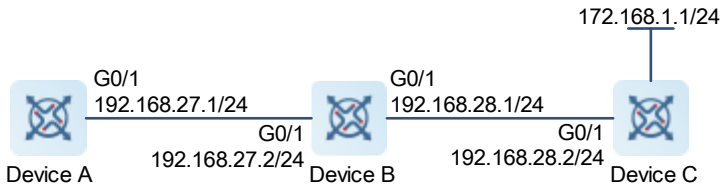
Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Key Monitoring

Command	Purpose
display key chain config [*key-chain-name*]	Displays the configurations of a key chain.

1.4 Configuration Examples

1.4.1 Configuring Key-based Authentication



1. Requirements

Device A and Device B are interconnected using the RIP routing protocol. To improve security, you can configure the MD5 encryption algorithm between Device A and Device B to encrypt RIP packets.

Device B accesses 172.168.1.1/24 via the static route.

2. Topology

Figure 1-1 Configuring Key-based Authentication

3. Notes

- Configure keys on all routers.
- Configure RIP on all routers.
- Enable RIP authentication on all routers.

4. Procedure

(1) Configure the IP addresses of interfaces.

Configure Device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# interface gigabitEthernet 0/1
Device A(cfg-if)# ip address 192.168.27.1 255.255.255.0
Device A(cfg-if)# exit
```

Configure Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# interface gigabitEthernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip address 192.168.27.2 255.255.255.0
Device B(cfg-if-GigabitEthernet 0/1)# exit
```

(2) Configure keys and lifetime of each key.

Configure Device A.

```
Device A# config-system terminal
Device A(cfg)# key chain ripchain
Device A(cfg-keychain)# key 1
Device A(cfg-keychain-key)# key-string Hello
Device A(cfg-keychain-key)# accept-lifetime 16:30:00 Oct 1 2013 duration 43200
Device A(cfg-keychain-key)# send-lifetime 16:30:00 Oct 1 2013 duration 43200
Device A(cfg-keychain-key)# exit
Device A(cfg-keychain)# key 2
```

```
Device A(cfg-keychain-key)# key-string World
Device A(cfg-keychain-key)# accept-lifetime 04:00:00 Oct 2 2013 infinite
Device A(cfg-keychain-key)# send-lifetime 04:00:00 Oct 2 2013 infinite
Device A(cfg-keychain-key)# exit
```

Configure Device B.

```
Device B# config-system terminal
Device B(cfg)# key chain ripchain
Device B(cfg-keychain)# key 1
Device B(cfg-keychain-key)# key-string Hello
Device B(cfg-keychain-key)# accept-lifetime 16:30:00 Oct 1 2013 duration 43200
Device B(cfg-keychain-key)# send-lifetime 16:30:00 Oct 1 2013 duration 43200
Device B(cfg-keychain-key)# exit
Device B(cfg-keychain)# key 2
Device B(cfg-keychain-key)# key-string World
Device B(cfg-keychain-key)# accept-lifetime 04:00:00 Oct 2 2013 infinite
Device B(cfg-keychain-key)# send-lifetime 04:00:00 Oct 2 2013 infinite
Device B(cfg-keychain-key)# exit
```

(3) Configure the basic RIP.

Configure Device A.

```
Device A(cfg)# router-protocol rip
Device A(cfg-router)# version 2
Device A(cfg-router)# network-advertise 192.168.27.0
Device A(cfg-router)# exit
```

Configure Device B.

```
Device B(cfg)# router-protocol rip
Device B(cfg-router)# version 2
Device B(cfg-router)# network-advertise 192.168.27.0
Device B(cfg-router)# redistribute-route static
Device B(cfg-router)# exit
```

(4) Set the interface authentication mode to MD5, and specify the authentication key chain.

Configure Device A.

```
Device A(cfg)# interface gigabitEthernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# ip rip enable-auth keychain ripchain
Device A(cfg-if)# ip rip enable-auth mode md5
```

Configure Device B.

```
Device B(cfg)# interface gigabitEthernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip address 192.168.27.2 255.255.255.0 Device B(cfg-if-GigabitEthernet
0/1)# ip rip enable-auth keychain ripchain
Device B(cfg-if-GigabitEthernet 0/1)# ip rip enable-auth mode md5
```

5. Verification

Check whether Device A can receive routes from Device B.

```
Device A# display ip route-config rip
R       172.168.0.0/16 [120/1] via 192.168.27.2, 00:05:16, GigabitEthernet 0/1
```

6. Configuration Files

- Device A configuration file

```
!
key chain ripchain
 key 1
  key-string Hello
  accept-lifetime 16:30:00 Oct 1 2013 duration 43200
  send-lifetime 16:30:00 Oct 1 2013 duration 43200
 key 2
  key-string World
  accept-lifetime 04:00:00 Oct 2 2013 infinite
  send-lifetime 04:00:00 Oct 2 2013 infinite
!
interface gigabitEthernet 0/1
 ip address 192.168.27.1 255.255.255.0
 ip rip enable-auth keychain ripchain
 ip rip enable-auth mode md5
!
router-protocol rip
 version 2
 network-advertise 192.168.27.0
!
```

- Device B configuration file

```
!
key chain ripchain
 key 1
  key-string Hello
  accept-lifetime 16:30:00 Oct 1 2013 duration 43200
  send-lifetime 16:30:00 Oct 1 2013 duration 43200
key 2
  key-string World
  accept-lifetime 04:00:00 Oct 2 2013 infinite
  send-lifetime 04:00:00 Oct 2 2013 infinite
!
interface gigabitEthernet 0/1
 ip address 192.168.27.2 255.255.255.0
```

```
 ip rip enable-auth keychain ripchain
 ip rip enable-auth mode md5
!
router-protocol rip
 version 2
 network-advertise 192.168.27.0
 redistribute-route static
!
```

7. Common Errors

- A key is not correctly associated with a routing protocol, resulting in authentication failures.
- The keys configured on multiple routers are inconsistent, resulting in authentication failures.

1 Configuring Multicast Basics

IP transmission methods are categorized into unicast, multicast, and broadcast. In IP multicast, an IP packet is sent from a source and forwarded to a specific group of receivers. Compared with unicast and broadcast, IP multicast saves bandwidth and reduces network loads. Therefore, IP multicast is applied to different network services that have high requirements for real timeliness, for example, Internet TV, distance education, live broadcast and multimedia conference.

1.1 Basic Concepts of Multicast

As shown in Figure 1-1, there are packet sending sources and receivers on a network. Users who are interested in information raise information requirements. Then, the information sending source sends information only to these users.

Figure 1-1 Topology of Multicast Data Transmission

- Multicast group: It is marked based on a multicast IP address. After a host is added to a multicast group, the host becomes a member of the multicast group and can receive multicast packets destined to the multicast group.
- Multicast source: Indicates a packet sender, for example, the source in Figure 1-1. Different multicast sources can send packets to a multicast group, and a multicast source can send multicast packets to different multicast groups.

- Member of multicast group: Indicates a host that is added to a multicast group, for example, Host A and Host C in Figure 1-1. Members in a multicast group can be dynamically added to or removed from the multicast group.
- Multicast device: the device that supports the multicast function. For example, the devices in Figure 1-1 can provide multicast routing and member management functions.

1.2 Multicast Service Models

Based on members in a multicast group, the service models of multicast can be categorized into Any-Source Multicast (ASM) and Source-Specific Multicast (SSM). The two service models use different address ranges of multicast groups.

1.2.1 ASM Model

In the ASM model, multicast data is assigned to multicast groups. The address of a multicast group is used as a network service ID. Any multicast source can send packets to this multicast group, and hosts join the group to receive multicast packets from this multicast group. The address of the multicast group in the ASM model is unique on the multicast network.

1.2.2 SSM Model

In the SSM model, multicast data is assigned to specific multicast sources and multicast groups. When you add a host to a multicast group, you can configure it to receive or not receive data from the specified multicast sources After the host is added to the multicast group, the host can receive only multicast data that is sent to this multicast group by the specified multicast sources. In the SSM model, different multicast sources can use the same address of a multicast group.

1.3 Multicast Address

The multicast technology provides network layer multicast for communication between a multicast source and members in a multicast group based on a multicast IP address. The multicast technology ensures transmission of multicast data in a local physical network based on a multicast MAC address. The IP address must be mapped to the MAC address to ensure correct transmission of the multicast data, because the members in the multicast group are unknown.

1.3.1 IPv4 Multicast Address

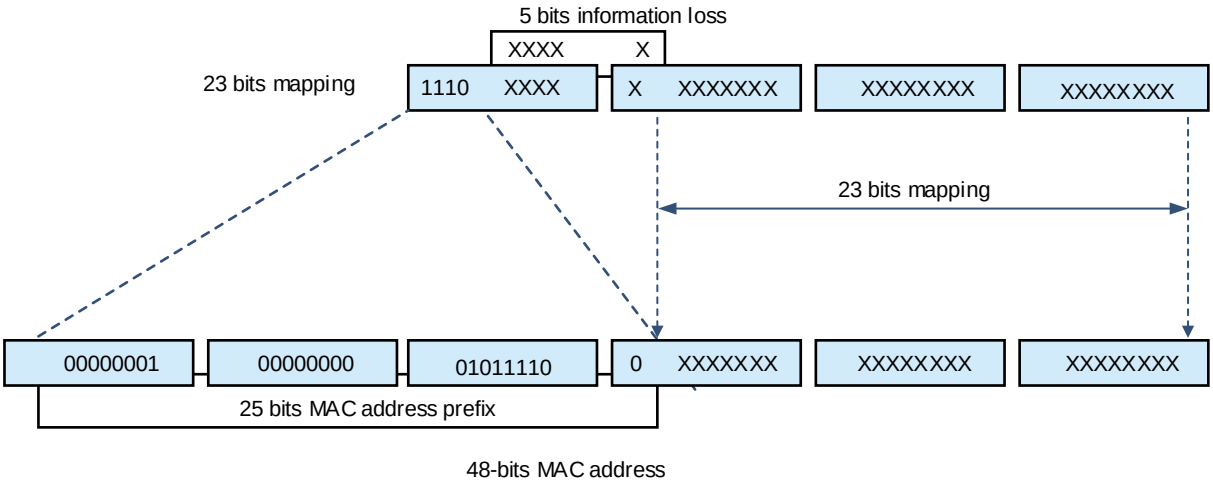
The four higher-order bits of a class D IP address are 1110, and the IP address range is from 224.0.0.0 to 239.255.255.255. These four bits are assigned by the Internet Assigned Numbers Authority (IANA) to IPv4 multicast. Table 1-1 lists how IPv4 multicast addresses are allocated.

Table 1-1 Assignment of IPv4 Multicast Addresses

Address Range	Description
224.0.0.0~224.0.0.255	Address of a permanent group
224.0.1.0~231.255.255.255 233.0.0.0~238.255.255.255	ASM multicast address

Address Range	Description
232.0.0.0~232.255.255.255	Default SSM multicast address
239.0.0.0~239.255.255.255	Address of a local management group

Table 1-2 Addresses of Common Permanent Groups



Address of a Permanent Group	Description
224.0.0.0	Unallocated
224.0.0.1	All hosts and routers in a network segment
224.0.0.2	All multicast devices
224.0.0.3	Unallocated
224.0.0.4	Distance Vector Multicast Routing Protocol (DVMRP) router
224.0.0.5	Open Shortest Path First (OSPF) router
224.0.0.6	OSPF specified router
224.0.0.7	Shared tree (ST) router
224.0.0.8	ST host
224.0.0.9	Routing Information Protocol version 2 (RIP-2) router
224.0.0.11	Mobile proxy
224.0.0.12	Dynamic Host Configuration Protocol (DHCP) server/relay proxy
224.0.0.13	All Protocol Independent Multicast (PIM) devices
224.0.0.14	Resource Reservation Protocol (RRP) encapsulation
224.0.0.15	All Core-Based Tree (CBT) routers
224.0.0.16	Specified Subnetwork Bandwidth Management (SBM)
224.0.0.17	All SBMs
224.0.0.18	Virtual Router Redundancy Protocol (VRRP)

1.3.2 IPv4 Multicast MAC Address

Based on IANA regulation, the higher-order 24 bits of an IPv4 multicast MAC address is 0x01005e, the 25th bit is 0, and the lower-order 23 bits are those of the IPv4 multicast address. Figure 1-2 shows the mapping. The four higher-order bits of an IPv4 multicast address is fixed at 1110, corresponding to the higher-order 25 bits of the multicast MAC address. The lower-order 23 bits in the lower-order 28 bits of the IPv4 multicast address map

to the lower-order 23 bits of the multicast MAC address. The lost information indicating by five bits causes the 32 IPv4 addresses to map to the same MAC address.

Figure 1-2 Mapping of IPv4 Multicast Address to IPv4 Multicast MAC Address

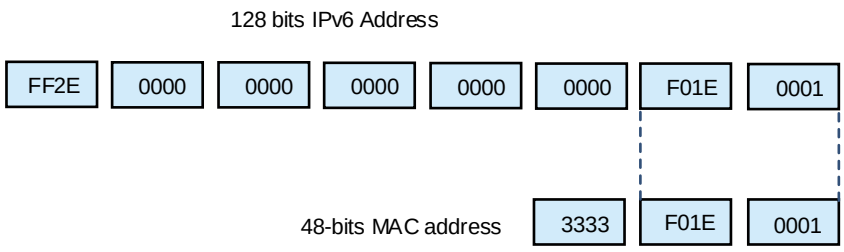
1.3.3 IPv6 Multicast Address

An IPv6 address consists of 128 bits. An IPv6 multicast address always starts with FF.

Table 1-3 Assignment of IPv6 Multicast Addresses

Address Range	Description
FF0x::/32	Addresses of a reserved group
FF1x::/32 (x cannot be 1 or 2) FF2x::/32 (x cannot be 1 or 2)	ASM multicast address
FF3x::/32 (x cannot be 1 or 2)	Default SSM multicast address

Table 1-4 Common IPv6 Multicast Addresses and Description



Range	IPv6 Multicast Address	Description
Local range of a node (or an interface)	FF01::1	Addresses of all nodes (interfaces)
	FF01::2	Addresses of all routers
Local range of a link	FF02::1	Addresses of all nodes
	FF02::2	Addresses of all routers
	FF02::3	Unallocated
	FF02::4	DVMRP router

Range	IPv6 Multicast Address	Description
	FF02::5	OSPF IGP router
	FF02::6	OSPF IGP DR
	FF02::7	ST router
	FF02::8	ST host
	FF02::9	RIP router
	FF02::A	EIGRP router
	FF02::B	Mobile proxy
	FF02::D	All PIM routers
	FF02::E	RSVP encapsulation
	FF02::1:1	Link name
	FF02::1:2	All DHCP proxies
	FF02::1:FFXX:XXXX	Solicited-Node address. XX:XXXX indicates the lower-order 24 bits of an IPv6 address of a node.
Local range of station	FF05::2	Addresses of all routers
	FF05::1:3	All DHCP servers
	FF05::1:4	All DHCP relays
	FF05::1:1000~FF05::1:13FF	Service location

1.3.4 IPv6 Multicast MAC Address

The higher-order 16 bits of an IPv6 multicast MAC address is 0x3333, and the lower-order 32 bits are those of the IPv6 multicast address. Figure 1-3 shows the mapping of the IPv6 multicast address FF2E::F01E:1 to the MAC address. There are more IPv6 multicast addresses mapped to the same MAC address.

Figure 1-3 Mapping of IPv6 Address to Multicast MAC Address

1.4 IPv4 Multicast Protocols

A complete set of protocols is developed during the development of multicast to complete multicast data transmission. IPv4 multicast covers the following protocols:

- Internet Group Management Protocol (IGMP): Manages IPv4 multicast members and runs in the network segment that hosts are connected to. IGMP supports data communication with the upstream multicast routing protocols, and maintains and manages relationship of members by adding or removing the members. Three versions of IGMP are available:
  - IGMPv1: Supports the ASM model, and supports the SSM model only when SSM mapping is configured.
  - IGMPv2: Supports the ASM model, and supports the SSM model only when SSM mapping is configured.
  - IGMPv3: Supports the ASM and SSM models.
- PIM: It is a multicast routing protocol in an IPv4 network, and used for route-based query and forwarding of multicast data. PIM includes the following two types:
  - Protocol Independent Multicast Dense Mode (PIM-DM): Applies to a small-size network in which members of a multicast group are densely distributed. The protocol is not distinguished in the ASM and SSM models.
  - Protocol Independent Multicast Sparse Mode (PIM-SM): Applies to a network in any form, and especially applies to a large-size network in which members of a multicast group are sparsely distributed. The protocol is distinguished in the ASM and SSM models based on the data and the multicast addresses in protocol packets.
- Internet Group Management Protocol Snooping (IGMP Snooping): Creates a multicast L2 forwarding table by listening to the IGMP packets between upstream L3 devices and member hosts, and manages and controls multicast packet forwarding on L2 network to suppress multicast data flooding.
- Multicast Source Discovery Protocol (MSDP): Connects multiple PIM-SM domains, shares multicast sources among the PIM-SM domains, and forwards multicast packets across the domains.

1.5 IPv6 Multicast Protocols

IPv6 multicast covers the following protocols:

- Multicast Listener Discovery (MLD): Manages IPv6 multicast members and runs in the network segment that hosts are connected to. MLD supports data communication with the upstream multicast routing protocols, and maintains and manages relationship of members by adding or removing the members. Two versions of MLD are available:
  - MLDv1: Supports the ASM model, and supports the SSM model only when SSM mapping is configured.
  - MLDv2: Supports the ASM and SSM models.
- PIM (IPv6): It is a multicast routing protocol in an IPv6 network, and used for route-based query and forwarding of multicast data. This protocol applies to a network in any form, and especially applies to a large-size network in which members of a multicast group are sparsely distributed. The protocol is distinguished in the ASM and SSM models based on the data and the multicast addresses in protocol packets.

- Multicast Listener Discovery Snooping (MLD Snooping): Creates a multicast L2 forwarding table by listening to the MLD packets between upstream L3 devices and member hosts, and manages and controls multicast packet forwarding on L2 network to suppress multicast data flooding.

1.6 Basic Concepts of PIM

- PIM device

  A device on which PIM is enabled. Multicast packets are forwarded on the PIM device.

- PIM interface

  An interface on which PIM is enabled. The PIM interface that receives multicast packets is an upstream interface, and the PIM interface that sends multicast packets is a downstream interface. The network segment where the upstream interface resides is an upstream network segment, and the network segment where the downstream interface resides is a downstream network segment.

- PIM network

  Connections of PIM devices through the PIM interfaces constitute a PIM network.

- PIM domain

  On some PIM interfaces, borders can be set to divide a large PIM network into multiple PIM domains. The borders can reject specified multicast packets or control transmission of PIM messages.

- Rendezvous point (RP)

  A PIM device functioning as an RP collects multicast source and group member information on a network.

- Candidate-RP (C-RP)

  A device selects RPs from C-RPs based on the election mechanism, and enables the RPs to serve different multicast groups.

- Designated router (DR)

  A PIM device can function as a DR. A DR that is connected to a multicast source and reports multicast source information to the RP is referred to as a source DR. A DR that is connected to members of a multicast group and reports the group member information to the RP is referred to as a member DR.

- Candidate-BSR (C-BSR)

  PIM devices can be configured as C-BSRs, from which a BSR is elected. When the BSR becomes faulty, other C-BSRs initiate a new election request to elect a new BSR. This avoids service interruption.

- Bootstrap router (BSR)

  A PIM device functioning as a BSR collects and releases RP information in a PIM-SM domain. A BSR is elected from candidate-BSRs. Only one BSR is available in a PIM-SM domain. However, there can be multiple candidate-BSRs in the PIM-SM domain.

- Multicast distribution tree

  Multicast packets are transmitted from one point to multiple points. The forwarding path is displayed as a tree. This forwarding path is referred to as a multicast distribution tree (MDT). There are two types of MDTs:

  - RP tree (RPT): The RP is regarded as the root, and the DRs that connect group members are regarded as leaves.
  - Shortest path tree (SPT): The DR that connects multicast sources is regarded as the root, and the RPs

or DRs that connect group members are regarded as leaves.

- (*, G) and (S, G)
  - (*, G) refers to a routing entry corresponding to packets that are sent from any multicast source to Group G. The forwarding path corresponding to the packets that are sent from any multicast source to Group G is referred to as an RPT.
  - (S, G) refers to a routing entry corresponding to packets that are sent from source S to Group G. The forwarding path corresponding to the packets that are sent from source S to Group G is an SPT.

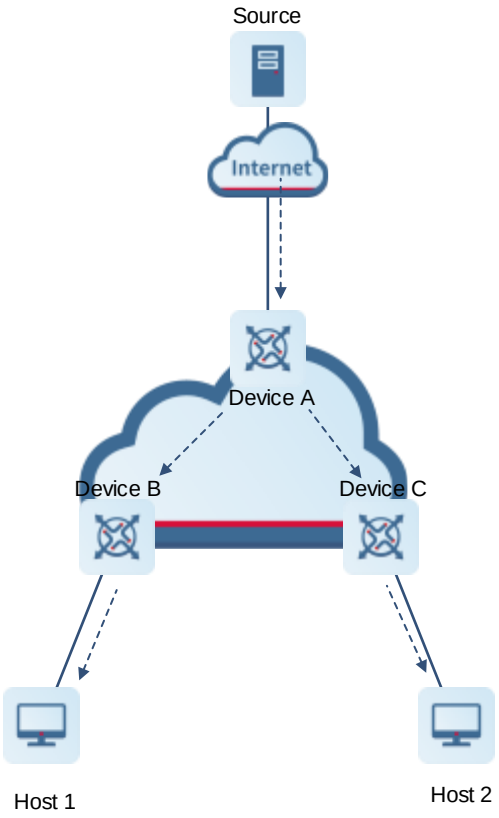
1 Configuring IPv4 Multicast Route Management

1.1 Introduction

1.1.1 Overview

IPv4 multicast transmits a packet from a source to multiple devices. The multicast packet is sent from the source, forwarded by intermediate devices, and then received by receivers in a specified group.

Figure 1-1 Multicast Topology vs. Unicast Topology



Compared with unicast, multicast reduces redundant traffic, relieves transmission loads of servers and intermediate devices, and completes one-to-multiple content transmission with high efficiency. Multicast is applied to different network services that have high requirements for real timeliness, for example, Internet TV, distance education, live broadcast and multimedia conference.

Proper multicast routes must be configured on the intermediate devices so that IPv4 multicast packets can be correctly forwarded. This chapter describes how to create and maintain IPv4 multicast routes and control multicast packet forwarding based on the multicast routes.

1.1.2 Basic Topology of IPv4 Multicast

Figure 1-2 shows a simple multicast topology that includes a multicast source, multicast devices (Device A, Device B, and Device C), and members in a multicast group.

Figure 1-2 Basic Topology of IPv4 Multicast

As shown in Figure 1-2, the transmission process of a multicast packet is as follows.

(1) The multicast source functions as a packet sender and sends a multicast packet to one or more multicast groups.

(2) The multicast packet is forwarded by the intermediate devices to the packet receivers (members in the multicast group). The intermediate devices are routers or switches that support the multicast function and can correctly forward the multicast packet. They are referred to as multicast devices collectively.

(3) This multicast group contains multiple members and they reside in different network segments on the network. Therefore, the multicast packet sent from the multicast source may be replicated into multiple copies by the multicast devices and then sent to the members in the multicast group.

(4) The members in the multicast group receive the multicast packet from the source.

1.1.3 Basic Concepts of IPv4 Multicast

1. PIM

Protocol Independent Multicast (PIM) is a multicast routing protocol that provides multicast routes based on unicast static routes or unicast routing tables that are generated based on the unicast route protocols. PIM is independent from the unicast routing protocols used and can use the static routes or unicast routing tables that are generated based on any unicast routing protocol, for example, Routing Information Protocol (RIP), Open Shortest Path First (OSPF), Intermediate System-to-Intermediate System (IS-IS), and Border Gateway Protocol (BGP).

PIM generates multicast routing entries based on the reverse path forwarding (RPF) mechanism, and controls multicast packet forwarding based on the entries. For more information about RPF, see 1.1.5 RPF Checking.

2. Multicast Routing Entry and Forwarding Entry

A multicast routing entry is generated based on multicast routing protocols. Specific routing entries vary with the routing protocols, and they are a comprehension of the routing protocol entries.

A multicast forwarding entry is used to guide multicast packet forwarding, and it is generated based on routing entry information.

3. Multicast Network

Numerous multicast devices constitute a multicast network, and multicast packets are transmitted between multicast sources and members in multicast groups on the network. Multicast packet query and forwarding between multicast devices are completed by running PIM. These PIM running devices are referred to as PIM routers.

PIM takes effect to device interfaces. An interface with PIM enabled is referred to as a PIM interface. A PIM interface that receives a multicast packet is an upstream interface and the interface resides in an upstream network segment. A PIM interface that sends a multicast packet is a downstream interface and the interface resides in a downstream network segment.

PIM routers are connected through PIM interfaces, which constitutes a PIM network.

4. Multicast Border

Data in a multicast network is not transmitted boundlessly. You can configure an access control list (ACL) on a PIM interface of a device to filter multicast packets and allow packets of specific multicast groups to pass. That is, set a border to control multicast packet transmission.

By configuring borders on PIM interfaces, you can divide a large PIM network into multiple PIM domains.

1.1.4 Principle of IPv4 Multicast Forwarding

To ensure correct forwarding of multicast packets by multicast devices, enable multicast routing protocols on the devices.

Upon receiving a multicast packet, a multicast device checks whether the multicast packet is valid and selects proper paths based on the routing table to forward the packet to one or more downstream devices. The basic process of IPv4 multicast forwarding is as follows:

(1) A multicast device receives a multicast packet from an upstream interface.

(2) The multicast device queries the multicast routing table to obtain proper forwarding paths. If no proper forwarding path is found, the multicast device performs RPF checking to determine forwarding paths and updates the multicast routing table.

(3) The multicast device forwards this packet to the outbound interfaces of all the determined forwarding paths.

1.1.5 RPF Checking

1. Basic Principles

In unicast transmission, the destination address in a packet corresponds to a specific address in a network. Provided that the destination address is determined, a network device can determine the outbound interface of the packet. In multicast transmission, a multicast address corresponds to members in a multicast group and a

multicast device does not know the IP address of each member. Therefore, the receiver addresses cannot be determined based on the destination address.

RPF checking is used to determine outbound interfaces of a multicast packet. The core idea behind RPF checking is that: An RPF route is generated to check whether the theoretical destination interface of a multicast packet is consistent with the actual interface. If they are not consistent, the packet is discarded. If they are consistent, the packet is forwarded to all the determined outbound interfaces.

2. RPF Checking Procedure

The RPF checking procedure consists of the following steps:

(1) Select optimal routes.

Take the address (the source IP address in a multicast packet) of the multicast source as the destination address and select optimal routes from the local device to the destination address.

The optimal routes are selected from the unicast routing table, Multiprotocol Extensions for BGP-4 (MBGP) routing table, and multicast static routing table, respectively.

(2) Determine an RPF route.

Select a route from the determined optimal routes of the routing tables as an RPF route based on rules. Table 1-1 lists the specific rules.

Table 1-1 RPF Routing Rules

Select RPF Route Based on the Longest Match	Rule Priority (a Smaller Number Indicates a Higher Priority)	Description
No	1	The route with the highest priority is selected.
	2	An RPF route is selected in the sequence of multicast static route, MBGP route, and unicast route.
Yes	1	The route with the longest match mask is selected.
	2	The route with the highest priority is selected.
	3	An RPF route is selected in the sequence of multicast static route, MBGP route, and unicast route.

An RPF route includes RPF interface information and the information is used for checking the RPF interface.

- In a unicast route and an MBGP route, the outbound interface in a routing entry is used as an RPF interface, with the next hop being an RPF neighbor.
- In a multicast static routing entry, the RPF interface and RPF neighbor are specified.

(3) Check the RPF interface.

Check whether the inbound interface of the multicast packet is consistent with the RPF interface.

- If yes, the RPF interface passes the checking.
- Otherwise, the RPF interface fails the checking.

1.1.6 RPF Checking and Multicast Packet Forwarding

When a multicast packet is forwarded, query a path from the routing table first. If no proper path is found, RPF checking is performed. Path information that is generated after RPF checking passes is updated to the routing table and can be queried for packet forwarding next time.

The rules of forwarding a multicast packet are as follows:

- No forwarding entry exists in a multicast routing table.

  RPF checking is performed for this packet. The RPF interface is used as an inbound interface and updated to the routing table.

  - If the RPF interface passes the checking, the packet is forwarded to all outbound interfaces.
  - If the RPF interface fails the checking, this packet is discarded.

- There are forwarding entries in a multicast routing table.
  - If the inbound interface of the packet matches the inbound interface in an entry, the packet is forwarded to all outbound interfaces.
  - If the inbound interface of the packet does not match the inbound interface in an entry, RPF checking is performed. If the RPF interface is consistent with the inbound interface in an entry, the packet is discarded. If the RPF interface is not consistent with the inbound interface in an entry, the inbound interface in the entry is updated as an RPF interface and the inbound interface in the packet is compared with the RPF interface to determine whether they are consistent.

1.2 Restrictions and Guidelines

- All the configuration items must be configured after the basic functions of IPv4 multicast are configured.
- The multicast routing function is implemented based on unicast routes. Before applying the multicast function, ensure that the unicast communication between network nodes is normal.

1.3 Configuration Task Summary

IPv4 multicast route management configuration includes the following tasks:

(1) Configuring Basic Functions of IPv4 Multicast

(2) (Optional) Configuring a packet forwarding rule. The following configuration tasks are optional. Select tasks for configuration according to actual condition.

- Configuring RPF Route Selection Based on the Longest Match Rule
- Configuring Static Routes of IPv4 Multicast
- Configuring IPv4 Multicast Borders
- Configuring L2 Direction Control for Multicast Streams
- Configuring TTL Threshold
- Configuring Forced Forwarding of Multicast Packets by Software

(3) (Optional) Configuring multicast entries. The following configuration tasks are optional. Select tasks for configuration according to actual condition.

- Configuring Entry Capacity of IPv4 Multicast Routing Table

- Configuring the Overwriting Mechanism upon Overflow of Multicast Hardware Forwarding Entries

(4) (Optional) Configuring Immediate Delivery of Entries to the Forwarding Plane

(5) (Optional) Configuring Multicast Non-Stop Forwarding Parameters

(6) (Optional) Configuring the Multicast Lossless Work Mode

1.4 Configuring Basic Functions of IPv4 Multicast

1.4.1 Overview

To configure basic functions of IPv4 multicast, enable the IPv4 multicast routing function and the IPv4 multicast protocols on a device so that the device has the multicast packet forwarding function and can provide IPv4 multicast services for multicast sources and hosts in multicast groups.

1.4.2 Restrictions and Guidelines

- The IPv4 multicast routing function should be enabled on each router unless otherwise specified.
- IPv4 unicast routes must be configured so that PIM can use the unicast routes to generate multicast routes.
- After L3 multicast is enabled for a private virtual local area network (PVLAN) and a super VLAN, if there is a multicast source in a sub VLAN, the entry count increases by 1. This is because the inbound validity will be checked during multicast forwarding, and therefore an extra entry will be generated, and the inbound of this entry is the sub VLAN that the multicast stream enters.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable IPv4 multicast routing.

ip mrouting-enable

The IPv4 multicast routing function is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(5) Enable an IPv4 multicast protocol on an interface. Select at least one of them to configure.

- Enable Protocol Independent Multicast Dense Mode (PIM-DM) on the interface.

  ip pim dense-mode

PIM-DM is disabled for an interface by default.

PIM-DM is a multicast routing protocol that is used in dense mode and applies to small-sized networks where members in a multicast group are densely distributed. For more information about PIM-DM, see *Configuring PIM-DM*.

- Enable Protocol Independent Multicast Sparse Mode (PIM-SM) on the interface.

  ip pim sparse-mode

  PIM-SM is disabled for an interface by default.

  PIM-SM is a multicast routing protocol that is used in sparse mode and applies to large-sized networks where members in a multicast group are sparsely distributed. For more information about PIM-SM, see *Configuring PIM-SM*.

1.5 Configuring RPF Route Selection Based on the Longest Match Rule

1.5.1 Overview

In multicast routing, there may be different routing tables, for example, multicast static routing table, MBGP routing table, and unicast routing table. An optimal route should be selected from all the routing tables and used as an RPF route.

If the longest match rule is used, the route with the longest match mask is selected from the optimal routes in different routing tables as the RPF route. If the masks are equal in length, the route with the highest priority is selected from the optimal routes. If the priorities are consistent, a route is selected in the sequence of multicast static route, MBGP route, and unicast route.

1.5.2 Restrictions and Guidelines

The longest match rule can be configured on each device unless otherwise specified.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure RPF route selection based on the longest match rule.

ip multicast rpf-routing longest-match

By default, the route with the highest priority is selected as the RPF route. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.

1.6 Configuring Static Routes of IPv4 Multicast

1.6.1 Overview

You can configure static routes of IPv4 multicast to specify RPF interfaces or RPF neighbors for multicast packets from specific multicast sources. This function can be used to change and connect RPF routes.

- Change an RPF route: If you want a device to receive multicast packets from a multicast source through a

specified interface, but this interface is not the required interface based on the RPF checking result, you need to configure a multicast static route to specify this required interface as an RPF interface.

- Connect an RPF route: If a unicast route is interrupted, a multicast route failed to be generated by RPF. You can configure a multicast static route to specify an RPF interface to complete RPF checking and realize multicast packet forwarding.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a multicast static route.

ip rpf-mroute *ipv4-source-address mask* { [**bgp** | **isis** | **ospf** | **rip** | **static-route**] { *ipv4-rpf-address* | *interface-type interface-number* } } [*distance*]

No multicast static route is configured by default. To specify an outbound interface for a multicast static route, set the outbound interface to point-to-point type.

1.7 Configuring IPv4 Multicast Borders

1.7.1 Overview

After IPv4 multicast borders are configured, a multicast network can be divided into different domains so that specified multicast packets are transmitted in a domain.

The multicast border function filters out specified multicast packets based on an ACL to forbid packets of this type from entering or leaving an interface.

1.7.2 Restrictions and Guidelines

IP multicast borders can be configured on each PIM router interface unless otherwise specified.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.

interface loopback *interface-number*

(4) Configure an IP multicast border.

ip multicast scope-boundary { *acl-name* | *acl-number* } [**in** | **out**]

No multicast border is configured by default.

This command is associated with a standard access control list (ACL). If an extended ACL is used, an error occurs in filtering.

1.8 Configuring L2 Direction Control for Multicast Streams

1.8.1 Overview

By configuring L2 direction control for multicast streams, you can control multicast stream forwarding on an interface.

You can configure this command multiple times for a multicast stream. That is, configure multiple interfaces to forward the stream. After direction control is configured for a multicast stream, this multicast stream can be forwarded only by these configured interfaces. Other interfaces are not allowed to forward the stream.

1.8.2 Restrictions and Guidelines

This command controls only the forwarding of multicast streams on interfaces, but does not directly affect the processing of protocol packets by the multicast protocols. However, some features of the multicast protocols (PIM-DM or PIM-SM) depend on the multicast streams. Behaviors of the multicast routing protocols may be affected.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure L2 direction control for multicast streams.

ip multicast static *ipv4-source-address ipv4-group-address interface-type interface-number*

No L2 direction control is configured for multicast streams by default.

1.9 Configuring TTL Threshold

1.9.1 Overview

The time to live (TTL) value in an IP packet is used to define the maximum number of hops that this packet can transmit through.

To configure a TTL threshold means to configure the minimum TTL value of multicast packets allowed on an interface. Before forwarding a multicast packet on an interface, the device checks whether the TTL value in the packet is greater than the TTL threshold. If yes, the device forwards the packet. Otherwise, the device discards this packet.

1.9.2 Restrictions and Guidelines

- A TTL threshold can be configured on each PIM router interface unless otherwise specified.
- The TTL threshold must be configured on router interfaces and takes effect only to multicast packets.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure a TTL threshold for an interface.

ip multicast packet-ttl-threshold *ttl-threshold-value*

The default TTL threshold for an interface is **0**.

1.10 Configuring Forced Forwarding of Multicast Packets by Software

1.10.1 Overview

After the mechanism of forced forwarding of multicast packets by software is configured, multicast packets destined to the local device can be forwarded to other interfaces by software.

1.10.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable forced forwarding of multicast packets by software.

msf force-forwarding

The mechanism of forced forwarding of multicast packets by software is disabled by default.

1.11 Configuring Entry Capacity of IPv4 Multicast Routing Table

1.11.1 Overview

A device creates and maintains a multicast route forwarding entry for each received multicast packet. Therefore, the entry quantity increases continuously. If the number of entries maintained by a device surpasses the limited hardware resources of the device, hardware forwarding may be changed to software forwarding, which consumes device memory and reduces device performance.

The entry capacity of an IPv4 multicast routing table refers to the maximum number of entries that can be added to the IPv4 multicast routing table. You can configure a proper entry capacity based on actual network situation and service performance without affecting running of the device.

1.11.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure entry capacity of an IPv4 multicast routing table.

ip multicast max-route *max-route* [*max-threshold*]

The default entry capacity of an IPv4 multicast routing table is **1000** entries.

1.12 Configuring the Overwriting Mechanism upon Overflow of Multicast Hardware Forwarding Entries

1.12.1 Overview

The hardware forwarding entries are limited. If they are used up, the device uses software forwarding entries. Compared with hardware forwarding entries, software forwarding entries feature lower performance, occupy device memory, and deteriorate device performance.

After the overwriting mechanism upon overflow of multicast hardware forwarding entries is enabled, new entries can overwrite the earliest entries when hardware forwarding entries are used up.

1.12.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the overwriting mechanism upon overflow of multicast hardware forwarding entries.

msf ipmc-overflow override

The overwriting mechanism upon overflow of multicast hardware forwarding entries is disabled by default.

1.13 Configuring Immediate Delivery of Entries to the Forwarding Plane

1.13.1 Overview

A routing table generated based on a routing table contains entries guiding multicast packet forwarding. After the function of immediate delivery of entries to the forwarding plane is configured, the forwarding rules specified by the entries take effect immediately.

1.13.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the function of immediate delivery of IPv4 multicast L2 entries to the forwarding plane.

msf immediately-install

1.14 Configuring Multicast Non-Stop Forwarding Parameters

1.14.1 Overview

In certain active/standby switchover scenarios, multicast protocols such as PIM-SM and Internet Group Management Protocol (IGMP) Snooping need re-convergence during the switchover. You can configure non-stop forwarding parameters to ensure continuous forwarding of multicast streams during re-convergence of the multicast protocols.

1.14.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure multicast non-stop forwarding parameters.

msf nsf { **convergence-time** *convergence-time* | **leak** *leak-time* }

The maximum period for multicast protocol convergence is **20** seconds and the packet leakage time is **30** seconds by default.

After the configured protocol convergence period times out, all multicast forwarding entries that are not updated during the convergence period are deleted.

1.15 Configuring the Multicast Lossless Work Mode

1.15.1 Overview

Devices run independently in a distributed environment, and the hardware settings of multicast prefixes and multicast egresses on the devices cannot guarantee the time sequence. Therefore, there is a large probability that packet loss occurs on the multicast services when the multicast hardware is updated. The multicast

lossless work mode is a technology aiming to ensure that no packet loss occurs on the multicast services when multicast hardware is updated in distributed environments.

1.15.2 Restrictions and Guidelines

- Configuring the multicast lossless work mode can ensure that the multicast services do not encounter packet loss in distributed scenarios.
- After the multicast lossless work mode is enabled, the installation performance of multicast entries is reduced by about 80%.

1.15.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the multicast lossless work mode.

multicast xgv-lossless

1.16 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

Caution

The output debugging information of the **debugging** command occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **cleanup** commands to clear information.

Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

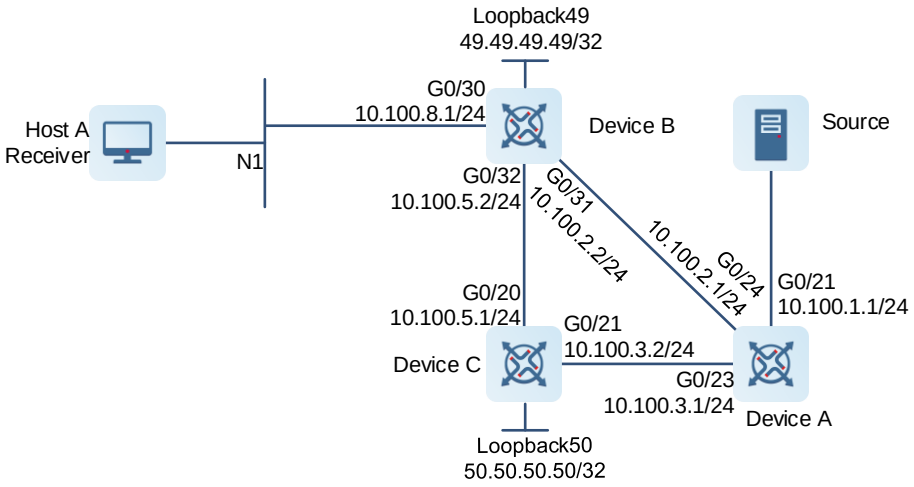
Table 1-2 Monitoring

Command	Purpose
cleanup ip mrouting-table { *ipv4-group-address* [*ipv4-source-address*] | * }	Clears the IPv4 multicast routing table.
cleanup ip mrouting-table statistics { *ipv4-group-address* [*ipv4-source-address*] | * }	Resets the statistics in the IPv4 multicast routing table.
display ip mrouting-table [*ipv4-group-address* | *ipv4-source-address*] * [**dense** | **sparse**] [**summary**]	Displays the IPv4 multicast routing table.

Command	Purpose
display ip mrouting-table [*ipv4-group-address* | *ipv4-source-address*] * [**dense** | **sparse**] **count**	Displays the statistics in the IPv4 multicast routing table.
display ip mrouting-table static-route	Displays the information about IPv4 multicast static route.
display ip rpf-routing *ipv4-source-address*	Displays the RPF information of a specified IPv4 source address.
display ip mvif [*interface-type interface-number*]	Displays the information about IPv4 multicast interfaces.
display ip mrf mfc	Displays the IPv4 L3 multicast routing table.
display msf global	Displays details of the MSF process.
display msf nsf	Displays the configuration of IPv4 multicast non-stop forwarding.
display msf msc	Displays the IPv4 multi-layer multicast routing table.
debugging nsm mcast all	Debugs the running procedure of the multicast core.
debugging nsm mcast fib-msg	Debugs the communication procedure between the IPv4 multicast core and the protocol module.
debugging nsm mcast vif	Debugs the interface running procedure about the IPv4 multicast core.
debugging nsm mcast stats	Debugs the interface and entry statistics processing procedure about the IPv4 multicast core.
debugging ip mrf forwarding	Debugs the IPv4 L3 multicast packet forwarding procedure.
debugging ip mrf mfc	Debugs the operation procedure of L3 multicast forwarding entries on an IPv4 network.
debugging ip mrf event	Debugs the processing procedure of L3 multicast forwarding events on an IPv4 network.
debugging msf forwarding	Debugs the IPv4 multi-layer multicast packet forwarding procedure.
debugging msf msc	Debugs the operation procedure of multi-layer multicast forwarding entries on an IPv4 network.

Command	Purpose
debugging msf ssp	Debugs the bottom-layer hardware processing procedure of IPv4 multi-layer multicast forwarding.
debugging msf api	Debugs the API calling procedure of IPv4 multi-layer multicast forwarding.
debugging msf event	Debugs the processing procedure of multi-layer multicast forwarding events on an IPv4 network.

1.17 Configuration Examples



1.17.1 Configuring IP Multicast Static Route to Change RPF Routes

1. Requirements

As shown in Figure 1-3, Device A, Device B and Device C run the OSPF routing protocol, and the PIM-SM function is enabled on each interface of these devices. Multicast data from the multicast source Source is sent to Host A through the Device A -> Device B link. To reduce the burden of the Device A -> Device B link and separate multicast and unicast data streams, multicast data from the multicast source Source is to be transmitted through the Device A -> Device C -> Device B path.

2. Topology

Figure 1-3 Topology of Configuring IP Multicast Static Route to Change RPF Routes

3. Notes

As shown in Figure 1-3, configuring a multicast static route on Device B to change the RPF interface for receiving multicast data can separate multicast and unicast data streams shown in the figure. Unicast data is transmitted through the Device A -> Device B path, while multicast data through the Device A -> Device C -> Device B path. The specific configuration method is as follows:

- Configure an IP address and unicast routing protocol on the multicast device. Unicast route reachability is the basis for the multicast protocol to work properly.
- Enable the IP multicast routing function on all multicast devices; enable the PIM-SM function on the interface connecting the multicast device, and the interface connecting the host and the multicast source; and configure C-BSR and C-RP on Device C.
- Configure RPF multicast static routing function on Device B, and specify the RPF neighbor as Device C to change the forwarding path of multicast packets.

4. Procedure

(1) Configure an IP address and unicast routing protocol on the multicast device.

Configure an IP address and unicast routing protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/21)# ip address 10.100.1.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/23)# ip address 10.100.3.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
DeviceA(cfg)# interface GigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/24)# ip address 10.100.2.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
DeviceA(cfg)# router-protocol ospf 49
DeviceA(cfg-router)# network-advertise 10.100.1.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.2.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.3.0 0.0.0.255 area 0
DeviceA(cfg-router)# exit
```

Configure an IP address and unicast routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/30)# ip address 10.100.8.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/31)# ip address 10.100.2.2 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/32)# ip address 10.100.5.2 255.255.255.0
```

```
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ip address 49.49.49.49 255.255.255.255
DeviceB(cfg-if-Loopback 49)# exit
DeviceB(cfg)# router-protocol ospf 49
DeviceB(cfg-router)# network-advertise 10.100.2.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.8.0 0.0.0.255 area 0
DeviceB(cfg-router)# exit
```

Configure an IP address and unicast routing protocol on Device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/20)# ip address 10.100.5.1 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/21)# ip address 10.100.3.2 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface Loopback 50
DeviceC(cfg-if-Loopback 50)# ip address 50.50.50.50 255.255.255.255
DeviceC(cfg-if-Loopback 50)# exit
DeviceC(cfg)# router-protocol ospf 49
DeviceC(cfg-router)# network-advertise 10.100.3.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 50.50.50.50 0.0.0.0 area 0
DeviceC(cfg-router)# exit
```

(2) Enable the IP multicast routing function on all multicast devices; enable the PIM-SM function on the interface connecting the multicast device, and the interface connecting the host and the multicast source; and configure C-BSR and C-RP on Device C.

Enable the multicast routing function and PIM-SMv6 related functions on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
DeviceA(cfg)# interface GigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
```

Enable the multicast routing function and PIM-SMv6 related functions on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip mrouting-enable
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ip pim sparse-mode
DeviceB(cfg-if-Loopback 49)# exit
```

Enable the multicast routing function and PIM-SMv6 related functions on Device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ip mrouting-enable
DeviceC(cfg)# ipv6 mrouting-enable
DeviceC(cfg)# interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface Loopback 50
DeviceC(cfg-if-Loopback 50)# ip pim sparse-mode
DeviceC(cfg-if-Loopback 50)# exit
```

Configure C-BSR and C-RP on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip pim c-bsr GigabitEthernet 0/21
DeviceA(cfg)# ip pim c-rp GigabitEthernet 0/21
```

(2) Configure RPF multicast static routing function on Device B, and specify the RPF neighbor as Device C to change the forwarding path of multicast packets.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip rpf-mroute 10.100.1.0 255.255.255.0 10.100.5.1
```

5. Verification

(1) Run the **display ip mld groups** command on Device B to check whether Host A has successfully joined the multicast group 225.0.0.11, and whether the multicast source 10.100.1.2 has sent packets to the multicast group 225.0.0.11.

```
DeviceB# display ip igmp groups
IGMP Connected Group Membership
```

```
Group Address      Interface                    Uptime     Expires    Last Reporter
225.0.0.11         GigabitEthernet 0/30         00:01:03   00:03:37   10.100.8.2
DeviceB#
```

(2) Run the **display ip mrouting-table** command on Device A to check the multicast routing table and verify that the next hop is Device C and the outbound interface is GigabitEthernet 0/23.

```
DeviceA# display ip mrouting-table

IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed,
    R - RPT, S - SPT, s - SSM Group
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)

(10.100.1.2, 225.0.0.11), uptime 00:01:58, stat expires 00:02:38
Owner PIMSM, Flags: TFS
 Incoming interface: GigabitEthernet 0/21
 Outgoing interface list:
  GigabitEthernet 0/23 (1)

DeviceA#
```

(3) Run the **display ip rpf-routing** command on Device B to verify that the next hop of the multicast source is Device C and the RPF interface is GigabitEthernet 0/32.

```
DeviceB# display ip rpf-routing 10.100.1.0
RPF information for 10.100.1.0
RPF interface: GigabitEthernet 0/32
  RPF neighbor: 10.100.5.1
  RPF route: 10.100.1.0/24
  RPF type: static-route
  RPF recursion count: 0
  Doing distance-preferred lookups across tables
Distance: 0
  Metric: 0
DeviceB#
```

6. Configuration Files

- Device A configuration file

```

```

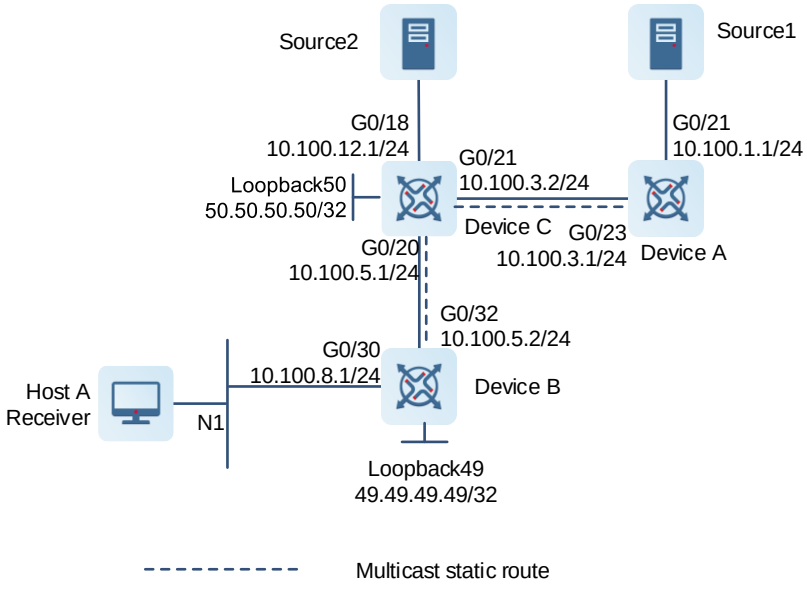
7. Common Errors

- An IPv6 unicast route is incorrectly configured.
- IPv6 multicast routing is not enabled on a multicast device.
- No IPv6 multicast routing protocol is enabled on an interface.



1.17.2 Configuring Multicast Static Routes to Connect RPF Routes

1. Requirements

As shown in Figure 1-4, the OSPF protocol is run on Device B and Device C, not Device A which runs a unicast routing protocol. The PIM-SM function is enabled on all interfaces on Device A, Device B and Device C. Host A can receive packets from Source 2 normally. It is required that Host A should also be able to receive multicast packets from Source 1.

2. Topology

Figure 1-4 Topology of Configuring IPv4 Multicast Static Routes to Connect RPF Routes

3. Notes

If a multicast static route is configured, an RPF route can be created to reach the multicast source Source 1 through the Device B ->Device C ->Device A path. The specific configuration method is as follows:

- Configure an IP address for each interface on these three devices, and configure the OSPF routing protocol on Device B and Device C, but not on Device A which runs a unicast routing protocol.
- Enable the IP multicast routing function, configure the PIM-SM protocol and C-BSR and C-RP on each Layer 3 interface of all devices, and configure the MLD function on the interface connected to the host.
- Configure a multicast static route on Device B and Device C to reach the multicast source Source 1.

4. Procedure

(1) Configure an IP address for each interface on each device, and configure the OSPF routing protocol on Device B and Device C, but not on Device A which runs a unicast routing protocol.

Configure an IP address for each interface on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/21)# ip address 10.100.1.1 24
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/23)# ip address 10.100.3.1 24
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
DeviceA(cfg)# ip route-config 50.50.50.50 255.255.255.255 10.100.3.2
```

Configure an IP address for each interface and OSPF routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/30)# ip address 10.100.8.1 24
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/32)# ip address 10.100.5.2 24
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ip address 49.49.49.49 24
DeviceB(cfg-if-Loopback 49)# exit
DeviceB(cfg)# router-protocol ospf 49
DeviceB(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.8.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 49.49.49.49 0.0.0.0 area 0
DeviceB(cfg-router)# exit
```

Configure an IP address for each interface and OSPF routing protocol on Device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface GigabitEthernet 0/18
DeviceC(cfg-if-GigabitEthernet 0/18)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/18)# ip address 10.100.12.1 24
DeviceC(cfg-if-GigabitEthernet 0/18)# exit
DeviceC(cfg)# interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/20)# ip address 10.100.5.1 24
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/21)# ip address 10.100.3.2 24
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface Loopback 50
DeviceC(cfg-if-Loopback 50)# ip address 50.50.50.50 32
DeviceC(cfg-if-Loopback 50)# exit
DeviceC(cfg)# router-protocol ospf 49
DeviceC(cfg-router)# network-advertise 10.100.3.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 10.100.12.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 50.50.50.50 0.0.0.0 area 0
DeviceC(cfg-router)# exit
```

(2) Enable the IP multicast routing function, configure the PIM-SM protocol and C-BSR and C-RP on each Layer 3 interface of all devices, and configure the MLD function on the interface connected to the host.

Enable the IP multicast routing function and the PIM-SM protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
```

Enable the IP multicast routing function and the PIM-SM protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip mrouting-enable
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ip pim sparse-mode
DeviceB(cfg-if-Loopback 49)# exit
```

Enable the IP multicast routing function and the PIM-SM protocol on Device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ip mrouting-enable
DeviceC(cfg)# interface GigabitEthernet 0/18
DeviceC(cfg-if-GigabitEthernet 0/18)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/18)# exit
DeviceC(cfg)# interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface Loopback 50
DeviceC(cfg-if-Loopback 50)# ip pim sparse-mode
DeviceC(cfg-if-Loopback 50)# exit
DeviceC(cfg)# ip pim c-bsr Loopback 50
DeviceC(cfg)# ip pim c-rp Loopback 50
```

Both Source 1 (10.100.1.2/24) and Source 2 (10.100.12.2/24) send multicast packets to the multicast group (225.0.0.10). Host A joins the multicast group 225.0.0.10 and can receive the multicast packets sent by Source 2, but not the multicast packets sent by Source 1.

Run the **display ip rpf-routing** 10.100.1.2 command on Device C. The route does not exist, showing that there is no RPF route from Device C to Source 1.

(3) Configure a multicast static route on Device B and Device C to reach the multicast source Source 1.

Configure a RPF multicast static route on Device B, and configure the RPF neighbor to Source 1 as Device C.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip rpf-mroute 10.100.1.0 255.255.255.0 10.100.5.1
```

Configure a RPF multicast static route on Device C, and configure the RPF neighbor to Source 1 as Device A.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ip rpf-mroute 10.100.1.0 255.255.255.0 10.100.3.1
```

5. Verification

Run the **display ip rpf-routing** 10.100.1.2 command on Device B to check the RPF information of Source 1. The RPF information is shown as follows.

```
DeviceB# display ip rpf-routing 10.100.1.2
RPF information for 10.100.1.2
RPF interface: GigabitEthernet 0/32
  RPF neighbor: 10.100.5.1
  RPF route: 10.100.1.0/24
  RPF type: static-route
  RPF recursion count: 0
  Doing distance-preferred lookups across tables
Distance: 0
  Metric: 0
```

Run the **display ip rpf-routing** 10.100.1.2 command on Device C to check the RPF information of Source 1. The RPF information is shown as follows.

```
DeviceC# display ip rpf-routing 10.100.1.2
RPF information for 10.100.1.2
RPF interface: GigabitEthernet 0/21
  RPF neighbor: 10.100.3.1
  RPF route: 10.100.1.0/24
  RPF type: static-route
  RPF recursion count: 0
  Doing distance-preferred lookups across tables
Distance: 0
  Metric: 0
```

Both multicast sources Source 1 and Source 2 send multicast packets to the multicast group 225.0.0.10, and Host A joins the multicast group 225.0.0.10.

Run the **display ip pim-info sparse-mode mroute** command on Device C to view the routing table information. There are entries for Source 1 in the multicast routing tables of Device C, indicating that Host A can receive multicast packets from Source 1.

```
DeviceC#
display ip pim-info sparse-mode mroute

7. Common Errors

- An IP unicast route is incorrectly configured.
- An IPv4 unicast route is incorrectly configured.
- IPv4 multicast routing is not enabled on a router.
- IGMP function is not enabled on an interface.

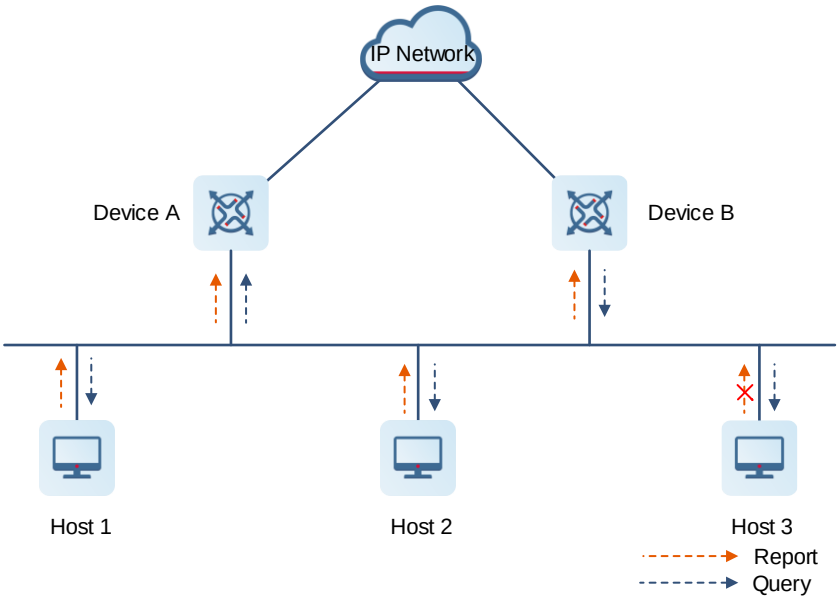
1 Configuring IGMP

1.1 Introduction

1.1.1 Overview

Multicast devices in a multicast network must maintain members in a multicast group that are connected to the same network segment with the multicast devices. Hosts need to be added to the multicast group dynamically so that a multicast packet can be correctly transmitted to the hosts that need the packet. With the development of multicast applications and ever growing of the multicast network, a protocol is needed to manage the members in the multicast group.

The Internet Group Management Protocol (IGMP) is a TCP/IP protocol that manages members in an IPv4 multicast group and runs on the multicast devices and hosts residing on the stub of the multicast network, creating and maintaining membership of the multicast group between the hosts and connected multicast devices. At present, IGMP is available in three versions: IGMPv1, IGMPv2, and IGMPv3. The three versions support the Any-Source Multicast (ASM) and Source-Specific Multicast (SSM) models as follows:



- The three versions of IGMP support the ASM model.
- IGMPv3 can be directly applied to the SSM model.
- IGMPv1 and IGMPv2 can be applied to the SSM model only when the IGMP SSM mapping technology is configured.

1.1.2 Basic Principles of IGMPv1

IGMPv1 runs on multicast devices and hosts, and manages members in a multicast group by communication between the multicast devices and hosts. The IGMP behavior of a multicast device is referred to as device behavior, and the IGMP behavior of a host is referred to as host behavior.

1. Topology of IGMPv1

Figure 1-1 Basic Topology of IGMP

The mechanism of IGMPv1 is introduced by taking the networking diagram shown in Figure 1-1. IGMP runs on hosts (host 1, host 2, and host 3) that need to be added to a multicast group and multicast devices (device A and device B) that are directly connected to the hosts.

A host sends an IGMP Report packet to a multicast device to report that the host joins the multicast group. The multicast device sends an IGMP Query packet to the host to discover the membership of the multicast group.

There are two important concepts involved in IGMPv1 running:

- Querier

  A querier is a multicast device that sends query packets and receives packets of a host. The querier is used to discover members of a multicast group on a connected network segment.

  If multiple multicast devices running IGMP reside on a network segment, one of the multicast devices is selected as a querier, and other devices function as non-queriers. In IGMPv1, a designated router (DR) elected based on the multicast routing protocols functions as a querier. For more information about DR, see *Configuring PIM-SM*.

- IGMPv1 packet

  IGMPv1 packets are classified into IGMP Query packets and IGMP Report packets.

  - IGMP Query packet: A packet sent by a multicast device to a host to query members of a multicast group on the connected network segment.
  - IGMP Report packet: A packet sent by a host to a multicast device to join a multicast group.

2. Work Process of IGMPv1

Management of multicast group members is divided into host joining a multicast group and host leaving from the multicast group.

- Group-specific queries

IGMPv1 only supports general queries, that is, query without specific multicast source and multicast group.

- Host joining a multicast group

  Communication after a host joins a multicast group falls into active joining and response query.

  - Active joining steps are as follows:

    When a host initiates a join request, the host sends an IGMP Report packet to the network segment it resides, to report that it joins a multicast group.

    The querier receives the IGMP Report packet, and creates a forwarding entry for the members in the multicast group.

  - Response query steps are as follows:

    The querier periodically sends an IGMP Query packet to all hosts in the local network segment in multicast mode.

    The host that joins the multicast group replies an IGMP Report packet to the querier in multicast mode. Other hosts that do not join the multicast group do not respond.

    The querier creates and maintains forwarding entries for the members in each multicast group.

- Host leaving a multicast group

  a A host leaves a multicast group without notifying the querier (types of packets for leaving a multicast group are not defined in IGMPv1).

  a The querier does not receive an IGMP Report packet from a multicast group in a specified period and removes the forwarding entry of this multicast group after the specified timer times out.

1.1.3 Basic Principles of IGMPv2

On the basis of the features of IGMPv1, IGMPv2 comes with a querier election mechanism and a group leaving mechanism.

1. Querier Election Mechanism

In IGMPv1, no querier election rule exists, a DR is selected as a querier using multicast routing protocols. Compared with IGMPv1, in IGMPv2, group-specific queries are supported, and a querier election mechanism is developed. The main communication process is as follows:

(1) A multicast device running IGMPv2 considers itself a querier and sends an IGMP Query (common group) packet (with destination address 224.0.0.1) to the connected network segment.

(2) Upon receiving the query packet, another multicast device compares the source IP address in the packet with the local IP address. If the source IP address is smaller than the local IP address, the querier changes to a non-querier. In this way, only one querier survives finally on the connected network segment.

(3) After the multicast device changes to a non-querier, a timer starts. The timeout period of the timer is referred to as "survival period of other querier". After timer times out, the multicast device considers itself a querier and re-initiates a querier election process. If the multicast device receives an IGMP Query packet from the querier before the timer times out, the timer is reset.

2. Group Leaving Mechanism

In IGMPv1, a host leaves a multicast group without notifying the multicast device. The multicast device detects the leaving of the host in hindsight only after the timer times out. In IGMPv2, an IGMP Leave packet is

developed. When a host leaves the multicast group, the host sends an IGMP Leave packet to notify the multicast device. The main communication process is as follows:

(1) When a host leaves a multicast group, the host sends an IGMP Leave packet to all multicast devices (destination address 224.0.0.2) on the connected network segment.

(2) Upon receiving the packet, the querier sends a query packet (the destination address is the multicast group address that the host resides) of the specified multicast group to the connected network segment.

(3) If this multicast group contains other hosts, the hosts reply an IGMP Report packet to the querier within the maximum response time upon receiving the query packet.

(4) If the querier receives replies from the hosts of the multicast group within the maximum response time, there are members in the multicast group. The querier continues maintaining the forwarding entry of this multicast group. Otherwise, the querier clears the entry of this multicast group.

1.1.4 Basic Principles of IGMPv3

On the basis of the features of IGMPv1 and IGMPv2, IGMPv3 comes with a multicast source filtering function and enhanced IGMP Query packet and IGMP Report packet.

1. Multicast Source Filtering Function

The multicast source filtering function requires the cooperation of the querier and a host.

- Host action

  A host supports filtering of a specific multicast source. When the host tries to join a multicast group, it adds information of one or multiple sources to an IGMP Report packet, expresses the correspondence between multicast group and multicast source list as (S1, S2, S3... Sn, G), and sets the mode of the multicast sources to INCLUDE or EXCLUDE. In INCLUDE mode, the host receives packets from this multicast source. In EXCLUDE mode, the host rejects packets from this multicast source. When the correspondence between the multicast group and the multicast source list changes, the IGMPv3 Membership Report message will store the relationship change in the group record field and send it to the IGMP querier.

  Group records are divided into the following types:

  - IS_IN: The filtering mode of a multicast source is INCLUDE, indicating that only packets from this specified multicast source to this multicast group are received.
  - IS_EX: The filtering mode of a multicast source is EXCLUDE, indicating that packets from this specified multicast source to this multicast group are rejected.
  - TO_IN: The filtering mode is changed from EXCLUDE to INCLUDE.
  - TO_EX: The filtering mode is changed from INCLUDE to EXCLUDE.
  - ALLOW: Multicast packets from specified multicast sources to this multicast group are received. If the filtering mode is INCLUDE, these multicast sources are added to the original source list. If the filtering mode is EXCLUDE, these multicast sources are removed from the original source list.
  - BLOCK: Multicast packets from specified multicast sources to this multicast group are rejected. If the filtering mode is INCLUDE, these multicast sources are removed from the original source list. If the filtering mode is EXCLUDE, these multicast sources are added to the original source list.

- Querier action

  When receiving multicast source information in INCLUDE mode, the multicast device acts as follows:

- If this multicast source is active, the multicast device forwards the packet from this multicast source.
- If this multicast source is inactive, the multicast device does not forward the packet from this multicast source.

When receiving multicast source information in EXCLUDE mode, the multicast device acts as follows:

- If other hosts need packets from this multicast source, the multicast device continues forwarding the packet from this multicast source.
- If this multicast source is inactive, the multicast device does not forward the packet from this multicast source.
- For other multicast sources not in EXCLUDE mode, the multicast device needs to forward the packets.

2. Enhanced IGMP Query Packet and IGMP Report Packet

- Enhanced IGMP Query Packet

  IGMPv1 supports common group query, and IGMPv2 supports specific group query. On the basis of the features of IGMPv1 and IGMPv2, IGMPv3 supports specific source and group query. Compared with IGMPv1 and IGMPv2, IGMPv3 supports specific source group queries on the basis of IGMPv1 and IGMPv2, that is, specific multicast source and multicast group queries. When receiving a report from a group member indicating a change in the correspondence between the multicast group and the multicast source list, the IGMP querier will send a specific source group query message. If a group member wants to receive multicast data traffic from any of the sources, it will send the feedback message. IGMP querier then updates the multicast source list corresponding to the group according to the feedback membership report.

- Enhanced IGMP Report Packet

  In IGMPv3, an IGMP Report packet carries records of one or multiple groups. The group records include the multicast source addresses and multicast group addresses. When a host joins a multicast group, it can explicitly express that it needs to receive or not receive multicast data traffic sent by a specific multicast source.

1.1.5 IGMP SSM Mapping

In actual network environment, most multicast devices support IGMPv3. However, there are a great number of old multicast devices that support only IGMPv1 or IGMPv2. Consequently, these old multicast devices cannot provide hosts with the multicast services in the SSM model using IGMPv3. After the IGMP SSM mapping technology is applied, the multicast devices can provide hosts with the multicast services in the SSM model without upgrading to IGMPv3.

The IGMP SSM mapping technology enables the multicast devices to support IGMPv3 by mapping the multicast group information in IGMPv1 Report packets and IGMPv2 Report packets to the multicast group information that carries specific multicast sources. After an SSM mapping rule is configured on the multicast devices, upon receiving IGMPv1 Report packets and IGMPv2 Report packets, the multicast devices process the packets based on the multicast group information in the packets.

- If a multicast group is not in the SSM group address range, the multicast services are provided in the ASM model.
- If the multicast group is in the SSM group address range and no SSM mapping rule corresponding to this multicast group is configured on the multicast device, the multicast device cannot provide multicast services in the SSM model and then discards the packets.

- If the multicast group is in the SSM group address range and an SSM mapping rule corresponding to this multicast group is configured on the multicast device, the multicast group information in the packets is converted to the multicast group information that carries specific multicast sources and the multicast device provides the multicast services in the SSM model.

1.1.6 IGMP Proxy

In a simple tree network topology, a border multicast device does not need to run complex multicast routing protocols such as Protocol Independent Multicast (PIM), you can configure the IGMP proxy function on this multicast device. This multicast device functions as an intermediate proxy between upstream IGMP querier and downstream hosts.

A device running the IGMP proxy functions as a multicast device and a host at the same time. For an upstream IGMP querier, this device plays the role of a host and executes host actions. For a downstream host, this device plays the role of an IGMP querier and executes querier actions.

1.1.7 Protocols and Standards

- RFC 1112: Host Extensions for IP Multicasting
- RFC 2236: Internet Group Management Protocol, Version 2
- RFC 3376: Internet Group Management Protocol, Version 3
- RFC 4605: Internet Group Management Protocol (IGMP)/Multicast Listener Discovery

1.2 Configuration Task Summary

IGMP configuration includes the following tasks:

- Configuring Basic Functions of IGMP
- (Optional) Configuring IGMP Parameters. All the configuration tasks below are optional. Select the configuration tasks as required.
  - Configuring an IGMP Version
  - Configuring the Maximum Response Time for Query Packets
  - Configuring Common Group Query
  - Configuring Specific Group Query
  - Configuring Survival Period of Other Querier
- (Optional) Configuring IGMP Group Filtering
- (Optional) Configuring the IGMP Proxy Function
- (Optional) Configuring the IGMP SSM Mapping Function
- (Optional) Configuring the Router Alert Option of IGMP Packets
- (Optional) Enabling Source Address Checking for IGMP Report Packets
- (Optional) Enabling Fast Leave
- (Optional) Configuring the Querier Robustness Variable
- (Optional) Adding a Static Interface to a Group
- (Optional) Simulating a Host to Join a Group

1.3 Configuring Basic Functions of IGMP

1.3.1 Overview

Basic functions of IGMP lay a foundation for other functions, enable multicast devices to run IGMP, and help collect and manage members in a multicast group.

You cannot directly enable the basic functions of IGMP. You need to enable the multicast routing function on a device to make the basic functions of IGMP take effect.

1.3.2 Restrictions and Guidelines

Before the basic functions of IGMP are enabled, you must enable the Protocol Independent Multicast Sparse Mode (PIM-SM) or Protocol Independent Multicast Dense Mode (PIM-DM) function on an interface to make the basic functions of IGMP take effect. To disable the basic functions of IGMP take effect, you need to remove the configuration of the PIM-SM or PIM-DM function.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable IPv4 multicast routing.

ip mrouting-enable

The multicast routing is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(5) Enable the PIM-SM or PIM-DM function on an interface. Select at least one of them to configure.

- Enable PIM-DM on an interface.

  ip pim dense-mode

  The PIM-DM function is disabled on an interface by default.
- Enable PIM-SM on an interface.

  ip pim sparse-mode

  The PIM-SM function is disabled on an interface by default.

1.4 Configuring IGMP Parameters

1.4.1 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring an IGMP Version
- Configuring the Maximum Response Time for Query Packets
- Configuring Common Group Query
- Configuring Specific Group Query
- Configuring Survival Period of Other Querier

1.4.2 Configuring an IGMP Version

1. Overview

IGMP comes with three versions: IGMPv1, IGMPv2, and IGMPv3. A later version corresponds to stronger protocol functions. You can select an IGMP version based on network requirements and IGMP support of upstream and downstream devices.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure an IGMP version.

ip igmp specify-version { **1** | **2** | **3** }

IGMPv2 runs on an interface by default.

After this command is run, the IGMP function module automatically restarts.

1.4.3 Configuring the Maximum Response Time for Query Packets

1. Overview

After sending a query packet, the querier needs to receive a reply packet from a host in the specified time. Otherwise, the querier considers that no member exists in the corresponding multicast group and deletes the

group information. This specified time is referred to as the maximum response time for a query packet, and it can be set to a proper time value based on actual network topology.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the maximum response time for query packets on an interface.

ip igmp max-response-time *query-max-response*

The maximum response time for query packets on an interface is **10** seconds by default.

1.4.4 Configuring Common Group Query

1. Overview

Common group query means querying members in a multicast group. You can configure an interval for sending common group query packets.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the interval for querying a common group member.

ip igmp query-period *query-period*

The interval for querying a common group member is **125** seconds by default.

1.4.5 Configuring Specific Group Query

1. Overview

Specific group query means querying members in a specified multicast group. You can configure an interval and times for sending specific group query packets.

Upon receiving an IGMP Leave packet on an interface, the querier continuously sends specific group query packets and waits for responses from hosts. If no host replies in the specified time, the querier considers that this multicast group does not contain any member, and deletes this interface from the IGMP group member records. Then, this interface does not forward packets from this multicast group. The timeout period is a product of the sending interval of specific group query packets and the times for sending the specific group query packets.

2. Restrictions and Guidelines

The parameter of specific group query can be configured in IGMPv2 and IGMPv3. The parameter is not supported in IGMPv1.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the parameters of specific group query. Select at least one of them to configure.

- Configure the interval for sending specific group query packets.

  ip igmp last-member-query-period *last-member-query-interval*

  The interval for sending specific group query packets is **1** second by default.
- Configure the times for sending specific group query packets.

  ip igmp last-member-query-number *last-member-query-count-number*

  Specific group query packets are sent twice by default.

1.4.6 Configuring Survival Period of Other Querier

1. Overview

A querier election mechanism is introduced in IGMPv2. Based on the mechanism, non-queriers maintain a timer and the timeout period of the timer is referred to as "survival period of other querier". If the timer times out, a multicast device considers itself a querier and re-initiates a querier election request. During networking, you can determine proper survival period of other querier based on network topology configuration.

2. Restrictions and Guidelines

The querier election mechanism can be configured in IGMPv2 and IGMPv3. It is not supported in IGMPv1.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure survival period of other querier.

ip igmp other-querier-timeout *query-timeout*

The survival period of other querier is **255** seconds by default.

1.5 Configuring IGMP Group Filtering

1.5.1 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Filtering a Multicast Group
- Configuring the Maximum Number of Group Members

1.5.2 Filtering a Multicast Group

1. Overview

If you do not want hosts in the network segment where an interface resides to join a multicast group, you can configure access control list (ACL) rules on the interface as a filter. The interface filters IGMP Report packets of the hosts based on the ACL rules and allows the hosts to join specific groups.

2. Restrictions and Guidelines

- For more information about ACL, see *Configuring ACL*.
- Extended ACL rules can be configured in IGMPv3. When a received IGMP Report packet is (S1, S2, S3…Sn,

G), an ACL rule is used to match (0, G). Therefore, to normally filter (S1, S2, S3…Sn, G), a (0, G) extended ACL rule must be configured.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Filter out groups that you do not want a host to join.

ip igmp restricted-group { *acl-name* | *acl-number* }

Hosts can join any group by default.

1.5.3 Configuring the Maximum Number of Group Members

1. Overview

To configure the maximum number of group members means configuring the maximum number of multicast groups that a host can join.

The configuration can be completed in interface or global configuration mode. If the configuration is completed in global configuration mode, the number of group members for a multicast device is limited. If the configuration is completed in interface configuration mode, the number of group members on an interface is limited. If the number of group member records exceeds the interface limit or global limit, subsequent received IGMP Report packets are ignored.

2. Restrictions and Guidelines

- Group member records that are generated in EXCLUDE mode list are not counted in the group members.
- Interface and global limits can be configured separately. If the global limit is smaller than the interface limit, the global limit prevails.

3. Procedure (Global Configuration Mode)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the maximum number of IGMP group members in global configuration mode.

ip igmp max-member-record *limit-number* [**except** *acl-name* | **except** *acl-number*]

The maximum number of IGMP group members is **64000** in global configuration mode by default.

4. Procedure (Interface Configuration Mode)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the maximum number of IGMP group members on an interface.

ip igmp max-member-record *limit-number* [**except** *acl-name* | **except** *acl-number*]

The maximum number of IGMP group members on an interface is **4000** by default.

1.6 Configuring the IGMP Proxy Function

1.6.1 Overview

In a simple tree network topology, you can configure the IGMP proxy function and use it as an intermediate proxy between upstream IGMP querier and downstream hosts without running complex multicast routing protocols such as PIM.

On the device that runs the IGMP proxy, interfaces are classified into proxy service interfaces and MRoute proxy interfaces.

The proxy service interfaces execute host behaviors, receive IGMP packets from upstream devices, and forward the packets to the MRoute proxy interfaces.

The MRoute proxy interfaces execute device behaviors, receive IGMP Report packets from downstream devices, and forward the packets to the proxy service interfaces.

1.6.2 Restrictions and Guidelines

- The basic functions of IGMP must be configured.
- The interfaces connected to upstream devices must be configured as proxy service interfaces and the interfaces connected to hosts must be configured as MRoute proxy interfaces. The two types of interfaces must be used at the same time. If only one type of interfaces are configured, the IGMP proxy function will be abnormal.

- If the proxy service interfaces are switched over from L3 interface to L2 interface, the routing proxy configured on the MRoute proxy interfaces is automatically disabled.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the IGMP proxy function. The configuration steps below are mutually exclusive. Please configure only one task.

- Configure an interface as a proxy service interface.

  ip igmp enable-proxy-service

  No interface is configured as a proxy service interface by default.

  The interface directly connected to an upstream device can be configured as a proxy service interface unless otherwise specified. A device supports 32 proxy service interfaces at most. When a proxy service interface receives an IGMP Report packet, the proxy service interface makes response based on the IGMP group member records.

- Configure an interface as an MRoute proxy interface.

  ip igmp enable-mrouting-proxy *interface-type interface-number*

  No interface is configured as an MRoute proxy interface by default.

  The interface directly connected to a downstream device can be configured as an MRoute proxy interface unless otherwise specified.

1.7 Configuring the IGMP SSM Mapping Function

1.7.1 Overview

At present, the SSM multicast model (supporting filtering multicast sources) is supported in IGMPv3 only. To enable the SSM multicast model to be supported in IGMPv1 and IGMPv2, you can configure the IGMP SSM mapping function on a device, and add multicast group information of specified multicast sources to IGMPv1 and IGMPv2 packets so that the hosts can use the SSM multicast services provided by the device on the basis of running IGMPv1 or IGMPv2.

1.7.2 Restrictions and Guidelines

- When a device receives an IGMPv1 or IGMPv2 Report packet, the device adds the static mapping source address.
- The IGMP SSM mapping function applies to only IGMPv1 and IGMPv2 packets. You are advised to enable IGMPv3 on an interface to ensure that IGMP packets of different versions can obtain the SSM multicast services.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the IGMP SSM mapping function.

ip igmp ssm-policy enable

The IGMP SSM mapping function is disabled by default.

(4) Configure a static mapping entry.

ip igmp ssm-policy static { *acl-name* | *acl-number* } *source-address*

No SSM static mapping entry is configured by default.

1.8 Configuring the Router Alert Option of IGMP Packets

1.8.1 Overview

The Router Alert option in an IP packet header is used to warn a router device to check content in the IP packet. The router device can determine whether to add this option to a packet to be sent and whether to check this option in a received packet. The device does not check this option by default.

After the Router Alert option is configured, if an IGMP packet carries the Router Alert option, the multicast device checks the IGMP packet and updates the controlled content. If the IGMP packet does not carry the Router Alert option, the multicast device does not check the content in the packet and directly forwards the packet.

1.8.2 Restrictions and Guidelines

After the Router Alert option is configured, the multicast device must add this option to a packet to be sent and check this option in a received packet. Otherwise, an error occurs in IGMP packet receiving.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure to check the Router Alert option in an IGMP packet.

ip igmp enforce-router-alert

The Router Alert option in an IGMP packet is not checked by default.

After this option is configured, IGMP packets that do not carry the Router Alert option are discarded.

(4) Add the Router Alert option to an IGMP packet to be sent.

ip igmp send-router-alert

The Router Alert option is not added to an IGMP packet to be sent by default.

1.9 Enabling Source Address Checking for IGMP Report Packets

1.9.1 Overview

To prevent false packets, you can enable the source address checking function for IGMP packets so that a multicast device receives only IGMP Report packets whose source addresses are on the same network segment as the receiving interface.

1.9.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable source address checking for IGMP Report packets.

ip igmp enforce-source-subnet

The source address checking function for IGMP Report packets is disabled by default.

1.10 Enabling Fast Leave

1.10.1 Overview

After the fast leave function is enabled, if a device receives an IGMP Leave packet of a specified group, the device directly deletes this interface from the group member records to shorten the leave latency.

1.10.2 Restrictions and Guidelines

This function applies to an interface that runs IGMPv2 or IGMPv3 and that is connected to only one host.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Enable the fast leave function.

ip igmp leave-now group-acl { *acl-name* | *acl-number* }

The fast leave function on an interface is disabled by default.

1.11 Configuring the Querier Robustness Variable

1.11.1 Overview

The querier robustness variable is used to calculate the aging time of a forwarding entry after a device receives an IGMP Report packet. Aging time = Query interval × Robustness variable + 10

1.11.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Configure the querier robustness variable.

ip igmp robustness-variable *robustness-variable-number*

The default querier robustness variable is **2**.

1.12 Adding a Static Interface to a Group

In normal cases, an interface can join a multicast group only after the interface receives an IGMP Report packet from the multicast group.

If you manually add an interface to a group, the interface can be added to the group and exchanges multicast group information with the PIM router without IGMP packet exchange.

1.12.1 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Add a static interface to a group.

ip igmp static-group-entries *ipv4-group-address*

No static interface is added to an IPv4 multicast group by default.

1.13 Simulating a Host to Join a Group

1.13.1 Overview

By simulating a host to join a group, you can simulate host behaviors and send a Join packet to the upstream devices to join the group. This function is used to test the multicast function.

1.13.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*

- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Simulate a host to join a group.

ip igmp add-to-group *ipv4-group-address*

The behavior of simulating a host to join a multicast group is not performed by default.

1.14 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

⚠ Caution

The output debugging information of the **debugging** command occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **cleanup** commands to clear information.

⚠ Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

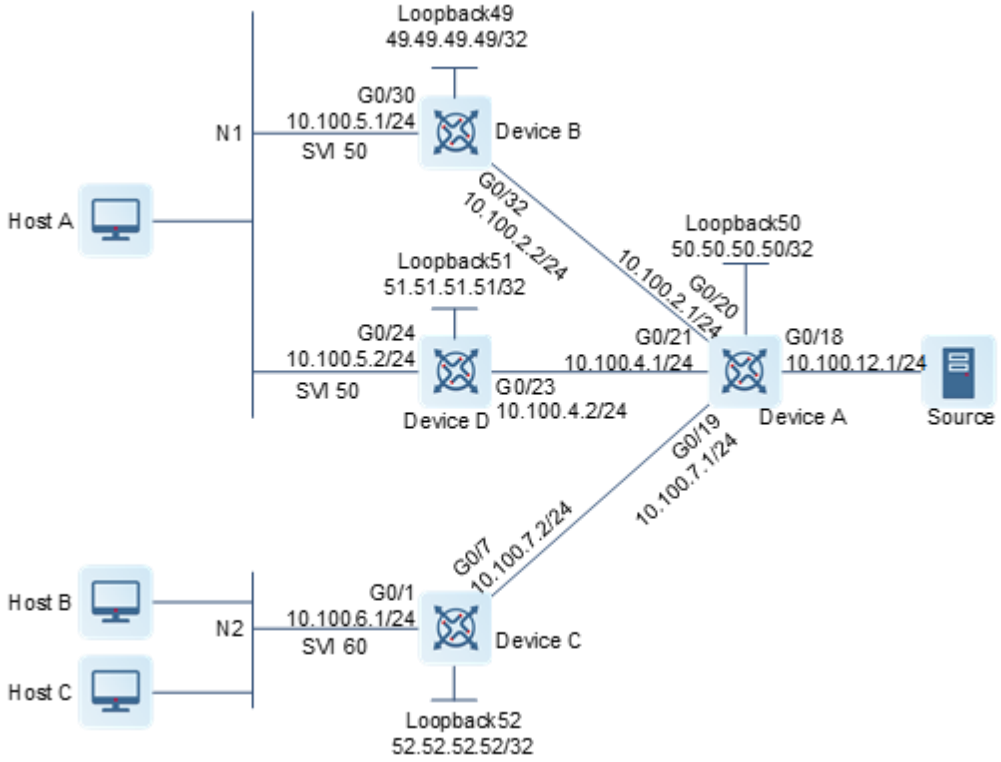
Command	Purpose
cleanup ip igmp-cache dynamic-group	Clears dynamic group member records in the IGMP cache.
cleanup ip igmp-cache interface *interface-type interface-number*	Clears all IGMP statistics and group member records on the interface.
display ip igmp-info groups [*interface-type interface-number*] [*ipv4-group-address*] [**detail**]	Displays groups directly connected to the device and group information learned from IGMP.
display ip igmp-info interface [*interface-type interface-number*]	Displays IGMP configurations of the interface.
display ip igmp-info ssm-policy [*ipv4-group-address*]	Displays IGMP SSM mapping information.
display debugging	Displays the status of the IGMP debugging switch.
debugging ip igmp-info all	Debugs all IGMP information.
debugging ip igmp-info decode	Debugs IGMP packet resolution.
debugging ip igmp-info encode	Debugs IGMP packet encoding.

Command	Purpose
debugging ip igmp-info events	Debugs IGMP event information.
debugging ip igmp-info fsm	Debugs IGMP Finite State Machine (FSM).
debugging ip igmp-info tib	Debugs IGMP state machine information.
debugging ip igmp-info warning	Debugs IGMP warning.

1.15 Configuration Examples

1.15.1 Configuring Basic Functions of IGMP

1. Requirements



As shown in Figure 1-2, Host A, Host B and Host C on the shared networks N1 and N2 in the IP network want to receive video traffic from the source Source in multicast mode. This requires the static multicast group 225.0.0.10 to be configured on N1, while hosts on N2 can only join the multicast group 225.0.0.11.

- Run OSPF in the network to achieve reachability of any node through unicast routing.
- Device B and Device D are connected to N1 through SVI50. Because the IP address of Device B is lower than that of Device D, Device B acts as a querier, while Host A is the receiver of multicast traffic from N1.
- Device C is connected to N2 through SVI60, and Host B is the receiver of multicast traffic from N2.

Device B, Device C and Device D connect to other devices on the IP PIM network through Layer 3 interfaces.

2. Topology

Figure 1-2 Topology of IGMP with Basic Functions

3. Notes

- Configure an IP unicast routing protocol (OSPF) on multicast devices, and enable unicast routes to be reachable to the loopback interface.
- Enable the IP multicast routing function on all multicast devices.
- Enable the PIM-SM function on device interconnection interfaces and interfaces for connecting hosts and multicast sources.
- Configure the static multicast group function on device interfaces connecting N1.
- Configure the multicast group access control function on device interfaces connecting N2.

4. Procedure

(1) Configure IP addresses for interfaces on each device, and enable the unicast routing protocol.

Configure the IP address for each interface on Device A, and enable the OSPF protocol to realize inter-network communication.

```
DeviceA> privilege
DeviceA#config-system terminal
DeviceA(cfg)# interface gigabitethernet 0/18
DeviceA(cfg-if-GigabitEthernet 0/18)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/18)# ip address 10.100.12.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/18)# exit
```

```
DeviceA(cfg)# interface gigabitethernet 0/19
DeviceA(cfg-if-GigabitEthernet 0/19)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/19)# ip address 10.100.7.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/19)# exit
DeviceA(cfg)# interface gigabitethernet 0/20
DeviceA(cfg-if-GigabitEthernet 0/20)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/20)# ip address 10.100.2.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/20)# exit
DeviceA(cfg)# interface gigabitethernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/21)# ip address 10.100.4.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface loopback 50
DeviceA(cfg-if-Loopback 53)# ip address 50.50.50.50 255.255.255.255
DeviceA(cfg-if-Loopback 53)# exit
DeviceA(cfg)# router-protocol ospf 49
DeviceA(cfg-router)# network-advertise 10.100.2.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.4.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.7.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.12.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 50.50.50.50 0.0.0.0 area 0
DeviceA(cfg-router)# exit
```

Configure the IP address for each interface on Device B, and enable the OSPF protocol to realize inter-network communication.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# vlan 50
DeviceB(cfg-vlan)# exit
DeviceB(cfg)# interface vlan 50
DeviceB(cfg-if-VLAN 50)# ip address 10.100.5.1 255.255.255.0
DeviceB(cfg-if-VLAN 50)# exit
DeviceB(cfg)# interface gigabitethernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# switch-port access vlan 50
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface gigabitethernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# switch-port mode trunk
DeviceB(cfg-if-GigabitEthernet 0/31)# switch-port trunk native vlan 50
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface gigabitethernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/32)# ip address 10.100.2.2 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface loopback 49
DeviceB(cfg-if-Loopback 49)# ip address 49.49.49.49 255.255.255.255
DeviceB(cfg-if-Loopback 49)# exit
DeviceB(cfg)# router-protocol ospf 49
```

```
DeviceB(cfg-router)# network-advertise 10.100.2.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 49.49.49.49 0.0.0.0 area 0
DeviceB(cfg-router)# exit
```

Configure the IP address for each interface on Device C, and enable the OSPF protocol to realize inter-network communication.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# vlan 60
DeviceC(cfg-vlan)# exit
DeviceC(cfg)# interface vlan 60
DeviceC(cfg-if-VLAN 60)# ip address 10.100.6.1 255.255.255.0
DeviceC(cfg-if-VLAN 60)# exit
DeviceC(cfg)# interface gigabitethernet 0/1
DeviceC(cfg-if-GigabitEthernet 0/1)# switch-port access vlan 60
DeviceC(cfg-if-GigabitEthernet 0/1)# exit
DeviceC(cfg)# interface gigabitethernet 0/7
DeviceC(cfg-if-GigabitEthernet 0/7)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/7)# ip address 10.100.7.2 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/7)# exit
DeviceC(cfg)# interface loopback 52
DeviceC(cfg-if-Loopback 52)# ip address 52.52.52.52 255.255.255.255
DeviceC(cfg-if-Loopback 52)# exit
DeviceC(cfg)# router-protocol ospf 49
DeviceC(cfg-router)# network-advertise 10.100.6.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 10.100.7.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 52.52.52.52 0.0.0.0 area 0
DeviceC(cfg-router)# exit
```

Configure the IP address for each interface on Device D, and enable the OSPF protocol to realize inter-network communication.

```
DeviceD> privilege
DeviceD# config-system terminal
DeviceD(cfg)# vlan 50
DeviceD(cfg-vlan)# exit
DeviceD(cfg)# interface GigabitEthernet 0/23
DeviceD(cfg-if-GigabitEthernet 0/23)# unset switch-port
DeviceD(cfg-if-GigabitEthernet 0/23)# ip address 10.100.4.2 255.255.255.0
DeviceD(cfg-if-GigabitEthernet 0/23)# exit
DeviceD(cfg)# interface GigabitEthernet 0/24
DeviceD(cfg-if-GigabitEthernet 0/24)# switch-port mode trunk
DeviceD(cfg-if-GigabitEthernet 0/24)# switch-port trunk native vlan 50
DeviceD(cfg-if-GigabitEthernet 0/24)# exit
DeviceD(cfg)# interface Loopback 51
DeviceD(cfg-if-Loopback 51)# ip address 51.51.51.51 255.255.255.255
DeviceD(cfg-if-Loopback 51)# exit
```

```
DeviceD(cfg)# router-protocol ospf 49
DeviceD(cfg-router)# network-advertise 10.100.4.0 0.0.0.255 area 0
DeviceD(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceD(cfg-router)# network-advertise 51.51.51.51 0.0.0.0 area 0
DeviceD(cfg-router)# exit
```

(2) Enable the IP multicast routing function on all devices, and enable the PIM-SM function on device interconnection interfaces and interfaces for connecting hosts and multicast sources.

Enable the IP multicast routing function and the PIM-SM function on Device A.

```
DeviceA(cfg)# ip mrouting-enable
DeviceA(cfg)# interface gigabitethernet 0/18
DeviceA(cfg-if-GigabitEthernet 0/18)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/18)# exit
DeviceA(cfg)# interface GigabitEthernet 0/19
DeviceA(cfg-if-GigabitEthernet 0/19)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/19)# exit
DeviceA(cfg)# interface GigabitEthernet 0/20
DeviceA(cfg-if-GigabitEthernet 0/20)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/20)# exit
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
```

Configure RP. Configure C-BSR and C-RP on Device A.

```
DeviceA(cfg)# ip pim c-bsr Loopback 50
DeviceA(cfg)# ip pim c-rp Loopback 50
```

Enable the IP multicast routing function and the PIM-SM function on Device B.

```
DeviceB(cfg)# ip mrouting-enable
DeviceB(cfg)# interface VLAN 50
DeviceB(cfg-if-VLAN 50)# ip pim sparse-mode
DeviceB(cfg-if-VLAN 50)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ip pim sparse-mode
DeviceB(cfg-if-Loopback 49)# exit
```

Enable the IP multicast routing function and the PIM-SM function on Device C.

```
DeviceC(cfg)# ip mrouting-enable
DeviceC(cfg)# interface VLAN 60
DeviceC(cfg-if-VLAN 60)# ip pim sparse-mode
DeviceC(cfg-if-VLAN 60)# exit
DeviceC(cfg)# interface GigabitEthernet 0/7
DeviceC(cfg-if-GigabitEthernet 0/7)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/7)# exit
DeviceC(cfg)# interface Loopback 52
```

```
DeviceC(cfg-if-Loopback 52)# ip pim sparse-mode
DeviceC(cfg-if-Loopback 52)# exit
```

Enable the IP multicast routing function and the PIM-SM function on Device D.

```
DeviceD(cfg)# ip mrouting-enable
DeviceD(cfg)# interface GigabitEthernet 0/23
DeviceD(cfg-if-GigabitEthernet 0/23)# ip pim sparse-mode
DeviceD(cfg-if-GigabitEthernet 0/23)# exit
DeviceD(cfg)# interface vlan 50
DeviceD(cfg-if-vlan 50)# ip pim sparse-mode
DeviceD(cfg-if-vlan 50)# exit
DeviceD(cfg)# interface Loopback 51
DeviceD(cfg-if-Loopback 51)# ip pim sparse-mode
DeviceD(cfg-if-Loopback 51)# exit
```

(3) Configure the static multicast group function on device interfaces connecting N1.

Configure the static multicast group function on the SVI50 interface of Device B, and configure the static multicast group address as 225.0.0.10.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface VLAN 50
DeviceB(cfg-if-VLAN 50)# ip igmp static-group-entries 225.0.0.10
DeviceB(cfg-if-VLAN 50)# exit
```

Configure the static multicast group function on the SVI50 interface of Device D, and configure the static multicast group address as 225.0.0.10.

```
DeviceD> privilege
DeviceD# config-system terminal
DeviceD(cfg)# interface VLAN 50
DeviceD(cfg-if-VLAN 50)# ip igmp static-group-entries 225.0.0.10
DeviceD(cfg-if-VLAN 50)# exit
```

(4) Configure the multicast group access control function on device interfaces connecting N2.

Configure the multicast group access control function on the SVI60 interface of Device C. Member hosts on N2 can only join the multicast group 225.0.0.11.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ip access-control-list standard ip-group
DeviceC(cfg-stdacl)# permit 225.0.0.11 0.0.0.0
DeviceC(cfg-stdacl)# exit
DeviceC(cfg)# interface VLAN 60
DeviceC(cfg-if-VLAN 60)# ip igmp restricted-group ip-group
DeviceC(cfg-if-VLAN 60)# exit
```

5. Verification

(1) Run the **display ip igmp-info interface** command to check the operation of IGMP configuration on each device. It can be seen that Device B is the querier, because on N1, the IP address of SVI50 on Device B is low.

Run the **display ip igmp-info interface** command. It can be seen that Device B is the querier.

```
DeviceB# display ip igmp-info interface VLAN 50
Interface VLAN 50 (Index 4146)
IGMP Enabled, Active, Querier, Version 2 (default)
Internet address is 10.100.5.1
IGMP interface limit is 4000
IGMP interface has 1 group-record states
IGMP interface has 1 static-group-entries records
IGMP activity: 8 joins, 0 leaves
IGMP query interval is 125 seconds
IGMP querier timeout is 255 seconds
IGMP max query response time is 10 seconds
Last member query response interval is 10
Last member query count is 2
Group Membership interval is 260 seconds
Robustness Variable is 2
 Querier timer on, remain time:25
DeviceB#
```

Run the **display ip igmp-info interface** command. It can be seen that Device D is not selected as the querier.

```
DeviceD# display ip igmp-info interface VLAN 50
Interface VLAN 50 (Index 4146)
IGMP Active, Non-Querier, Version 2 (default)
Internet address is 10.100.5.2
IGMP interface limit is 4000
IGMP interface has 0 group-record states
 IGMP interface has 0 static-group records
 IGMP activity: 0 joins, 0 leaves
 IGMP querying router is 10.100.5.1
 IGMP query interval is 125 seconds
 IGMP querier timeout is 255 seconds
 IGMP max query response time is 10 seconds
 Last member query response interval is 10
 Last member query count is 2
 Group Membership interval is 260 seconds
 Robustness Variable is 2
 Querier timer OFF
DeviceB#
```

(2) Run the **display ip pim-info sparse-mode mroute** command to check multicast routing table entries on each device.

Multicast routing table entries on Device A are shown as follows. There are (*,225.0.0.10), (10.100.12.2, 225.0.0.10) and (*,225.0.0.11), (10.100.12.2, 225.0.0.11) entries.

```
DeviceA# display ip pim-info sparse-mode mroute
IP Multicast Routing Table
```

```
(*,*,RP) Entries: 0
(*,G) Entries: 2
(S,G) Entries: 2
(S,G,rpt) Entries: 2

DeviceC#
```

Run the display ip igmp-info groups command to check that SVI50 interfaces on Device B and Device D join the static multicast group 225.0.0.10.

```
DeviceB# display ip igmp-info groups
IGMP Connected Group Membership
Group Address      Interface                Uptime      Expires     Last Reporter
225.0.0.10         VLAN 50                              01:48:10    stopped     0.0.0.0
DeviceB#
```

```
DeviceD# display ip igmp-info groups
IGMP Connected Group Membership
Group Address      Interface                Uptime      Expires     Last Reporter
225.0.0.10         VLAN 50                              01:01:55    stopped     0.0.0.0
DeviceD#
```

The host on SVI60 joins multicast groups 225.0.0.10 and 225.0.0.11. Run the **display ip igmp-info groups** command, and it can be seen that the host on SVI60 can only join the multicast group 225.0.0.11.

```
DeviceC# display ip igmp-info groups
IGMP Connected Group Membership
Group Address      Interface                Uptime      Expires     Last Reporter
225.0.0.11         VLAN 60                              01:16:11    00:04:03    10.100.6.2
DeviceC#
```

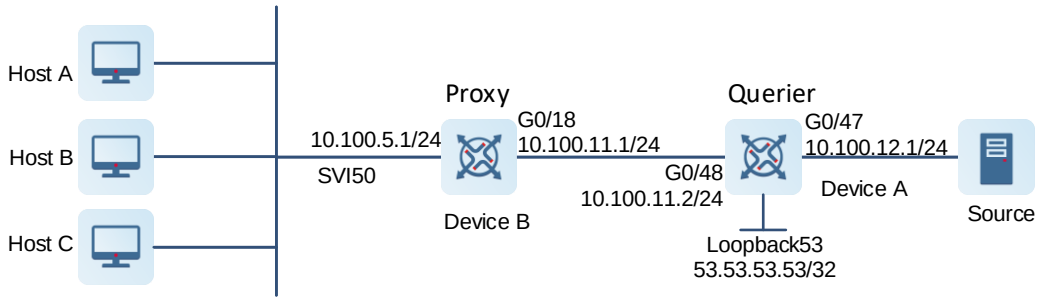
7. Common Errors

- Multicast routing is disabled on multicasting devices on the network.
- No multicast interface is available on the network.



1.15.2 Configuring the IGMP Proxy Function

1. Requirements

As shown in Figure 1-3, member hosts Host A and Host B on the IP stub network want to receive video traffic from the source Source in multicast mode, and require Device B to use the IGMP proxy function to maintain multicast membership and normal data forwarding without running PIM-SM. PIM-SM is running on the network. The member hosts Host A and Host B on the stub network receive the multicast traffic sent by the source Source through the multicast group addresses 225.0.0.10 and 225.0.0.11. IGMP proxy function is configured on Device B to maintain group membership and maintain normal multicast data forwarding without running PIM-SM.

2. Topology

Figure 1-3 Topology of IGMP Proxy Configuration

3. Notes

- Configure an IP unicast routing protocol (OSPF) on multicast devices, and enable unicast routes to be reachable to the loopback interface.
- Enable the IP multicast routing function on all multicast devices, and the PIM-SM function on device interconnection interfaces and interfaces for connecting hosts and multicast sources.
- Configure a proxy service interface.
- Configure an MRoute proxy interface.

4. Procedure

(1) Configure an IP unicast routing protocol (OSPF) on multicast devices, and enable unicast routes to be reachable to the loopback interface.

Configure the IP address for each interface on Device A, and enable the OSPF protocol to realize inter-network communication.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/47)# ip address 10.100.12.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/48)# ip address 10.100.11.2 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# interface loopback 53
DeviceA(cfg-if-Loopback 53)# ip address 53.53.53.53 255.255.255.255
DeviceA(cfg-if-Loopback 53)# exit
DeviceA(cfg)# router-protocol ospf 49
DeviceA(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.12.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 53.53.53.53 0.0.0.0 area 0
DeviceA(cfg-router)# exit
```

Configure the IP address for each interface on Device B, and enable the OSPF protocol to realize inter-network communication.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# vlan 50
DeviceB(cfg)# interface VLAN 50
DeviceB(cfg-if-VLAN 50)# ip address 10.100.5.1 255.255.255.0
DeviceB(cfg-if-VLAN 50)# exit
DeviceB(cfg)# interface GigabitEthernet 0/19
DeviceB(cfg-if-GigabitEthernet 0/19)# switch-port access vlan 50
DeviceB(cfg-if-GigabitEthernet 0/19)#interface GigabitEthernet 0/20
DeviceB(cfg-if-GigabitEthernet 0/20)# switch-port access vlan 50
DeviceB(cfg-if-GigabitEthernet 0/20)#interface GigabitEthernet 0/21
DeviceB(cfg-if-GigabitEthernet 0/21)# switch-port access vlan 50
DeviceB(cfg-if-GigabitEthernet 0/21)# exit
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/18)# ip address 10.100.11.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# router-protocol ospf 49
DeviceB(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceB(cfg-router)# exit
```

(2) Enable the IP multicast routing function on all multicast devices, and the PIM-SM function on device interconnection interfaces and interfaces for connecting hosts and multicast sources.

Enable the IP multicast routing function and the PIM-SM function on Device A.

```
DeviceA(cfg)# ip mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# interface loopback 53
DeviceA(cfg-if-Loopback 0)# ip pim sparse-mode
DeviceA(cfg-if-Loopback 0)# exit
```

Configure RP. Configure C-BSR and C-RP on Device A.

```
DeviceA(cfg)# ip pim c-bsr Loopback 53
DeviceA(cfg)# ip pim c-rp Loopback 53
```

(3) Enable basic IGMP functions on Device B.

```
DeviceB(cfg)# ip mrouting-enable
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# interface vlan 50
DeviceB(cfg-if-VLAN 50)# ip pim sparse-mode
DeviceB(cfg-if-VLAN 50)# exit
```

(4) Configure a proxy service interface.

Configure the proxy service on interface GigabitEthernet 0/24 on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)#ip igmp enable-proxy-service
DeviceB(cfg-if-GigabitEthernet 0/18)#exit
```

(5) Configure an MRoute proxy interface.

Configure the MRoute proxy function on interface SVI50 on Device B.

```
DeviceB(cfg)# interface VLAN 50
DeviceB(cfg-if-VLAN 50)# ip igmp enable-mrouting GigabitEthernet 0/18
```

5. Verification

Run the **display ip igmp-info groups** command on Device B to check proxy entries.

```
DeviceB# display ip igmp-info groups
IGMP Connected Group Membership
Group Address      Interface                Uptime      Expires     Last Reporter
225.0.0.10         VLAN 50                              00:17:44    00:03:13    10.100.5.2
225.0.0.11         VLAN 50                              00:17:42    00:03:08    10.100.5.4
```

```
IGMP Proxy-server Connected Group Membership
Group Address      Interface                Uptime
225.0.0.10         GigabitEthernet 0/18     00:12:49
225.0.0.11         GigabitEthernet 0/18     00:12:49
DeviceB#
```

Run the **display ip igmp-info groups** command on Device A to verify that member addresses that join the multicast groups 225.0.0.10 and 225.0.0.11 are the IP addresses of Device B.

```
DeviceA# display ip igmp-info groups
IGMP Connected Group Membership
Group Address      Interface                Uptime      Expires     Last Reporter
225.0.0.10         GigabitEthernet0/48                  00:14:16    00:03:06    10.100.11.1
225.0.0.11         GigabitEthernet0/48                  00:14:16    00:03:06    10.100.11.1
DeviceA#
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ip mrouting-enable
!
interface GigabitEthernet 0/47
 unset switch-port
 ip address 10.100.12.1 255.255.255.0
 ip pim sparse-mode
!
interface GigabitEthernet 0/48
 unset switch-port
 ip address 10.100.11.2 255.255.255.0
 ip pim sparse-mode
!
interface Loopback 53
 ip address 53.53.53.53 255.255.255.255

 network-advertise 10.100.11.0 0.0.0.255 area 0
!
End
```

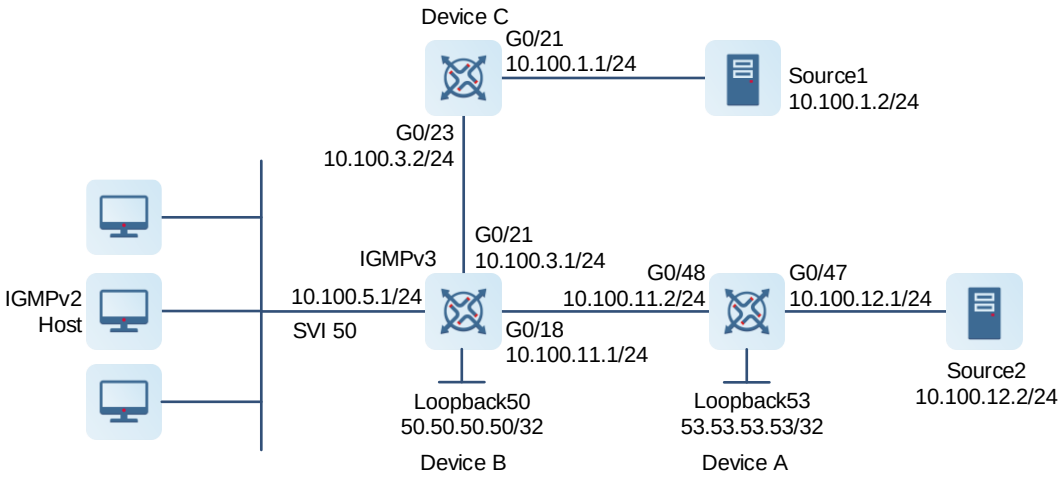
7. Common Errors

- The basic functions of IGMP are not configured on the proxy service interface.



1.15.3 Configuring SSM-MAP

1. Requirements

As shown in Figure 1-4, on the IP network, the member host Host wants to receive video traffic from Source 2, but not video traffic from Source 1 without IGMPv3. The SSM mode can be used to provide multicast services. The SSM group address range on the network is 232.0.0.0/8 by default. The member host runs the IGMP2 protocol, and does not support IGMPv3. The host wants to receive only the multicast traffic sent by Source 2, not multicast traffic sent by Source 1.

2. Topology

Figure 1-4 Topology of SSM-MAP Configuration

3. Notes

- Configure an IP unicast routing protocol (OSPF) on multicast devices, and enable unicast routes to be reachable to the loopback interface.
- Enable the IP multicast routing function on all multicast devices, and the PIM-SM function on device interconnection interfaces and interfaces for connecting hosts and multicast sources.
- Configure the SSM group address range.
- Enable the SSM-MAP function.
- Configure the SSM-MAP static linked list.

4. Procedure

(1) Configure an IP unicast routing protocol (OSPF) on multicast devices, and enable unicast routes to be reachable to the loopback interface.

Configure the IP address for each interface on Device A, and enable the OSPF protocol to realize inter-network communication.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/47)# ip address 10.100.12.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/48)# ip address 10.100.11.2 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# interface loopback 53
DeviceA(cfg-if-Loopback 53)# ip address 53.53.53.53 255.255.255.255
```

```
DeviceA(cfg-if-Loopback 53)# exit
DeviceA(cfg)# router-protocol ospf 49
DeviceA(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.12.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 53.53.53.53 0.0.0.0 area 0
DeviceA(cfg-router)# exit
```

Configure the IP address for each interface on Device B, and enable the OSPF protocol to realize inter-network communication.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# vlan 50
DeviceB(cfg)# interface VLAN 50
DeviceB(cfg-if-VLAN 50)# ip address 10.100.5.1 255.255.255.0
DeviceB(cfg-if-VLAN 50)# exit
DeviceB(cfg)# interface GigabitEthernet 0/19
DeviceB(cfg-if-GigabitEthernet 0/19)# switch-port access vlan 50
DeviceB(cfg-if-GigabitEthernet 0/19)# interface GigabitEthernet 0/20
DeviceB(cfg-if-GigabitEthernet 0/20)# switch-port access vlan 50
DeviceB(cfg-if-GigabitEthernet 0/20)# interface GigabitEthernet 0/22
DeviceB(cfg-if-GigabitEthernet 0/21)# switch-port access vlan 50
DeviceB(cfg-if-GigabitEthernet 0/21)# exit
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/18)# ip address 10.100.11.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# interface GigabitEthernet 0/21
DeviceB(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/21)# ip address 10.100.3.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface loopback 50
DeviceA(cfg-if-Loopback 50)# ip address 50.50.50.50 255.255.255.255
DeviceA(cfg-if-Loopback 50)# exit
DeviceB(cfg)# router-protocol ospf 49
DeviceB(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.3.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 50.50.50.50 0.0.0.0 area 0
DeviceB(cfg-router)# exit
```

Configure the IP address for each interface on Device C, and enable the OSPF protocol to realize inter-network communication.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/21)# ip address 10.100.1.1 255.255.255.0
```

```
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface GigabitEthernet 0/23
DeviceC(cfg-if-GigabitEthernet 0/23)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/23)# ip address 10.100.3.2 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/23)# exit
DeviceC(cfg)# router-protocol ospf 49
DeviceC(cfg-router)# network-advertise 10.100.1.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 10.100.3.0 0.0.0.255 area 0
DeviceC(cfg-router)# exit
```

(2) Enable the IP multicast routing function on all multicast devices, and the PIM-SM function on device interconnection interfaces and interfaces for connecting hosts and multicast sources.

Enable the IP multicast routing function and the PIM-SM function on Device A.

```
DeviceA(cfg)# ip mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# interface loopback 53
DeviceA(cfg-if-Loopback 53)# ip pim sparse-mode
DeviceA(cfg-if-Loopback 53)# exit
```

Enable the IP multicast routing function and the PIM-SM function on Device B.

```
DeviceB(cfg)# ip mrouting-enable
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# interface GigabitEthernet 0/21
DeviceB(cfg-if-GigabitEthernet 0/21)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/21)# exit
DeviceB(cfg)# interface VLAN 50
DeviceB(cfg-if-VLAN 50)# ip pim sparse-mode
DeviceB(cfg-if-VLAN 50)# exit
DeviceB(cfg)# interface loopback 50
DeviceB(cfg-if-Loopback 50)# ip pim sparse-mode
DeviceB(cfg-if-Loopback 50)# exit
```

Enable the IP multicast routing function and the PIM-SM function on Device C.

```
DeviceC(cfg)# ip mrouting-enable
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface GigabitEthernet 0/23
DeviceC(cfg-if-GigabitEthernet 0/23)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/23)# exit
```

Configure the IGMP version as IGMPv3 on the interface SVI50 connecting the member host on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface VLAN 50
DeviceB(cfg-if-VLAN 50)# ip igmp specify-version 3
DeviceB(cfg-if-VLAN 50)# exit
```

(3) Configure the SSM group address range.

Configure the SSM multicast group address range on all devices. The following takes the configuration of SSM multicast group address range on Device A as an example. The configuration procedure is the same for Device B and Device C and is omitted.

```
DeviceA(cfg)# ip pim enable-ssm default
```

(4) Enable the SSM-MAP function.

Enable the SSM-MAP function on Device B.

```
DeviceB(cfg)# ip igmp ssm-policy enable
```

(5) Configure the SSM-MAP static linked list.

Configure multicast addresses in 232.0.0.0/24 on Device B to map to Source 1.

```
DeviceB(cfg)# ip access-control-list standard ipv4-map-acl
DeviceB(cfg-stdacl)# permit 232.0.0.0 0.0.0.255
DeviceB(cfg)# ip igmp ssm-policy static ipv4-map-acl 10.100.12.2
```

5. Verification

Verify the SSM-MAP information.

```
DeviceB# display ip igmp-info ssm-policy
SSM Mapping : Enabled
Database      : Static mappings configured
DeviceB#
```

Verify the multicast source information mapped to the multicast group 232.0.0.10.

```
DeviceB# display ip igmp-info ssm-policy 232.0.0.10
Group address: 232.0.0.10
Database      : Static
Source list   : 10.100.12.2
DeviceB#
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ip mrouting-enable
!

 network-advertise 10.100.3.0 0.0.0.255 area 0
!
ip pim enable-ssm default
!
end
```

7. Common Errors

- The basic functions of IGMP are not enabled.
- SSM service is not enabled.
- SSM address range is not configured.
- SSM service address is not configured when using the SSM service.
- The SSM service address range configured on each multicast device is inconsistent.

1.16 Common Misconfigurations

1.16.1 On-demand Clients Failed to Request On-demand Multicast Services

- Phenomenon
  The multicast function is enabled on the network, but the client failed to request one-demand multicast services.
- Troubleshooting
  a Check that the connectivity between the on-demand client and the multicast server is normal.
  Run the **display ip route-config** command to check that there is a unicast route table entry to the multicast source on the device. If not, configure a unicast routing protocol.
  b Check that the configuration of each device is correct.
  Run the **display ip pim-info** { **dense-mode | sparse-mode** } **interface** command to check the PIM information on the interface. If no information is displayed on the interface, it means that PIM-SM function is not enabled. In this case, run the **ip pim sparse-mode** command on the interface to enable the PIM-SM function.
  c Check that the multicast receiver joins the multicast group.
  Run the **display ip igmp-info groups** command to check that the member host has successfully joined the corresponding multicast group on the multicast device on the same network segment as the member host.
  d Check that the multicast table entries of the multicast source and receiver are correct.
  Run the **display ip pim-info** { **dense-mode | sparse-mode** } command to check that the multicast table entries on each device are correct.

1.14.2 Configuring Basic Functions of PIM-SM in the SSM Model 47

1 Configuring PIM-SM

1.1 Introduction

The Protocol Independent Multicast (PIM) is an intra-domain multicast routing protocol that is independent from unicast routing protocols. Any unicast routing protocol, for example, static route, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF), can provide routing information for IP multicast. Multicast routing is independent from unicast routing, and simply uses unicast routing tables to generate multicast routing information. The Protocol Independent Multicast-Sparse Mode (PIM-SM) is used most widely, and applies to networks of any form, especially large networks where group members are scattered in a wide area. Compared with other intra-domain multicast routing protocols, PIM-SM has irreplaceable advantages.

1.2 Principles

PIM-SM considers that not all hosts need to receive multicast data, and sends multicast data to hosts that require the multicast data.

A PIM multicast device provides multicast service in any-source multicast (ASM) and source-specific multicast (SSM) models. For groups in the SSM address range, the SSM model is used. For other groups, the ASM model is used. In the ASM model, a host joins a specified multicast group G without the multicast source S specified. In the SSM model, a host can join a specified multicast group G to receive multicast data from a specified source S.

1.2.1 ASM Model

1. Basic Principles

PIM-SM in the ASM model is implemented as follows:

- A rendezvous point (RP) is used as a root of a rendezvous point tree (RPT) for transition. The designated router (DR) connected to a host sends a join message to the RP of a multicast group, and the multicast devices on the route create (*, G) entries hop by hop. Based on the entries, an RPT is created with the RP as the root.
- To send data to a multicast group, the source DR sends a register message to the RP to create an (S, G) entry on the RP. After the registration succeeds, the multicast source sends multicast data to the RP. After the multicast data arrives at the RP, it is copied and sent to the host via the RPT.

In the ASM model, the key mechanisms of PIM-SM include PIM neighbor creation, DR election, RP, bootstrap router (BSR), multicast source registration, shortest path tree (SPT) switchover, and assertion.

2. PIM Neighbor Creation

Neighbor relationship must be created between PIM multicast devices to form a PIM network, so that PIM control messages and multicast packets can be transmitted on the network. A Hello message is sent from a PIM interface. In the multicast packet with the Hello message encapsulated, the destination address is 224.0.0.13 (indicating all PIM multicast devices in the same network segment), the source address is the IP address of the PIM interface, and the time to live (TTL) value is 1. The Hello message is used to:

- Discover PIM neighbors.

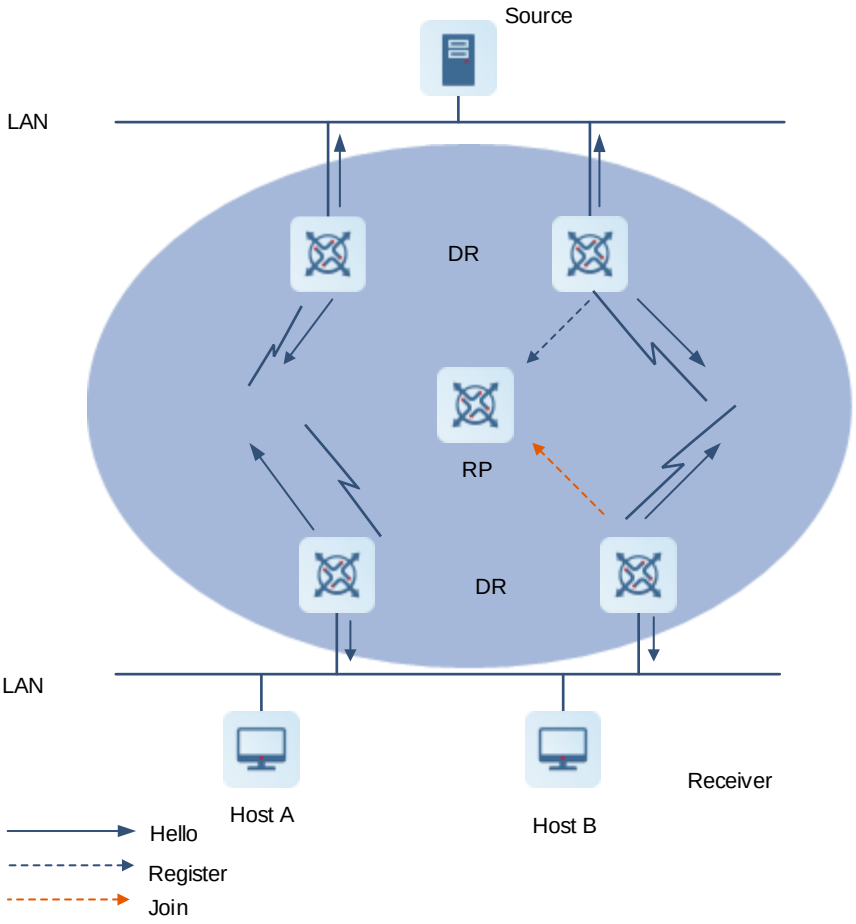
  PIM multicast devices in the same network segment receive the multicast packet with the destination address as 224.0.0.13, obtain neighbor information, and create neighbor relationship. After the neighbor relationship is created, the PIM interfaces can receive and process other PIM packets and create multicast routing entries.

  When a PIM interface is enabled or detects a new neighbor, a Triggered-Hello-Delay message is used to generate a random time. Within the time, the interface sends Hello messages.

- Negotiate protocol parameters. The Hello message contains the following key parameters:
  - **DR Priority**: The priority of a multicast device for DR election. The device with a higher priority is selected.
  - **Holdtime**: The neighbor is considered reachable before timeout.
  - **Propagation Delay**: Duration between the time when a PIM device receives a prune packet and the time when the PIM device sends the prune packet to the uplink devices.
  - **Override-Interval**: The interval to override the prune.

- Maintain neighbor relationship.

  A Hello message is sent periodically between PIM multicast devices. If no new Hello message is received from a PIM neighbor within the hold time, this neighbor is considered unreachable and then removed from the neighbor list. Any change of PIM neighbors will cause change of the multicast topology in the network. If an uplink or a downlink neighbor in a multicast distribution tree (MDT) is unreachable, multicast routes converge again and the MDT is reshaped.



3. DR Election

As shown in Figure 1-1, the source DR sends a register message to the RP. Member DRs send join messages to the RP and forward multicast data to members in a multicast group. In the network segment to which members and multicast source are connected, multiple PIM devices obtain IP addresses and DR priorities of neighbors based on the Hello messages sent between the PIM devices during PIM neighbor creation. The PIM device that is elected becomes a member DR or source DR. The election rules are as follows:

(1) The DR priorities are compared. The device with a higher priority is selected.

(2) If the DR priorities are the same or there is any neighbor in the shared network segment that does not support DR priority, the IP addresses of the devices are compared. The device with a larger IP address is selected.

Figure 1-1 Schematic Diagram of DR Election

4. BSR Election

In the PIM network, the BSR periodically generates bootstrap messages (BSMs) that include a series of candidate-RPs (C-RPs) and corresponding group addresses. The BSMs are sent in the entire domain hop by hop. All PIM multicast devices in the network receive the BSMs and record the C-RPs and corresponding group addresses.

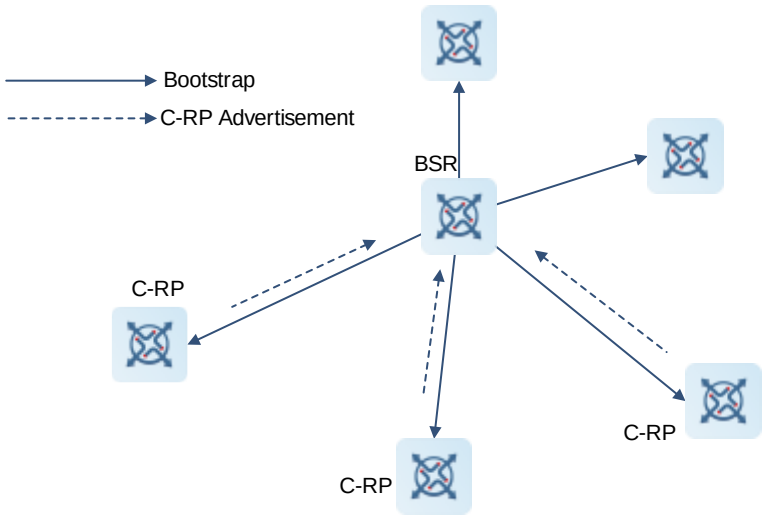
In the PIM-SM domain, one or multiple candidate-BSRs (C-BSRs) are configured and the BSR is elected based on rules.

5. RP Election

In the PIM network, the RP processes register messages of the source DR and join packets of group members. The process from the multicast source to members of the multicast group is divided into two sections: The SPT that uses the source DR as the root and the RP as the leaf, and the RPT that uses the RP as the root and member DRs as leaves. In the PIM-SM network with the ASM model, the RP must act as a transition to create or forward data.

In the PIM network, an RP can serve one or more groups, and a group can be served by only one RP. In the PIM network, the RP can be configured as static or dynamic.

- Static RP



A static RP sets the RP address on each PIM multicast device to enable the entire PIM network to know the RP address.

- Dynamic RP

  As shown in Figure 1-2, multiple C-RPs can be configured in a PIM-SM domain to elect an RP dynamically. These C-RPs add their own addresses and served multicast groups to advertisement packets and sent the packets to the BSR periodically in unicast mode. The BSR is elected from the configured C-BSRs based on rules. The BSR periodically generates BSMs that include a series of C-RPs and corresponding group addresses. The BSMs are sent in the entire domain. Each PIM device in the domain receives and saves these BSMs, and applies the same hash algorithms to compute and elect an RP for each group. The BSR and RP election process is as follows:

  - BSR election process: Initially, each C-BSR considers itself a BSR and sends a BSM throughout the network. The BSMs carry the C-BSR addresses and priorities. Upon receiving the BSMs, each PIM device compares the C-BSR addresses and priorities to elect the BSR.
  - RP election process: The C-RPs periodically send advertisement packets to the BSR in unicast mode to advertise the C-RP addresses, priorities, and addresses of the served groups. The BSR collects the information as RP-Set, encapsulates the information in a BSM, and sends the messages to each PIM device in the network. Upon receiving the RP-Set, the PIM devices in the network use the same algorithms for computation to obtain the RP that serves each group. Each PIM device obtains the RP position of each group.

Figure 1-2 Schematic Diagram of Dynamic RP Election

6. Multicast Source Registration

Figure 1-3 Schematic Diagram of Multicast Source Registration

As shown in Figure 1-3, when a multicast source sends data to a group, the source DR sends a register message to the RP so that the RP obtains the source information and a multicast packet and forwards the multicast packet to the members in the group. The forwarding process is as follows:

(1) The multicast source sends a multicast packet to the source DR.

(2) The source DR encapsulates the multicast packet in a register message and sends the message to the RP in unicast mode.

(3) Upon receiving the register message, the RP decapsulates the message and forwards the multicast packet to the members in a group via the RPT. Meanwhile, the RP sends an (S, G) join packet to the source. The PIM devices on the route create (S, G) entries, and finally create an SPT from the source to the RP.

(4) The source DR S forwards multicast packets based on this SPT. The multicast data is sent to the RP in the form of multicast packets.

(5) Upon receiving multicast packets from the source, the RP discards the register message and sends a register-stop message to the source.

(6) Upon receiving the register-stop message, the source DR stops encapsulating the register message, forwards multicast packets via the SPT, and periodically sends a register-probe message to the RP.

(7) Upon receiving the register-probe message, the RP sends a register-stop message to the source DR and updates the (S, G) entries.

(8) Upon receiving the register-stop message, the source DR continues forwarding multicast packets via the SPT without encapsulating the register message.

7. RPT Construction

When a group member joins the network, the DR connecting to the group member sends a join packet to the RP. If a multicast source has sent a multicast packet to the RP, the multicast packet will be sent to the group member via the RPT.

The RPT construction procedure is as follows:

- When a member DR receives an IGMP (*, G) INCLUDE Report packet, if the member DR is not an RP of the group G, the member DR sends a (*, G) join packet to the RP and the multicast devices on the route create the (*, G) entries hop by hop to generate an RPT that uses the RP as the root.
- During RPT construction, each PIM device checks the reverse path forwarding (RPF) when sending a join packet to the RP to find the unicast route to the RP. The outbound interface of the unicast route is an uplink interface, and the next hop of the unicast route is the RPF neighbor. The join packet is sent from the member DR to the RP.

8. SPT Switchover

In the PIM-SM network of the ASM model, one or multiple multicast groups correspond to one RP. Before SPT switchover, all packets of multicast groups sent to the RP service must be transitioned by the RP. When the sending rate of multicast packets grows, the RP load is increased. To solve this problem, the PIM-SM switches over the SPT to relieve the RP load. SPT switchover can be triggered by the RP or a member DR.

- SPT switchover triggered by the RP

  After receiving a register message from the source DR, the RP decapsulates the register message, forwards the multicast packets in the message to the group members via the RPT, and sends an (S, G) join packet to the source DR. The PIM multicast devices on the route create (S, G) entries hop by hop to create an SPT from the RP to the source.

- SPT switchover triggered by a member DR

  a When receiving the first multicast packet from the RP, the member DR obtains the source address.

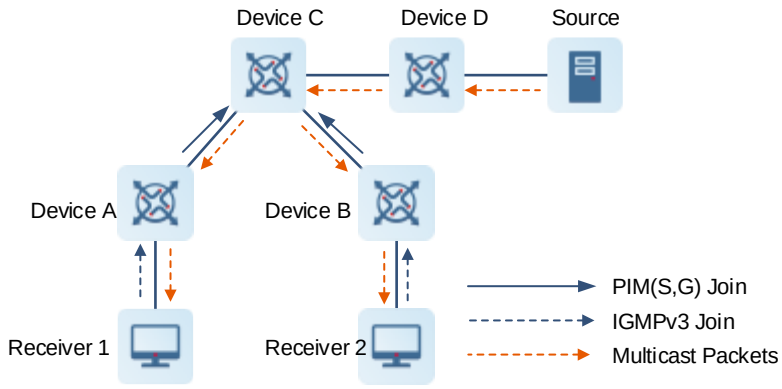
  b The member DR sends an (S, G) join packet to the source. The PIM devices on the route create (S, G) entries and create an SPT from the member DR to the source DR.

  c After the SPT is created, the member DR sends a prune packet to the RP hop by hop and removes the downlink interface from the (*, G) entries. After the pruning, the RP does not forward multicast packets to the member DR via the RPT.

  d The SPT from the member DR to the source DR does not pass the RP. The RP sends a prune packet to the source DR to remove the downlink interface from the (S, G) entries. After the pruning, the source DR does not forward packets to the RP via the original "RP-source DR" SPT.

1.2.2 SSM Model

1. Basic Principles



In the SSM model, members in a multicast group can specify to receive or reject data from a multicast source. The group members get to know the (S, G) entries of sources through access to the server or receiving advertisements. After understanding requirement of group members, the member DR sends a join packet to the source DR. This join packet is transmitted to the multicast source hop by hop to create an SPT from the source to the group members.

Note

- To implement the SSM model on IPv4, complete multicast interconnection through the PIM-SM and configure IGMPv3 to manage relationship between the hosts and devices.
- SSM model requirements: The hosts must know the addresses of multicast sources in advance using other network services so that the hosts can select multicast sources.

- On the devices that reside on the route from the hosts to the multicast source, the PIM-SM and SSM functions must be enabled.

Figure 1-4 SSM Model

Note

After the SSM function is enabled, the default group range of the SSM is **232/8**. You can modify the group range of the SSM using commands.

In the SSM model, the key mechanisms of PIM-SM include neighbor creation, DR election, and SPT creation.

2. PIM Neighbor Creation

For more information about the PIM neighbor creation mechanism in the SSM model, see the PIM neighbor creation mechanism in the ASM model in 1.2.1 2. PIM Neighbor Creation.

3. DR Election

For more information about the DR election mechanism in the SSM model, see the DR election mechanism in the ASM model in 1.2.1 3. DR Election.

4. SPT Construction

The SPT construction mechanism is as follows:

(1) The member DR learns through IGMPv3 that a group member wants to receive data of a multicast source and sends an (S, G) join packet to the source hop by hop.

(2) The PIM multicast devices on the route receive the (S, G) join packet and create the (S, G) entries, creating an SPT from the group member to the source.

(3) After the SPT is created, the multicast source distributes the multicast packets to the group member via the SPT.

1.2.3 Protocols and Standards

- RFC 4601: Protocol Independent Multicast-Sparse Mode (PIM-SM)
- RFC 5059: Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- RFC 3962: Protocol Independent Multicast-Dense Mode protocol
- RFC 4607: Source-Specific Multicast for IP

1.3 Restrictions and Guidelines

- Before PIM-SM is enabled, enable the multicast routing and forwarding function in global configuration mode. Otherwise, multicast packets cannot be sent even if PIM-SM is enabled.
- In the IPv4 multicast network, the PIM (IPv4) protocol must be run on all L3 devices. Otherwise, a forwarding route cannot be created.

1.4 Configuration Task Summary

The PIM-SM configuration includes the following tasks:

(1) Enabling the PIM-SM Function

(2) Configuring a model for PIM-SM. Select at least one of the configuration tasks to complete.

- Configuring PIM-SM in the ASM Model
- Configuring PIM-SM in the SSM Model

(3) Configuring PIM Neighbor Parameters. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Neighbor Message Time Parameters
- Configuring Neighbor Tracking
- Configuring Neighbor Filtering

(4) (Optional) Configuring DR Priority

(5) Configuring Parameters of the Join/Prune Packets. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Join/Prune Packet Sending Interval
- Configuring the Prune Delay

(6) (Optional) Enabling PIM-SM on the Super VLAN Interface

(7) (Optional) Enabling PIM BFD Correlation

1.5 Enabling the PIM-SM Function

1.5.1 Overview

Neighbor relationship must be created between PIM multicast devices to form a PIM-SM network, so that PIM control messages and multicast packets can be transmitted on the network. The PIM-SM function must be configured on all interfaces so that PIM neighbor creation, multicast entry creation, and multicast packet forwarding can be successful.

In a PIM network, if you want an interface, for example, a stub network device interface connecting to hosts, to receive multicast packets without involving the PIM network topology construction, you can set the interface to the PIM-SM passive mode. After the PIM-SM passive mode is configured, the interface does not process PIM packets. This improves device performance.

1.5.2 Restrictions and Guidelines

- The IPv4 multicast routing function must be enabled on each multicast device.

- The PIM-SM function should be enabled on the following interfaces: interfaces interconnecting multicast devices, interfaces connecting the static RP, C-RP and C-BSRs, and interfaces connecting multicast sources and hosts.
- PIM interfaces must be L3 interfaces, including: Layer 3 Ethernet interface, Layer 3 link aggregation, SVI, loopback interface, and VXLAN routed interface.

1.5.3 Prerequisites

All PIM interfaces can be reached via IPv4 unicast routes.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable IPv4 multicast routing.

ip mrouting-enable

The IPv4 multicast routing function is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(5) Enable the PIM-SM function.

ip pim sparse-mode

The PIM-SM function is disabled by default.

(6) (Optional) Enable the PIM-SM passive mode.

ip pim sparse-mode passive

The PIM-SM passive mode is disabled by default.

1.6 Configuring PIM-SM in the ASM Model

1.6.1 Overview

The PIM-SM network supports the multicast service in the ASM and SSM models. Either one model or two models can be configured.

PIM-SM in the ASM model can provide hosts with multicast services of any source. A host joining a multicast group can receive multicast packets destined to this multicast group from any source.

If you require a PIM network to support the multicast service in the ASM model, an RP must be configured. There are three methods to configure an RP:

- Configure a static RP.
- Configure a dynamic RP.
- Configure static and dynamic RPs. If static and dynamic RPs are available at the same time, dynamic RPs are preferred.

1.6.2 Configuration Tasks

The PIM-SM ASM model configuration includes the following tasks. Select the tasks to configure a static RP or a dynamic RP, or configure both.

- Configuring a Static RP
- Configuring a Dynamic RP
  - Configuring C-BSRs and Related Parameters
  - Configuring C-RPs and Related Parameters
  - (Optional) Configuring Registration Parameters
- (Optional) Configuring the Last Hop Device to Switch over from the RPT to SPT

1.6.3 Prerequisites

In the PIM-SM multicast network, all nodes are reachable via IPv4 unicast routes.

1.6.4 Configuring a Static RP

1. Overview

You can manually configure a static RP to prevent frequent packet interaction between the BSR and C-RPs or between the BSR and PIM multicast devices and avoid bandwidth occupation. If the multicast network is simple or small, you can configure a static RP.

2. Restrictions and Guidelines

- Static RPs must be configured on every multicast device.
- The multicast device selected as a static RP must boast high performance.
- You are advised to use the loopback interface as a static RP address.
- Static RPs configured on multicast devices should be consistent, including RP address and address range of the served groups.
- If multiple static RPs are configured to correspond to different addresses of groups, the RPs can implement load balancing.
- If multiple static RPs serve the same group, the static RP with a larger IP address is selected first.
- You can use the control list to configure an RP to serve multiple (referencing an ACL) or all (not referencing an ACL) multicast groups. However, an RP can adopt only one configuration. The last configuration overrides the preceding configurations.

3. Prerequisites

Before an address range of a group is configured for an RP, ensure that the corresponding ACL is created and specify a multicast group range for the static RP to serve. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a static RP.

ip pim static-rp-addr *ipv4-rp-address* [{ *acl-name* | *acl-number* }]

No static RP is configured by default.

1.6.5 Configuring C-BSRs and Related Parameters

1. Overview

In the PIM-SM domain of the ASM model, a unique BSR must be available. The BSR collects and releases RP information.

- The BSR is elected from C-BSRs based on rules. The election rules are as follows:
  - a The priorities of the C-BSRs are compared. The device with a higher priority is selected.
  - b If the priorities are the same, the IP addresses are compared. The device with a larger IP address is selected.
  - c The winner is elected as the BSR in the domain and periodically sends BSMs in the domain. A BSM contains the BSR IP address, RP-Set and hash mask information. The hash mask is used for hash calculation during C-RP election. In the hold time of a BSM, if other C-BSRs do not receive the BSM from the BSR, the BSR is considered unreachable and a new round of BSR election is initiated.
- To avoid fraud by an illegitimate BSR, a BSR range can be specified on all PIM devices in the domain so that the PIM devices ignore a BSM that is sent from an illegitimate BSR.
- To limit BSM flooding, you can configure a BSR border on an interface. Upon receiving BSMs, this interface discards the BSMs without forwarding them. This limits the BSM flooding.

2. Restrictions and Guidelines

- C-BSRs must be configured on one or multiple multicast devices.
- The multicast devices selected as C-BSRs must boast high performance. The C-RPs and C-BSRs can reside on the same or different multicast devices.
- You are advised to use the loopback interface as a C-BSR address.
- If multiple C-BSRs are configured, they can implement redundancy backup.
- You are advised to configure a valid BSR address range on all PIM devices in the domain.
- A BSR border must be configured on the interface between domains.

3. Prerequisites

- Enabling the PIM-SM Function.
- Before a valid BSR address range is configured on PIM devices, ensure that the corresponding ACL is created and specify a valid BSR range. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

a Enter the privileged EXEC mode.

privilege

b Enter the global configuration mode.

config-system terminal

c Configure C-BSRs and related parameters.

ip pim c-bsr *interface-type interface-number* [*hash-mask-length* [*priority-value*]]

No C-BSR is configured by default.

(2) (Optional) Configure a valid BSR address range on all PIM devices.

ip pim accept-bsr { **list** *acl-name* | **list** *acl-number* }

All BSMs are received by default.

(3) (Optional) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) (Optional) Configure a BSR border on the interface between PIM-SM domains.

ip pim bsr-boundary

No BSR border is configured by default.

If multiple domains exist, the BSR border must be configured on the interface between two domains.

1.6.6 Configuring C-RPs and Related Parameters

1. Overview

- After a multicast device is configured as a C-RP, the C-RP periodically sends an advertisement packet to the BSR in unicast mode. The packet includes the RP priority, advertisement packet hold time (greater than the interval of sending the advertisement packet), RP address, address of the served group, and prefix of the multicast address. Upon receiving the advertisement packet, the BSR collects the information in the packet as RP-Set in the advertisement packet hold time, encapsulates the information in a BSM, and sends the message to all PIM devices. Upon receiving the BSM from the BSR, the PIM devices in the domain apply the same algorithms for hash calculation to calculate the C-RP serving each multicast group. After the advertisement packet hold timer times out, if the BSR does not receive a next advertisement packet from the

C-RP, this C-RP is considered unreachable.

- To prevent fraud by an illegitimate C-RP, a C-RP range can be specified on the BSR. If an advertisement packet comes from an illegitimate C-RP, the packet is ignored.
- The BSR can determine whether to receive an advertisement packet with the prefix of the multicast address being 0 from a C-RP. When the prefix of the multicast address is 0, this C-RP serves all multicast groups.
- When receiving the BSM from the BSR, each PIM multicast device in the domain applies rules to select the RP. The RP election rules are as follows:
  a The address of the multicast group that a host joins is compared with the mask length of the group address range that the C-RP serves. The device with the longest mask is selected.
  b If the addresses are consistent with the mask length, the priorities of the C-RPs are compared. The device with the smallest priority value is selected.
  c If the priorities are consistent, hash values are calculated and compared. The device with the largest hash value is selected.
  d If the hash values are the same, the IP addresses of the C-RPs are compared. The device with the largest IP address is selected.

2. Restrictions and Guidelines

- C-RPs must be configured on one or multiple multicast devices.
- The multicast devices selected as C-RPs must boast high performance. The C-RPs and C-BSRs can reside on the same or different multicast devices.
- You are advised to use the loopback interface as a C-RP address.
- If multiple C-RPs are configured to serve the same group, they can implement redundancy backup.
- If multiple C-RPs are configured to serve different groups, they can implement load balancing.
- A valid C-RP range can be configured on the BSR.
- To specify a group range for C-RPs to serve, you can add the ACL option to the **ip pim c-rp** command. The group range is calculated based on the permit access control entry (ACE), rather than the deny ACE.

3. Prerequisites

- Enabling the PIM-SM Function.
- If the **group-list** parameter is used to limit the range of groups served by the RP, ensure that the corresponding ACL is created and specify a multicast group range for the RP to serve. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

- Configure C-RPs and related parameters.
  a Enter the privileged EXEC mode.
  privilege
  b Enter the global configuration mode.
  config-system terminal
  c Configure C-RPs.

ip pim c-rp *interface-type interface-number* [**interval** *interval* | **priority** *priority-value* | { **group-acl** *acl-name* | **group-acl** *acl-number* }] *

No C-RP is configured by default.

- (Optional) Configure the BSR to receive C-RP advertisement packets with the prefix of the multicast address being 0. This C-RP serves all the multicast groups.

  a Enter the privileged EXEC mode.

  privilege

  b Enter the global configuration mode.

  config-system terminal

  c Configure the BSR to receive advertisement packets from the C-RP that serves all multicast groups.

  ip pim accept-crp-with-null-group

  The function for the BSR to receive advertisement packets from the C-RP that serves all multicast groups is disabled by default.

  You are advised to enable this function on all C-BSRs.

- (Optional) Configure a valid C-RP range on the BSR.

  a Enter the privileged EXEC mode.

  privilege

  b Enter the global configuration mode.

  config-system terminal

  c Configure a valid C-RP range.

  ip pim accept-crp { **list** *acl-name* | **list** *acl-number* }

  The C-BSRs receive all external C-RP advertisement packets by default.

  You are advised to enable this function on all C-BSRs.

- (Optional) Configure to ignore RP priority on all PIM multicast devices and reselect an RP.

  a Enter the privileged EXEC mode.

  privilege

  b Enter the global configuration mode.

  config-system terminal

  c Configure to ignore the RP priority for RP election.

  ip pim ignore-rp-set-priority

  If the address of the multicast group that a host joins is consistent with the mask length of the group address range that the C-RPs serve, the RP with the highest priority is selected by default.

  You can configure to ignore C-RP priority on each multicast device.

1.6.7 Configuring Registration Parameters

1. Overview

When a multicast source sends multicast data, the data arrives at the source DR first. Upon receiving the multicast data, the source DR encapsulates the multicast data as a register message and sends the message to the RP. Related parameters of the register message are configured on the source DR and RP.

- You can configure the following parameters on the source DR:
  - RP reachability checking: Before sending a register message, the source DR determines whether the RP is reachable. If the RP is reachable, the message is sent. Otherwise, the message is not sent.
  - Limit on the rate of sending the register message: The rate of sending each register message in (S, G) status is limited. If multiple register messages in (S, G) status are sent from the same source, the rate of the register messages is limited to the product of *N* × Limit value.
  - Source address in the register message: The source address in the register message is the address of the DR interface connected to the multicast source by default. If a security policy is configured on the RP to filter out this address, the RP does not receive register messages from this source DR. In this case, you can specify a reachable source address as the source address of the register message.
  - Register suppression time: When the RP receives multicast packets sent by the multicast source via the SPT, the RP sends a register-stop message to the source DR. Within the register- suppression time, the source DR stops encapsulating the register message and sends multicast packets to the RP via the SPT. After the register suppression timer times out, if the source DR does not receive another register-stop message from the RP, the source DR continues to encapsulate the register message and send the message to the RP.
  - Null message detection time: Before the register suppression timer times out, the RP receives a null message from the source DR, refreshes the local (S, G) entries, and sends a register-stop message to the source DR so that the source DR refreshes the register suppression timer. Otherwise, the source DR continues to encapsulate the register message and send multicast packets to the RP in the form of the register message.
- You can configure the following parameters on the RP:
  - (S, G) address range of source: Provide multicast services for hosts in the permitted multicast group in the ASM model. After this parameter is configured, the RP replies a register-stop message upon receiving data from an unauthorized source.
  - Length of register message checksum: Adjust the calculation method of the register message checksum and calculate the checksum of the entire PIM protocol packets (including encapsulated multicast packets) or the checksum of PIM headers of separate register messages.
  - Register message decapsulation and delivery to downlink interface: Configure this parameter on the RP to decapsulate the received register message and forward the multicast packets in the register message.
  - Register message (S, G) entry timeout period: Configure this parameter to configure the timeout period of (S, G) entries. The (S, G) entries age if no packet is received within the register message timeout period.

2. Restrictions and Guidelines

- The source address in the specified register message must be reachable in unicast mode. You are advised to use the loopback interface of the source DR as the source address of the register message.
- If the **ip pim rp-register-kat** command is not configured, modifying the register suppression time on the RP changes the (S, G) entry timeout period.
- Configuring a limit to the register message rate reduces the load of the source DR and RP. Only register messages under the limit are sent.
- The register-probe time cannot be greater than a half of the register suppression time. Otherwise, the configuration failed and an alarm is generated.
- The sum of the three times of register suppression time and the register-probe time does not exceed 65,535. Otherwise, the configuration failed and an alarm is generated.

3. Prerequisites

- Enabling the PIM-SM Function.
- Before an (S, G) address range is configured for the source, if the **list** parameter is specified, ensure that the corresponding ACL is created and specify an (S, G) address range for the source. For more information about ACL configuration, see *Configuring ACL*.
- Before an (S, G) address range is configured for the source, if the **route-map** parameter is specified, ensure that the corresponding route map is created and specify an (S, G) address range for the source. For more information about route map configuration, see *Configuring Route Policies*.
- Before the register message checksum calculation is applied to entire packets, if the **group-list** parameter is specified, ensure that the corresponding ACL is created and specify the register message checksum calculation to apply to the entire packets in a multicast group address range. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configure registration parameters on the source DR.
  - a Enter the privileged EXEC mode.

    privilege
  - b Enter the global configuration mode.

    config-system terminal
  - c Enable RP reachability checking on the source DR.

    ip pim register-rp-reachability

    The RP reachability checking function is disabled by default.
  - d Limit the rate of sending register messages on the source DR.

    ip pim limit-register-rate *rate*

    The sending rate of register messages is not limited by default.
  - e Configure a source address in the register messages on the source DR.

    ip pim register-source-addr { *ipv4-local-address* | *interface-type interface-number* }

The source IP address in the register messages is the address of the DR interface connected to the source by default.

f Configure the register suppression time on the source DR.

ip pim register-suppression *suppression-time*

The default register suppression time is **60** seconds.

g Configure the null message detection time on the source DR.

ip pim probe-interval *probe-interval*

The default register-probe time is **5** seconds.

- Configure registration parameters on the RP.

a Enter the privileged EXEC mode.

privilege

b Enter the global configuration mode.

config-system terminal

c Configure the (S, G) address range for the source on the RP.

ip pim restricted-register { { **list** *acl-name* | **list** *acl-number* } | **route-map** *route-map-name* } *

The (S, G) address range of register messages is not limited by default. The RP receives register messages of all (S, G) addresses.

d Enable register message checksum calculation to be applied to the entire packets on the RP.

ip pim register-checksum-wholepkt [{ **group-acl** *acl-name* | **group-acl** *acl-number* }]

By default, the register message checksum of headers of only PIM packets and register messages, rather than the entire packets, is calculated.

If the **group-acl** parameter is not specified, this configuration applies to all group addresses.

e Enable the RP to decapsulate the received register messages and forward the multicast packets in the received register messages on the RP.

ip pim register-decapsulate-forward

The function for the RP to decapsulate the register messages and forward the multicast packets is disabled by default.

The register message decapsulation and multicast packet forwarding function is implemented by the corresponding software. If there are too many register messages to be decapsulated and forwarded, the CPU is overloaded. Therefore, you are not advised to enable this function.

f Configure the timeout period for the (S, G) entries created upon receiving the register message on the RP.

ip pim rp-register-kat *interval*

By default, the timeout period for the (S, G) entries is the sum of three times of the register suppression time and the register-probe time.

1.6.8 Configuring the Last Hop Device to Switch over from the RPT to SPT

1. Overview

If the multicast traffic in a network is heavy, the RP easily gets overloaded and then faulty. To relieve the RP load, you can initiate SPT switchover through the member DR. You can specify multicast groups to perform SPT switchover.

2. Prerequisites

- Enabling the PIM-SM Function.
- Before an address range of a group is configured for SPT switchover, ensure that the corresponding ACL is created and specify a multicast group range for SPT switchover. For more information about ACL configuration, see *Configuring ACL*.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the SPT switchover function.

ip pim spt-switching [{ **group-acl** *acl-name* | **group-acl** *acl-number* }]

The SPT switchover function is disabled by default.

If the **group-acl** parameter is not specified, all groups support SPT switchover.

1.7 Configuring PIM-SM in the SSM Model

1.7.1 Overview

The PIM-SM function in the SSM model can provide specified source services for hosts so that the hosts can determine to receive or reject multicast data of specified sources based on needs.

1.7.2 Restrictions and Guidelines

- If you require a PIM network to support the multicast service in the SSM model, the SSM function must be enabled.
- The SSM function must be enabled on each multicast device.
- The address range of SSM groups configured on all multicast devices must be consistent.
- IGMPv3 or SSM mapping must be enabled.

1.7.3 Prerequisites

- In the multicast network, all nodes are reachable via IPv4 unicast routes.
- Enabling the PIM-SM Function.
- Before an SSM group range is configured using an ACL, ensure that the corresponding ACL is created and specify an SSM multicast group range. For more information about ACL configuration, see *Configuring ACL*.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the SSM function.

ip pim enable-ssm { **default** | **range** { *acl-name* | *acl-number* } }

The SSM function is disabled by default.

1.8 Configuring PIM Neighbor Parameters

1.8.1 Overview

PIM multicast devices transmit hello messages to discover neighbors, coordinate protocol parameters and maintain neighbor relationships.

1.8.2 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Neighbor Message Time Parameters
- Configuring Neighbor Tracking
- Configuring Neighbor Filtering

1.8.3 Prerequisites

- In the multicast network, all nodes are reachable via IPv4 unicast routes.
- Enabling the PIM-SM Function.

1.8.4 Configuring the Neighbor Message Time Parameters

1. Overview

The neighbor message time parameters include hello message sending interval and hello message sending delay.

- The hello message sending interval can be configured, and the hello message hold time is 3.5 times the hello message sending interval. If no new hello message is received within the hello message hold time, the neighbor is considered unreachable.
- When the PIM interface is enabled or detects a new neighbor, random time is generated and it is referred to as hello message sending delay. Within the delay time, the interface sends hello messages out.

2. Restrictions and Guidelines

If the hello message hold time is greater than 65,535 seconds, the hello message sending interval is automatically set to 18,725 seconds.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the neighbor message time parameters. Select at least one of them to configure.

- Configure the hello message sending interval.

  ip pim query-period *hello-interval*

  The hello message is sent at an interval of **30** seconds by default.
- Configure the hello message sending delay.

  ip pim triggered-hello-delay *delay*

  The hello message sending delay is **5** seconds by default.

1.8.5 Configuring Neighbor Tracking

1. Overview

After the suppression capability of an interface is enabled, when a multicast device plans to send a join packet to an uplink multicast device but it receives a join packet sent from the neighbor to the uplink multicast device, this local multicast device suppresses its own join packet. If the suppression capability of the interface is disabled, the join packet can be sent. When the suppression capability of downlink hosts is disabled, an uplink device can determine the number of the downlink hosts based on the quantity of received join packets. This is neighbor tracking.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.

interface vlan *interface-number*

- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Enable the neighbor tracking function.

ip pim neighbor-tracking

The neighbor tracking function is disabled by default.

1.8.6 Configuring Neighbor Filtering

1. Overview

The neighbor filtering function can protect neighborhood. Controlling neighbors can strengthen PIM network security and limit the valid address range of neighbors. If a neighbor is filtered out based on an access filtering list, PIM-SM does not create peer relationship with the neighbor or stops the peer relationship with this neighbor.

2. Prerequisites

Before an access filtering list is configured, ensure that the corresponding ACL is created and specify a valid neighbor address range. For more information about ACL configuration, see *Configuring ACL*.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Enable the neighbor filtering function.

ip pim peering-filter { *acl-name* | *acl-number* }

The neighbor filtering function is disabled by default.

1.9 Configuring DR Priority

1.9.1 Overview

In a network segment shared by multicast sources and group members, multiple PIM multicast devices exist. The PIM multicast devices elect a DR based on neighbor messages. A device with the highest priority is

selected. If the priorities are the same or some PIM devices do not support the DR priority function, the IP addresses are compared and the PIM multicast device with the largest IP address is selected. The selected PIM device functions as a DR, transmits protocol packets between the sources and members, and forwards multicast packets.

1.9.2 Prerequisites

- In the multicast network, all nodes are reachable via IPv4 unicast routes.
- Enabling the PIM-SM Function.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure a DR priority in hello messages.

ip pim dr-elected-priority *priority-value*

The default DR priority in hello messages is **1**.

1.10 Configuring Parameters of the Join/Prune Packets

1.10.1 Overview

A device sends a join packet to request an uplink device to forward multicast packets and sends a prune packet to request the uplink device to stop forwarding multicast packets. The request route is referred to as an RPT or SPT.

1.10.2 Restrictions and Guidelines

- The network administrator must ensure that the prune override interval is smaller than the join-prune packet hold time. Otherwise, a short interrupt may occur.
- When the PIM multicast device receives a prune message from an uplink interface, there are other downlink devices existent in the shared network segment. If this PIM multicast device still needs to receive multicast data, the PIM multicast device must send a prune override message to the uplink device within the override interval.

1.10.3 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Join/Prune Packet Sending Interval
- Configuring the Prune Delay

1.10.4 Prerequisites

Enabling the PIM-SM Function.

1.10.5 Configuring Join/Prune Packet Sending Interval

1. Overview

A PIM device periodically sends the join/prune packet to an uplink device to update the forwarding status. The join packet is used to request data forwarding and the prune packet is used to stop data forwarding. Upon receiving the join/prune packet, the uplink device starts the join/prune packet hold time timer.

- If a join packet hold time timer times out, the PIM device is suppressed to forward multicast packets of the corresponding multicast group through the downlink interface.
- If a prune packet hold time timer times, the PIM device is restored to forward the multicast packets of the corresponding multicast group through the downlink interface.

2. Restrictions and Guidelines

The join/prune packet sending interval must be smaller than the join/prune packet hold time. Generally, the join/prune packet hold time is 3.5 times the join/prune packet sending interval.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the join/prune packet sending interval.

ip pim jp-timer *jp-timer-interval*

The join/prune packet is sent at an interval of **60** seconds by default.

1.10.6 Configuring the Prune Delay

1. Overview

Upon receiving a prune packet from a downlink device, the multicast device does not perform prune immediately and it waits for a period of time. This period of time is divided into two parts: The part from the time when the multicast device receives a prune message to the time when the multicast device sends the prune message to the uplink device is referred to as the prune propagation delay; the part from the time when the PIM device receives a prune packet to the time when the device continues to forward the multicast packets to a downlink device is referred to as the override interval. The period from the time when the multicast device receives a prune message to the time when the prune action is performed is the sum of the propagation delay and the override interval.

2. Restrictions and Guidelines

In the period from the time when the multicast device receives a prune message to the time when the prune action is performed, if the PIM device receives a prune override message from the downlink interface, the PIM device cancels pruning.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the prune message propagation delay.

ip pim propagation-delay *propagation-delay*

The default propagation delay of an interface is **500** ms.

(5) Configure the prune override interval.

ip pim override-interval *override-interval*

The default override interval is **2500** ms.

1.11 Enabling PIM-SM on the Super VLAN Interface

1. Overview

In most scenarios of a PIM network, the PIM-SM protocol does not need to be enabled on a super VLAN interface. A super VLAN interface is connected to many sub VLANs. If the PIM-SM protocol is enabled on the super VLAN interface, the device replicates and sends a multicast protocol packet to all the sub VLANs, which easily surpasses the processing capability of the device and causes packet loss even protocol flapping. In some scenarios, the PIM-SM protocol must be enabled on the super VLAN interface. You can configure the command to enable the protocol packets to be sent to the specified sub VLANs or all sub VLANs. If the packets are sent to all VLANs, protocol flapping may occur.

2. Restrictions and Guidelines

- This function must be enabled on the super VLAN interface.
- If you enable protocol packets to be sent to all sub VLANs, the packets may surpass the processing capability of the device, causing protocol flapping.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the SVI configuration mode.

interface vlan *interface-number*

(4) Enable PIM-SM protocol packets to be sent to specified sub VLANs.

ip pim sparse-mode subvlan [*subvlan-id* | **all**]

The PIM-SM function is disabled on a super VLAN interface by default.

1.12 Enabling PIM BFD Correlation

1. Overview

In some shared multicast networks, PIM neighbor status change triggers re-initiation of some mechanisms, for example, DR election mechanism. Generally, a PIM neighbor triggers a new round of election after the neighborhood times out, causing multicast data interruption. PIM bidirectional forwarding detection (BFD) correlation can quickly detect link status and neighbor faults in a shared network segment and trigger a new round of DR election. This reduces multicast data transmission interrupt time and ensures reliability of the multicast network.

2. Restrictions and Guidelines

- If DR election or assertion election is required in a multicast network, you are advised to enable PIM-SM BFD correlation.
- The PIM BFD function must be enabled on the interconnection interface of the multicast devices.
- PIM interfaces must be L3 interfaces, including: Layer 3 Ethernet interface, Layer 3 link aggregation, SVI, loopback interface, VXLAN routed interface.

3. Prerequisites

- In the network, all nodes are reachable via IPv4 unicast routes.
- Enabling the PIM-SM Function.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.

interface aggregateport *interface-number*

- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Enable PIM BFD correlation.

ip pim bfd

PIM BFD correlation is disabled by default.

1.13 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

Caution

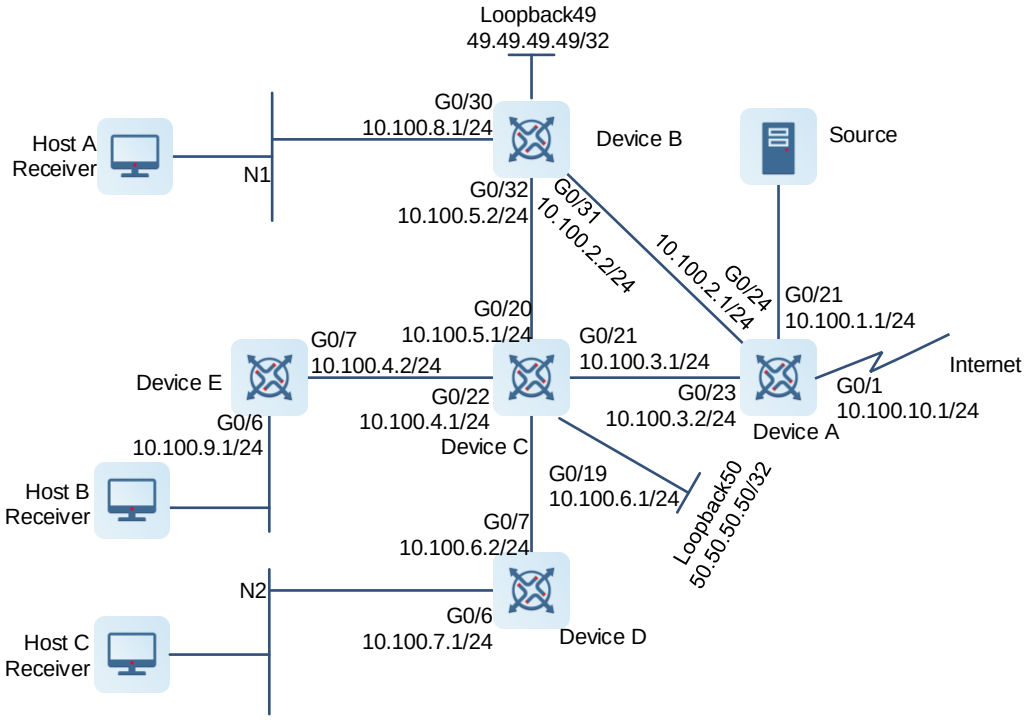
Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
cleanup ip mroute { *ipv4-group-address* [*ipv4-source-address*] | ***** }	Clears multicast routing entries.
cleanup ip mroute statistics { *ipv4-group-address* [*ipv4-source-address*] | ***** }	Clears statistical information about multicast routing.
cleanup ip pim-info sparse-mode bsr rp-set *	Clears dynamic RP information.
cleanup ip pim-info sparse-mode track	Clears statistical information about PIM-SM protocol packets.
display ip pim-info sparse-mode bsr-router	Displays details about the BSR.
display ip pim-info sparse-mode interface [*interface-type interface-number*] [**detail**]	Displays PIM-SM information of an interface.
display ip pim-info sparse-mode local-members [*interface-type interface-number*]	Displays local IGMP information about a PIM-SM interface.
display ip pim-info sparse-mode mroute [*group-or-source-address* [*group-or-source-address*]]	Displays information about the PIM-SM multicast routing table.
display ip pim-info sparse-mode mroute [*ipv4-group-or-source-address* [*ipv4-group-or-source-address*]]	Displays PIM-SM neighbor information.

Command	Purpose
display ip pim-info sparse-mode nexthop	Displays the PIM-SM next hop information in an NSM.
display ip pim-info sparse-mode rp-group-hash *ipv4-group-address*	Displays RP information corresponding to a group address.
display ip pim-info sparse-mode rp mapping	Displays all RPs and the groups served by the RPs.
display ip pim-info sparse-mode track	Displays the number of PIM packets sent and received since the statistic start time.

1.14 Configuration Examples



1.14.1 Configuring Basic Functions of PIM-SM in the ASM Model

1. Requirements

As shown in Figure 1-5, the internal network is connected to the Internet. The PIM-SM protocol is configured on each multicast device to provide ASM multicast services for hosts in networks N1 and N2 so that hosts joining a multicast group can receive multicast data destined to this multicast group from any multicast source, including video-on-demand information.

2. Topology

Figure 1-5 PIM-SM Multicast Network Topology in the ASM Model

3. Notes

- Configure IP addresses and unicast routing protocols for multicast devices. The PIM routing protocol in a multicast domain depends on unicast routing protocols. Normal communication of unicast routing lays a foundation of multicast routing. Ensure that each PIM node is reachable via unicast routes.
- Enable the multicast function on all multicast devices. Enabling the multicast function is a prerequisite of PIM-SM configuration.
- Enable the basic functions of PIM-SM on all interfaces of the multicast devices. The other functions of PIM-SM can be enabled only after the basic functions of PIM-SM are enabled.
- Enable the IGMP function on the interface connected to hosts so that the hosts can join or leave a multicast group by sending IGMP messages. The multicast devices acting as leaf nodes maintain group membership based on the IGMP protocol.
- Configure RPs. In the PIM-SM network in the ASM model, the RP is a transitional station for forwarding multicast data. It is recommended that the multicast device with many traffic flows be configured as an RP, for example, device C in Figure 1-5.
- Configure a BSR border on the interface connected to the Internet. BSMs must be transmitted in the PIM-SM domain within the border to improve the multicast controllability.

4. Procedure

(1) Configure IP addresses and enable unicast routing protocols on interfaces of different devices.

Configure IPv4 addresses on interfaces of device A, and configure the OSPF protocol to implement internetworking.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitEthernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/1)# ip address 10.100.10.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
DeviceA(cfg)# interface gigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/21)# ip address 10.100.1.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)#interface gigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/23)# ip address 10.100.3.2 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
DeviceA(cfg)# interface gigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/24)# ip address 10.100.2.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
DeviceA(cfg)# router-protocol ospf 49
DeviceA(cfg-router)# network-advertise 10.100.1.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.10.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.2.0 0.0.0.255 area 0
```

```
DeviceA(cfg-router)# network-advertise 10.100.3.0 0.0.0.255 area 0
DeviceA(cfg-router)# exit
```

Configure IPv4 addresses on interfaces of device B, and configure the OSPF protocol to implement internetworking.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/30)# ip address 10.100.8.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/31)# ip address 10.100.2.2 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/32)# ip address 10.100.5.2 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface loopback 49
DeviceB(cfg-if-Loopback 49)# ip address 49.49.49.49 255.255.255.255
DeviceB(cfg-if-Loopback 49)# exit
DeviceB(cfg)# router-protocol ospf 49
DeviceB(cfg-router)# network-advertise 10.100.8.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.2.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 49.49.49.49 0.0.0.0 area 0
DeviceB(cfg-router)# exit
```

Configure IPv4 addresses on interfaces of device C, and configure the OSPF protocol to implement internetworking.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface GigabitEthernet 0/19
DeviceC(cfg-if-GigabitEthernet 0/19)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/19)# ip address 10.100.6.1 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/19)# exit
DeviceC(cfg)#interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/20)# ip address 10.100.5.1 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/21)# ip address 10.100.3.1 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface GigabitEthernet 0/22
DeviceC(cfg-if-GigabitEthernet 0/22)# unset switch-port
```

```
DeviceC(cfg-if-GigabitEthernet 0/22)# ip address 10.100.4.1 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/22)# exit
DeviceC(cfg)# interface loopback 50
DeviceC(cfg-if-Loopback 50)# ip address 50.50.50.50 255.255.255.255
DeviceC(cfg-if-Loopback 50)# exit
DeviceC(cfg)# router-protocol ospf 49
DeviceC(cfg-router)# network-advertise 10.100.6.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 10.100.3.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 10.100.4.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 50.50.50.50 0.0.0.0 area 0
DeviceC(cfg-router)# exit
```

Configure IPv4 addresses on interfaces of device D, and configure the OSPF protocol to implement internetworking.

```
DeviceD> privilege
DeviceD# config-system terminal
DeviceD(cfg)# interface GigabitEthernet 0/6
DeviceD(cfg-if-GigabitEthernet 0/6)# unset switch-port
DeviceD(cfg-if-GigabitEthernet 0/6)# ip address 10.100.7.1 255.255.255.0
DeviceD(cfg-if-GigabitEthernet 0/6)# exit
DeviceD(cfg)# interface GigabitEthernet 0/7
DeviceD(cfg-if-GigabitEthernet 0/7)# unset switch-port
DeviceD(cfg-if-GigabitEthernet 0/7)# ip address 10.100.6.2 255.255.255.0
DeviceD(cfg-if-GigabitEthernet 0/7)# exit
DeviceD(cfg)# router-protocol ospf 49
DeviceD(cfg-router)# network-advertise 10.100.6.0 0.0.0.255 area 0
DeviceD(cfg-router)# network-advertise 10.100.7.0 0.0.0.255 area 0
DeviceD(cfg-router)# exit
```

Configure IPv4 addresses on interfaces of device E, and configure the OSPF protocol to implement internetworking.

```
DeviceE> privilege
DeviceE# config-system terminal
DeviceE(cfg)# interface GigabitEthernet 0/6
DeviceE(cfg-if-GigabitEthernet 0/6)# unset switch-port
DeviceE(cfg-if-GigabitEthernet 0/6)# ip address 10.100.9.1 255.255.255.0
DeviceE(cfg-if-GigabitEthernet 0/6)# interface GigabitEthernet 0/7
DeviceE(cfg-if-GigabitEthernet 0/7)# unset switch-port
DeviceE(cfg-if-GigabitEthernet 0/7)# ip address 10.100.4.2 255.255.255.0
DeviceE(cfg-if-GigabitEthernet 0/7)# exit
DeviceE(cfg)# router-protocol ospf 49
DeviceE(cfg-router)# network-advertise 10.100.9.0 0.0.0.255 area 0
DeviceE(cfg-router)# network-advertise 10.100.4.0 0.0.0.255 area 0
DeviceE(cfg-router)# exit
```

(2) Enable the multicast and PIM-SM functions on all multicast devices, and enable the IGMP function on all multicast devices connected to hosts.

Enable the multicast and PIM-SM functions on device A.

```
DeviceA(cfg)# ip mrouting-enable
DeviceA(cfg)# interface gigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface gigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
DeviceA(cfg)# interface gigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
```

Enable the multicast, PIM-SM, and IGMP functions on device B.

```
DeviceB(cfg)# ip mrouting-enable
DeviceB(cfg)# interface gigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface gigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface gigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface loopback 49
DeviceB(cfg-if-Loopback 49)# ip pim sparse-mode
DeviceB(cfg-if-Loopback 49)# exit
```

Enable the multicast and PIM-SM functions on device C.

```
DeviceC(cfg)# ip mrouting-enable
DeviceC(cfg)# interface gigabitEthernet 0/19
DeviceC(cfg-if-GigabitEthernet 0/19)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/19)# exit
DeviceC(cfg)# interface gigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface gigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface gigabitEthernet 0/22
DeviceC(cfg-if-GigabitEthernet 0/22)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/22)# exit
DeviceC(cfg)# interface loopback 50
DeviceC(cfg-if-Loopback 50)# ip pim sparse-mode
DeviceC(cfg-if-Loopback 50)# exit
```

Enable the multicast, PIM-SM, and IGMP functions on device D.

```
DeviceD(cfg)# ip mrouting-enable
```

```
DeviceD(cfg)# interface gigabitEthernet 0/6
DeviceD(cfg-if-GigabitEthernet 0/6)# ip pim sparse-mode
DeviceD(cfg-if-GigabitEthernet 0/6)# exit
DeviceD(cfg)# interface gigabitEthernet 0/7
DeviceD(cfg-if-GigabitEthernet 0/7)# ip pim sparse-mode
DeviceD(cfg-if-GigabitEthernet 0/7)# exit
```

Enable the multicast, PIM-SM, and IGMP functions on device E.

```
DeviceE(cfg)# ip mrouting-enable
DeviceE(cfg)# interface gigabitEthernet 0/6
DeviceE(cfg-if-GigabitEthernet 0/6)# ip pim sparse-mode
DeviceE(cfg-if-GigabitEthernet 0/6)# exit
DeviceE(cfg)# interface gigabitEthernet 0/7
DeviceE(cfg-if-GigabitEthernet 0/7)# ip pim sparse-mode
DeviceE(cfg-if-GigabitEthernet 0/7)# exit
```

(3) Configure RPs.

Note

There are two methods to configure RPs: dynamic RPs and static RPs. You can configure either or both types of RPs. If static and dynamic RPs are available at the same time, the dynamic RPs are preferred by default.

Configure dynamic RPs. One or multiple multicast devices in the PIM-SM domain must be configured as C-RPs and C-BSRs. In this example, device B and device C are configured as C-RP and C-BSR. The address range of the served groups of the RP, as well as the interfaces of the C-RP and C-BSR are configured on device B and device C. The loopback interface is configured as the interface of the C-RP and C-BSR.

Configure C-RP and C-BSR and address range of the served groups of the RP on device B.

```
DeviceB(cfg)# ip pim c-bsr loopback 49
DeviceB(cfg)# ip access-control-list standard 49
DeviceB(cfg-stdacl)# permit 224.0.0.0 0.255.255.255
DeviceB(cfg)# ip pim c-rp loopback 49 group-list 49
```

Configure C-RP and C-BSR and address range of the served groups of the RP on device C.

```
DeviceC(cfg)# ip pim c-bsr loopback 50
DeviceC(cfg)# ip access-control-list standard 50
DeviceC(cfg-stdacl)# permit 225.0.0.0 0.255.255.255
DeviceC(cfg-stdacl)# exit
DeviceC(cfg)# ip pim c-rp loopback 50 group-acl-list 50
```

Configure static RPs. The addresses of static RPs must be specified on all multicast devices.

Configure a static RP on device A.

```
DeviceA(cfg)# ip pim static-rp-addr 50.50.50.50
```

Configure a static RP on device B.

```
DeviceB(cfg)# ip pim static-rp-addr 50.50.50.50
```

Configure a static RP on device C.

```
DeviceC(cfg)# ip pim static-rp-addr 50.50.50.50
```

Configure a static RP on device D.

```
DeviceD(cfg)# ip pim static-rp-addr 50.50.50.50
```

Configure a static RP on device E.

```
DeviceE(cfg)# ip pim static-rp-addr 50.50.50.50
```

(4) Configure a BSR border on the device A interface connected to the Internet.

```
DeviceA(cfg-if-GigabitEthernet 0/1)# ip pim bsr-boundary
```

5. Verification

(1) Run the **display ip pim-info sparse-mode interface** command to display the PIM-SM running information on the interfaces.

The PIM-SM running information on the interface of device A is as follows:

```
DeviceA# display ip pim-info sparse-mode interface
Address          Interface                    VIFindex Ver/Mode Nbr-Count DR-Prior
DR
10.100.1.1       GigabitEthernet 0/21         1        v2/S     0         1
10.100.1.1
10.100.3.2       GigabitEthernet 0/23         2        v2/S     1         1
10.100.3.2
10.100.2.1       GigabitEthernet 0/24         3        v2/S     0         1
10.100.2.1
DeviceA#
```

The PIM-SM running information on the interface of device B is as follows:

```
DeviceB# display ip pim-info sparse-mode interface
Address          Interface                    VIFindex Ver/Mode Nbr-Count DR-Prior
DR
10.100.8.1       GigabitEthernet 0/30         1        v2/S     0         1
10.100.8.1
10.100.2.2       GigabitEthernet 0/31         4        v2/S     1         1
10.100.2.2
10.100.5.2       GigabitEthernet 0/32         2        v2/S     1         1
10.100.5.2
49.49.49.49      Loopback 49                  3        v2/S     0         1
49.49.49.49
DeviceB#
```

The PIM-SM running information on the interface of device C is as follows:

```
DeviceC# display ip pim-info sparse-mode interface
Address          Interface                    VIFindex Ver/Mode Nbr-Count DR-Prior
DR
10.100.6.1       GigabitEthernet 0/19         1        v2/S     1         1
10.100.6.2
10.100.5.1       GigabitEthernet 0/20         2        v2/S     1         1
10.100.5.2
```

```
10.100.3.1      GigabitEthernet 0/21          3          v2/S    1          1
10.100.3.2
10.100.4.1      GigabitEthernet 0/22          4          v2/S    1          1
10.100.4.2
50.50.50.50     Loopback 50                   5          v2/S    0          1
50.50.50.50
DeviceC#
```

The PIM-SM running information on the interface of device D is as follows:

```
DeviceD# display ip pim-info sparse-mode interface
Address          Interface                    VIFindex Ver/Mode Nbr-Count DR-Prior
DR
10.100.7.1       GigabitEthernet 0/6          1        v2/S     0         1
10.100.7.1
10.100.6.2       GigabitEthernet 0/7          2        v2/S     1         1
10.100.6.2
DeviceD#
```

The PIM-SM running information on the interface of device E is as follows:

```
DeviceE# display ip pim-info sparse-mode interface
Address          Interface                    VIFindex Ver/Mode Nbr-Count DR-Prior
DR
10.100.9.1       GigabitEthernet 0/6          1        v2/S     0         1
10.100.9.1
10.100.4.2       GigabitEthernet 0/7          2        v2/S     1         1
10.100.4.2
DeviceE#
```

(2) Run the **display ip pim-info sparse-mode bsr-router** command to display the election information of the BSRs.

The election information on device A is as follows:

```
DeviceA# display ip pim-info sparse-mode bsr-router
PIMv2 Bootstrap information
  BSR address: 50.50.50.50
  Uptime:       00:48:33, BSR Priority: 64, Hash mask length: 10
  Expires:      00:01:32
  Role: Non-candidate BSR     Priority: 0, Hash mask length: 10
  State: Accept Preferred
DeviceA#
```

The election information on device B is as follows:

```
DeviceB# display ip pim-info sparse-mode bsr-router
PIMv2 Bootstrap information
  BSR address: 50.50.50.50
  Uptime:       00:49:26, BSR Priority: 64, Hash mask length: 10
  Expires:      00:01:39
  Role: Candidate BSR     Priority: 64, Hash mask length: 10
  State: Candidate BSR
```

```
  Candidate RP: 49.49.49.49(Loopback 49)
    Advertisement interval 60 seconds
    Next Cand_RP_advertisement in 00:00:19
DeviceB#
```

The election information on device C is as follows:

```
DeviceC# display ip pim-info sparse-mode bsr-router
PIMv2 Bootstrap information
This system is the Bootstrap Router (BSR)
  BSR address: 50.50.50.50
  Uptime:        00:51:04, BSR Priority: 64, Hash mask length: 10
  Next bootstrap message in 00:00:56
  Role: Candidate BSR     Priority: 64, Hash mask length: 10
  State: Elected BSR
DeviceC#
```

The election information on device D is as follows:

```
DeviceD# display ip pim-info sparse-mode bsr-router
PIMv2 Bootstrap information
  BSR address: 50.50.50.50
  Uptime:        00:51:38, BSR Priority: 64, Hash mask length: 10
  Expires:       00:01:28
  Role: Non-candidate BSR     Priority: 0, Hash mask length: 10
  State: Accept Preferred
DeviceD#
```

The election information on device E is as follows:

```
DeviceE# display ip pim-info sparse-mode bsr-router
PIMv2 Bootstrap information
  BSR address: 50.50.50.50
  Uptime:        00:52:24, BSR Priority: 64, Hash mask length: 10
  Expires:       00:01:42
  Role: Non-candidate BSR     Priority: 0, Hash mask length: 10
  State: Accept Preferred
DeviceE#
```

(3) Run the **display ip pim-info sparse-mode rp mapping** command to display the RP information on the multicast devices.

The RP information on device A is as follows:

```
DeviceA# display ip pim-info sparse-mode rp mapping
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/8
  RP: 49.49.49.49(Not self)
    Info source: 50.50.50.50, via bootstrap, priority 192
          Uptime: 00:55:25, expires: 00:01:52
Group(s): 225.0.0.0/8
  RP: 50.50.50.50(Not self)
```

```
    Info source: 50.50.50.50, via bootstrap, priority 192
        Uptime: 00:00:48, expires: 00:01:52
Group(s): 224.0.0.0/4, Static
    RP: 50.50.50.50(Not self) , Static
        Uptime: 00:50:13
DeviceA#
```

The RP information on device B is as follows:

```
DeviceB# display ip pim-info sparse-mode rp mapping
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/8
  RP: 49.49.49.49(Self)
    Info source: 50.50.50.50, via bootstrap, priority 192
        Uptime: 00:56:12, expires: 00:02:05
Group(s): 225.0.0.0/8
  RP: 50.50.50.50(Not self)
    Info source: 50.50.50.50, via bootstrap, priority 192
        Uptime: 00:01:35, expires: 00:02:05
Group(s): 224.0.0.0/4, Static
    RP: 50.50.50.50(Not self) , Static
        Uptime: 00:49:36
DeviceB#
```

The RP information on device C is as follows:

```
DeviceC# display ip pim-info sparse-mode rp mapping
PIM Group-to-RP Mappings
This system is the Bootstrap Router (v2)
Group(s): 224.0.0.0/8
  RP: 49.49.49.49(Not self)
    Info source: 49.49.49.49, via bootstrap, priority 192
        Uptime: 00:56:17, expires: 00:02:13
Group(s): 225.0.0.0/8
  RP: 50.50.50.50(Self)
    Info source: 50.50.50.50, via bootstrap, priority 192
        Uptime: 00:01:40, expires: 00:01:50
Group(s): 224.0.0.0/4, Static
    RP: 50.50.50.50(Self) , Static
        Uptime: 00:49:39
DeviceC#
```

The RP information on device D is as follows:

```
DeviceD# display ip pim-info sparse-mode rp mapping
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/8
  RP: 49.49.49.49(Not self)
    Info source: 50.50.50.50, via bootstrap, priority 192
        Uptime: 00:56:22, expires: 00:01:55
Group(s): 225.0.0.0/8
```

```
  RP: 50.50.50.50(Not self)
    Info source: 50.50.50.50, via bootstrap, priority 192
          Uptime: 00:01:45, expires: 00:01:55
Group(s): 224.0.0.0/4, Static
    RP: 50.50.50.50(Not self) , Static
          Uptime: 00:49:40
DeviceD#
```

The RP information on device E is as follows:

```
DeviceE# display ip pim-info sparse-mode rp mapping
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/8
  RP: 49.49.49.49(Not self)
    Info source: 50.50.50.50, via bootstrap, priority 192
          Uptime: 00:56:27, expires: 00:01:50
Group(s): 225.0.0.0/8
  RP: 50.50.50.50(Not self)
    Info source: 50.50.50.50, via bootstrap, priority 192
          Uptime: 00:01:50, expires: 00:01:50
Group(s): 224.0.0.0/4, Static
    RP: 50.50.50.50(Not self) , Static
          Uptime: 00:49:43
DeviceE#
```

(4) Run the **display ip pim-info sparse-mode mroute** command to display the multicast routing tables of PIM-SM. The multicast source (10.100.1.2/24) sends traffic to the multicast groups (225.0.0.1/24) and (224.0.1.1/24). Host A joins the multicast group (225.0.0.1), and host B joins the multicast group (224.0.1.1).

The routing table information on device A is as follows:

```
DeviceA# display ip pim-info sparse-mode mroute
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 0
(S,G) Entries: 2
(S,G,rpt) Entries: 2
FCR Entries: 0
REG Entries: 2

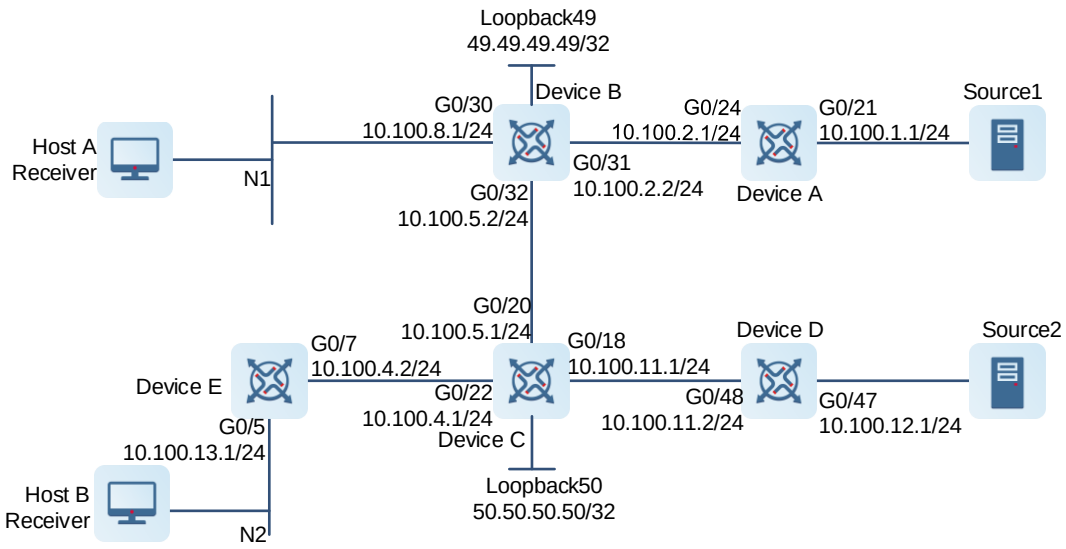
7. Common Errors

- The multicast routing function is not enabled on multicast devices.
- The multicast function is not enabled on any interface.
- No BSR border is configured between PIM-SM domains.
- No RP is configured.
- No static RP is configured on a multicast device, or the configured static RP on this multicast device is not consistent with the configuration on other multicast devices.
- C-RPs are configured, but no C-BSR is configured.
- Static RP, C-RP or C-BSR is unreachable via unicast routes.



1.14.2 Configuring Basic Functions of PIM-SM in the SSM Model

1. Requirements

As shown in Figure 1-6, the PIM-SM protocol is enabled on multicast devices to provide SSM services for hosts in N1 and N2 so that the hosts can receive multicast data from specified multicast sources to the multicast group that the hosts join, for example, video-on-demand.

2. Topology

Figure 1-6 PIM-SM Multicast Network Topology in the SSM Model

3. Notes

- Configure IP addresses and unicast routing protocols for multicast devices. The PIM routing protocol in a multicast domain depends on unicast routing protocols. Normal communication of unicast routing lays a foundation of multicast routing. Ensure that each PIM node is reachable via unicast routes.
- Enable the multicast function on all multicast devices. Enabling the multicast function is a prerequisite of

PIM-SM configuration.

- Enable the basic functions of PIM-SM on all interfaces of the multicast devices. The other functions of PIM-SM can be enabled only after the basic functions of PIM-SM are enabled.
- Enable the IGMP function on the interface connected to hosts and set the IGMP version to v3 so that the hosts can join or leave a multicast group by sending IGMP messages based on the specified source. The multicast devices acting as leaf nodes maintain group membership based on the IGMP protocol.
- Configure the same address range of SSM on all multicast devices. The SSM services provided by the multicast devices in the PIM-SM domain are dedicated to specified groups, which realizes multicast controllability.

4. Procedure

(1) Configure IP addresses and enable unicast routing protocols on interfaces of different devices.

Configure IP addresses and enable unicast routing protocols on interfaces of device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/21)# ip address 10.100.1.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/24)# ip address 10.100.2.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
DeviceA(cfg)# router-protocol ospf 49
DeviceA(cfg-router)# network-advertise 10.100.1.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.2.0 0.0.0.255 area 0
DeviceA(cfg-router)# exit
```

Configure IP addresses and enable unicast routing protocols on interfaces of device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/30)# ip address 10.100.8.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/31)# ip address 10.100.2.2 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)#interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/32)# ip address 10.100.5.2 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ip address 49.49.49.49 255.255.255.255
```

```
DeviceB(cfg-if-Loopback 49)# exit
DeviceB(cfg)# router-protocol ospf 49
DeviceB(cfg-router)# network-advertise 10.100.2.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.8.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 49.49.49.49 0.0.0.0 area 0
DeviceB(cfg-router)# exit
```

Configure IP addresses and enable unicast routing protocols on interfaces of device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface GigabitEthernet 0/18
DeviceC(cfg-if-GigabitEthernet 0/18)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/18)# ip address 10.100.11.1 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/18)# exit
DeviceC(cfg)#interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/20)# ip address 10.100.5.1 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/22
DeviceC(cfg-if-GigabitEthernet 0/22)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/22)# ip address 10.100.4.1 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/22)# exit
DeviceC(cfg)# interface Loopback 50
DeviceC(cfg-if-Loopback 50)# ip address 50.50.50.50 255.255.255.255
DeviceC(cfg-if-Loopback 50)# exit
DeviceC(cfg)# router-protocol ospf 49
DeviceC(cfg-router)# network-advertise 10.100.4.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 10.100.5.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 50.50.50.50 0.0.0.0 area 0
DeviceC(cfg-router)# exit
```

Configure IP addresses and enable unicast routing protocols on interfaces of device D.

```
DeviceD> privilege
DeviceD# config-system terminal
DeviceD(cfg)# interface GigabitEthernet 0/47
DeviceD(cfg-if-GigabitEthernet 0/47)# unset switch-port
DeviceD(cfg-if-GigabitEthernet 0/47)# ip address 10.100.12.1 255.255.255.0
DeviceD(cfg-if-GigabitEthernet 0/47)# exit
DeviceD(cfg)# interface GigabitEthernet 0/48
DeviceD(cfg-if-GigabitEthernet 0/48)# unset switch-port
DeviceD(cfg-if-GigabitEthernet 0/48)# ip address 10.100.11.2 255.255.255.0
DeviceD(cfg-if-GigabitEthernet 0/48)# exit
DeviceD(cfg)# router-protocol ospf 49
DeviceD(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceD(cfg-router)# network-advertise 10.100.12.0 0.0.0.255 area 0
```

```
DeviceD(cfg-router)# exit
DeviceD(cfg)# router-protocol ospf 49
DeviceD(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceD(cfg-router)# network-advertise 10.100.12.0 0.0.0.255 area 0
DeviceD(cfg-router)# exit
```

Configure IP addresses and enable unicast routing protocols on interfaces of device E.

```
DeviceE> privilege
DeviceE# config-system terminal
DeviceE(cfg)# interface GigabitEthernet 0/5
DeviceE(cfg-if-GigabitEthernet 0/5)# unset switch-port
DeviceE(cfg-if-GigabitEthernet 0/5)# ip address 10.100.13.1 255.255.255.0
DeviceE(cfg-if-GigabitEthernet 0/5)# exit
DeviceE(cfg)# interface GigabitEthernet 0/7
DeviceE(cfg-if-GigabitEthernet 0/7)# unset switch-port
DeviceE(cfg-if-GigabitEthernet 0/7)# ip address 10.100.4.2 255.255.255.0
DeviceE(cfg-if-GigabitEthernet 0/7)# exit
DeviceE(cfg)# router-protocol ospf 49
DeviceE(cfg-router)# network-advertise 10.100.4.0 0.0.0.255 area 0
DeviceE(cfg-router)# network-advertise 10.100.13.0 0.0.0.255 area 0
DeviceE(cfg-router)# exit
```

(2) Enable the multicast and PIM-SM functions on all multicast devices, and enable the IGMP function on all multicast devices connected to hosts.

Enable the multicast and PIM-SM functions on device A.

```
DeviceA(cfg)# ip mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
```

Enable the multicast, PIM-SM, and IGMP functions on device B, and set the IGMP version to v3.

```
DeviceB(cfg)# ip mrouting-enable
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/30)# ip igmp specify-version 3
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# ip pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ip pim sparse-mode
```

```
DeviceB(cfg-if-Loopback 49)# exit
```

Enable the multicast and PIM-SM functions on device C.

```
DeviceC(cfg)# ip mrouting-enable
DeviceC(cfg)# interface GigabitEthernet 0/18
DeviceC(cfg-if-GigabitEthernet 0/18)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/18)# exit
DeviceC(cfg)# interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/22
DeviceC(cfg-if-GigabitEthernet 0/22)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/22)# exit
DeviceC(cfg)#interface Loopback 50
DeviceC(cfg-if-Loopback 50)# ip pim sparse-mode
DeviceC(cfg-if-Loopback 50)# exit
```

Enable the multicast and PIM-SM functions on device D.

```
DeviceD(cfg)# ip mrouting-enable
DeviceD(cfg)# interface GigabitEthernet 0/47
DeviceD(cfg-if-GigabitEthernet 0/47)# ip pim sparse-mode
DeviceD(cfg-if-GigabitEthernet 0/47)# exit
DeviceD(cfg)# interface GigabitEthernet 0/48
DeviceD(cfg-if-GigabitEthernet 0/48)# ip pim sparse-mode
DeviceD(cfg-if-GigabitEthernet 0/48)# exit
```

Enable the multicast, PIM-SM, and IGMP functions on device E, and set the IGMP version to v3.

```
DeviceE(cfg)# ip mrouting-enable
DeviceE(cfg)# interface GigabitEthernet 0/5
DeviceE(cfg-if-GigabitEthernet 0/5)# ip pim sparse-mode
DeviceE(cfg-if-GigabitEthernet 0/5)# ip igmp specify-version 3
DeviceE(cfg-if-GigabitEthernet 0/5)# exit
DeviceE(cfg)# interface GigabitEthernet 0/7
DeviceE(cfg-if-GigabitEthernet 0/7)# ip pim sparse-mode
DeviceE(cfg-if-GigabitEthernet 0/7)# exit
```

(3) Enable the SSM function and configure an address range of multicast groups on all multicast devices.

Set the address range of an SSM multicast group to 232.1.1.0/24 on device A.

```
DeviceA(cfg)# ip access-control-list standard 59
DeviceA(cfg-stdacl)#permit 232.1.1.0 0.0.0.255
DeviceA(cfg-stdacl)#exit
DeviceA(cfg)# ip pim enable-ssm range 59
```

Set the address range of an SSM multicast group to 232.1.1.0/24 on device B.

```
DeviceB(cfg)# ip access-control-list standard 59
DeviceB(cfg-stdacl)#permit 232.1.1.0 0.0.0.255
DeviceB(cfg-stdacl)#exit
DeviceB(cfg)# ip pim enable-ssm range 59
```

Set the address range of an SSM multicast group to 232.1.1.0/24 on device C.

```
DeviceC(cfg)# ip access-control-list standard 59
DeviceC(cfg-stdacl)#permit 232.1.1.0 0.0.0.255
DeviceC(cfg-stdacl)#exit
DeviceC(cfg)# ip pim enable-ssm range 59
```

Set the address range of an SSM multicast group to 232.1.1.0/24 on device D.

```
DeviceD(cfg)# ip access-control-list standard 59
DeviceD(cfg-stdacl)#permit 232.1.1.0 0.0.0.255
DeviceD(cfg-stdacl)#exit
DeviceD(cfg)# ip pim enable-ssm range 59
```

Set the address range of an SSM multicast group to 232.1.1.0/24 on device E.

```
DeviceE(cfg)# ip access-control-list standard 59
DeviceE(cfg-stdacl)#permit 232.1.1.0 0.0.0.255
DeviceE(cfg-stdacl)#exit
DeviceE(cfg)# ip pim enable-ssm range 59
```

5. Verification

(1) Run the **display ip pim-info sparse-mode interface** command to display PIM-SM running information on the interfaces. The PIM-SM running information on the interfaces of device A is as follows. The PIM-SM running information on the interfaces of devices B, C, D, and E is the same.

```
DeviceA# display ip pim-info sparse-mode interface
Address          Interface                      VIFindex Ver/Mode Nbr-Count DR-Prior
DR
10.100.1.1       GigabitEthernet 0/21           3        v2/S     0         1
10.100.1.1
10.100.2.1       GigabitEthernet 0/24           1        v2/S     0         1
10.100.2.1
DeviceA#
```

(2) Run the **display ip pim-info sparse-mode mroute** command to display the multicast routing tables of PIM-SM. Host A needs to receive packets sent from source 1 (10.100.1.2/24) and source 2 (10.100.12.2/24) to the multicast group (232.1.1.10/24). Host B needs to receive packets sent from source 1 (10.100.1.2/24) to the multicast group (232.1.1.10/24). The information output is as follows:

The routing table information on device A is as follows:

```
DeviceA# display ip pim-info sparse-mode mroute

7. Common Errors

- An IPv4 unicast route is incorrectly configured.
- IPv4 multicast routing function is not enabled on a multicast device.
- The SSM function is not enabled on a multicast device, or the SSM group address range on this multicast device is not consistent with the configuration on other multicast devices.
- The PIM-SM function is not enabled on an interface, for example, the gateway interface connecting to hosts or a multicast source.
- The IGMPv3 function is not enabled on an interface connected to hosts.

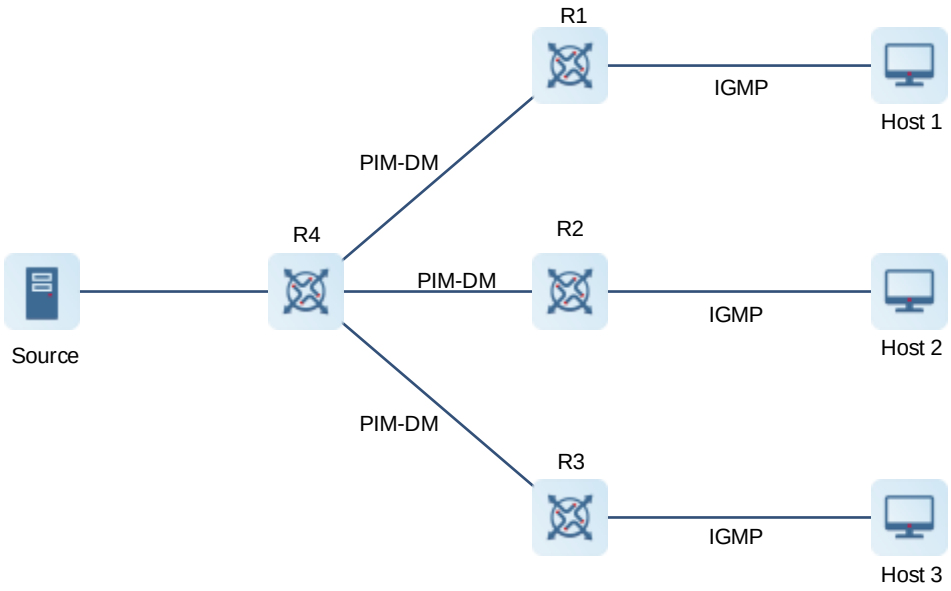
1 Configuring PIM-DM

1.1 Introduction

1.1.1 Overview



In multicast packet transmission, devices need to run multicast routing protocols to control multicast packet forwarding. A multicast network can be composed of multiple domains. The most typical multicast routing protocol is Protocol Independent Multicast (PIM). Based on implementation mechanism, PIM is categorized into Protocol Independent Multicast-Dense Mode (PIM-DM) and Protocol Independent Multicast-Sparse Mode (PIM-SM).

PIM-DM runs on multicast devices and is used to discover and maintain multicast routing information and determine a forwarding route of multicast packets.

Compared with PIM-SM, PIM-DM applies to small networks where multicast group members densely reside. Ideally, multicast group members on every path need to receive packets in the PIM network, and each forwarding node pushes and distributes the multicast packets in the entire network.

1.1.2 PIM-DM Network Deployment

Figure 1-1 PIM-DM Deployment Topology

As shown in Figure 1-1, when a multicast device is connected to other multicast devices, PIM must be deployed on this multicast device. Here, PIM-DM is deployed.

1.1.3 Principles

The basic principles of PIM-DM are as follows:

(1) Assume that all paths in a network have multicast group members and the multicast source sends multicast packets throughout the entire network.

(2) The entire path can be considered a tree with the source as the root node and group members as leaf nodes. This tree is the shortest path tree (SPT). Initially, some leaf nodes are not group members and they must be pruned to get a correct tree structure.

(3) If a new host joins the tree or an existing node leaves the tree, the tree structure must be readjusted. Multicast packets are forwarded on the paths of this tree, and the forwarding path is the shortest path from the source to the group members.

The working mechanisms of PIM-DM include neighbor creation, flooding, pruning, state refresh, graft, and assertion.

1. Neighbor Creation

Neighbors are the basis of PIM-DM. Neighbor relationships must be created between PIM routers before PIM control messages can be exchanged or multicast packets can be forwarded.

Neighbor creation is implemented based on the hello messages sent by the PIM interfaces and is composed of neighbor discovery, protocol parameter negotiation, and neighbor relationship maintenance.

- Discover neighbors

  A PIM interface periodically sends hello messages with the destination address being 224.0.0.13 (ff02::d for IPv6), source address being the IP address of the interface, and time to live (TTL) value being **1**. PIM routers in the same network segment receive the packets with the destination address 224.0.0.13 (ff02::d for IPv6). In this way, the PIM routers obtain neighbor information and create neighbor relationships.

  When a PIM interface is enabled or detects a new neighbor, a Triggered-Hello-Delay message is used to generate a random time. Within the time, the interface sends hello messages.

- Negotiate protocol parameters

  Protocol parameters are negotiated by hello messages. The key parameters are described as follows:

  - **DR_Priority**: The priority of a router for designated router (DR) election. The router with a higher priority is selected.
  - **Holdtime**: The neighbor is considered reachable within the hold time.
  - **Propagation Delay**: Duration between the time when a PIM device receives a prune packet and the time when the PIM device sends the prune packet to the upstream devices.
  - **Override-Interval**: The interval to override the prune.

- Maintain neighbor relationship

  A hello message is sent periodically between PIM routers. If a hello message is not received from a PIM neighbor within the hold time, the neighbor is considered unreachable and is deleted from the neighbor list. Any change of PIM neighbors will cause change of the multicast topology in the network. If an upstream or a downstream neighbor in a multicast distribution tree (MDT) is unreachable, multicast routes converge again and the MDT is reshaped.

2. Flooding

Multicast packets flooded to an entire network from a source is referred to flooding. Flooding enables all nodes in a network to receive these packets.

Multicast devices check reverse path forwarding (RPF) in the packets. If the checking fails, the packets are discarded. If the checking is passed and an outbound interface is detected, the multicast packets are forwarded through the outbound interface. This enables all node members in the network to receive these multicast packets.

3. Pruning

If no group member exists on a path branch, the path branch is pruned. This enables packets to be forwarded to paths with group members available.

(1) Multicast devices check RPF in the packets. If the checking is passed but no outbound interface exists, no group member exists on this path. A prune packet is sent to the upstream device.

(2) Upon receiving the prune packet, the upstream device marks the packet sending interface as pruned and sets a prune state timer.

(3) After all unnecessary paths are pruned, the remaining paths are necessary and they form an SPT.

- Prune override

After a PIM router sends a prune packet to the upstream device, the PIM router does not prune the downstream path immediately. If the downstream device has multicast requirements, it can send a prune override message to the PIM router to override the prune.

If the PIM router receives a prune override message from the downstream device in the prune-pending timer (PPT), the PIM router cancels pruning. PPT = Propagation delay + Override interval

4. State Refresh

A prune state timer is maintained on a device during pruning. When the timer times out, the device continues to forward packets. PIM-DM refreshes the timer state using a state refresh message (SRM) to avoid unnecessary prune state changes.

The multicast device nearest to the source periodically sends the SRM to the downstream devices. Upon receiving the SRM, the downstream devices add the local topology state information to the SRM by modifying some fields in the SRM, and continue to forward the SRM to downstream devices. Finally, the SRM arrives leaf devices and the states of all devices in the network get updated.

5. Graft

If a group member sends data to a group corresponding to a path being pruned, the path must be restored to the forwarding state. This is referred to as graft.

(1) When a group member sends data to a group corresponding to a path being pruned, the other devices on this path receive the join message and send a graft packet to the upstream device to apply for joining the SPT.

(2) Upon receiving the graft packet, the upstream device replies a Graft-Ack packet and starts to forward multicast packets to the downstream devices on this path.

(3) The downstream devices receive the Graft-Ack packet. If the downstream devices do not receive the Graft-Ack packet, they send the graft packet again and again until they receive the Graft-Ack packet.

6. Assertion

In a network segment where multiple PIM routers reside, the same multicast packet may be transmitted to the routers in the network segment multiple times. In this case, a special PIM router can be specified to forward multicast packets and avoid duplicate forwarding. This is referred to as assertion.

1.1.4 PIM-DM and MIB

Connected to other agents, the Simple Network Management Protocol (SNMP) manager uses information in the Management Information Base (MIB) to directly manage the PIM-DM function.

The MIB specifies variables (namely information that can be queried and set by the management process) maintained by network elements and directly manages the PIM-DM function.

1.1.5 Protocols and Standards

- RFC 3973: Protocol Independent Multicast - Dense Mode (PIM-DM)
- RFC 2715: Interoperability Rules for Multicast Routing Protocols

1.2 Restrictions and Guidelines

- If PIM-DM neighbor relationships between devices are created through links and downstream devices have no or few needs to receive multicast packets, the system performance is excessively consumed. In this scenario, PIM-SM is recommended for the environment deployment.
- Before PIM-DM is used, ensure that unicast routes are reachable in the network.

1.3 Configuration Task Summary

The PIM-DM configuration includes the following tasks:

(1) Configuring Basic Functions of PIM-DM

(2) (Optional) Configuring PIM-DM Passive Mode

(3) (Optional) Configuring PIM Neighbors

(4) (Optional) Configuring PIM State Refresh

(5) (Optional) Enabling the PIM-BFD Function

(6) (Optional) Enabling the MIB Function

1.4 Configuring Basic Functions of PIM-DM

1.4.1 Overview

A PIM network is created to provide IPv4 multicast services for sources and hosts in the network. Neighbor relationships must be created between PIM routers before PIM control messages can be exchanged or multicast packets can be forwarded.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable IPv4 multicast routing.

ip mrouting-enable

The multicast routing function is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(5) Enable the PIM-DM function.

ip pim dense-mode

The PIM-DM function is disabled on an interface by default.

The function can be enabled on the interconnection interfaces of routers, and interfaces connecting to multicast sources and user hosts.

(6) (Optional) Enable the PIM-DM function on a super VLAN interface.

ip pim dense-mode subvlan [*subvlan-id* | **all**]

The PIM-DM function is disabled on a super VLAN interface by default.

In most scenarios, the PIM-DM protocol is disabled by default and not needed on a super VLAN interface. This interface does not send or receive PIM packets. To enable PIM-DM to run on the super VLAN interface, specify a sub VLAN or all sub VLANs to receive packets. Note that if all sub VLANs are specified to receive packets, the transmission performance may be reduced, causing neighbor flapping.

1.5 Configuring PIM-DM Passive Mode

1.5.1 Overview

In a PIM network, if you want an interface, for example, a stub network device interface connecting to hosts, to receive multicast packets without involving the PIM network topology construction, you can set the interface to the PIM-DM passive mode. After the PIM-SM passive mode is configured, the interface does not process PIM-DM packets.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Enable the PIM-DM passive mode on an interface.

ip pim dense-mode passive

The PIM-DM passive mode is disabled on an interface by default.

1.6 Configuring PIM Neighbors

1.6.1 Overview

PIM devices support adjustment to protocol parameters in hello messages and neighbor filtering to improve network security.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure PIM neighbors. The following configuration tasks are optional. Select tasks for configuration according to actual condition.

- Configure hello message sending interval.

  ip pim query-period *query-period*

  Hello messages are sent at an interval of **30** seconds by default.

  Every time when the hello message sending interval is updated, the hello message hold time value is automatically updated as 3.5 times the interval. If the product of the hello message sending interval and 3.5 is greater than 65,535, the hello message hold time value is updated as 65,535.

- Configure propagation delay of hello messages on an interface.

  ip pim propagation-delay *propagation-delay-time*

  The default propagation delay of hello messages on an interface is 500 ms.

- Configure prune override interval of hello messages.

  ip pim override-interval *override-interval*

  The default prune override interval of hello messages is 2500 ms.

- Configure PIM neighbor filtering.

  ip pim peering-filter { *acl-name* | *acl-number* }

  The neighbor filtering function is disabled on an interface by default.

  Only addresses that meet ACL filtering conditions can be used as PIM neighbors of the current interface. Otherwise, the addresses filtered out cannot be neighbors.

1.7 Configuring PIM State Refresh

1.7.1 Overview

PIM devices support enabling or disabling PIM state refresh and adjusting PIM SRM sending interval.

1.7.2 Restrictions and Guidelines

- If the state refresh function is disabled, SRMs are not processed or forwarded.
- Disabling the state refresh function may cause the converged PIM-DM MDT to re-converge, which leads to unnecessary bandwidth waste and multicast routing table flapping. Therefore, you are not advised to disable this function in general conditions.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the PIM-DM state refresh function. The following configuration tasks are optional. Select tasks for configuration according to actual condition.

- Disable the PIM-DM state refresh function on an interface.

  ip pim refresh-state disable

  The PIM-DM SRMs are processed and forwarded by default.

- Configure the PIM-DM SRM sending interval on an interface.

  ip pim refresh-state origination-period *origination-period*

  The PIM-DM SRMs are sent at an interval of **60** seconds by default.

1.8 Enabling the PIM-BFD Function

1.8.1 Overview

PIM-DM supports correlation with the bidirectional forwarding detection (BFD) function. After the PIM-BFD function is enabled on the interconnection interfaces of routers, the interfaces are used as BFD interfaces to quickly detect neighbor changes and specify a router to forward multicast packets in a specified network segment based on the assertion rule.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Enable the PIM-BFD function on an interface.

ip pim bfd

The PIM-BFD function is disabled on an interface by default.

1.9 Enabling the MIB Function

1.9.1 Overview

The MIB function allows PIM devices to manage PIM-DM using the elements in the MIB.

1.9.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the MIB function to manage PIM-DM.

ip pim mib dense-mode

PIM-DM is not managed by the MIB function by default.

1.10 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

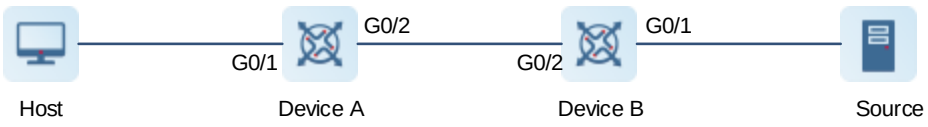
Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
cleanup ip pim-info dense-mode track	Clears statistical information about PIM-DM protocol packets.
display ip pim-info dense-mode interface [*interface-type interface-number*] [**detail**]	Displays PIM-DM interface information.
display ip pim-info dense-mode neighbor [*interface-type interface-number*]	Displays the PIM-DM neighbor information.
display ip pim-info dense-mode nexthop	Displays the PIM-DM next hop information.
display ip pim-info dense-mode mroute [*ipv4-group-or-source-address-1* [*ipv4-group-or-source-address-2*]] [**summary**]	Displays information about the PIM-DM routing table.
display ip pim-info dense-mode track	Displays statistical information about PIM-DM protocol packets.

1.11 Configuration Examples



1.11.1 Configuring Basic Functions of PIM-DM

1. Requirements

Configure the basic functions of PIM-DM on multiple devices to form a PIM-DM network, so that a host can receive multicast traffic from a multicast source.

2. Topology

Figure 1-2 Topology of Basic PIM-DM

3. Notes

- Configure an IPv4 unicast routing protocol, for example, OSPF, on routers.
- Enable the IPv4 multicast routing function on all routers.
- Configure basic functions of PIM-DM on the interconnection interfaces of routers and interfaces connecting to multicast sources and user hosts.

4. Procedure

(1) Configure IP addresses for interfaces and enable unicast routing protocols (omitted).

(2) Configure the IPv4 multicast routing function.

Configure the IPv4 multicast routing function on Device A.

```
Device A> privilege
Device A#config-system terminal
Device A(cfg)#ip mrouting-enable
```

Configure the IPv4 multicast routing function on Device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# ip mrouting-enable
```

(3) Configure basic functions of PIM-DM.

Configure basic functions of PIM-DM on Device A.

```
Device A(cfg)# interface GigabitEthernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# ip pim dense-mode
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# interface GigabitEthernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# ip pim dense-mode
```

Configure basic functions of PIM-DM on Device B.

```
Device B(cfg)# interface GigabitEthernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip pim dense-mode
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface GigabitEthernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# ip pim dense-mode
```

5. Verification

Verify that multicast source (192.168.1.10) can send packets to G (229.1.1.1), and that Receiver A joins G, so the host can receive packets from G.

Check the PIM-DM routing tables on Device A and Device B.

```
DeviceA# display ip pim-info dense-mode mroute
PIM-DM Multicast Routing Table
(192.168.1.10, 229.1.1.1)
  MRT lifetime expires in 182 seconds
  Source directly connected on GigabitEthernet 0/1
  State-Refresh Originator State: Originator
   SRT:57, SAT:147
```

```
  Upstream IF: GigabitEthernet 0/1
    Upstream State: Forwarding
    Assert State: NoInfo
  Downstream IF List:
    GigabitEthernet 0/2, in 'olist':
      Downstream State: NoInfo
      Assert State: NoInfo
```

6. Configuration Files

- Device A configuration file

```
!
ip mrouting-enable
!
interface GigabitEthernet 0/1
 unset switch-port
 ip pim dense-mode
!
interface GigabitEthernet 0/2
 unset switch-port
 ip pim dense-mode
!
```

- Device B configuration file

```
!
ip mrouting-enable
!
interface GigabitEthernet 0/1
 unset switch-port
 ip pim dense-mode
!
interface GigabitEthernet 0/2
 unset switch-port
 ip pim dense-mode
!
```

7. Common Errors

- An IPv4 unicast route is incorrectly configured.
- IPv4 multicast routing is not enabled on a router.
- PIM-DM function is not enabled on an interface.

1 Configuring IGMP Snooping

1.1 Introduction

Internet Group Management Protocol (IGMP) snooping is a process of snooping protocol packets between an L3 multicast device and hosts to manage and control forwarding of IP multicast traffic at the data link layer, implementing L2 multicast.

Generally, multicast packets need to pass through L2 switches, especially in some local area networks (LANs). As shown in Figure 1-1, the Protocol Independent Multicast (PIM) multicast device sends packets to hosts through an L2 switch. Because multicast group addresses cannot be learned on L2 devices, the packets will be broadcast in the VLAN. This wastes bandwidth and affects security. After the IGMP snooping function is configured, the L2 switch can listen to IGMP packets between hosts and the uplink PIM multicast device and establish L2 multicast forwarding entries to ensure that multicast data is forwarded only to specific hosts. This prevents multicast data from being broadcast in the L2 network.

Figure 1-1 Network Topology

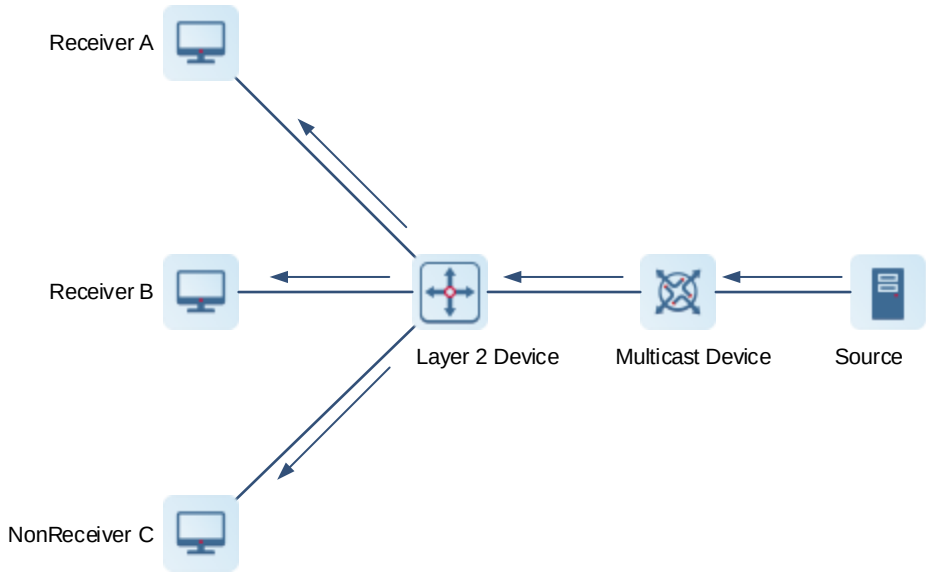
1.1.2 Principles

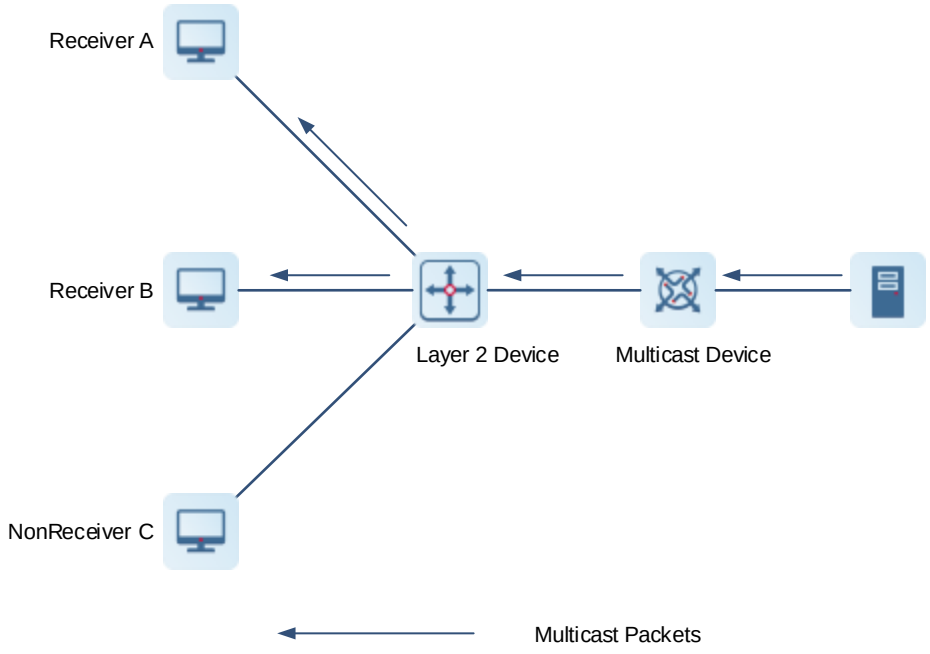
IGMP snooping is a basic L2 multicast function that forwards and controls multicast data at the data link layer. By listening to and analyzing protocol packets between hosts and the L3 multicast device, the L2 device

running IGMP snooping establishes and maintains L2 multicast forwarding entries to ensure on-demand forwarding of multicast data at the link layer.

As shown in Figure 1-2, when IGMP snooping is not configured on the L2 device, IP multicast packets are broadcast in the VLAN. As shown in Figure 1-3, when IGMP snooping is enabled on the L2 device, IP multicast packets are forwarded only to the member hosts of the multicast group. This prevents multicast data from being broadcast in the L2 network.

Figure 1-2 Multicast Data Transmission When IGMP Snooping Is Disabled





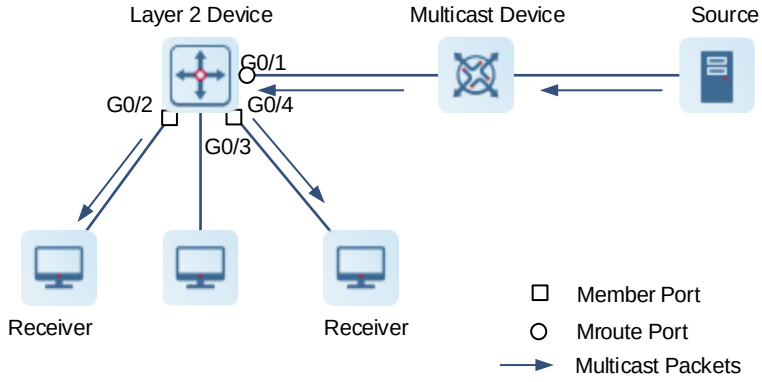


Figure 1-3 Multicast Data Transmission When IGMP Snooping Is Enabled

1.1.3 Port Types

IGMP snooping is enabled on a per-VLAN basis. IGMP snooping ports are ports in a VLAN. The device running IGMP snooping identifies ports in a VLAN as multicast router ports or member ports to manage and control forwarding of IP multicast data in the VLAN.

Figure 1-4 IGMP Snooping Ports

- A multicast router port connects the L2 multicast device to an L3 multicast device, and indicates the direction of the multicast source. By listening to IGMP packets, the L2 multicast device can automatically discover and maintain dynamic multicast router ports. You can also configure static multicast router ports.
- A member port connects the L2 multicast device to a host in a multicast group, and indicates the direction of a multicast group member. It is also called a listener port. By listening to IGMP packets, the L2 multicast device can automatically discover and maintain dynamic member ports. You can also configure static member ports.

As shown in Figure 1-4, IGMP snooping is enabled on the L2 multicast device, and the multicast data is received from a multicast router port and sent out from a member port.

1.1.4 Working Mechanism

A device running IGMP snooping analyzes received IGMP packets to discover and identify multicast router ports and member ports and establish and maintain IGMP snooping forwarding entries. The device can identify and process the following types of IGMP packets:

1. Query Packets

The IGMP querier periodically sends a general Query packet, and sends a group-specific Query packet when it receives a Leave packet. When the device running IGMP snooping receives a Query packet, the device performs the following actions in the VLAN:

- The device forwards the IGMP Query packet through all ports (except the port receiving the packet).
- If the port receiving the Query packet is a dynamic multicast router port, the device resets the aging timer of the port. After the timer times out, the port is no longer used as a dynamic multicast router port.
- If the port receiving the Query packet is not a dynamic multicast router port, the device uses the port as the dynamic multicast router port and starts the aging timer. After the timer times out, the port is no longer used as a dynamic multicast router port.

- If the function of dynamical multicast router port learning is disabled, the device will not learn dynamic multicast router ports.

2. Report Packets

When a member host receives a Query packet, the host will respond with a Report packet. If a host wants to join a multicast group, the host will proactively send a Report packet. The device running IGMP snooping can process IGMPv1 and IGMPv2 packets by default. For Report packets of IGMPv3, the device only processes the group information and does not process the carried source information.

When the device running IGMP snooping receives a Report packet, the device performs the following actions in the VLAN:

- The device forwards the Report packet through all multicast router ports. If Report packet suppression is enabled on the device, the device forwards only the first Report packet of each group in an IGMP query interval.
- If the port receiving the Report packet is a dynamic member port, the device resets the aging timer of the port. After the timer times out, the port is no longer used as a dynamic member port.
- If the port receiving the Report packet is not a member port, the device uses the port as the dynamic member port and starts the aging timer. After the timer times out, the port is no longer used as a dynamic member port.

3. Leave Packets

If a host wants to leave a multicast group, the host will proactively send a Leave packet. When the device running IGMP snooping receives a Leave packet, the device performs the following actions in the VLAN:

- The device forwards the Leave packet through all multicast router ports.
- If the port receiving the Leave packet is a dynamic member port and the fast leave function is configured, the device immediately deletes the port from the IGMP snooping forwarding entry of the corresponding multicast group. The port is no longer used as a dynamic member port of the group.
- If the port receiving the Leave packet is a dynamic member port but the fast leave function is not configured, the port status remains unchanged. When the aging timer of the port times out, the device deletes the port from the IGMP snooping forwarding entry of the corresponding multicast group. The port is no longer used as a dynamic member port of the group.

1.1.5 Protocols and Standards

- RFC 4541: Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches

1.2 Configuration Task Summary

IGMP snooping configuration includes the following tasks:

(1) Configuring Basic IGMP Snooping Functions. Select either of the following configuration tasks to configure.

- Configuring Basic IGMP Snooping Functions in IVGL Mode
- Configuring Basic IGMP Snooping Functions in SVGL Mode
- Configuring Basic IGMP Snooping Functions in IVGL-SVGL Mode

(2) Configuring Protocol Packet Processing Parameters. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Static Multicast Router Port
- Configuring a Static Member Port
- Configuring Report Packet Suppression
- Configuring Port Fast Leave
- Configuring Dynamic Multicast Router Port Learning
- Configuring the Aging Time for Dynamic Multicast Router Ports
- Configuring the Aging Time for Dynamic Member Ports

(3) (Optional) Configuring IGMP Snooping Querier. The tasks are as follows:

- Enabling IGMP Snooping Querier
- Configuring the Source IP Address of a Querier
- (Optional) Configuring the IGMP Snooping Querier Version
- (Optional) Configuring the Maximum Response Time for Query Packets
- (Optional) Configuring the Interval for a Querier to Send Query Packets
- (Optional) Configuring the Querier Aging Time

(4) Configuring Multicast Security Control. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Profile
- Configuring a Range of Multicast Group Addresses for a ProfileConfiguring Multicast Preview
- Configuring the Maximum Number of Multicast Groups Allowed for Concurrent Request
- Configuring Source Port Check
- Configuring Source IP Address Check

(5) (Optional) Configuring QinQ Processing

1.3 Configuring Basic IGMP Snooping Functions

1.3.1 Overview

The device running IGMP snooping can provide independent or shared multicast services for user VLANs when operated in the following modes:

- Independent VLAN Group Learning (IVGL): provides independent multicast services for each user VLAN.
- Shared VLAN Group Learning (SVGL): provides shared multicast services for multiple user VLANs.
- IVGL-SVGL: provides both shared and independent multicast services for user VLANs.

1.3.2 Restrictions and Guidelines

- The SVGL mode and the IP multicast function are mutually exclusive. If the IP multicast function needs to be enabled on the device running IGMP snooping, the device can operate only in IVGL mode.
- If the device running IGMP snooping operates in SVGL or IVGL-SVGL mode, the multicast groups associated with the SVGL mode must be configured. First, define the multicast groups applied in the SVGL

mode in a profile. Then, apply this profile in the command for configuring the group range in SVGL mode.

- PIM snooping depends on the IVGL mode of IGMP snooping. If the PIM snooping function needs to be enabled on the device running IGMP snooping, the device can operate only in IVGL mode.

1.3.3 Configuration Tasks

Basic IGMP snooping function configuration includes the following tasks. Please configure only one task.

- Configuring Basic IGMP Snooping Functions in IVGL Mode
- Configuring Basic IGMP Snooping Functions in SVGL Mode
- Configuring Basic IGMP Snooping Functions in IVGL-SVGL Mode

Basic IGMP snooping function configuration includes the following tasks.

1.3.4 Notes

The following table lists products supporting different basic IGMP snooping functions.

Table 1-1 Products Supporting Different Basic IGMP Snooping Functions

Function	Product Supporting the Function
Configuring Basic IGMP Snooping Functions in IVGL Mode	S6980-64QC S6920-4C S6580-24DC8QC S6510-32CQ S6510-48VS8CQ S6250-48XS8CQ
Configuring Basic IGMP Snooping Functions in SVGL Mode	S6980-64QC S6920-4C S6580-24DC8QC S6510-32CQ S6510-48VS8CQ S6250-48XS8CQ
Configuring Basic IGMP Snooping Functions in IVGL-SVGL Mode	S6980-64QC S6920-4C S6580-24DC8QC S6510-32CQ S6510-48VS8CQ S6250-48XS8CQ

1.3.5 Configuring Basic IGMP Snooping Functions in IVGL Mode

1. Overview

In IVGL mode, the device running IGMP snooping provides independent multicast services for each user VLAN. Multicast traffic can be forwarded only in the belonged VLAN, and hosts can request multicast traffic only in the belonged VLAN.

2. Restrictions and Guidelines

- Unless otherwise specified, you are advised to enable IGMP snooping globally on all L2 access devices connecting to hosts.
- After IGMP snooping is enabled globally, it takes effect to all VLANs. You can disable IGMP snooping on any VLAN. When the multicast service is disabled on a VLAN, the multicast services on other VLANs are not affected.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable IGMP snooping globally and run the IVGL mode.

ip igmp snooping-mode ivgl

IGMP snooping is disabled by default.

(4) (Optional) Disable IGMP snooping on a VLAN.

unset ip igmp snooping-mode vlan *vlan-id*

After IGMP snooping is enabled globally, it takes effect to all VLANs by default.

If IGMP snooping is disabled globally, it is ineffective on all VLANs.

You can disable IGMP snooping on a VLAN only after IGMP snooping is enabled globally.

1.3.6 Configuring Basic IGMP Snooping Functions in SVGL Mode

1. Overview

In SVGL mode, the device running IGMP snooping can provide shared multicast services for multiple user VLANs. Shared multicast services are usually used to provide the same video on demand (VOD) service for users in multiple VLANs. Compared with independent multicast services, shared multicast services save bandwidth.

VLANs for shared multicast services are classified into a shared VLAN and sub VLANs. Multicast traffic of multicast groups applied in SVGL mode on the shared VLAN is forwarded from the shared VLAN to sub VLANs, and hosts on sub VLANs request multicast traffic of multicast groups applied in SVGL mode from the shared VLAN.

2. Restrictions and Guidelines

- To share multicast services among VLANs, you need to configure multicast groups applied in SVGL mode after configuring the SVGL mode.

- Shared multicast services apply only to the shared VLAN and sub VLANs and use group addresses applied in SVGL mode.

3. Prerequisites

Before configuring multicast groups associated with the SVGL mode, ensure that the corresponding profile is created and a range of multicast groups that are permitted or denied by the filter is specified. For details about profile configuration, see 1.6.4 Configuring a Profile.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable IGMP snooping globally and run the SVGL mode.

ip igmp snooping-mode svgl

IGMP snooping is disabled by default.

(4) Configure multicast groups associated with the SVGL mode.

ip igmp snooping-mode svgl group-profile *profile-number*

No multicast group is associated with the SVGL mode by default.

(5) (Optional) Specify a shared VLAN.

ip igmp snooping-mode svgl shared-vlan *vlan-id*

The default shared VLAN in SVGL mode is VLAN 1.

(6) (Optional) Specify sub VLANs in SVGL mode.

ip igmp snooping-mode svgl subvlan *vlan-range*

By default, all VLANs except the shared VLAN are sub VLANs in SVGL mode.

1.3.7 Configuring Basic IGMP Snooping Functions in IVGL-SVGL Mode

1. Overview

The IVGL-SVGL mode is also called the hybrid mode. In IVGL-SVGL mode, the device running IGMP snooping can provide both shared and independent multicast services for user VLANs.

- In the shared VLAN and sub VLANs, shared multicast services apply to the multicast traffic of multicast groups applied in SVGL mode, and independent multicast services apply to other multicast traffic.
- In other VLANs (except the shared VLAN and sub VLANs), independent multicast services are provided.

2. Restrictions and Guidelines

- After configuring the IVGL-SVGL mode, you must specify the multicast groups associated with the SVGL mode.
- When a user VLAN is configured as a shared VLAN or sub VLAN, the user VLAN enjoys both shared and independent multicast services. When a user VLAN is configured as other VLANs, it enjoys only independent multicast services.

3. Prerequisites

Before configuring multicast groups associated with the SVGL mode, ensure that the corresponding profile is created and a range of multicast groups that are permitted or denied by the filter is specified. For details about profile configuration, see 1.6.4 Configuring a Profile.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable IGMP snooping globally and run the IVGL-SVGL mode.

ip igmp snooping-mode ivgl-svgl

IGMP snooping is disabled by default.

(4) Configure multicast groups associated with the SVGL mode.

ip igmp snooping-mode svgl group-profile *profile-number*

No multicast group is associated with the SVGL mode by default.

(5) (Optional) Specify a shared VLAN.

ip igmp snooping-mode svgl shared-vlan *vlan-id*

The default shared VLAN in SVGL mode is VLAN 1.

(6) (Optional) Specify sub VLANs in SVGL mode.

ip igmp snooping-mode svgl subvlan *vlan-range*

All VLANs except the shared VLAN are sub VLANs in SVGL mode by default.

1.4 Configuring Protocol Packet Processing Parameters

1.4.1 Overview

By controlling protocol packet processing, an L2 multicast device can establish static or dynamic multicast forwarding entries. In addition, the device can adjust parameters to refresh dynamic multicast forwarding entries and IGMP snooping membership quickly.

1.4.2 Restrictions and Guidelines

Configuring Basic IGMP Snooping Functions Related configuration functions take effect only after basic IGMP snooping functions are configured.

1.4.3 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Static Multicast Router Port
- Configuring a Static Member Port
- Configuring Report Packet Suppression
- Configuring Port Fast Leave

- Configuring Dynamic Multicast Router Port Learning
- Configuring the Aging Time for Dynamic Multicast Router Ports
- Configuring the Aging Time for Dynamic Member Ports

1.4.4 Configuring a Static Multicast Router Port

1. Overview

A multicast router port is used to receive uplink multicast data and forward IGMP Report and Leave packets. Static multicast router ports never age and can forward IGMP Report and Leave packets to the uplink IGMP querier stably.

2. Restrictions and Guidelines

- In SVGL mode, if no sub VLAN is configured, the configuration of static multicast router ports is valid only in the shared VLAN. In other VLANs, static multicast router ports can be configured but do not take effect. If sub VLANs are configured, the configuration of static multicast router ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static multicast router ports can be configured but do not take effect.
- In SVGL-IVGL mode, if no sub VLAN is configured, the configuration of static multicast router ports is valid in all VLANs. If sub VLANs are configured, the configuration of static multicast router ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static multicast router ports can be configured but do not take effect.
- In IVGL mode, the configuration of static multicast router ports is valid in all VLANs.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a static multicast router port.

ip igmp snooping-mode vlan *vlan-id* **multicast-route interface** *interface-type interface-number*

No static multicast router port is configured by default.

1.4.5 Configuring a Static Member Port

1. Overview

When a member port connecting to a member host is configured as a static member port, the host can receive multicast traffic from the specified multicast group no matter whether the host joins the multicast group. Static member ports never age.

2. Restrictions and Guidelines

- In SVGL mode, if no sub VLAN is configured, the configuration of static member ports is valid only in the shared VLAN. In other VLANs, static member ports can be configured but do not take effect. If sub VLANs are configured, the configuration of static member ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static member ports can be configured but do not take effect.
- In SVGL-IVGL mode, if no sub VLAN is configured, the configuration of static member ports is valid in all

VLANs. If sub VLANs are configured, the configuration of static member ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static member ports can be configured but do not take effect.

- In IVGL mode, the configuration of static member ports is valid in all VLANs.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a static member port.

ip igmp snooping-mode vlan *vlan-id* **static-member** *ipv4-group-address* **interface** *interface-type interface-number*

No static member port is configured by default.

1.4.6 Configuring Report Packet Suppression

1. Overview

IGMP Query and Report packets are exchanged periodically to maintain the group membership. When many hosts in a network join the same multicast group, a large number of IGMP packets will be sent to the IGMP multicast device, which wastes network bandwidth and affects the performance of the IGMP multicast device. Report packet suppression can optimize this situation.

When Report packet suppression is configured, the IGMP multicast device only forwards the first Report packet from a specific VLAN for a multicast group to the multicast router port and suppresses subsequent Report packets for the same multicast group during one query interval. This function reduces the number of packets in the network.

2. Restrictions and Guidelines

Only IGMPv1 and IGMPv2 Report packets can be suppressed, and IGMPv3 Report packets cannot be suppressed.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure Report packet suppression.

ip igmp snooping-mode suppress enable

Report packet suppression is disabled by default.

1.4.7 Configuring Port Fast Leave

1. Overview

When the port fast leave function is enabled and a port receives a Leave packet (including the IGMPv2 Leave packet and IGMPv3 Report packet of the INCLUDE type without carrying any source address), the port is directly deleted from the member port list of the corresponding multicast forwarding entry. When receiving group-specific Query packets and multicast data, the device does not forward the packets to this port.

2. Restrictions and Guidelines

The port fast leave function is applicable when only one host is connected to each port. This function helps save bandwidth and resources.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the port fast leave function.

ip igmp snooping-mode inf-fast-leave enable

The port fast leave function is disabled by default.

1.1.1 Configuring Dynamic Multicast Router Port Learning

1. Overview

In some application scenarios, a user host may send Query packets and PIM neighbor messages. When the L2 device receives such Query packets or PIM neighbor messages, the L2 device will set the port receiving the packets as a dynamic multicast router port. All multicast packets in the VLAN will be forwarded to this port, and the host receives a large number of useless multicast packets. In addition, Query packets and PIM neighbor messages sent by user hosts may affect the status of the L3 multicast routing protocol, such as the querier and designated router (DR) election. In this case, you can disable dynamic multicast router port learning to resolve this problem and improve network security.

2. Restrictions and Guidelines

Disabling dynamic multicast router port learning and enabling a static multicast router port do not affect each other.

3. Procedure

(4) Enter the privileged EXEC mode.

privilege

(5) Enter the global configuration mode.

config-system terminal

(6) Configure dynamic multicast router port learning.

ip igmp snooping-mode [**vlan** *vlan-id*] **multicast-route learn dvmrp-pim**

Dynamic multicast router port learning is enabled by default.

1.4.8 Configuring the Aging Time for Dynamic Multicast Router Ports

1. Overview

A multicast router port is used to receive uplink multicast data and forward IGMP Report and Leave packets. After enabling IGMP snooping, an L2 device can dynamically learn multicast router ports to forward multicast packets for the uplink device. If a dynamic multicast router port does not receive a Query packet or neighbor message from the uplink device within the aging time due to unstable network or packet congestion, the L2 device will delete the dynamic multicast router port, which may cause multicast data interruption.

2. Restrictions and Guidelines

- You can adjust the aging time of dynamic multicast router ports based on the network load. When the network load is heavy, set the aging time to a larger value. A too short aging time may cause dynamic multicast router ports to be added and deleted frequently, resulting in data interruption.
- You can set the aging time based on the interval for the connected multicast router to send IGMP Query packets. Generally, the aging time is set to twice the interval plus the response time of the last IGMP Query packet.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the aging time for dynamic multicast router ports.

ip igmp snooping-mode dyn-mr-aging-interval *dynamic-mroute-aging-time*

The default aging time of dynamic multicast router ports is 300s.

1.4.9 Configuring the Aging Time for Dynamic Member Ports

1. Overview

When the device running IGMP snooping receives an IGMP Join packet from a host to join an IP multicast group, the device adds the port receiving the packet to the member port list and sets an aging time for the port. If the port is already in the member port list, the device resets the aging timer of the port. After the timer times out, it is deemed that no user host receives multicast packets through this port, and the multicast device deletes the port from the IGMP snooping member port list.

2. Restrictions and Guidelines

- You can adjust the aging time of dynamic member ports based on the network load. When the network load is heavy, set the aging time to a larger value. A too short aging time may cause dynamic member ports to be added and deleted frequently, resulting in data interruption.
- After the aging time is configured, the aging timer value of dynamic member ports is *host-aging-interval* for subsequent IGMP Join packets. The configured aging time takes effect after the next Join packet is received, and the started member port aging timers are not updated.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the aging time for dynamic member ports.

ip igmp snooping-mode host-aging-interval *host-aging-time*

The default aging time of dynamic member ports is 260s.

1.5 Configuring IGMP Snooping Querier

1.5.1 Overview

In a three-layer multicast network, the L3 multicast device serves as the querier and runs IGMP to maintain group membership. The L2 multicast device only needs to listen to IGMP packets to establish and maintain multicast forwarding entries, implementing L2 multicast. When a multicast source and user host are in the same L2 network, the query function is unavailable because the L2 device does not support IGMP. To resolve this problem, you can enable the IGMP snooping querier function on the L2 device so that the L2 device sends IGMP Query packets to user hosts on behalf of the L3 multicast device, and listens to and maintains IGMP Report packets responded by user hosts to establish L2 multicast forwarding entries. When multiple devices are configured as the querier in the L2 network and a device receives IGMP Query packets from other devices, an IGMP snooping querier is elected.

1.5.2 Restrictions and Guidelines

- After the querier function is enabled, you must specify a source IP address for the querier so that the querier function can take effect.
- When a device with the querier function enabled receives a PIM or Distance Vector Multicast Routing Protocol (DVMRP) packet, it regards that a multicast router exists in the network. To prevent the IGMP routing function of the multicast router from being affected, the querier function of the device becomes invalid and the multicast router in the network serves as the IGMP snooping querier.
- The query interval configured for the querier must be greater than the maximum response time of Query packets. Otherwise, the configuration fails.

1.5.3 Prerequisites

Configuring Basic IGMP Snooping Functions

1.5.4 Configuration Tasks

IGMP snooping querier configuration includes the following tasks:

- Enabling IGMP Snooping Querier
- Configuring the Source IP Address of a Querier
- (Optional) Configuring the IGMP Snooping Querier Version
- (Optional) Configuring the Maximum Response Time for Query Packets

- (Optional) Configuring the Interval for a Querier to Send Query Packets
- (Optional) Configuring the Querier Aging Time

1.5.5 Enabling IGMP Snooping Querier

1. Overview

After the IGMP snooping querier function is enabled on an L2 device, the L2 device sends IGMP Query packets to user hosts on behalf of the L3 device.

2. Restrictions and Guidelines

- The IGMP snooping querier function must be enabled globally and on a specific VLAN. The IGMP snooping querier function on a specific VLAN takes effect only after the function is enabled globally.
- You can disable the IGMP snooping querier function for a specific VLAN.
- If the IGMP snooping querier function is disabled globally, the function is disabled on all VLANs.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the IGMP snooping querier function.

ip igmp snooping-mode [**vlan** *vlan-id*] **querier**

The IGMP snooping querier function is disabled by default.

1.5.6 Configuring the Source IP Address of a Querier

1. Overview

You can configure the source IP address of a querier globally or on a specific VLAN. If the source IP address of the querier is not configured, the querier function does not take effect.

2. Restrictions and Guidelines

The querier source IP address configured on a specific VLAN, if any, prevails.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the source IP address of a querier.

ip igmp snooping-mode [**vlan** *vlan-id*] **querier source-address** *ipv4-source-address*

By default, no VLAN is specified, and the source IP address configuration applies to all VLANs.

1.5.7 Configuring the IGMP Snooping Querier Version

1. Overview

You can configure the IGMP snooping querier version to specify the version of IGMP Query packets sent by the querier. The supported IGMP versions include IGMPv1, and IGMPv2.

2. Restrictions and Guidelines

- An IGMP snooping querier supports IGMPv1, and IGMPv2, IGMPv2 is used by default. You can run the corresponding command to enable an IGMP snooping querier to run IGMPv1.
- The IGMP snooping querier version configured on a specific VLAN, if any, prevails.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the IGMP snooping querier version.

ip igmp snooping-mode [**vlan** *vlan-id*] **querier version 1**

An IGMP snooping querier runs IGMPv2 by default.

1.5.8 Configuring the Maximum Response Time for Query Packets

1. Overview

When hosts in the directly-connected network segment of the device serving as the IGMP snooping querier receive a Query packet from the device, the hosts need to return a Report packet within the maximum response time. This function allows you to configure the maximum response time for Query packets on the device. If no host returns a Report packet within the maximum response time, the device considers that no group member exists in the directly-connected network segment and deletes the group information.

2. Restrictions and Guidelines

- You can adjust the maximum response time for Query packets based on the network load. When the network load is light, you are advised to set the maximum response time for Query packets to a small value to enable hosts to make quick responses to IGMP Query packets. When the network load is heavy, set a large maximum response time to avoid network congestion due to flooding of Report packets sent by hosts after the timer times out.
- Because IGMPv1 does not support carrying the maximum response time in packets, this configuration does not take effect to a querier running IGMPv1.
- You can configure different maximum response time values for queriers in different VLANs. The maximum response time configured on a specific VLAN, if any, prevails.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the maximum response time for Query packets.

ip igmp snooping-mode [**vlan** *vlan-id*] **querier max-response-time** *max-response-time*

The maximum response time for Query packets is 10s by default.

1.5.9 Configuring the Interval for a Querier to Send Query Packets

1. Overview

An IGMP snooping querier periodically sends Query packets. This parameter is used to define the interval for sending Query packets.

2. Restrictions and Guidelines

You can configure the interval for a querier to send Query packets globally or on a specific VLAN. The query interval specified on a VLAN, if any, prevails.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the interval for a querier to send Query packets.

ip igmp snooping-mode [**vlan** *vlan-id*] **querier query-period** *query-interval*

The default interval for an IGMP snooping querier to send Query packets is 60s.

1.5.10 Configuring the Querier Aging Time

1. Overview

When multiple queriers are configured in an L2 network, querier election will be performed, and the device elected as the querier will send Query packets periodically. Other candidate queriers receive Query packets from the elected querier. If a candidate querier does not receive Query packets from the elected querier within a specific period of time, the candidate querier regards that it is the only querier in the directly-connected network segment and initiates a new round querier election. This parameter is used to define the timeout time for candidate queriers to receive Query packets from the elected querier.

2. Restrictions and Guidelines

The querier aging time configured on a specific VLAN, if any, prevails.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the querier aging time.

ip igmp snooping-mode [**vlan** *vlan-id*] **querier other-querier-timer present** *timeout*

The default aging time of IGMP snooping queriers is 125s.

1.6 Configuring Multicast Security Control

1.6.1 Overview

After multicast security control is configured, the device running IGMP snooping can control the multicast service scope and load to prevent invalid multicast traffic and improve L2 multicast network security.

1.6.2 Prerequisites

Configuring Basic IGMP Snooping Functions

1.6.3 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Profile
- Configuring a Range of Multicast Group Addresses for a ProfileConfiguring Multicast Preview
- Configuring the Maximum Number of Multicast Groups Allowed for Concurrent Request
- Configuring Source Port Check
- Configuring Source IP Address Check

1.6.4 Configuring a Profile

1. Overview

A profile is used to define a range of multicast groups that permit or deny user access for reference by other functions.

- When the SVGL mode is enabled, a profile is used to define a range of multicast groups applied in SVGL mode.
- When multicast filtering is configured on a port, a profile is used to define a range of multicast groups that permit or deny user access through the port.
- When multicast filtering is configured on a VLAN, a profile is used to define a range of multicast groups that permit or deny user access on the VLAN.
- When the preview function is enabled, a profile is used to define a range of multicast groups to be previewed.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a profile.

ip igmp group-profile *profile-number*

No profile is created by default.

(4) Define a range of multicast groups for a profile.

range *start-ipv4-address* [*end-ipv4-address*]

No multicast group range is defined for a profile by default.

Multiple multicast group ranges can be configured at the same time. If two multicast group ranges overlap, the ranges will be merged automatically.

(5) Configure the filtering action for a profile. The configuration steps below are mutually exclusive. Please configure only one task.

- Set the filtering action of a profile to Deny.

  deny

  If only the Deny action is configured and no multicast group range is configured, no group is denied. The effect is the same as permitting all groups.

- (Optional) Set the filtering action of a profile to Permit.

  permit

  If only the Permit action is configured and no multicast group range is configured, no group is permitted. The effect is the same as denying all groups.

The Deny action is performed for a profile by default.

1.6.5 Configuring a Range of Multicast Group Addresses for a Profile

1. Overview

Generally, the device running ports and VLANs can join any multicast group. By configuring a range of multicast groups that permit or deny user access, you can customize the multicast service scope for users to guarantee the interest of operators and prevent invalid multicast traffic.

2. Restrictions and Guidelines

- By applying a profile to a VLAN, you can restrict the multicast groups that users can join in the VLAN.
- By applying a profile to a port, you can restrict the multicast groups that users can join on the port.

3. Prerequisites

Before configuring a range of multicast group addresses for a profile, ensure that the corresponding profile is created and a range of multicast groups is specified for the profile. For details about profile configuration, see 1.6.4 Configuring a Profile.

4. Procedure

Configure a range of multicast groups for a profile. Select at least one of them to configure.

a Enter the privileged EXEC mode.

privilege

b Enter the global configuration mode.

config-system terminal

(1) (Optional) Configure the limit of VLAN group address range.

ip igmp snooping-mode vlan *vlan-id* **group-filter** *profile-number*

By default, a VLAN is allowed to join any group.

(2) (Optional) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(3) (Optional) Configure the limit of interface group address range.

ip igmp snooping-mode group-filter *profile-number*

By default, an interface is allowed to join any group.

1.6.6 Configuring Multicast Preview

1. Overview

In video applications, the administrator configures a VLAN filter or port filter to control some premium channels. Users who do not subscribe to these channels cannot watch these channels on demand. The multicast preview function allows unpaid users to preview premium channels before they decide whether to pay for watching. This function can be used together with multicast permission control.

2. Restrictions and Guidelines

After the preview duration ends, unpaid users can no longer watch premium channels on demand. The previewed content can be previewed again after 300s.

3. Prerequisites

Before configuring multicast preview, ensure that the corresponding profile is created and a range of multicast groups allowed for preview is specified. For details about profile configuration, see 1.6.4 Configuring a Profile.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure multicast preview.

ip igmp snooping-mode preview *profile-number*

The multicast preview function is disabled by default.

(4) (Optional) Configure the preview duration.

ip igmp snooping-mode preview interval preview-*interval*

The default multicast preview duration is 60s.

1.6.7 Configuring the Maximum Number of Multicast Groups Allowed for Concurrent Request

1. Overview

If too much multicast traffic is requested concurrently, the multicast device will be severely burdened. Configuring the maximum number of multicast groups allowed for concurrent request can guarantee the bandwidth. You can limit the number of multicast groups allowed for concurrent request globally or on a port.

- Global maximum number of multicast groups allowed for concurrent request: This configuration contains statically configured and dynamically learned multicast groups.
- Maximum number of multicast groups allowed for concurrent request on a port: This configuration contains only dynamically learned multicast groups on a port and does not include statically configured multicast groups.

2. Restrictions and Guidelines

- To limit the number of multicast groups allowed for concurrent request globally, configure the global maximum number of multicast groups allowed for concurrent request.
- To limit the number of multicast groups allowed for concurrent request on a port, configure the maximum number of multicast groups that can be dynamically learned by the port.
- The number of multicast groups that can be dynamically learned by a port is counted based on the VLANs to which the port belongs. For example, if a port belongs to three VLANs and the port receives requests of multicast group 224.1.1.1 from each VLAN, the multicast group count on the port is 3 instead of 1.

3. Procedure

Configure the maximum number of multicast groups allowed for concurrent request. Select at least one of them to configure.

a Enter the privileged EXEC mode.

privilege

b Enter the global configuration mode.

config-system terminal

c (Optional) Configure the maximum number of multicast groups allowed for concurrent request globally.

ip igmp snooping-mode l2-entry-limit *l2-entry-limit*

The maximum number of multicast groups allowed for concurrent request globally is 64,000 by default.

d (Optional) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 2 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*

e Configure the maximum number of multicast groups that can be dynamically learned by a port.

ip igmp snooping-mode max-member-record *max-member-record*

The maximum number of multicast groups that can be dynamically learned by a port is 64,000 by default.

1.6.8 Configuring Source Port Check

1. Overview

The source port check function restricts users to receive only multicast traffic on multicast router ports to prevent users from sending invalid multicast traffic.

- After the source port check function is enabled, only multicast traffic received on multicast router ports is valid. Multicast traffic received on other ports is invalid and will be discarded.
- When the source port check function is disabled, multicast traffic received on any port is valid.

2. Restrictions and Guidelines

- To restrict users to receive multicast traffic only on multicast router ports, configure this function.
- If no multicast router port exists after the source port check function is enabled, the device will discard received multicast traffic.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure source port check.

ip igmp snooping-mode source-inf port

Source port check is disabled by default.

1.6.9 Configuring Source IP Address Check

1. Overview

The source IP address check function strictly restricts the source IP address of multicast traffic to prevent invalid multicast traffic.

Source IP address check contains the following two configurations:

- Default source IP address check: A source IP address is specified for each multicast group in all VLANs. Only multicast traffic with the source IP address the same as the preset one is valid.
- Group-specific source IP address check: A source IP address is specified for a specific multicast group in a specific VLAN. The multicast device forwards only data traffic of the specific multicast group received in the VLAN that has the same source IP address as the preset one and discards other multicast traffic from the specific multicast group.

2. Restrictions and Guidelines

- When source IP address check is enabled or disabled, all multicast forwarding entries on the L2 device will be deleted and the device needs to learn entries in the next query interval.
- Group-specific source IP address check can be configured only after default source IP address check is configured.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure default source IP address check.

ip igmp snooping-mode source-inf default-server *ipv4-source-address*

Source IP address check is disabled by default.

(4) Configure group-specific source IP address check.

ip igmp snooping-mode limit-ipmc vlan *vlan-id* **address** *ipv4-group-address* **server** *ipv4-source-address*

Only the multicast source address is checked by default.

1.7 Configuring QinQ Processing

Note

This command is not supported by the S6980-64QC, or S6580-24DC8QC.

1.7.1 Overview

On a device with IGMP snooping enabled and a dot1q-tunnel (QinQ) port configured, IGMP snooping will process the IGMP packets received on the QinQ port using the following two modes:

- Mode 1: Create multicast entries on the VLAN where the IGMP packets are located. Forwarding IGMP packets on the VLAN where these packets are located is called transparent transmission. For example, IGMP snooping is enabled for a device, Port A on the device is designated as the QinQ port, the default VLAN of this port is VLAN 1, and Port A allows the passage of VLAN 1 and VLAN 10 packets. When an IGMP Report packet is sent from VLAN 10 to Port A, IGMP snooping establishes a multicast entry for VLAN 10 and forwards the IGMP Report packet to the multicast router port of VLAN 10.
- Mode 2: Create multicast entries on the default VLAN of the QinQ port. Encapsulate the IGMP packets with the VLAN tag of the default VLAN where the QinQ port is located and forward the packets within the default VLAN. For example, IGMP snooping is enabled for a device, Port A on the device is designated as the QinQ port, the default VLAN of this port is VLAN 1, and Port A allows the passage of VLAN 1 and VLAN 10 packets. When an IGMP Report packet is sent from VLAN 10 to Port A, IGMP snooping establishes a multicast entry for VLAN 1, encapsulates the IGMP Report packet with the tag of VLAN 1, and forwards the packet to the multicast router port of VLAN 1.

IGMP snooping works in mode 2 by default. You can run the ip igmp snooping-mode tunnel command to enable IGMP snooping to work in mode 1.

1.7.2 Restrictions and Guidelines

If the QinQ port needs to forward multicast packets on the VLANs specified by the VLAN IDs (VIDs) of the packets, transparent packet transmission needs to be configured on the QinQ port.

1.7.3 Prerequisites

- Configuring Basic IGMP Snooping Functions
- Configure basic QinQ functions. For details about QinQ configuration, see *Configuring QinQ*.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure transparent packet transmission on the QinQ port.

ip igmp snooping-mode tunnel

The function of transparent IGMP packet transmission on the QinQ port is disabled by default.

1.8 Monitoring

Run the display command to check the running status of a configured function to verify the configuration effect.

Run the debugging command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the cleanup commands to clear information.

Caution

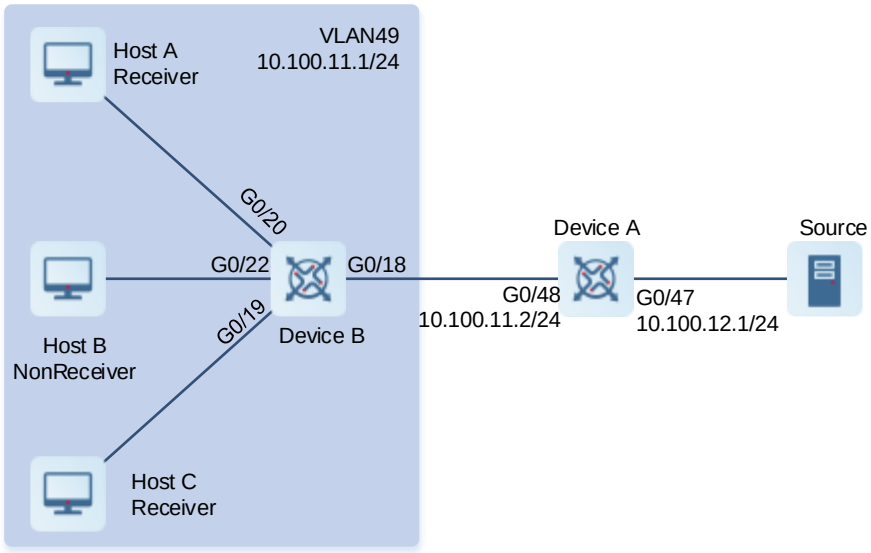
Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-2 Monitoring

Command	Purpose
cleanup ip igmp-cache snooping-mode stats	Clears IGMP snooping statistics.
cleanup ip igmp-cache snooping-mode gda-table	Clears dynamic multicast router ports and member ports.
display ip igmp-info snooping [**vlan** *vlan-id*]	Displays basic IGMP snooping configurations.
display ip igmp-info snooping statistics [**vlan** *vlan-id*]	Displays IGMP snooping statistics.
display ip igmp-info snooping multicast-router	Displays multicast router ports.

Command	Purpose
display ip igmp-info snooping gda-table	Displays IGMP snooping forwarding entries.
display ip igmp-info group-profile [*profile-number*]	Displays a profile.
display ip igmp-info snooping interface [*interface-type interface-number*]	Displays IGMP snooping configurations on a port.
display ip igmp-info snooping querier [**detail**]	Displays the IGMP snooping querier.
display ip igmp-info snooping thread-info	Displays detailed user information of the IGMP snooping process.
debugging igmp-snp	Debugs all IGMP snooping functions.
debugging igmp-snp event	Debugs IGMP snooping events.
debugging igmp-snp packet	Debugs IGMP snooping packets.
debugging igmp-snp msf	Debugs communication between IGMP snooping and Multicast Source Filter (MSF).
debugging igmp-snp warning	Debugs IGMP snooping warnings.

1.9 Configuration Examples



1.9.1 Configuring Basic IGMP Snooping Functions in IVGL Mode

1. Requirements

In the multicast network shown in Figure 1-5, the router (Device A) connects to the user network through the switch (Device B), and IGMP snooping is run on Device A. The multicast source sends data to multicast group 225.0.0.10. There are three hosts (Host A, Host B, and Host C) in the network. Host A and Host C join multicast group 225.0.0.10. Only Host A and Host C can receive multicast data that the multicast source sends to multicast group 225.0.0.10.

2. Topology

Figure 1-5 Topology of Basic IGMP Snooping Functions in IVGL Mode

3. Notes

Configure basic IGMP snooping functions on Device B.

- Configure the IP addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and Protocol Independent Multicast-Sparse Mode (PIM-SM) related functions on Device A.
- Enable IGMP snooping and run the IVGL mode on Device B.

4. Procedure

(1) Configure the IP addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IP address and unicast routing protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/47)# ip address 10.100.12.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/48)# ip address 10.100.11.2 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# router-protocol ospf 49
DeviceA(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.12.0 0.0.0.255 area 0
```

```
DeviceA(cfg-router)# exit
```

Configure the IP address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# vlan 49
DeviceB(cfg-vlan)# exit
DeviceB(cfg)# interface vlan 49
DeviceB(cfg-if-VLAN 49)#ip address 10.100.11.1 255.255.255.0
DeviceB(cfg-if-VLAN 49)# exit
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# interface GigabitEthernet 0/19
DeviceB(cfg-if-GigabitEthernet 0/19)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/19)# exit
DeviceB(cfg)# interface GigabitEthernet 0/20
DeviceB(cfg-if-GigabitEthernet 0/20)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/20)# exit
DeviceB(cfg)# interface GigabitEthernet 0/22
DeviceB(cfg-if-GigabitEthernet 0/22)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/22)# exit
DeviceB(cfg)# router-protocol ospf 49
DeviceB(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceB(cfg-router)# exit
```

(2) Enable multicast routing and PIM-SM related functions on Device A.

```
DeviceA(cfg)# ip mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# ip pim c-bsr GigabitEthernet 0/47
DeviceA(cfg)# ip pim c-rp GigabitEthernet 0/47
```

(3) Enable IGMP snooping and run the IVGL mode on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip igmp snooping-mode ivgl
```

5. Verification

Send packets from the multicast source (10.100.12.2) to multicast group G (225.0.0.10). Enable Host A and Host C to join G.

Run the **display ip igmp-info snooping gda-table** command on Device B to display the IGMP snooping forwarding entry and check whether the member port list contains only GigabitEthernet 0/19 and GigabitEthernet 0/20.

```
DeviceB# display ip igmp-info snooping gda-table
Multicast Switching Cache Table
   D: DYNAMIC
   S: STATIC
   M: MROUTE
(*, 225.0.0.10, 49):
   VLAN(49) 3 OPORTS:
      GigabitEthernet 0/18(M)
      GigabitEthernet 0/19(DM)
      GigabitEthernet 0/20(DM)
```

Run the **display ip igmp-info snooping** command on Device B and check whether the IGMP snooping working mode is IVGL.

```
DeviceB# display ip igmp-info snooping
IGMP Snooping running mode: IVGL
IGMP Snooping L2-entry-limit: 64000
Source port check: Disable
Source ip check: Disable
IGMP Fast-Leave: Disable
IGMP Report suppress: Disable
IGMP Global Querier: Disable
IGMP Preview: Disable
IGMP Tunnel: Disable

 network-advertise 10.100.11.0 0.0.0.255 area 0
!
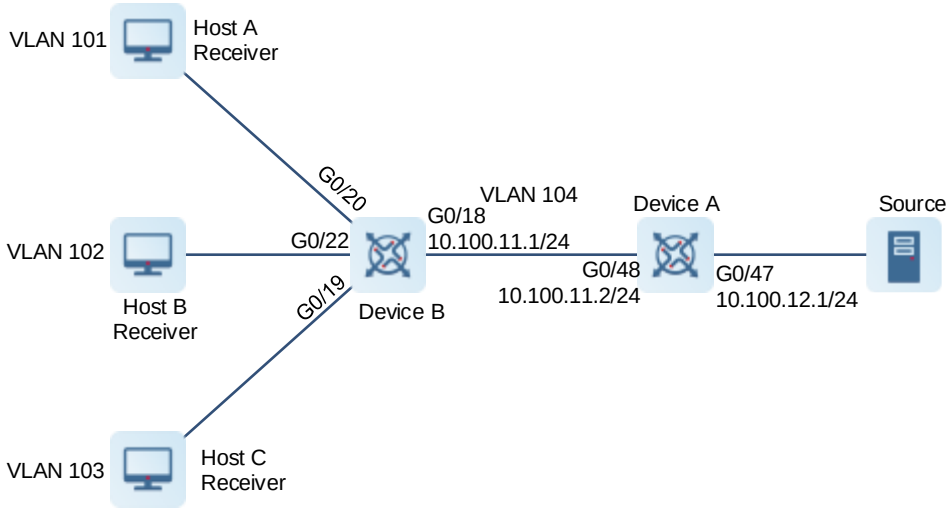
ip igmp snooping-mode ivgl
!
```

7. Common Errors

- The working mode of IGMP snooping is improper.



1.9.2 Configuring Basic IGMP Snooping Functions in SVGL Mode

1. Requirements

In the multicast network shown in Figure 1-6, the router (Device A) connects to the user network through the switch (Device B), IGMP snooping is run on Device A, and Device A directly connects to the multicast source. The multicast source sends data to multicast group 225.0.0.10. Host A, Host B, and Host C are connected to VLAN 101, VLAN 102, and VLAN 103, respectively, and the three hosts join multicast group 225.0.0.10. Host A, Host B, and Host C can receive multicast data that the multicast source sends to multicast group 225.0.0.10.

2. Topology

Figure 1-6 Topology of Basic IGMP Snooping Functions in SVGL Mode

3. Notes

Configure basic IGMP snooping functions on Device B.

- Configure the IP addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and PIM-SM related functions on Device A.
- Enable IGMP snooping and run the SVGL mode on Device B.
- Configure the multicast groups associated with the IGMP snooping SVGL mode on Device B and specify the shared VLAN and sub VLANs.

4. Procedure

(1) Configure the IP addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IP address and unicast routing protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# unset switch-port
```

```
DeviceA(cfg-if-GigabitEthernet 0/47)# ip address 10.100.12.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# vlan 104
DeviceA(cfg)# interface vlan 104
DeviceA(cfg-if-VLAN 104)# ip address 10.100.11.2 255.255.255.0
DeviceA(cfg-if-VLAN 104)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# switch-port mode trunk
DeviceA(cfg-if-GigabitEthernet 0/48)# switch-port trunk native vlan 104
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# router-protocol ospf 49
DeviceA(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.12.0 0.0.0.255 area 0
DeviceA(cfg-router)# exit
```

Configure the IP address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# vlan range 101-104
DeviceB(cfg-vlan-range)# exit
DeviceB(cfg)# interface VLAN 101
DeviceB(cfg-if-VLAN 101)# ip address 10.100.101.1 255.255.255.0
DeviceB(cfg-if-VLAN 101)# exit
DeviceB(cfg)# interface VLAN 102
DeviceB(cfg-if-VLAN 102)# ip address 10.100.102.1 255.255.255.0
DeviceB(cfg-if-VLAN 102)# exit
DeviceB(cfg)# interface VLAN 103
DeviceB(cfg-if-VLAN 103)# ip address 10.100.103.1 255.255.255.0
DeviceB(cfg-if-VLAN 103)# exit
DeviceB(cfg)# interface VLAN 104
DeviceB(cfg-if-VLAN 104)# ip address 10.100.11.1 255.255.255.0
DeviceB(cfg-if-VLAN 104)# exit
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port mode trunk
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port trunk native vlan 104
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# interface GigabitEthernet 0/19
DeviceB(cfg-if-GigabitEthernet 0/19)# switch-port access vlan 103
DeviceB(cfg-if-GigabitEthernet 0/19)# exit
DeviceB(cfg)# interface GigabitEthernet 0/20
DeviceB(cfg-if-GigabitEthernet 0/20)# switch-port access vlan 101
DeviceB(cfg-if-GigabitEthernet 0/20)# exit
DeviceB(cfg)# interface GigabitEthernet 0/22
DeviceB(cfg-if-GigabitEthernet 0/22)# switch-port access vlan 102
DeviceB(cfg-if-GigabitEthernet 0/22)# exit
DeviceB(cfg)# router-protocol ospf 49
DeviceB(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
```

```
DeviceB(cfg-router)# network-advertise 10.100.101.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.102.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.103.0 0.0.0.255 area 0
DeviceB(cfg-router)# exit
```

(2) Enable multicast routing and PIM-SM related functions on Device A.

```
DeviceA(cfg)# ip mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface vlan 104
DeviceA(cfg-if-VLAN 104)# ip pim sparse-mode
DeviceA(cfg-if-VLAN 104)# exit
DeviceA(cfg)# ip pim c-bsr GigabitEthernet 0/47
DeviceA(cfg)# ip pim c-rp GigabitEthernet 0/47
```

(3) Enable IGMP snooping and run the IVGL mode on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip igmp snooping-mode svgl
```

(4) Configure the multicast groups associated with the IGMP snooping SVGL mode on Device B and specify the shared VLAN and sub VLANs.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip igmp group-profile 1
DeviceB(cfg-profile)# permit
DeviceB(cfg-profile)# range 224.1.1.1 238.1.1.1
DeviceB(cfg-profile)# exit
DeviceB(cfg)# ip igmp snooping-mode svgl group-profile 1
DeviceB(cfg)# ip igmp snooping-mode svgl shared-vlan 104
DeviceB(cfg)# ip igmp snooping-mode svgl subvlan 101-103
```

5. Verification

Send packets from the multicast source (10.100.12.2) to multicast group G (225.0.0.10). Enable Host A, Host B, and Host C to join G.

Run the **display ip igmp-info snooping gda-table** command on Device B to display the IGMP snooping forwarding entry and check whether the member port list contains GigabitEthernet 0/19, GigabitEthernet 0/20, and GigabitEthernet 0/22.

```
DeviceB# display ip igmp-info snooping gda-table
Multicast Switching Cache Table
  D: DYNAMIC
  S: STATIC
  M: MROUTE
(*, 225.0.0.10, 104):
  VLAN(104) 1 OPORTS:
    GigabitEthernet 0/18(M)
```

```
VLAN(102) 1 OPORTS:
   GigabitEthernet 0/22(D)

VLAN(103) 1 OPORTS:
   GigabitEthernet 0/19(D)

VLAN(101) 1 OPORTS:
   GigabitEthernet 0/20(D)
```

Run the **display ip igmp-info snooping** command on Device B and check whether the IGMP snooping working mode is SVGL.

```
DeviceB# display ip igmp-info snooping
IGMP Snooping running mode: SVGL

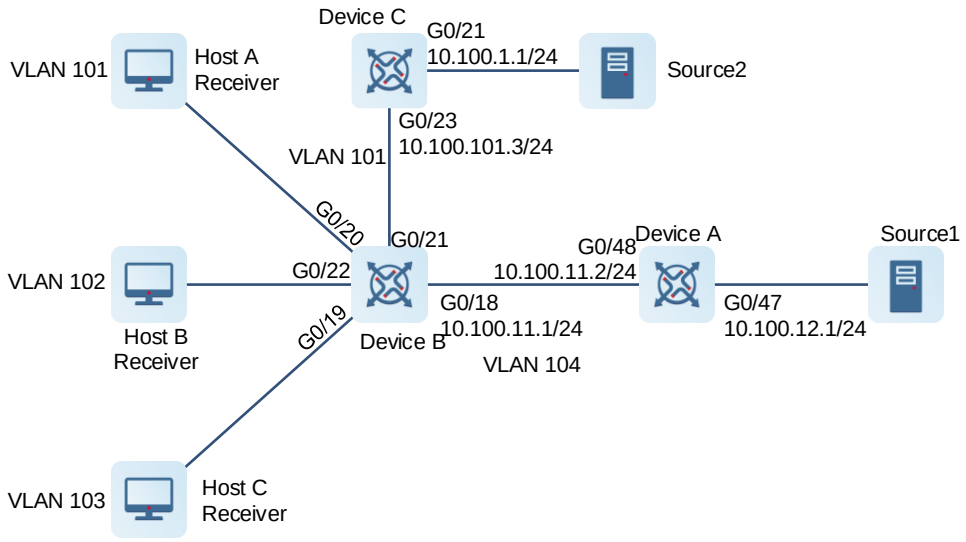
7. Common Errors

- The multicast groups associated with the SVGL mode are not configured.
- The sent multicast traffic is not in the multicast groups associated with the SVGL mode.



1.9.3 Configuring Basic IGMP Snooping Functions in IVGL-SVGL Mode

1. Requirements

In the multicast network shown in Figure 1-7, the routers (Device A and Device C) connect to the user network through the switch (Device B), IGMP snooping is run on Device A and Device C, and Device A and Device C directly connect to the multicast sources. Multicast source 1 sends data to multicast group 225.0.0.10, and multicast source 2 sends data to multicast group 239.0.0.11. Host A, Host B, and Host C are connected to VLAN 101, VLAN 102, and VLAN 103, respectively. Host B and Host C join multicast group 225.0.0.10, and Host A joins multicast groups 225.0.0.10 and 239.0.0.11. Host B and Host C can receive multicast data that source 1 sends to multicast group 225.0.0.10, and Host A can receive multicast data that source 1 sends to multicast group 225.0.0.10 and multicast data that source 2 sends to multicast group 239.0.0.11. Host A, Host B, and Host C enjoy shared multicast services, and Host A also enjoys independent multicast services.

2. Topology

Figure 1-7 Topology of Basic IGMP Snooping Functions in IVGL-SVGL Mode

3. Notes

Configure basic IGMP snooping functions in IVGL-SVGL mode on Device B.

- Configure the IP addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and PIM-SM related functions on Device A and Device C.
- Enable IGMP snooping and run the IVGL-SVGL mode on Device B.
- Configure the multicast groups associated with the IGMP snooping SVGL mode on Device B and specify the shared VLAN and sub VLANs.

4. Procedure

(1) Configure the IP addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IP address and unicast routing protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/47)# ip address 10.100.12.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# vlan 104
DeviceA(cfg)# interface vlan 104
DeviceA(cfg-if-VLAN 104)# ip address 10.100.11.2 255.255.255.0
DeviceA(cfg-if-VLAN 104)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# switch-port mode trunk
```

```
DeviceA(cfg-if-GigabitEthernet 0/48)# switch-port trunk native vlan 104
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# router-protocol ospf 49
DeviceA(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.12.0 0.0.0.255 area 0
DeviceA(cfg-router)# exit
```

Configure the IP address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# vlan range 101-104
DeviceB(cfg-vlan-range)# exit

DeviceB(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.101.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.102.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 10.100.103.0 0.0.0.255 area 0
DeviceB(cfg-router)# exit
```

Configure the IP address and unicast routing protocol on Device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/21)# ip address 10.100.1.1 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface GigabitEthernet 0/23
DeviceC(cfg-if-GigabitEthernet 0/23)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/23)# ip address 10.100.101.3 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/23)# exit
DeviceC(cfg)# router-protocol ospf 49
DeviceC(cfg-router)# network-advertise 10.100.1.0 0.0.0.255 area 0
DeviceC(cfg-router)# network-advertise 10.100.101.0 0.0.0.255 area 0
DeviceC(cfg-router)# exit
```

(2) Enable multicast routing and PIM-SM related functions on Device A and Device C.

Enable multicast routing and PIM-SM related functions on Device A.

```
DeviceA(cfg)# ip mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface vlan 104
DeviceA(cfg-if-VLAN 104)# ip pim sparse-mode
DeviceA(cfg-if-VLAN 104)# exit
DeviceA(cfg)# ip pim c-bsr GigabitEthernet 0/47
DeviceA(cfg)# ip pim c-rp GigabitEthernet 0/47
```

Enable multicast routing and PIM-SM related functions on Device C.

```
DeviceC(cfg)# ip mrouting-enable
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/21)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface GigabitEthernet 0/23
DeviceC(cfg-if-GigabitEthernet 0/23)# ip pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/23)# exit
```

(3) Enable IGMP snooping and run the IVGL mode on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip igmp snooping-mode ivgl-svgl
```

(4) Configure the multicast groups associated with the IGMP snooping SVGL mode on Device B and specify the shared VLAN and sub VLANs.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip igmp group-profile 1
DeviceB(cfg-profile)# permit
```

```
DeviceB(cfg-profile)# range 224.1.1.1 238.1.1.1
DeviceB(cfg-profile)# exit
DeviceB(cfg)# ip igmp snooping-mode svgl group-profile 1
DeviceB(cfg)# ip igmp snooping-mode svgl shared-vlan 104
DeviceB(cfg)# ip igmp snooping-mode svgl subvlan 101-103
```

5. Verification

Run the **display ip igmp-info snooping gda-table** command on Device B to display the IGMP snooping forwarding entries and check whether the member port list of entry (*, 225.0.0.10, 104) contains GigabitEthernet 0/22, GigabitEthernet 0/20, and GigabitEthernet 0/19 and the member port list of entry (*, 239.0.0.11, 101) contains GigabitEthernet 0/20.

```
DeviceB# display ip igmp-info snooping gda-table
Multicast Switching Cache Table
  D: DYNAMIC
  S: STATIC
  M: MROUTE
(*, 239.0.0.11, 101):
  VLAN(101) 2 OPORTS:
    GigabitEthernet 0/20(D)
    GigabitEthernet 0/21(M)

(*, 225.0.0.10, 104):
  VLAN(104) 1 OPORTS:
    GigabitEthernet 0/18(M)

  VLAN(102) 1 OPORTS:
    GigabitEthernet 0/22(D)

  VLAN(101) 1 OPORTS:
    GigabitEthernet 0/20(D)

  VLAN(103) 1 OPORTS:
    GigabitEthernet 0/19(D)
```

Run the **display ip igmp-info snooping** command on Device B and check whether the IGMP snooping working mode is IVGL-SVGL.

```
DeviceB# display ip igmp-info snooping
IGMP Snooping running mode: IVGL-SVGL

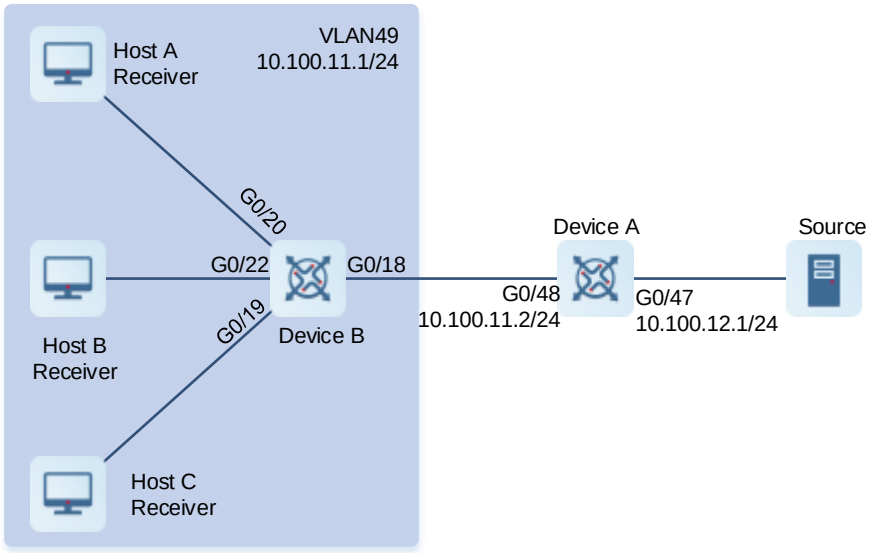
7. Common Errors

- The multicast groups associated with the SVGL mode are not configured.
- The sent multicast traffic is not in the multicast groups associated with the SVGL mode.
- The group addresses of multicast traffic in IVGL mode are within the multicast group range in SVGL mode. As a result, IVGL forwarding cannot be implemented.



1.9.4 Configuring Static Ports to Implement L2 Multicast

1. Requirements

In the multicast network shown in Figure 1-8, Host A, Host B, and Host C need to receive data that a multicast source sends to a specific multicast group stably. The router (Device A) connects to the user network through the L2 device (Device B). The static IGMP multicast groups 225.0.0.10 to 225.0.0.12 are configured on the user-side L3 port on Device A. Host A and Host B want to receive data of multicast group 225.0.0.10 stably, and Host C wants to receive data of multicast group 225.0.0.11 stably.

2. Topology

Figure 1-8 Topology of Static Ports to Implement L2 Multicast

3. Notes

Configure IGMP snooping static multicast router ports and member ports on Device B.

- Configure the IP addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and IGMP static multicast groups on Device A.
- Enable IGMP snooping on Device B.
- Configure static multicast router ports and member ports on Device B.

4. Procedure

(1) Configure the IP addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IP address and unicast routing protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/47)# ip address 10.100.12.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/48)# ip address 10.100.11.2 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# router-protocol ospf 49
DeviceA(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 10.100.12.0 0.0.0.255 area 0
DeviceA(cfg-router)# exit
```

Configure the IP address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# vlan 49
DeviceB(cfg-vlan)# exit
DeviceB(cfg)# interface vlan 49
DeviceB(cfg-if-VLAN 49)#ip address 10.100.11.1 255.255.255.0
DeviceB(cfg-if-VLAN 49)# exit
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# interface GigabitEthernet 0/19
DeviceB(cfg-if-GigabitEthernet 0/19)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/19)# exit
DeviceB(cfg)# interface GigabitEthernet 0/20
DeviceB(cfg-if-GigabitEthernet 0/20)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/20)# exit
```

```
DeviceB(cfg)# interface GigabitEthernet 0/22
DeviceB(cfg-if-GigabitEthernet 0/22)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/22)# exit
DeviceB(cfg)# router-protocol ospf 49
DeviceB(cfg-router)# network-advertise 10.100.11.0 0.0.0.255 area 0
DeviceB(cfg-router)# exit
```

(2) Enable IP multicast routing and PIM-SM related functions on Device A.

```
DeviceA(cfg)# ip mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# ip igmp static-group 225.0.0.10
DeviceA(cfg-if-GigabitEthernet 0/48)# ip igmp static-group 225.0.0.11
DeviceA(cfg-if-GigabitEthernet 0/48)# ip igmp static-group 225.0.0.12
DeviceA(cfg-if-GigabitEthernet 0/48)# ip pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# ip pim c-bsr GigabitEthernet 0/47
DeviceA(cfg)# ip pim c-rp GigabitEthernet 0/47
```

(3) Enable basic IGMP snooping functions on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip igmp snooping-mode ivgl
```

(4) Configure static multicast router ports and member ports on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip igmp snooping-mode vlan 49 static-member 225.0.0.11 interface GigabitEthernet 0/19
DeviceB(cfg)# ip igmp snooping-mode vlan 49 static-member 225.0.0.10 interface GigabitEthernet 0/22
DeviceB(cfg)# ip igmp snooping-mode vlan 49 static-member 225.0.0.10 interface GigabitEthernet 0/20
DeviceB(cfg)# ip igmp snooping-mode vlan 49 multicast-router interface GigabitEthernet 0/18
```

5. Verification

Run the **display ip igmp-info snooping multicast-router** command and check whether the static router port is GigabitEthernet 0/18.

```
DeviceB# display ip igmp-info snooping mrouter
Multicast Switching Mroute Port
  D: DYNAMIC
  S: STATIC
(*, *, 49):
  VLAN(49)   1 MROUTES:
    GigabitEthernet 0/18(DS)

(*, *, 101):
  VLAN(101)   1 MROUTES:
```

```
    GigabitEthernet 0/21(D)
```

Run the **display ip igmp-info snooping gda-table** command and check whether the static member ports of multicast group 225.0.0.10 are GigabitEthernet 0/20 and GigabitEthernet 0/22 and the static member port of multicast group 225.0.0.11 is GigabitEthernet 0/19.

```
DeviceB# display ip igmp-info snooping gda-table
Multicast Switching Cache Table
  D: DYNAMIC
  S: STATIC
  M: MROUTE
(*, 225.0.0.10, 49):
  VLAN(49) 3 OPORTS:
    GigabitEthernet 0/18(M)
    GigabitEthernet 0/20(S)
    GigabitEthernet 0/22(S)

(*, 225.0.0.11, 49):
  VLAN(49) 2 OPORTS:
    GigabitEthernet 0/18(M)
    GigabitEthernet 0/19(S)
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!

```

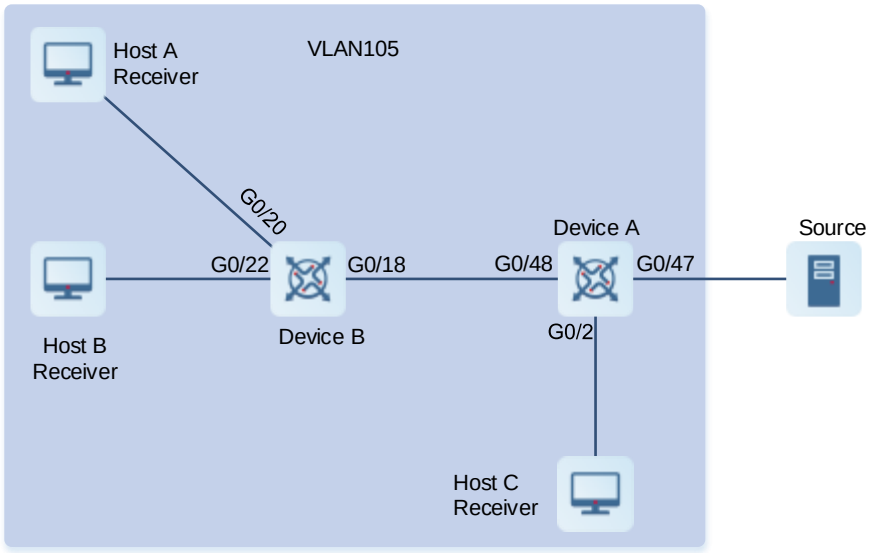
7. Common Errors

- Basic IGMP snooping functions are not configured or fail to be configured.



1.9.5 Configuring IGMP Snooping Querier

1. Requirements

In a two-layer multicast network, as shown in Figure 1-9, the multicast source sends multicast data to multicast groups 225.0.0.10 and 225.0.0.11. Host A and Host C join multicast group 225.0.0.10, and Host B joins multicast group 225.0.0.11. All receivers use IGMPv2. IGMP snooping is used to transfer multicast data in the two-layer network.

2. Topology

Figure 1-9 Topology of IGMP Snooping Querier

3. Notes

Enable IGMP snooping on Device A and Device B, and configure Device A as the IGMP snooping querier.

- Configure VLANs and IP addresses on Device A and Device B.
- Enable IGMP snooping and run the IVGL mode on Device A and Device B.
- Configure the IGMP snooping querier function for VLAN 105 on Device A.

4. Procedure

(1) Configure VLANs and IP addresses on Device A and Device B.

Configure the VLAN and IP address on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# vlan range 1,105
DeviceA(cfg)# interface VLAN105
DeviceA(cfg-if-VLAN105)# ip address 10.100.12.1 255.255.255.0
DeviceA(cfg-if-VLAN105)# exit
DeviceA(cfg)# interface GigabitEthernet0/47
DeviceA(cfg-if-GigabitEthernet0/47)# switch-port access vlan 105
DeviceA(cfg-if-GigabitEthernet0/47)# interface GigabitEthernet0/48
DeviceA(cfg-if-GigabitEthernet0/48)# switch-port mode trunk
DeviceA(cfg-if-GigabitEthernet0/48)# switch-port trunk native vlan 105
DeviceA(cfg-if-GigabitEthernet0/48)# exit
```

Configure the VLAN and IP address on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
```

```
DeviceB(cfg)# vlan range 1,105
DeviceB(cfg)# interface VLAN105
DeviceB(cfg-if-VLAN105)# ip address 10.100.12.3 255.255.255.0
DeviceB(cfg-if-VLAN105)# exit
DeviceB(cfg-if-GigabitEthernet 0/18)# interface GigabitEthernet 0/2
DeviceB(cfg-if-GigabitEthernet 0/2)# switch-port mode trunk
DeviceB(cfg-if-GigabitEthernet 0/2)# exit
DeviceB(cfg)#interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port mode trunk
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port trunk native vlan 105
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# interface GigabitEthernet 0/20
DeviceB(cfg-if-GigabitEthernet 0/20)# switch-port access vlan 105
DeviceB(cfg-if-GigabitEthernet 0/20)# exit
DeviceB(cfg)# interface GigabitEthernet 0/22
DeviceB(cfg-if-GigabitEthernet 0/22)# switch-port access vlan 105
DeviceB(cfg-if-GigabitEthernet 0/22)# exit
```

(2) Configure basic IGMP snooping functions and run the IVGL mode on Device A and Device B.

Enable IGMP snooping and run the IVGL mode on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip igmp snooping-mode ivgl
```

Enable IGMP snooping and run the IVGL mode on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip igmp snooping-mode ivgl
```

(3) Configure the IGMP snooping querier function on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)#ip igmp snooping-mode querier
DeviceA(cfg)#ip igmp snooping-mode querier source-address 10.100.12.1
DeviceA(cfg)#ip igmp snooping-mode vlan 105 querier
```

5. Verification

Run the **display ip igmp-info snooping querier** command to check whether the querier of VLAN 1 takes effect.

```
DeviceA# display ip igmp-info snooping querier
Vlan        IP Address              IGMP Version            Port
------------------------------------------------------------
105         10.100.12.1                 2                    switch
DeviceA#
DeviceA# display ip igmp-info snooping querier vlan 105

Vlan 105:    IGMP switch querier status
```

```
------------------------------------------------------------
elected querier is 10.100.12.1              (this switch querier)
------------------------------------------------------------
admin state                          : Enable
admin version                        : 2

1 Configuring MSDP

1.1 Introduction

Multicast Source Discovery Protocol (MSDP) is used to connect multiple rendezvous points (RPs) on the multicast network and implement the following two functions.

- Use MSDP among multiple Protocol Independent Multicast Sparse-Mode (PIM-SM) domains to share the multicast source information of these PIM-SM domains to implement cross-domain multicast.

  With the increase of a network, a PIM network can be divided into multiple PIM-SM domains to facilitate management. The RPs in a domain cannot understand multicast source information in other domains. MSDP peers are created among the PIM-SM domains to interact source-active (SA) messages so that multicast source information can be shared and multicast packets can be forwarded to hosts in other domains.

- Use MSDP in a PIM-SM domain to share the multicast source information of multiple RPs to implement an anycast RP.

  After RPs in a PIM-SM domain are configured with the same address and MSDP peers are created on these RPs, the RPs can implement load sharing and backup in the PIM-SM domain.

1.1.1 Principles

1. MSDP Peer

Configure one or more pairs of MSDP peers on the network to connect RPs. The peers interact SA messages so that an RP can notify other RPs of the multicast source information on this RP. So far as the unicast route is reachable, the MSDP peer relationship can be established. MSDP peers can be configured on RPs as well as on any other PIM device, for example, X in Figure 1-1.

Figure 1-1 Positions of MSDP Peers

- RP connected to the multicast source

  Configure the MSDP peer on the RP connected to the multicast source. Then, this RP can use SA messages to send the local multicast source information to other RPs.

  As shown in Figure 1-1, DR 1 registers the multicast source information with RP 1. As a peer relationship is established between RP 1 and the PIM device X, RP 1 sends the multicast source information to the PIM device X.

- SA message forwarder

  Non-RPs (common PIM devices) can also act as MSDP peers, but only forward SA messages.

  As shown in Figure 1-1, X forwards SA messages sent from RP 1 to RP 2. In this way, the multicast source information is transferred to RP 2.

- RP connected to the multicast receiver

  Configure the MSDP peer on the RP connected to the multicast receiver. Then, this RP can trigger a join towards the multicast source based on the received SA message.

  As shown in Figure 1-1, DR 2 triggers a join towards RP 2. As RP 2 already obtains the multicast source information, RP 2 continues to trigger a join towards the multicast source, thus establishing a multicast distribution tree (MDT) from DR 1 to DR 2.

2. MSDP Packet

An MSDP packet is encapsulated in a TCP packet and follows the format of type-length-value (TLV), as shown in Figure 1-2.

Figure 1-2 Format of MSDP Packet

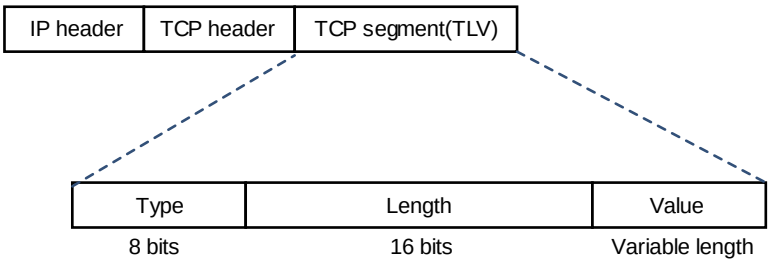

Table 1-1 Fields of MSDP Packet

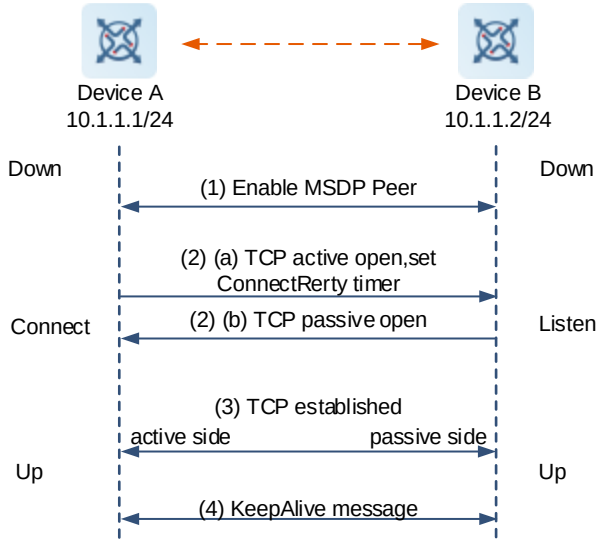
Field	Length	Description
Type	8 bits	Specifies a message type. ● **1**: Source-Active. Messages of this type carry multiple pairs of (S, G) information and they are transmitted among RPs. PIM-SM multicast packets can be encapsulated in the messages. ● **2**: Source-Active Request. Messages of this type request an (S, G) list of a specified group G to reduce the source join delay. ● **3**: Source-Active Response. Messages of this type are responses to the Source-Active Request. ● **4**: Keep Alive. Messages of this type hold the connection relationship of MSDP peers. ● **5**: Reserved. This is the reserved type of messages. ● **6**: MSDP traceroute in progress. Messages of this type specify the Traceroute function of MSDP and detect the reverse path forwarding (RPF) of SA messages. ● **7**: MSDP traceroute reply. Messages of this type specify the Traceroute function of MSDP and detect the RPF of SA messages.
Length	16 bits	Specifies the length of a message in bytes. The length includes the Type, Length and Value fields. Except for the Keep Alive message, the length of other messages must be 4 bytes at least and 9192 bytes at most.
Value	Subject to the length of the variable	Specifies the message content, which varies with the message type.



Based on Table 1-1, SA messages can carry multiple pairs of (S, G) information and they are transmitted among RPs. PIM-SM multicast packets can be encapsulated in the messages. The peers interact SA messages with each other to share multicast source information. Multicast packets are encapsulated in the SA messages to avoid the (S, G) entries in the SA messages timeout. If this is the case, hosts cannot receive the multicast packets of the source.

MSDP supports periodic sending of SA requests and SA responses to improve the source information update efficiency. With the mechanism, new hosts do not need to wait for an SA sending period to obtain valid (S, G) information, which reduces the time for the hosts to join a shortest path tree (SPT).

3. MSDP Peer Establishment Procedure

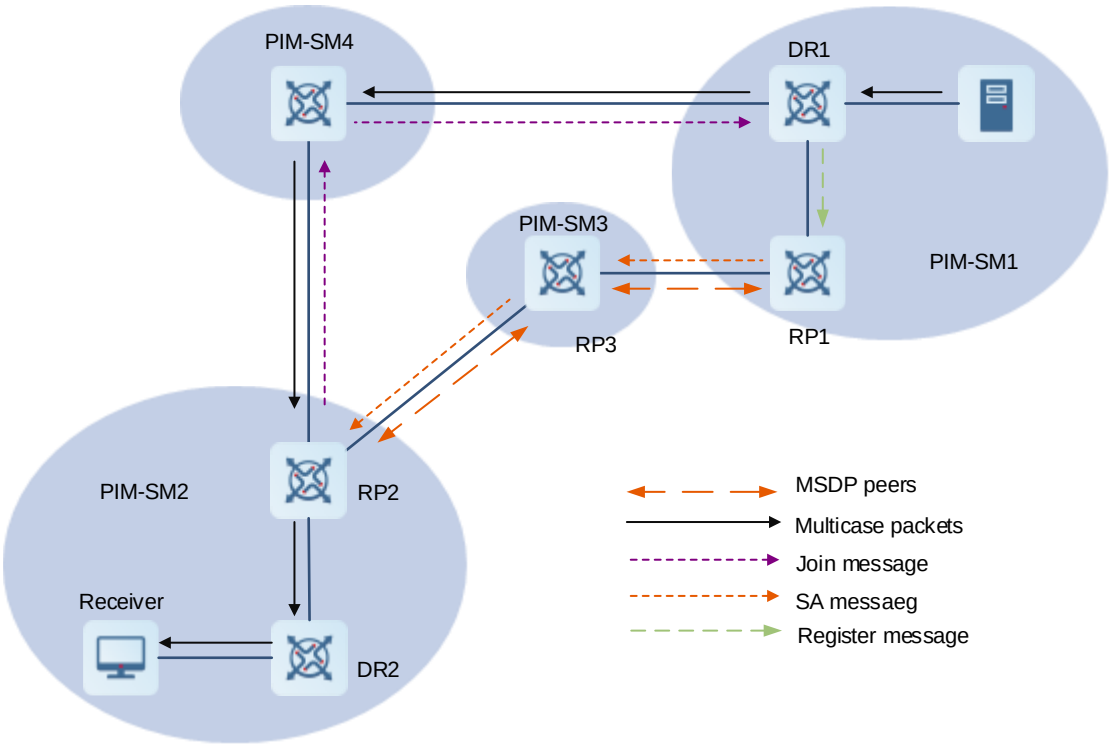
MSDP peers are connected over TCP through port 639. After a TCP connection is established between the peers, the connection is maintained through the keep alive messages.

Figure 1-3 MSDP Peer Connection Establishment Procedure

As shown in Figure 1-3, initially, the MSDP session state of device A and device B is down. The MSDP peer connection establishment procedure is as follows:

(1) Device A and device B specify the other party as a peer mutually and they compare their addresses.

a The IP address of device A is smaller than that of device B. Therefore, device A enters the connection status, initiates a connection request to device B, and starts a timer for reconnection.



b The IP address of device B is greater. Therefore, device B enters the listening status and waits for the connection request.

(2) After the MSDP session is established between device A and device B, the connection status is up. The two devices send keep alive messages to each other to notify the other party of keeping the MSDP session.

4. Inter-domain Multicast of MSDP

As shown in Figure 1-4, the multicast network is divided into four PIM-SM domains. In PIM-SM 1, the active source sends multicast data to the multicast group and registers with RP 1. In PIM-SM 2, the receiver joins the group, expecting to receive multicast data from the source in PIM-SM 1. The devices in PIM-SM 2 and PIM-SM 3 need to know the position of the source so as to obtain the corresponding multicast data. To implement this purpose, MSDP peer relationship must be established between RP 1 and RP 3 and between RP 3 and RP 2.

Figure 1-4 Inter-domain Multicast of MSDP

The working process of PIM-SM inter-domain multicast is as follows:

(1) The multicast source in PIM-SM 1 sends multicast data to the group. The multicast data is sent to source DR 1 for registration and encapsulated in messages and sent to RP 1. RP 1 obtains the multicast source information.

(2) Source RP 1 sends SA messages to RP 3 periodically. An SA message contains the multicast source address S, multicast group address G, and RP 1 address.

(3) Upon receiving the SA messages, RP 3 performs RPF checking and filters forwarding policies. After the messages pass the checking, they are sent to RP 2. Then, PIM-SM 2 and PIM-SM 3 obtain the source information.

(4) Upon receiving the SA messages, RP 2 checks whether the receiver of the group exists in PIM-SM 2.

- If the receiver exists in PIM-SM 2, an RPT about the group is created between RP 2 and the receiver. RP 2 creates an (S, G) pair and sends an (S, G) join packet to the source hop by hop to generate an SPT. The multicast data is sent to RP 2 along the SPT and then forwarded to the receiver along the RPT. Upon receiving the multicast data, member DR 2 decides whether to perform SPT switchover based on configuration.
- If the receiver does not exist in PIM-SM 2, RP 2 does not create an (S, G) pair or send join packets to the source.

5. Receiving and Forwarding SA Messages

An SA message contains the multicast source address, multicast group address, and RP address. The RP address is the IP address of the RP with which the multicast source is registered.

- The RP encapsulates the locally registered multicast source information in an SA message, and sends the

message to all its MSDP peers.

- On receiving the SA message, each MSDP peer performs the peer RPF check, compares the SA message with the content in the SA cache, and matches the SA message against the SA incoming and outgoing filtering rules. If the SA message passes the peer RPF check and meets the outgoing filtering rules and does not exist in the SA cache, this SA message is forwarded to other MSDP peers.
- For any SA message coming from an MSDP peer (address: N), the following peer RPF check rules are used to prevent loops and avoid SA message flooding:

  a If N is a member of the mesh group, the SA message passes the peer RPF check; otherwise, go to step b.

  b If N is the only active MSDP peer on the local device, the SA message passes the peer RPF check; otherwise, go to step c.

  c If N is the RP address in the SA message, the SA message passes the peer RPF check; otherwise, go to step d.

  d If an EBGP route to the RP address in the SA message exists on the local device and the next hop of this route is N, the SA message passes the peer RPF check; otherwise, go to step e.

  e If an optimum route to the RP address in the SA message exists on the local device, check as follows:

  If this optimum route is a distance vector route (such as the BGP/RIP route), and this router is advertised by N, the SA message passes the peer RPF check.

  If this optimum route is a link status route (such as the OSPF/IS-IS route), and the next hop of this router is N, the SA message passes the peer RPF check.

  Otherwise, go to step f.

  f If an optimum route to the RP address in the SA message exists on the local device, and this route is an MBGP/BGP route, extract the nearest autonomous system (AS) of the AS path of this MBGP/BGP route. If the local device has multiple MSDP peers in this AS and N is the MSDP peer with the largest IP address, or N is the only MSDP peer in this AS, the SA message passes the peer RPF check; otherwise, go to step g.

  g If N is the default MSDP peer, the SA message passes the peer RPF check; otherwise, go to step h.

  h The SA message fails in the peer RPF check.

- When MSDP peer relationship is established on any two members in a group, this group is a mesh group. The mesh group helps reduce the number of SA messages. As shown in Figure 1-5, device B, device C, and device D belong to the same mesh group.
  - For SA messages from device A outside the mesh group and received by device B in the mesh group, after the messages pass the peer RPF check and SA cache comparison, these SA messages are forwarded to other members in the group.
  - For SA messages from device B to device C and device D, they are no longer forwarded to other members in the group.

Figure 1-5 Mesh Group Topology

- The SA cache buffers status of SA messages. Expired SA messages will be deleted.
  - When an MSDP peer receives an SA message

    If this message does not exist in the SA cache and passes the peer RPF check, the message is stored in the SA cache.

    If this message already exists in the SA cache, the message is ignored. This helps suppress SA message flooding.
  - When an MSDP peer receives an SA message, if this message already exists in the SA cache, the message is immediately responded. This helps improve the protocol efficiency.

6. Anycast RP based on MSDP

Generally, each multicast group in a PIM-SM network is served by only one RP. If the RP is faulty or fails, the multicast traffic may be interrupted. Anycast RP enables multiple RPs with the same address to serve a multicast group to implement redundant backup between the RPs. The multicast sources or group members register with the nearest RPs so that the RPs synchronize source information. Anycast RP is implemented by creating MSDP peer relationship between these RPs.

Figure 1-6 Anycast RP based on MSDP

As shown in Figure 1-6, device A and device B in a PIM-SM domain establish peer relationship. The source sends multicast data to the group, and the receiver receives the multicast data as a member of the group. The working process of Anycast RP based on MSDP is as follows:

(1) When the source DR receives the multicast data from the source, the source DR registers with the nearest RP 1.

(2) When the member DR receives a join request packet from the receiver, the member DR forwards the join packet to RP 2. In this way, an RPT with RP 2 as the root is formed.

(3) RP 1 and RP 2 interact SA messages and share the (S, G) information of the multicast source. Upon obtaining the multicast source information, RP 2 sends the join packet to the source hop by hop to generate an SPT.

(4) The multicast data is forwarded to RP 2 through the SPT and then forwarded to the receiver through the RPT. The member DR decides whether to perform SPT switchover based on configuration.

1.1.2 Protocols and Standards

- RFC 3618: Multicast Source Discovery Protocol (MSDP)
- RFC 3446: Anycast Rendevous Point (RP) mechanism using Protocol Independent Multicast (PIM) and Multicast Source Discovery Protocol (MSDP)

1.2 Restrictions and Guidelines

Establish the MSDP peer relationship between multiple ASs so that group members can apply for the multicast streams across ASs.

- The inter-AS unicast route must be reachable.
- Run PIM-SM within each AS, and configure the BSR border.
- The IP address and local interface of the MSDP peer must be the same as those of the EBGP peer.

1.3 Configuration Task Summary

The IP multicast configuration includes the following tasks:

(1) Managing MSDP Peers.

- Configuring MSDP Peers
- (Optional) Configuring the Default MSDP Peer
- (Optional) Configuring an MSDP Mesh Group
- (Optional) Configuring the TCP Reconnection Interval of an MSDP Peer
- (Optional) Enabling MD5 Authentication on TCP Connections Between MSDP Peers
- (Optional) Configuring the Number of MSDP Peers Supported on a Device

(2) Restricting SA Messages. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the TTL Value of Multicast Packets in SA Messages
- Enabling the Function of Filtering Source Information Released Locally
- Enabling the Function of Filtering Received SA Requests
- Enabling the Function of Filtering Received SA Messages
- Enabling the Function of Filtering Sent SA Messages
- Configuring SA Cache Capacity

(3) Configuring an Anycast RP.

1.4 Prerequisites

- Unicast routing protocols are configured and the network in a domain is reachable.
- Basic PIM-SM functions are configured to implement multicast in a domain.

1.5 Managing MSDP Peers

1.5.1 Overview

MSDP peers in different PIM-SM domains interact SA messages to share inter-domain multicast source information.

1.5.2 Configuration Tasks

The MSDP peer management configuration includes the following tasks:

(1) Configuring MSDP Peers

(2) (Optional) Configuring the Default MSDP Peer

(3) (Optional) Configuring an MSDP Mesh Group

(4) (Optional) Configuring the TCP Reconnection Interval of an MSDP Peer

(5) (Optional) Enabling MD5 Authentication on TCP Connections Between MSDP Peers

(6) (Optional) Configuring the Number of MSDP Peers Supported on a Device

1.5.3 Configuring MSDP Peers

1. Overview

MSDP peers are identified based on addresses. The relationship between MSDP peers is bidirectional. Therefore, they must be created on both ends. You can manage MSDP peers by adding description information to a specified MSDP. A connection with a specified peer can be temporarily disabled by configuration.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Establish an MSDP peer relationship.

ip msdp add-peer *ipv4-peer-address* **source-interface** *interface-type interface-number*

No MSDP peer is added by default.

(4) (Optional) Configure description information for an MSDP peer.

ip msdp peer-description *ipv4-peer-address description*

No description information is added for an MSDP peer by default.

(5) (Optional) Disable an MSDP peer.

ip msdp peer-closing *ipv4-peer-address*

The connection with an MSDP peer is enabled by default.

Only the TCP connection with the MSDP peer is disabled, and this MSDP peer and the configuration of this MSDP peer are reserved.

1.5.4 Configuring the Default MSDP Peer

1. Overview

On an MSDP peer, if it is not necessary to perform peer RPF check on SA messages sent from a specified peer, configure this peer as the default peer.

2. Restrictions and Guidelines

- If the **prefix-list** keyword parameter is not specified, all SA messages are accepted.
- If an inexistent **prefix-list** is specified, all SA messages are accepted.
- If an existent **prefix-list** is specified, only the SA messages of RPs specified in this prefix list are accepted.

3. Prerequisites

- An MSDP peer relationship is established.
- If the **prefix-list** keyword parameter is specified, the prefix list must be created before a default MSDP peer is configured. For details about the prefix list configuration, see *Configuring Routing Policies*.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a default MSDP peer.

ip msdp peer-default-addr *ipv4-peer-address* [**prefix-list** *prefix-list-name*]

No default MSDP peer is configured by default.

1.5.5 Configuring an MSDP Mesh Group

1. Overview

When MSDP peer relationship is established on any two members in a group, this group is a mesh group. The mesh group helps reduce the number of SA messages and avoids SA message flooding between the peers. SA messages received by peers in a mesh group are processed in one of the following ways:

- For SA messages coming outside the mesh group, after the SA messages pass the peer RPF check and SA cache comparison, they are forwarded to the other members in the group.
- For SA messages from the internal mesh group, they are received without passing peer RPF check and are no longer forwarded to the other members in the group.

2. Restrictions and Guidelines

Among multiple MSDP peers, if SA messages from these peers pass RPF check by default, these peers can be added to a mesh group.

3. Prerequisites

An MSDP peer relationship is established.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a mesh group.

ip msdp peer-to-mesh-group *mesh-name ipv4-peer-address*

No mesh group is configured and no MSDP peer is added to any mesh group by default.

1.5.6 Configuring the TCP Reconnection Interval of an MSDP Peer

1. Overview

Within the TCP reconnection interval, the MSDP peer on the proactive connection side can initiate at most one TCP connection. In some application scenarios, for example, MSDP peer creation, restart, or failback, you can shorten the TCP reconnection interval to accelerate convergence of the MSDP peer relationship.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the TCP reconnection interval of an MSDP peer.

ip msdp retry-period *interval*

The default TCP reconnection interval is **30** seconds.

1.5.7 Enabling MD5 Authentication on TCP Connections Between MSDP Peers

1. Overview

MD5 authentication is enabled on TCP connections between MSDP peers to prevent invalid TCP connections and improve MSDP security. To authenticate the ID of an MSDP peer, you can enable MD5 authentication on the TCP connection established with this MSDP peer.

2. Restrictions and Guidelines

- The MSDP peers must have the consistent configuration, and the ciphers must be the same; otherwise, TCP connections fail.
- If the encryption level is set to 7, the cipher text length must be an even number equal to or greater than 4; otherwise, the configuration fails.
- If the configuration or cipher changes, the local device does not stop the current session. Instead, it attempts to use a new cipher to retain the current session until timeout.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable MD5 authentication on TCP connections between MSDP peers.

ip msdp peer-connection password *ipv4-peer-address* [**0** | **7**] *password-string*

The MD5 authentication function is disabled by default.

1.5.8 Configuring the Number of MSDP Peers Supported on a Device

1. Overview

You can configure the number of MSDP peers supported on a device. If the default number (64) cannot meet requirements, the number of the MSDP peers can be increased.

2. Restrictions and Guidelines

When the number of MSDP peers on the device exceeds the configured number, a notification is displayed to indicate configuration failure. In this case, you need to delete some peers to make the configuration take effect.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the number of MSDP peers supported on a device.

ip msdp peer-limit *peer-limit*

The maximum number of MSDP peers supported on a device is **64** by default.

1.6 Restricting SA Messages

1.6.1 Overview

MSDP peers share multicast source information by exchanging SA messages. Based on the actual network conditions, multicast packets encapsulated in SA messages can be defined, and SA requests and SA messages can be filtered.

1.6.2 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the TTL Value of Multicast Packets in SA Messages
- Enabling the Function of Filtering Source Information Released Locally
- Enabling the Function of Filtering Received SA Requests
- Enabling the Function of Filtering Received SA Messages
- Enabling the Function of Filtering Sent SA Messages
- Configuring SA Cache Capacity

1.6.3 Prerequisites

MSDP peer relationship is established between devices.

1.6.4 Configuring the TTL Value of Multicast Packets in SA Messages

1. Overview

If the interval of a multicast source for sending multicast data exceeds the timeout of an (S, G) entry, remote users cannot receive the multicast data sent by the multicast source. After the function of encapsulating multicast packets in SA messages is enabled on the source RP, the source RP encapsulates multicast packets in SA messages and sends them to the remote RPs. Upon receiving the messages, the remote RPs decapsulate the messages and transmit the packets in the local domain.

By configuring the time-to-live (TTL) value of multicast packets encapsulated in SA messages, you can control the sending of the multicast packets encapsulated in the SA messages.

- A multicast packet can be sent to MSDP peers only when the TTL value in the IP header of the multicast packet is equal to or greater than the preset TTL value.
- If the TTL value in the IP header of the multicast packet is smaller than the preset TTL value, the multicast packet is removed from the SA message and discarded before the SA message is sent to the MSDP peer.

Therefore, this function affects the sending of multicast packets in SA messages, and does not affect the sending of (S, G) information in the SA messages.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the TTL value of multicast packets in SA messages.

ip msdp sa-ttl-limit *ipv4-peer-address ttl-value*

The TTL value of the multicast packets in SA messages is not defined by default.

1.6.5 Enabling the Function of Filtering Source Information Released Locally

1. Overview

After source information registered on the local RP is filtered on an MSDP device, only allowed (S, G) information of the local or other domains can be released on the MSDP device.

2. Restrictions and Guidelines

- If the **list** keyword parameter is specified, only the (S, G) information matching this ACL is released.
- If the **route-map** keyword parameter is specified, only the (S, G) information matching this route map is released.
- If these two parameters are specified, only the (S, G) information matching the ACL and route map is released.
- If no parameter is specified, no (S, G) information is released.

3. Prerequisites

Before an IP multicast border is configured, ensure that the corresponding ACL or route map is created and an (S, G) range is specified.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Filter the source information released locally.

ip msdp redistribute-msg [{ **list** *acl-name* | **list** *acl-number* } | **route-map** *route-map-name*] *

All (S, G) information registered on the local RP is released on the MSDP device by default.

1.6.6 Enabling the Function of Filtering Received SA Requests

1. Overview

An MSDP device gives a reply by default when the device receives an SA request. If you want to control the SA request and reply range, you can enable the SA request filtering function on the MSDP device to filter received SA requests.

2. Restrictions and Guidelines

- If the **list** keyword parameter is not specified, all the SA request messages are ignored.
- If the **list** keyword parameter is specified but this ACL is not configured, all SA request messages are ignored.
- If the **list** keyword parameter is specified and this ACL is configured, only the SA requests allowed by the ACL are accepted, and other SA requests are ignored.

3. Prerequisites

Before a received SA request is filtered, ensure that the corresponding ACL is created and a multicast group range is specified.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Filter received SA requests.

ip msdp filter-peer-sa-query *ipv4-peer-address* [{ **list** *acl-name* | **list** *acl-number* }]

All SA request messages from MSDP peers are received and replied by default.

1.6.7 Enabling the Function of Filtering Received SA Messages

1. Overview

By default, SA messages are received and forwarded to other MSDP peers after they pass RPF check. You can configure filtering rules for incoming SA message on the MSDP device to filter received SA messages.

2. Restrictions and Guidelines

- If the function of filtering SA messages is enabled but no ACL or route map is configured, all incoming SA messages are filtered.
- If only one keyword (**list** or **route-map**) is specified and the multicast source (S, G) information in an SA message meets the rule specified by this keyword, this SA message is received.
- If only one keyword (**originate-rp-list** or **originate-rp-route-map**) is specified and the RP address contained in an SA message meets the rule specified by this keyword, this SA message is received.
- If two or more of the keywords (including **list**, **route-map, rp-list** and **rp-route-map**) are specified and the multicast source (S, G) information contained in an SA message meets the rules specified by these keywords, this SA message is received.

3. Prerequisites

Before an IP multicast border is configured, ensure that the corresponding ACL or route map is created and an (S, G) range is specified.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Filter received SA messages.

ip msdp sa-msg-filter inbound *ipv4-peer-address* [{ **list** *acl-name* | **list** *acl-number* } | **route-map** *route-map-name* | { **originate-rp-list** *acl-name* | **originate-rp-list** *acl-number* } | **originate-rp-route-map** *rp-route-map-name*] *

All SA messages from MSDP peers are received by default.

1.6.8 Enabling the Function of Filtering Sent SA Messages

1. Overview

By default, SA messages are received and forwarded to other MSDP peers after they pass RPF check. You can configure outgoing SA message filtering rules on the MSDP device to filter SA messages to be forwarded.

2. Restrictions and Guidelines

- If the function of filtering sent SA messages is enabled but no ACL or route map is specified, no SA message is sent to other MSDP peers.
- If only one of the keywords (including **list**, **route-map**, **originate-rp-list**, and **originate-rp-route-map**) is specified and the multicast source (S, G) information in an SA message meets the rule specified by this keyword, this SA message is forwarded to other MSDP peers.
- If two or more of the keywords (including **list**, **route-map**, **originate-rp-list**, and **originate-rp-route-map**) are specified and the multicast source (S, G) information in an SA message meets the rules specified by these keywords, this SA message is forwarded to other MSDP peers.

3. Prerequisites

Before an IP multicast border is configured, ensure that the corresponding ACL or route map is created and an (S, G) range is specified.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Filter sent SA messages.

ip msdp sa-msg-filter outbound *ipv4-peer-address* [{ **list** *acl-name* | **list** *acl-number* } | **route-map** *route-map-name* | { **originate-rp-list** *acl-name* | **originate-rp-list** *acl-number* } | **originate-rp-route-map** *rp-route-map*] *

By default, all SA messages are forwarded to MSDP peers.

1.6.9 Configuring SA Cache Capacity

1. Overview

If an SA cache is used to cache SA messages, the (S, G) entries contained in the SA messages are cached in the SA cache. When a device receives a new join message, the device searches for the SA cache to reduce the delay time of obtaining the multicast information. The more (S, G) entries cached, the greater the used memory space. To suppress SA message flooding, you can limit the number of SA cache entries from a specified MSDP peer or a device.

2. Restrictions and Guidelines

- You are advised to configure the SA cache capacity when you start a device.
- During MSDP running,
  - if the capacity is increased, the adjustment does not affect the SA cache entries that are originally learned.
  - If the capacity is decreased, all SA cache entries learned and initiated must be deleted and re-learned.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Limit the number of SA cache entries from a specified MSDP peer.

ip msdp peer-sa-cache-limit *ipv4-peer-address sa-limit*

The number of SA cache entries from a specified MSDP peer is not limited by default.

(4) (Optional) Configure the SA cache capacity supported on a device.

ip msdp global-sa-limit *sa-limit*

The default SA cache capacity supported on a device is **1024**.

1.7 Configuring an Anycast RP

1.7.1 Overview

RPs in a PIM-SM domain use the same RP address to serve the same group. MSDP peer relationship is established between RPs so that multicast sources and receivers can register with and join the nearest RP. The RPs implement redundancy and load sharing and help accelerate convergence of multicast routes.

1.7.2 Prerequisites

Basic multicast functions are enabled in the PIM-SM domain and multiple RPs are configured for the domain.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Establish an MSDP peer relationship.

ip msdp add-peer *ipv4-peer-address* **source-interface** *interface-type interface-number*

No MSDP peer is added by default.

(4) Modify the RP address in SA messages.

ip msdp originator-inf *interface-type interface-number*

By default, no primary address of an interface is specified as the initiator address in SA messages.

1.8 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **cleanup** commands to clear information.

Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-2 Monitoring

Command	Purpose
cleanup ip msdp-conn peer-addr *ipv4-peer-address*	Resets the TCP connection with a specified MSDP peer.
cleanup ip msdp-conn sa-cache [*ipv4-group-address*]	Clears the SA cache.
cleanup ip msdp-conn peer-stats [*ipv4-peer-address*]	Clears the statistics of MSDP peers.
display ip msdp-info count [*as-number*]	Displays the number of sources and the number of groups generated by SA messages.
display ip msdp-info peer-to-mesh-group	Displays information of a mesh group.
display ip msdp-info peer-detail [*ipv4-peer-address*]	Displays detailed information about MSDP peers.

Command	Purpose
display ip msdp-info rpf-peer *ipv4-address*	Displays information about the MSDP RPF peer corresponding to the address of a specified initiator.
display ip msdp-info sa-cache [*ipv4-group-address* **|** *ipv4-source-address*] [*ipv4-group-address* **|** *ipv4-source-address*] [*as-number*]	Displays learned (S, G) information.
display ip msdp-info sa-originated	Displays (S, G) information initiated by the local device.
display ip msdp-info peer-summary	Displays summary information of all MSDP peers.
debugging ip msdp-info peer	Debugs MSDP peers.

1.9 Configuration Examples

1.9.1 Enabling Basic Functions of MSDP

1. Requirements

MSDP peers are configured in different domains to connect the RPs. Multicast source information can be shared to other RPs.

2. Topology

Figure 1-7 Topology for Basic Functions of MSDP

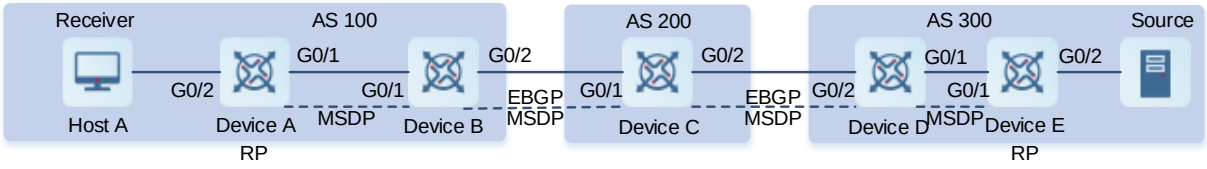


Table 1-3 Description of the Topology

Device	Interface	IP Address	Remarks
Device A	G0/1	10.110.1.1/24	-
	Loopback0	10.10.10.10/32	RP address, which is used to establish an MSDP connection.
Device B	G0/1	10.110.1.2/24	-
	G0/2	10.110.2.1/24	BSR border
	Loopback0	20.20.20.20/32	Used to establish the EBGP and MSDP connections.
Device C	G0/1	10.110.2.2/24	BSR border

Device	Interface	IP Address	Remarks
	G0/2	10.110.3.1/24	BSR border
	Loopback0	30.30.30.30/32	Used to establish the EBGP and MSDP connections.
Device D	G0/2	10.110.3.2/24	BSR border
	G0/1	10.110.4.1/24	-
	Loopback0	40.40.40.40/32	Used to establish the EBGP and MSDP connections.
Device E	G0/1	10.110.4.2/24	-
	Loopback0	50.50.50.50/32	RP address, which is used to establish an MSDP connection.

3. Notes

- Configure an IP address for an interface.
- Enable OSPF in each AS. Establish EBGP peer relationship between AS 200 and AS 100 and between AS 200 and AS 300. BGP and OSPF import learned routes to each other.
- Enable PIM-SM in each AS, configure C-BSRs and C-RPs, and configure the BSR border.
- Establish the MSDP peer relationship between EBGP peers and between the RP and EBGP peers.

Caution

The IP address and local interface of the MSDP peer must be the same as those of the EBGP peer.

4. Procedure

(1) Configure an IP address for each interface (omitted).

(2) Enable OSPF in each AS. Establish EBGP peer relationship between AS 200 and AS 100 and between AS 200 and AS 300. BGP and OSPF import learned routes to each other. For the omitted information, see *Configuring OSPFv2* and *Configuring BGP*

(3) Enable PIM-SM in each AS, configure C-BSRs and C-RPs, and configure the BSR border.

Configure device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# ip mrouting-enable
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# ip pim sparse-mode
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# interface loopback 0
Device A(cfg-if-Loopback 0)# ip pim sparse-mode
Device A(cfg-if-Loopback 0)# exit
Device A(cfg)# ip pim c-rp loopback 0
Device A(cfg)# ip pim c-bsr loopback 0
```

Configure device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# ip mrouting-enable
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip pim sparse-mode
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface gigabitethernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# ip pim sparse-mode
Device B(cfg-if-GigabitEthernet 0/2)# ip pim bsr-boundary
Device B(cfg-if-GigabitEthernet 0/2)# exit
Device B(cfg)# interface loopback 0
Device B(cfg-if-Loopback 0)# ip pim sparse-mode
Device B(cfg-if-Loopback 0)# exit
```

Configure device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# ip mrouting-enable
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# ip pim sparse-mode
Device C(cfg-if-GigabitEthernet 0/1)# ip pim bsr-boundary
Device C(cfg-if-GigabitEthernet 0/1)# exit
Device C(cfg)# interface gigabitethernet 0/2
Device C(cfg-if-GigabitEthernet 0/2)# ip pim sparse-mode
Device C(cfg-if-GigabitEthernet 0/2)# ip pim bsr-boundary
Device C(cfg-if-GigabitEthernet 0/2)# exit
Device C(cfg)# interface loopback 0
Device C(cfg-if-loopback 0)# ip pim sparse-mode
Device C(cfg-if-loopback 0)# exit
```

Configure device D.

```
Device D> privilege
Device D# config-system terminal
Device D(cfg)# ip mrouting-enable
Device D(cfg)# ip pim enable-ssm default
Device D(cfg)# interface gigabitethernet 0/1
Device D(cfg-if-GigabitEthernet 0/1)# ip pim sparse-mode
Device D(cfg-if-GigabitEthernet 0/1)# exit
Device D(cfg)# interface gigabitethernet 0/2
Device D(cfg-if-GigabitEthernet 0/2)# ip pim sparse-mode
Device D(cfg-if-GigabitEthernet 0/2)# ip pim bsr-boundary
Device D(cfg-if-GigabitEthernet 0/2)# exit
Device D(cfg)# interface loopback 0
Device D(cfg-if-Loopback 0)# ip pim sparse-mode
Device D(cfg-if-Loopback 0)# exit
```

Configure device E.

```
Device E> privilege
Device E# config-system terminal
Device E(cfg)# ip mrouting-enable
Device E(cfg)# interface gigabitethernet 0/1
Device E(cfg-if-GigabitEthernet 0/1)# ip pim sparse-mode
Device E(cfg-if-GigabitEthernet 0/1)# exit
Device E(cfg)# interface loopback 0
Device E(cfg-if-Loopback 0)# ip pim sparse-mode
Device E(cfg-if-Loopback 0)# exit
Device E(cfg)# ip pim c-rp loopback 0
Device E(cfg)# ip pim c-bsr loopback 0
```

(4) Establish the MSDP peer relationship between EBGP peers and between the RP and EBGP peers.

Configure device A.

```
Device A(cfg)# ip msdp add-peer 10.10.10.10 source-interface loopback 0
```

Configure device B.

```
Device B(cfg)# ip msdp add-peer 10.10.10.10 source-interface loopback 0
Device B(cfg)# ip msdp add-peer 30.30.30.30 source-interface loopback 0
```

Configure device C.

```
Device C(cfg)# ip msdp add-peer 20.20.20.20 source-interface loopback 0
Device C(cfg)# ip msdp add-peer 40.40.40.40 source-interface loopback 0
```

Configure device D.

```
Device D(cfg)# ip msdp add-peer 30.30.30.30 source-interface loopback 0
Device D(cfg)# ip msdp add-peer 50.50.50.50 source-interface loopback 0
```

Configure device E.

```
Device E(cfg)# ip msdp add-peer 50.50.50.50 source-interface loopback 0
```

5. Verification

(1) Use the multicast source to send a packet (200.200.200.200, 225.1.1.1). After a host joins the group 225.1.1.1, this host can receive this packet.

(2) Display the status and SA message of the MSDP peer on device D.

```
Device D# display ip msdp-info peer-summary
Msdp Peer Status Summary
Peer Address     As    State    Uptime/Downtime     Reset-Count    SA-Count    Peer-Description
30.30.30.30      200   Up       00:01:420                          1           No description

Device D# display ip msdp-info sa-cache
MSDP Source-Active Cache: 1 entries
  (200.200.200.200,225.1.1.1),RP:10.10.10.10,(M)BGP/AS 100, 00:00:18/00:01:57, Peer 30.30.30.30
Learned from peer 30.30.30.30, RPF peer 30.30.30.30,
SAs received: 1, Encapsulated data received: 1
```

6. Configuration Files

- Device A configuration file

```
!
ip mrouting-enable
!
interface GigabitEthernet 0/1

!
ip msdp add-peer 50.50.50.50 source-interface Loopback 0
!
ip pim c-bsr Loopback 0
ip pim c-rp Loopback 0
```

```
!
```

7. Common Errors

- The BSR border is not configured, or is not configured on a correct interface.
- PIM-SM is not enabled on the local interface and the peer interface on which MSDP peer connection is established.
- SA messages fail the peer RPF check.

1.9.2 Configuring an Anycast RP

1. Requirements

There are multiple RPs in a PIM domain. After an anycast RP based on MSDP peers is configured, receivers can join the nearest RP, and the multicast source can register with the nearest RP to implement load sharing between the RPs.

2. Topology

Figure 1-8 Anycast RP Topology

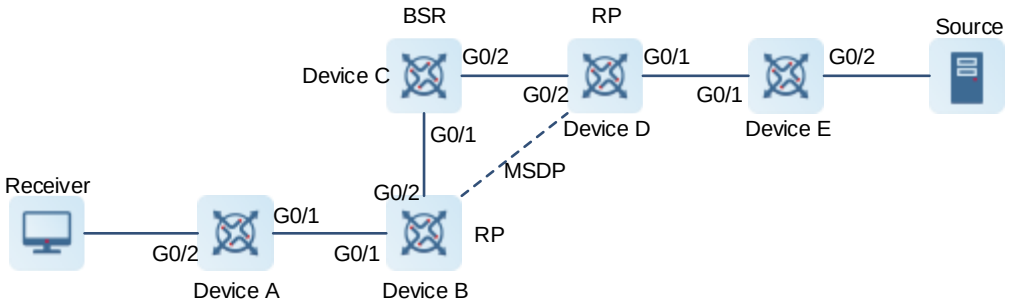

Table 1-4 Description of the Topology

Device	Interface	IP Address	Remarks
Device A	G0/1	10.110.1.1/24	
	G0/2	10.110.2.1/24	
Device B	G0/1	10.110.1.2/24	
	G0/2	10.110.3.1/24	
	Loopback0	10.10.10.10/32	A C-RP is configured.
	Loopback1	30.30.30.30/32	Used to establish an MSDP connection and modify the RP address in the SA message.
Device C	G0/1	10.110.3.2/24	
	G0/2	10.110.4.1/24	
	Loopback0	100.100.100.100/32	A C-BSR is configured.

Device	Interface	IP Address	Remarks
Device D	G0/1	10.110.5.1/24	
	G0/2	10.110.4.2/24	
	Loopback0	10.10.10.10/32	A C-RP is configured.
	Loopback1	20.20.20.20/32	Used to establish an MSDP connection and modify the RP address in the SA message.
Device E	G0/1	10.110.5.2/24	
	G0/2	10.110.6.1/24	

3. Notes

- Configure an IP address for each interface.
- Enable OSPF in each AS.
- Enable PIM-SM in each AS, and configure C-BSRs and C-RPs.
- Establish the MSDP peer relationship between RPs, and modify the RP address in the SA message.
- Configure a mesh group.

4. Procedure

(1) Configure an IP address for each interface (omitted).

(2) Enable OSPF in each AS (omitted). For the omitted information, see *Configuring OSPFv2*.

(3) Enable PIM-SM in each AS, and configure C-BSRs and C-RPs.

Configure device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# ip mrouting-enable
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# ip pim sparse-mode
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# interface GigabitEthernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# ip pim sparse-mode
Device A(cfg-if-GigabitEthernet 0/2)# exit
```

Configure device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# ip mrouting-enable
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# ip pim sparse-mode
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface gigabitethernet 0/2
```

```
Device B(cfg-if-GigabitEthernet 0/2)# ip pim sparse-mode
Device B(cfg-if-GigabitEthernet 0/2)# exit
Device B(cfg)# interface loopback 0
Device B(cfg-if-Loopback 0)# ip pim sparse-mode
Device B(cfg-if-Loopback 0)# exit
Device B(cfg)# interface loopback 1
Device B(cfg-if-Loopback 1)# ip pim sparse-mode
Device B(cfg-if-Loopback 1)# exit
Device B(cfg)# ip pim c-rp loopback 0
```

Configure device C.

```
Device C> privilege
Device C# config-system terminal
Device C(cfg)# ip mrouting-enable
Device C(cfg)# interface gigabitethernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# ip pim sparse-mode
Device C(cfg-if-GigabitEthernet 0/1)# exit
Device C(cfg)# interface gigabitethernet 0/2
Device C(cfg-if-GigabitEthernet 0/2)# ip pim sparse-mode
Device C(cfg-if-GigabitEthernet 0/2)# exit
Device C(cfg)# interface loopback 0
Device C(cfg-if-Loopback 0)# ip pim sparse-mode
Device C(cfg-if-Loopback 0)# exit
Device C(cfg)# ip pim c-bsr loopback0
```

Configure device D.

```
Device D> privilege
Device D# config-system terminal
Device D(cfg)# ip mrouting-enable
Device D(cfg)# interface gigabitethernet 0/1
Device D(cfg-if-GigabitEthernet 0/1)# ip pim sparse-mode
Device D(cfg-if-GigabitEthernet 0/1)# exit
Device D(cfg)# interface gigabitethernet 0/2
Device D(cfg-if-GigabitEthernet 0/2)# ip pim sparse-mode
Device D(cfg-if-GigabitEthernet 0/2)# exit
Device D(cfg)# interface loopback 0
Device D(cfg-if-Loopback 0)# ip pim sparse-mode
Device D(cfg-if-Loopback 0)# exit
Device D(cfg)# interface loopback 1
Device D(cfg-if-Loopback 1)# ip pim sparse-mode
Device D(cfg-if-Loopback 1)# exit
Device D(cfg)# ip pim c-rp loopback 0
```

Configure device E.

```
Device E> privilege
Device E#config-system terminal
Device E(cfg)#ip mrouting-enable
Device E(cfg)#interface gigabitethernet 0/1
```

```
Device E(cfg-if-GigabitEthernet 0/1)#ip pim sparse-mode
Device E(cfg-if-GigabitEthernet 0/1)# exit
Device E(cfg)#interface gigabitethernet 0/2
Device E(cfg-if-GigabitEthernet 0/2)#ip pim sparse-mode
Device E(cfg-if-GigabitEthernet 0/2)# exit
```

(4) Establish the MSDP peer relationship between RPs, and modify the RP address in the SA message.

Configure device D.

```
Device D(cfg)# ip msdp add-peer 30.30.30.30 source-interface loopback 1
Device D(cfg)# ip msdp originator-inf loopback 1
```

Configure device B.

```
Device B(cfg)# ip msdp add-peer 20.20.20.20 source-interface loopback 1
Device B(cfg)# ip msdp originator-inf loopback 1
```

(5) Configure a mesh group.

Configure device D.

```
Device D(cfg)# ip msdp peer-to-mesh-group mesh-name 30.30.30.30
```

Configure device B.

```
Device B(cfg)# ip msdp peer-to-mesh-group mesh-name 20.20.20.20
```

5. Verification

(1) Use the multicast source to send a packet (6.6.6.6, 225.1.1.1). After a host joins the group 225.1.1.1, this host can receive this packet.

(2) Display the status and SA message of the MSDP peer on device B.

Run the **display ip msdp-info summary** command to display status of the peers.

```
Device B# display ip msdp-info peer-summary
Msdp Peer Status Summary
Peer Address     As          State   Uptime/Downtime   Reset-Count   SA-Count   Peer-Description
20.20.20.20      Unknown     Up        00:01:420                     1          No description
```

Run the **display ip msdp-info sa-cache** command to display SA messages of the peers.

```
Device B# display ip msdp-info sa-cache
MSDP Source-Active Cache: 1 entries
  (6.6.6.6,225.1.1.1),RP:10.10.10.10,(M)BGP/AS unknown, 00:00:18/00:01:57, Peer 20.20.20.20
```

6. Configuration Files

- Device A configuration file

```
!
ip mrouting-enable
!
interface GigabitEthernet 0/1
 unset switch-port
 ip pim sparse-mode
!
interface GigabitEthernet 0/2
```

```
 unset switch-port
 ip pim sparse-mode
!
```

- Device B configuration file

```
!
ip mrouting-enable
!
interface GigabitEthernet 0/1
 unset switch-port
 ip pim sparse-mode
!
interface GigabitEthernet 0/2
 unset switch-port
 ip pim sparse-mode
!
interface Loopback 0
 ip pim sparse-mode
!
interface Loopback 1
 ip pim sparse-mode
!
ip msdp originator-inf Loopback 1
ip msdp add-peer 20.20.20.20 source-interface Loopback 1
ip msdp peer-to-mesh-group mesh-name 20.20.20.20
!
ip pim c-rp Loopback 0
!
```

- Device C configuration file

```
!
ip mrouting-enable
!
interface GigabitEthernet 0/1
 unset switch-port
 ip pim sparse-mode
!
interface GigabitEthernet 0/2
 unset switch-port
 ip pim sparse-mode
!
interface Loopback 0
 ip pim sparse-mode
!
ip pim c-bsr Loopback 0
!
```

- Device D configuration file

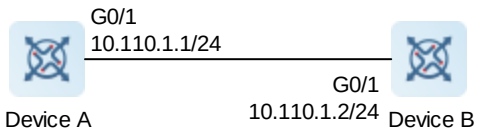
```
!
ip mrouting-enable
!
interface GigabitEthernet 0/1
 unset switch-port
 ip pim sparse-mode
!
interface GigabitEthernet 0/2
 unset switch-port
 ip pim sparse-mode
!
interface Loopback 0
 ip pim sparse-mode
!
interface Loopback 1
 ip pim sparse-mode
!
ip msdp originator-inf Loopback 1
ip msdp add-peer 30.30.30.30 source-interface Loopback 1
ip msdp peer-to-mesh-group mesh-name 30.30.30.30
!
ip pim c-rp Loopback 0
!
```

- Device E configuration file

```
!
ip mrouting-enable
!
interface GigabitEthernet 0/1
 unset switch-port
 ip pim sparse-mode
!
interface GigabitEthernet 0/2
 unset switch-port
 ip pim sparse-mode
!
```

7. Common Errors

- The C-BSRs and C-RPs are configured on the same interface.
- The RP address in the SA message is not modified.
- SA messages cannot pass the peer RPF check.



1.9.3 Enabling MD5 Authentication

1. Requirements

MD5 authentication is enabled on TCP connections between MSDP peers, and the number of SA cache entries from a specified MSDP peer is limited to prevent invalid TCP connections and improve MSDP security.

2. Topology

Figure 1-9 Topology of MD5 Authentication

3. Notes

- Establish the MSDP peer relationship between device A and device B.
- Enable MD5 authentication for the peer on device A.
- After MSDP timeout, configure the MD5 cipher of the peer on device B, which is the same as the cipher on device A. Then, the session is reconnected.
- Set the number of SA cache entries from the peer 10.110.1.2 to 10.

4. Procedure

(1) Configure IP addresses on interfaces of device A and device B, and enable basic functions of PIM-SM on the devices (omitted).

(2) Establish the MSDP peer relationship between device A and device B.

Add device B as an MSDP peer on device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# ip msdp add-peer 10.110.1.2 source-interface gigabitEthernet 0/1
```

Add device A as an MSDP peer on device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# ip msdp add-peer 10.110.1.1 source-interface gigabitEthernet 0/1
```

(3) Enable MD5 authentication for the peer on device A, and set the encryption level to 0 and the cypher to password123.

```
Device A(cfg)# ip msdp peer-connection password 10.110.1.2 0 password123
```

(4) After MSDP timeout, enable MD5 authentication for the peer on device B, and set the encryption level and cypher to be consistent with those on device A.

```
Device B(cfg)# ip msdp peer-connection password 10.110.1.1 0 password123
```

(5) Set the number of SA cache entries from the peer 10.110.1.2 to 10.

```
Device A(cfg)# ip msdp peer-sa-cahce-limit 10.110.1.2 10
```

5. Verification

(1) After the MSDP peer relationship is established between device A and device B, the peer status is up.

Check whether the status of the peer 10.110.1.2 is up on device A.

```
Device A# display ip msdp-info peer-detail
```

```
MSDP PEER 10.110.1.2 (No description), AS unknown
  Connection status:
    State: Up, Resets: 0, Connection source: GigabitEthernet 0/7 (10.110.1.1)

```

(2) After MD5 authentication is enabled for the peer on device A, run the **display ip msdp-info peer-detail** command to check whether the peer relationship between device A and device B is disconnected and the peer is down.

(3) After MD5 authentication is enabled for the peer on device B, run the **display ip msdp-info peer-detail** command to check whether the peer relationship between device A and device B is established and the peer is up again.

(4) Set the number of SA cache entries from the peer 10.110.1.2 to 10 on device A, and send 20 (S, G) entries to device B. A message is displayed on device A, indicating that the number of entries exceeds the limit.

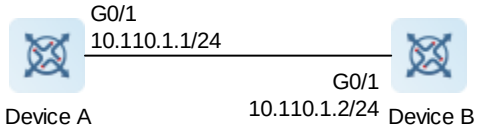
6. Configuration Files

- Device A configuration file

```
!
ip msdp add-peer 10.110.1.2 source-interface gigabitEthernet 0/1
ip msdp peer-connection password 10.110.1.2 0 password123
ip msdp peer-sa-cache-limit 10.110.1.2 10
!
```

- Device B configuration file

```
!
ip msdp add-peer 10.110.1.1 source-interface gigabitEthernet 0/1
ip msdp peer-connection password 10.110.1.1 0 password123
!
```



1.9.4 Managing MSDP Peers

1. Requirements

MSDP peer information is managed and configured, including configuring peer description information and disabling peer connections.

2. Topology

Figure 1-10 Topology of MSDP Peer Management

3. Notes

- Establish MSDP peer relationship between device A and device B.

- On device A, configure the peer description of device B as "peer-router-B".
- After 60 seconds, on device A, disable the peer device B.

4. Procedure

(1) Configure IP addresses on interfaces of device A and device B, and enable basic functions of PIM-SM on the devices (omitted).

(2) Establish the MSDP peer relationship between device A and device B.

Add device B as an MSDP peer on device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# ip msdp add-peer 10.110.1.2 source-interface gigabitEthernet 0/1
```

Add device A as an MSDP peer on device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# ip msdp add-peer 10.110.1.1 source-interface gigabitEthernet 0/1
```

(3) On device A, configure the peer description of device B as "peer-router-B".

```
Device A(cfg)# ip msdp peer-description 10.110.1.2 peer-router-B
```

(4) After 60 seconds, on device A, disable the peer device B.

```
Device A(cfg)# ip msdp peer-closing 10.110.1.2
```

5. Verification

Run the **display ip msdp-info peer-detail** command to display the summary information of a specified peer, including the description and connection status of this MSDP peer.

```
Device A# display ip msdp-info peer-detail 10.110.1.2
MSDP PEER 10.110.1.2 (peer-router-B), AS unknown
  Connection status:
    State: Up, Resets: 3, Connection source: GigabitEthernet 0/1 (10.110.1.1)
    Uptime(Downtime): 00:30:39, Message sent/received: 50/50
    Input messages discarded: 0
    Connection and counters cleared 00:51:06 ago
    Local Address of connection: 10.110.1.1
  SA Filtering:
    Input (S,G) Access-control-list filter: None
    Input (S,G) route-map filter: None
    Input RP Access-control-list filter: None
    Input RP Route-map filter: None
    Output (S,G) Access-control-list filter: None
    Output (S,G) Route-map filter: None
    Output RP Access-control-list filter: None
    Output RP Route-map filter: None
  SA-Requests:
    Input filter: None
  Peer ttl threshold: 0
```

```
SAs learned from this peer: 0, SAs limit: No-limit
Message counters:
  SA messages discarded: 0
  SA messages in/out: 0/0
  SA Requests discarded/in: 0/0
  SA Responses out: 0
  Data Packets in/out: 0/0
```

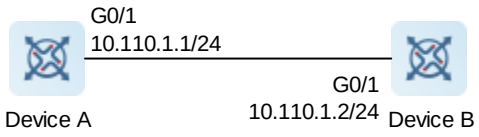
6. Configuration Files

- Device A configuration file

```
!
ip msdp add-peer 10.110.1.2 source-interface gigabitEthernet 0/1
ip msdp peer-closing 10.110.1.2
ip msdp peer-description 10.110.1.2 peer-router-B
!
```

- Device B configuration file

```
!
ip msdp add-peer 10.110.1.1 source-interface gigabitEthernet 0/1
!
```



1.9.5 Modifying Protocol Parameters

1. Requirements

In some application scenarios, for example, MSDP peer creation, restart, or failback, you can shorten the TCP reconnection interval to accelerate convergence of the MSDP peer relationship.

2. Topology

Figure 1-11 Topology for Protocol Parameter Modification

3. Notes

- Establish the MSDP peer relationship between device A and device B.
- Set the MSDP peer reconnection interval to 20 seconds on device A.

4. Procedure

(1) Configure IP addresses on interfaces of device A and device B, and enable basic functions of PIM-SM on the devices (omitted).

(2) Establish the MSDP peer relationship between device A and device B.

Add device B as an MSDP peer on device A.

```
Device A> privilege
```

```
Device A# config-system terminal
Device A(cfg)# ip msdp add-peer 10.110.1.2 source-interface gigabitEthernet 0/1
```

Add device A as an MSDP peer on device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# ip msdp add-peer 10.110.1.1 source-interface gigabitEthernet 0/1
```

(3) Set the MSDP peer reconnection interval to 20 seconds on device A.

```
Device(cfg)# ip msdp retry-period 20
```

5. Verification

(1) Disable the MSDP peer on device B, and enable the MSDP peer again immediately.

```
Device B(cfg)# ip msdp peer-closing 10.110.1.1
Device B(cfg)# unset ip msdp peer-closing 10.110.1.1
```

(2) Check whether the peer on device B can be reconnected in 20 seconds.

```
Device B# display ip msdp-info peer-detail 10.110.1.1
MSDP PEER 10.110.1.1 (peer-a), AS unknown
  Connection status:
    State: Up, Resets: 3, Connection source: GigabitEthernet 0/1 (10.110.1.2)
    Uptime(Downtime): 00:00:41, Message sent/received: 20/20
    Input messages discarded: 0
    Connection and counters cleared 01:37:02 ago
    Local Address of connection: 10.110.1.2
  SA Filtering:
    Input (S,G) Access-control-list filter: None
    Input (S,G) route-map filter: None
    Input RP Access-control-list filter: None
    Input RP Route-map filter: None
    Output (S,G) Access-control-list filter: None
    Output (S,G) Route-map filter: None
    Output RP Access-control-list filter: None
    Output RP Route-map filter: None
  SA-Requests:
    Input filter: None
  Peer ttl threshold: 0
  SAs learned from this peer: 0, SAs limit: No-limit
  Message counters:
    SA messages discarded: 0
    SA messages in/out: 0/0
    SA Requests discarded/in: 0/0
    SA Responses out: 0
    Data Packets in/out: 0/0
```

6. Configuration Files

- Device A configuration file

```
!
ip msdp retry-period 20
ip msdp add-peer 10.110.1.2 source-interface gigabitEthernet 0/1
!
```

- Device B configuration file

```
!
ip msdp add-peer 10.110.1.1 source-interface gigabitEthernet 0/1
!
```

1 Configuring IPv6 Multicast Route Management

1.1 Introduction

Multicast route management covers how to create and modify multicast routes to control multicast packet forwarding and how to detect and maintain correctness of multicast forwarding paths. Multicast route management mainly includes the static multicast routing and reverse path forwarding (RPF) check features. Static multicast routing is used to modify or connect RPF routes, and RPF check is used to ensure that multicast data is forwarded on correct paths.

1.1.1 IPv6 Multicast Routing and Forwarding

An IPv6 multicast routing table includes MLD group entries, multicast protocol routing entries, multicast routing entries, and multicast hardware routing entries. These entries are maintained by different multicast routing protocols in the multicast network. The optimal IPv6 multicast routes are delivered to the hardware routing table and used to guide IPv6 multicast data forwarding. The RPF mechanism ensures that multicast data is forwarded on correct paths.

- MLD group entries: They are created when a host sends MLD join packets and used to maintain group member information and ask the multicast routing protocol to create (S, G) or (*, G) entries.
- Multicast protocol routing entries: They function as basis of multicast routing and forwarding and are maintained by different multicast routing protocols (the most widely applied protocol is PIM).
- Multicast routing entries: They are generated by the multicast routing management module and delivered to a multicast hardware routing table. Different multicast routing protocols can be summarized based on the multicast routing entries to select an optimal route.
- Hardware routing entries: They are generated based on routing tables and used to guide multicast data forwarding.

1.1.2 RPF Check

1. Basic Principles

In unicast routing and forwarding, a device gets to know the outbound interface of packets based on the destination address. In multicast routing and forwarding, the destination address in multicast packets is a multicast address, based on which, a receiver address cannot be determined. However, the source address in multicast packets is determined and based on this source address, multicast packets can be forwarded on correct paths.

When receiving a multicast packet, a multicast device queries the unicast route of the multicast source based on the source address in the multicast packet and checks whether the outbound interface of this unicast route is consistent with the inbound interface of the multicast packet. If yes, it is considered that this multicast packet is forwarded on a correct path. The inbound interface of the multicast packet is referred to as an RPF interface.

2. RPF Check Procedure

Unicast route, MBGP route, and static multicast route are the basis of RPF check. If these three types of routing entries exist on a multicast device, the multicast device performs the following checks in order after receiving a multicast packet:

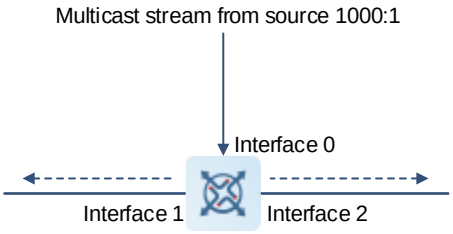
(1) Select an optimal route from each of the three types of routing entries, respectively, based on the source address in the packet.

- The outbound interface of a unicast route is an RPF interface and the next hop is an RPF neighbor.
- The outbound interface of an MBGP route is an RPF interface and the next hop is an RPF neighbor.
- The static multicast route is manually configured and an RPF interface and neighbor are specified.

(2) Select one route out of the three optimal routes as the RPF route. The selection rule is as follows:

- If the longest match rule is not configured for selecting an RPF route, the one with the highest priority is selected as the RPF route. If the three routes have the same priority, the RPF route is selected in the order of static multicast route, MBGP route, and unicast route.
- If the longest match rule is configured for selecting an RPF route, the one with the longest match is selected as the RPF route. If the three routes have the same mask, the one with the highest priority is selected as the RPF route. If they have the same priority, the RPF route is selected in the order of static multicast route, MBGP route, and unicast route.

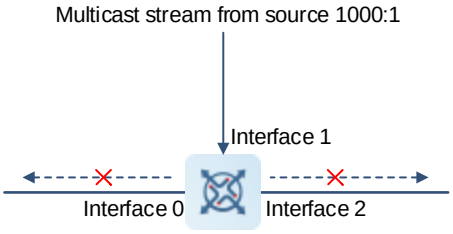
(3) Compare the RPF interface of the RPF route with the inbound interface of the multicast packet.



- If they are consistent, the route passes the RPF check and the multicast packet is forwarded to the downlink devices.
- If they are inconsistent, the route fails the RPF check and the received multicast packet is discarded.

Table 1-1 Routing Table on a Multicast Device

Network	Interface
1000::/64	Interface 0
2000::/64	Interface 1
3000::/64	Interface 2



As shown in Figure 1-1, the multicast device receives a multicast packet from the source 1000::1 through interface 0 and as listed in Table 1-1, the outbound interface of the route to the source 1000::1 is also interface 0. The outbound interface of the route is consistent with the inbound interface of the multicast packet. The route passes the RPF check and the multicast packet is forwarded on the correct path.

Figure 1-1 Topology of RPF Check Success

As shown in Figure 1-2, the multicast device receives a multicast packet from the source 1000::1 through interface 1 and the outbound interface of the route to the source 1000::1 is Interface 0. The outbound interface of the route is inconsistent with the inbound interface of the multicast packet. The route fails the RPF check and the multicast packet is discarded.

Figure 1-2 Topology of RPF Check Failure

3. Application Scenarios of RPF Check in Multicast Forwarding

A multicast device ensures that multicast packets are forwarded on correct paths and avoids loops on the forwarding paths based on the RPF check mechanism. In actual applications, if the multicast device performs RPF check each time it receives a multicast packet, the multicast device is overloaded. Therefore, upon receiving a multicast packet, the multicast device checks for corresponding (S, G) hardware routing entry, rather than performs RPF check. The checking process is as follows:

- If no (S, G) hardware routing entry exists, the multicast device performs RPF check, uses the RPF interface as an inbound interface, creates a multicast routing entry, and delivers the entry to the multicast forwarding table.
  - If the route passes the RPF check, the inbound interface of the multicast packet is consistent with the RPF interface. The multicast packet is forwarded to all the outbound interfaces in the forwarding table.
  - If the route fails the RPF check, the inbound interface of the multicast packet is inconsistent with the RPF interface. The multicast packet is discarded.
- If (S, G) hardware routing entries exist, the multicast device checks whether the inbound interface in the forwarding entry is consistent with the inbound interface of the multicast packet.
  - If they are consistent, the multicast packet is forwarded to all the outbound interfaces.
  - If they are inconsistent, the multicast device performs RPF check. If the RPF interface is consistent with the inbound interface in the hardware routing entry, the source path of the packet is incorrect but the (S, G) entry is correct. The multicast packet is discarded. If the RPF interface is inconsistent with the inbound interface in the hardware routing entry, the (S, G) entry expired. The inbound interface in the

entry is updated as an RPF interface. Then, the multicast device checks whether the RPF interface is consistent with the inbound interface of the packet. If they are consistent, this multicast packet is forwarded to all outbound interfaces in the forwarding table. Otherwise, this multicast packet is discarded.

1.1.3 Protocols and Standards

- RFC 2710: Multicast Listener Discovery (MLDv1) for IPv6
- RFC 3810: Multicast Listener Discovery Version 2 (MLDv2) for IPv6
- RFC 4601: Protocol Independent Multicast-Sparse Mode (PIM-SM)
- RFC 5059: Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- RFC 4607: Source-Specific Multicast for IP

1.2 Configuration Task Summary

The IPv6 multicast route management configuration includes the following tasks:

(1) Configuring Basic Functions of IPv6 Multicast

(2) (Optional) Configuring the Maximum Number of Entries in an IPv6 Multicast Routing Table

(3) (Optional) Configuring an IPv6 Multicast Border

(4) (Optional) Configuring an IPv6 Static Multicast Route

(5) (Optional) Enabling Forced Forwarding of Multicast Packets by Software

(6) (Optional) Enabling L2 Direction Control for Multicast Streams

(7) (Optional) Configuring RPF Route Selection Based on the Longest Match Rule

1.3 Prerequisites

- In the multicast network, all nodes are reachable via IPv6 unicast routes.
- Configuring Basic Functions of IPv6 Multicast.

1.4 Configuring Basic Functions of IPv6 Multicast

1.4.1 Overview

The multicast routing function is enabled in the local network and a PIM network is created to provide data sources and user hosts in the network with the IPv6 multicast service.

A device maintains the routing table used for multicast packet forwarding over an IPv6 multicast routing protocol (for example, PIM-SMv6), and learns information about the status of group members in the directly-connected network segments over the MLDv1/v2 protocol. A host joins a specific IPv6 multicast group by sending an MLD REPORT message.

1.4.2 Restrictions and Guidelines

- The IPv6 multicast routing function should be enabled on each multicast device.
- The IPv6 multicast routing function is enabled prior to different IPv6 multicast protocols.
- The IPv6 multicast routing function and the MLD Snooping function are mutually exclusive.

- The IPv6 multicast protocol function must be enabled on each interface in the multicast network.
- After L3 multicast is enabled in the private VLAN and super VLAN and a multicast source exists in a sub VLAN, an extra entry whose ingress is the sub VLAN into which the multicast stream enters must be copied due to the validity check during multicast forwarding. This increases a multicast hardware entry and decreases the multicast capacity by one.

1.4.3 Prerequisites

In the multicast network, all nodes are reachable via IPv6 unicast routes.

1.4.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the IPv6 multicast routing function.

ipv6 mrouting-enable

The IPv6 multicast routing function is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(5) Configure an IPv6 multicast protocol.

ipv6 pim dense-mode

No IPv6 multicast protocol is enabled by default.

1.5 Configuring the Maximum Number of Entries in an IPv6 Multicast Routing Table

1.5.1 Overview

Every multicast data packet received by a device is used to maintain relevant IPv6 multicast routing entries. However, excessive multicast routing entries may exhaust device memory and cause device performance to decrease. Users can restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements.

1.5.2 Restrictions and Guidelines

Due to limitations by hardware resources, routing entries that exceed the range permitted by hardware can be forwarded only by software, which causes performance to decrease.

1.5.3 Prerequisites

Configuring Basic Functions of IPv6 Multicast.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the maximum number of entries in an IPv6 multicast routing table.

ipv6 multicast max-route *limit* [*threshold*]

By default, a maximum of 4000 entries can be added to an IPv6 multicast routing table.

The configured value of *threshold* must be smaller than or equal to the configured value of *limit*.

1.6 Configuring an IPv6 Multicast Border

1.6.1 Overview

An IPv6 multicast border is configured to define the transmission range of multicast packets. When a multicast border is configured on an interface, this interface cannot forward or receive multicast packets, including those sent from the local host.

1.6.2 Restrictions and Guidelines

- The ACL referenced in this command can be a standard ACL or an extended ACL. If an extended ACL is used, only destination addresses need to be matched.
- This command can be used to filter MLD and PIM-SMv6 protocol packets relevant to the IPv6 multicast group range. Multicast data streams are not sent or received by this multicast border interface.

1.6.3 Prerequisites

- Configuring Basic Functions of IPv6 Multicast.
- Before an IPv6 multicast border is configured, ensure that the corresponding ACL is created and a multicast group range is specified. For details about ACL configuration, see *Configuring ACL*.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Enable the IPv6 multicast routing function.

ipv6 multicast scope-boundary *acl-name* [**in** | **out**]

No IPv6 multicast border is configured by default.

1.7 Configuring an IPv6 Static Multicast Route

1.7.1 Overview

An IPv6 static multicast route is configured to specify an RPF interface or RPF neighbor for multicast packets from a specific multicast source. This function is used to modify and connect RPF routes.

- Modify an RPF route. A device expects to receive multicast packets from a source through a specified interface. However, the RPF check result indicates that the RPF interface is not this specified interface. In this case, you need to configure an IPv6 static multicast route to specify this interface as an RPF interface. Upon receiving multicast packets from the source, the device performs RPF check. If the RPF check result indicates that the RPF interface is not this specified interface, the route fails the RPF check.
- Connect an RPF route. If the unicast route is interrupted, the RPF routing fails. In this case, you can configure a static multicast route to specify the RPF interface to complete the RPF check and implement multicast packet forwarding.

1.7.2 Restrictions and Guidelines

To specify an outbound interface rather than a next-hop IP address for the IPv6 static multicast route, ensure that the outbound interface is of the point-to-point type.

1.7.3 Prerequisites

Configuring Basic Functions of IPv6 Multicast.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an IPv6 static multicast route.

ipv6 rpf-mroute *ipv6-address/prefix-length* [*protocol*] { *ipv6-rpf-addrress* | *interface-type interface-number* } [*distance*]

No IPv6 static multicast route is configured by default.

1.8 Enabling Forced Forwarding of Multicast Packets by Software

1.8.1 Overview

After this function is enabled, all IPv6 multicast data packets destined for the CPU are forcedly forwarded by software.

1.8.2 Restrictions and Guidelines

The cache mechanism and forwarding performance problem may cause packet disorder if the multicast streams are heavy. You are not advised to run this command generally.

1.8.3 Prerequisites

Configuring Basic Functions of IPv6 Multicast.

1.8.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the function of forced forwarding of multicast packets by software.

msf6 force-forwarding

The function of forced forwarding of IPv6 multicast packets (destined for the CPU) by software is disabled by default.

1.9 Enabling L2 Direction Control for Multicast Streams

1.9.1 Overview

L2 direction control is enabled for multicast streams to control the forwarding of multicast streams on an interface. Multiple commands can be configured for a specified multicast stream so that the stream can be forwarded by multiple interfaces. After direction control is enabled for a multicast stream, the stream can be forwarded only by these configured interfaces. Other interfaces are not permitted to forward the stream.

1.9.2 Restrictions and Guidelines

This function controls only the forwarding of multicast streams on interfaces, but does not directly affect the processing of multicast protocols on the protocol packets. Some features (for example, establishment of L3 hardware routing entry) of multicast protocols (such as PIM-SMv6) are driven by multicast data streams, and therefore, the behavior of the multicast routing protocols may still be affected.

1.9.3 Prerequisites

Configuring Basic Functions of IPv6 Multicast.

1.9.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable L2 direction control for multicast streams.

ipv6 multicast static *ipv6-source-address ipv6-group-address interface-type interface-number*

L2 direction control is disabled for multicast streams by default.

1.10 Configuring RPF Route Selection Based on the Longest Match Rule

1.10.1 Overview

In multicast routing, various routing entries, such as static multicast routing entry, MBGP routing entry and unicast routing entry, may exist. If RPF route selection based on the longest match rule is configured, the route with the longest match mask is selected from the optimal routes of multiple routing entries as the RPF route. If the routes have the same mask length, the route with the highest priority is selected from the optimal routes. If they have the same priority, the RPF route is selected in the order of static multicast route, MBGP route, and unicast route.

1.10.2 Restrictions and Guidelines

It is recommended that RPF route selection based on the longest match rule be configured on each device unless otherwise specified.

1.10.3 Prerequisites

Configuring Basic Functions of IPv6 Multicast.

1.10.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure RPF route selection based on the longest match rule.

ipv6 multicast rpf-routing longest-match

By default, the route with the highest priority is selected as the RPF route. If the routes have the same priority, the RPF route is selected in the order of IPv6 static multicast route, IPv6 MBGP route and IPv6 unicast route.

1.11 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **cleanup** commands to clear information.

Caution

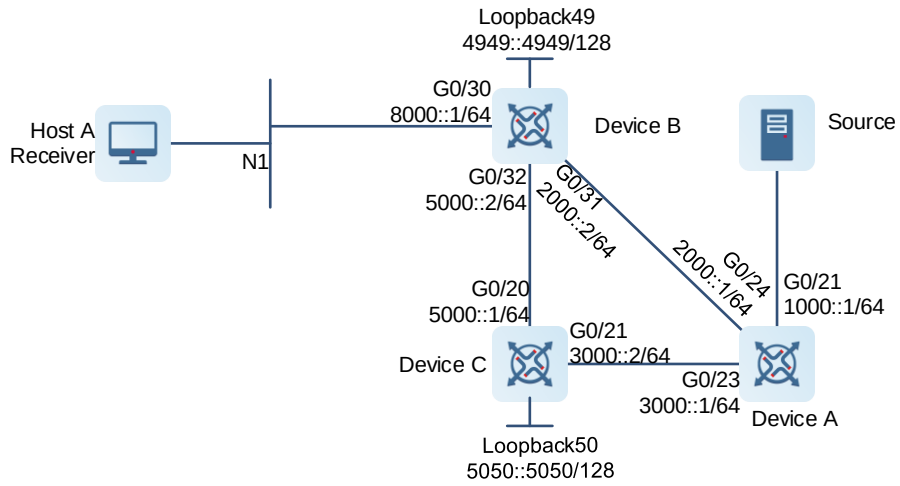
Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-2 Monitoring

Command	Purpose
cleanup ipv6 mrouting-table { *ipv6-group-address* [*ipv6-source–address*] | ***** }	Clears the IPv6 hardware routing entry.
cleanup ipv6 mrouting-table statistics { *ipv6-group-address* [*ipv6-source-address*] | ***** }	Clears the statistics about the IPv6 hardware routing entry.
display ipv6 mrouting-table [*ipv6-group-or-source-address* [*ipv6-group-or-source-address*]] [**sparse**] [**summary** | **count**]	Displays the IPv6 hardware routing entry.
display ipv6 rpf-routing *ipv6-source-address*	Displays the RPF information of a specified IPv6 source address.
display ipv6 mrouting-table static-route	Displays the IPv6 static multicast route information.
display ipv6 mvif [*interface-type interface-number*]	Displays information about the configured IPv6 multicast interface that takes effect.
display ipv6 mrf mfc	Displays the IPv6 L3 hardware routing entry.
display msf6 msc	Displays the IPv6 L2 and L3 hardware routing entry.
debugging nsm mcast6 all	Displays the running procedure of the multicast core.
debugging nsm mcast6 fib-msg	Displays the communication procedure between the IPv6 multicast core and protocol module.
debugging nsm mcast6 mif	Displays the interface running procedure of the IPv6 multicast core.
debugging nsm mcast6 stats	Displays the procedure for processing interfaces and behavior statistics of the IPv6 multicast core.
debugging ipv6 mrf6 forwarding	Displays the procedure for IPv6 L3 multicast forwarding.

Command	Purpose
debugging ipv6 mrf6 mfc	Displays the procedure for operating IPv6 L3 hardware routing entries.
debugging ipv6 mrf6 event	Displays the procedure for processing IPv6 L3 multicast forwarding events.
debugging msf6 forwarding	Displays the procedure for IPv6 L2 and L3 multicast packet forwarding.
debugging msf6 msc	Displays the procedure for operating IPv6 L2 and L3 hardware routing entries.
debugging msf6 ssp	Displays the bottom-layer hardware processing procedure of IPv6 L2 and L3 multicast forwarding.
debugging msf6 api	Displays the procedure for invoking API interfaces for IPv6 L2 and L3 multicast forwarding.
debugging msf6 event	Displays the procedure for processing IPv6 L2 and L3 multicast forwarding events.

1.12 Configuration Examples



1.12.1 Configuring an IPv6 Static Multicast Route to Modify the RPF Route

1. Requirements

As shown in Figure 1-3, Device A, Device B, and Device C run the OSPF protocol and the PIM-SMv6 function is enabled on each interface. Originally, multicast data sent by the multicast source to Host A is forwarded through the path Device A > Device B. To reduce the load of the link from Device A to Device B, multicast data stream is separated from the unicast data stream. Therefore, the multicast data from the multicast source is sent through the path Device A > Device C > Device B.

2. Topology

Figure 1-3 Topology of IPv6 Static Multicast Route Configuration for Modifying the RPF Route

3. Notes

As shown in Figure 1-3, separate multicast data from unicast data by configuring a static multicast route on Device B to modify the RPF interface of the multicast data. Unicast data is forwarded through the path Device A > Device B, and multicast data is forwarded through the path Device A > Device C > Device B. The specific configuration method is as follows:

- Configure an IPv6 address and a unicast routing protocol on the multicast devices. A reachable unicast route is a basis of multicast protocol running.
- Enable the IPv6 multicast routing function on all multicast devices. Enable the PIM-SMv6 function on the interfaces connecting multicast devices, the interfaces connecting user hosts, and the multicast source interfaces. Configure C-BSR and C-RP on Device C.
- Configure an RPF static multicast route on Device B, specify Device C as an RPF neighbor, and modify the forwarding path of the multicast data packets.

4. Procedure

(1) Configure an IPv6 address and a unicast routing protocol on the multicast devices.

Configure an IPv6 address and a unicast routing protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/21)# ipv6 address 1000::1/64
DeviceA(cfg-if-GigabitEthernet 0/21)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/23)# ipv6 address 3000::1/64
```

```
DeviceA(cfg-if-GigabitEthernet 0/23)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
DeviceA(cfg)# interface GigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/24)# ipv6 address 2000::1/64
DeviceA(cfg-if-GigabitEthernet 0/24)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/24)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
DeviceA(cfg)# ipv6 router-protocol ospf 4949
```

Configure an IPv6 address and a unicast routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 address 8000::1/64
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/31)# ipv6 address 2000::2/64
DeviceB(cfg-if-GigabitEthernet 0/31)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/32)# ipv6 address 5000::2/64
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ipv6 address 4949::4949/128
DeviceB(cfg-if-Loopback 49)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-Loopback 49)# exit
DeviceB(cfg)# ipv6 router-protocol ospf 4949
```

Configure an IPv6 address and a unicast routing protocol on Device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 address 5000::1/64
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 address 3000::2/64
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface Loopback 50
```

```
DeviceC(cfg-if-Loopback 50)# ipv6 address 5050::5050/128
DeviceC(cfg-if-Loopback 50)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-Loopback 50)# exit
DeviceC(cfg)# ipv6 router-protocol ospf 4949
```

(2) Enable the IPv6 multicast routing function on all multicast devices. Enable the PIM-SMv6 function on the interfaces connecting multicast devices, the interfaces connecting user hosts, and the multicast source interfaces. Configure C-BSR and C-RP on Device C.

Enable the multicast routing and PIM-SMv6 related functions on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ipv6 mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
DeviceA(cfg)# interface GigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
```

Enable the multicast routing and PIM-SMv6 related functions on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6 mrouting-enable
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# ipv6 pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# ipv6 pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ipv6 pim sparse-mode
DeviceB(cfg-if-Loopback 49)# exit
```

Enable the multicast routing and PIM-SMv6 related functions on Device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ipv6 mrouting-enable
DeviceC(cfg)# ipv6 mrouting-enable
DeviceC(cfg)# interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
```

```
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface Loopback 50
DeviceC(cfg-if-Loopback 50)# ipv6 pim sparse-mode
DeviceC(cfg-if-Loopback 50)# exit
```

Configure C-BSR and C-RP on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ipv6 pim c-bsr GigabitEthernet 0/21
DeviceA(cfg)# ipv6 pim c-rp GigabitEthernet 0/21
```

(3) Configure an RPF static multicast route on Device B, specify Device C as an RPF neighbor, and modify the forwarding path of the multicast data packets.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6    mrouting-table 1000::/64 5000::1
```

5. Verification

(1) Run the **display ipv6 mld groups** command on Device B to check whether Host A joins the group FF15::11 and the multicast source 1000::2 sends packets to the group FF15::11.

```
DeviceB# display ipv6 mld groups
MLD Connected Group Membership
Group Address                          Interface                          Uptime      Expires
Last Reporter
ff15::11                               GigabitEthernet 0/30               00:12:17    00:03:00
fe80::8205:88ff:fe22:b468
```

(2) Run the **display ipv6 mrouting-table** command on Device A to display the hardware routing entry and check whether the next hop is Device C and the outbound interface is GigabitEthernet 0/23.

```
DeviceA# display ipv6 mrouting-table

IPv6 Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed,
           R - RPT, S - SPT, s - SSM Group
Timers: Uptime/Stat Expiry
Interface State: Interface

(1000::2, ff15::11), uptime 00:08:53, stat expires 00:03:12
Owner PIMSMV6, Flags: TFS
  Incoming interface: GigabitEthernet 0/21
  Outgoing interface list:
    GigabitEthernet 0/23
```

(3) Run the **display ipv6 rpf-routing** command on Device B to check whether the next hop of the multicast source is Device C and the RPF interface is GigabitEthernet 0/32.

```
DeviceB# display ipv6 rpf-routing 1000::
RPF information for 1000::
RPF interface: GigabitEthernet 0/32
   RPF neighbor: 5000::1
   RPF route: 1000::/64
   RPF type: static-route
   RPF recursion count: 0
   Doing distance-preferred lookups across tables
Distance: 0
   Metric: 0
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ipv6 mrouting-enable
!

 graceful-restart
!
```

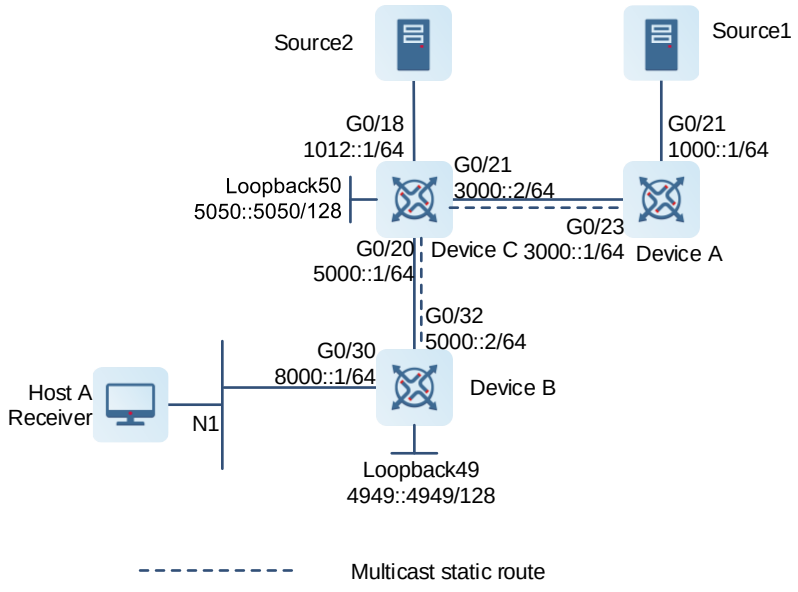
7. Common Errors

- IPv6 unicast routing is incorrectly configured.
- The IPv6 multicast routing function is not enabled on a multicast device.
- No IPv6 multicast protocol is enabled on an interface.



1.12.2 Configuring a Static Multicast Route to Connect the RPF Route

1. Requirements

As shown in Figure 1-4, Device B and Device C run the OSPF protocol, and the unicast route to Device A is isolated. The PIM-SMv6 function is enabled on the interfaces of Device A, Device B and Device C. Host A can normally receive multicast data packets from Source 2, and it is required to receive multicast data packets from Source 1 as well.

2. Topology

Figure 1-4 Topology of IPv6 Static Multicast Route Configuration for Connecting the RPF Route

3. Notes

Configure a static multicast route to establish an RPF route that is destined to source 1 based on the path Device B > Device C > Device A. The specific configuration method is as follows:

- Configure an IPv6 address for each interface of the devices, and configure the OSPF protocol on Device B and Device C to separate multicast routes from unicast routes on Device A.

- Enable the IPv6 multicast routing function, configure the PIM-SMv6 protocol on each L3 interface of the devices and configure the C-BSR and C-RP in the global configuration, and enable the MLD function on the interface connected to hosts.
- Configure static multicast routes to source 1 on Device B and Device C.

4. Procedure

(1) Configure an IPv6 address for each interface of the devices, and configure the OSPF protocol on Device B and Device C to separate multicast routes from unicast routes on Device A.

Configure an IPv6 address for the interface on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/21)# ipv6 address 1000::1/64
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/23)# ipv6 address 3000::1/64
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
DeviceA(cfg)# ipv6 route-config 5050::5050/128 3000::2
```

Configure an IPv6 address and the OSPF protocol for the interface on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 address 8000::1/64
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 ospf 4949 area 0
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/32)# ipv6 address 5000::2/64
DeviceB(cfg-if-GigabitEthernet 0/32)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ipv6 address 4949::4949/128
DeviceB(cfg-if-Loopback 49)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-Loopback 49)# exit
DeviceB(cfg)# ipv6 router-protocol ospf 4949
DeviceB(cfg-router)# exit
```

Configure an IPv6 address and the OSPF protocol for the interface on Device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface GigabitEthernet 0/18
DeviceC(cfg-if-GigabitEthernet 0/18)# unset switch-port
```

```
DeviceC(cfg-if-GigabitEthernet 0/18)# ipv6 address 1012::1/64
DeviceC(cfg-if-GigabitEthernet 0/18)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/18)# exit
DeviceC(cfg)# interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 address 5000::1/64
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 ospf 4949 area 0
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 address 3000::2/64
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface Loopback 50
DeviceC(cfg-if-Loopback 50)# ipv6 address 5050::5050/128
DeviceC(cfg-if-Loopback 50)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-Loopback 50)# exit
DeviceC(cfg)# ipv6 router-protocol ospf 4949
DeviceC(cfg-router)# exit
```

(2) Enable the IPv6 multicast routing function, configure the PIM-SMv6 protocol on each L3 interface of the devices and configure the C-BSR and C-RP in the global configuration, and enable the MLD function on the interface connected to hosts.

Enable the IPv6 multicast routing function and configure the PIM-SMv6 protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ipv6 mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
```

Enable the IPv6 multicast routing function and configure the PIM-SMv6 protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6 mrouting-enable
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# ipv6 pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ipv6 pim sparse-mode
DeviceB(cfg-if-Loopback 49)# exit
```

Enable the IPv6 multicast routing function and functions related to the PIM-SMv6 protocol on Device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ipv6 mrouting-enable
DeviceC(cfg)# interface GigabitEthernet 0/18
DeviceC(cfg-if-GigabitEthernet 0/18)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/18)# exit
DeviceC(cfg)# interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface Loopback 50
DeviceC(cfg-if-Loopback 50)# ipv6 pim sparse-mode
DeviceC(cfg-if-Loopback 50)# exit
DeviceC(cfg)# ipv6 pim c-bsr Loopback 50
DeviceC(cfg)# ipv6 pim c-rp Loopback 50
```

Enable Source 1 (1000::2/64) and Source 2 (1012::2/64) to send multicast data packets to the multicast group (FF14::10). Add Host A to the multicast group (FF14::10) so that Host A can receive multicast data packets from Source 2 but cannot receive multicast data packets from Source 1.

Run the **display ipv6 rpf -routing**1000::2 command on Device C. No route exists. No RPF route to Source 1 exists on Device C.

(3) Configure static multicast routes to source 1 on Device B and Device C.

On Device B, configure an RPF static multicast route and configure Device C as an RPF neighbor to Source 1.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6 rpf-mroute 1000::/64 5000::1
```

On Device C, configure an RPF static multicast route and configure Device A as an RPF neighbor to Source 1.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ipv6 rpf-mroute 1000::/64 3000::1
```

5. Verification

Run the **display ipv6 rpf-routing** 1000::2 command on Device B to display the RPF information of Source 1. The RPF information is displayed as follows:

```
DeviceB# display ipv6 rpf-routing 1000::2
RPF information for 1000::2
RPF interface: GigabitEthernet 0/32
  RPF neighbor: 5000::1
  RPF route: 1000::/64
  RPF type: static-route
```

```
  RPF recursion count: 0
  Doing distance-preferred lookups across tables
Distance: 0
  Metric: 0
```

Run the **display ipv6 rpf** 1000::2 command on Device C to display the RPF information of Source 1. The RPF information is displayed as follows:

```
DeviceC# display ipv6 rpf-routing 1000::2
RPF information for 1000::2
RPF interface: GigabitEthernet 0/21
  RPF neighbor: 3000::1
  RPF route: 1000::/64
  RPF type: static-route
  RPF recursion count: 0
  Doing distance-preferred lookups across tables
Distance: 0
  Metric: 0
```

Enable Source 1 and Source 2 to send multicast data packets to the multicast group (FF14::10), and add Host A to the multicast group.

Run the **display ipv6 pim-info sparse-mode mroute** command on Device C to display routing entry information. The multicast entries of Source 1 exist on Device C. Host A normally receives multicast data packets from Source 1.

```
DeviceC# display ipv6 pim-info sparse-mode mroute

1 Configuring MLD

1.1 Introduction

The Multicast Listener Discovery (MLD) protocol manages IPv6 multicast members.

MLD defines how to establish and maintain membership between multicast devices and member hosts in an IPv6 network, to decide a forwarding path of multicast streams. Figure 1-1 shows the topology of MLD in an IPv6 multicast network.

Figure 1-1 Topology of MLD in a Multicast Network

O Interface with the MLD function enabled

There are two versions of MLD: MLDv1 is based on version 2 of the Internet Group Management Protocol (IGMP) and MLDv2 is based on version 3 of IGMP. A later MLD version is backward-compatible with an earlier MLD version. MLDv1 completes IPv6 member management based on the query and report mechanism. MLDv2 supports member hosts to decide whether to receive packets from a specified multicast source on the basis of MLDv1.

- MLD of both versions supports the Any-Source Multicast (ASM) model.
- MLDv2 can be directly applied to the Source-Specific Multicast (SSM) model.
- MLDv1 can be applied to the SSM model only when MLD SSM mapping is configured.

1.1.2 Working Principles of MLDv1

The querier election mechanism, general group query and report mechanism, join mechanism, and leave mechanism are defined in MLDv1.

1. Types of MLDv1 Packets

MLDv1 supports the following four types of packets:

- General group query packet: A querier sends general group query packets to all multicast devices and hosts in the same network segment to understand groups with members.
- Group-specific query packet: A querier sends query packets to specified multicast groups in the same network segment to understand whether these groups contain members.
- Report packet: A host sends report packets to the querier to respond to the query packets or join a group.
- Leave packet: A host sends leave packets to the querier when the host leaves a group, notifying the querier that it leaves the specified group.

2. Working Mechanisms of MLDv1

- Querier election

  If multiple multicast devices exist in a network segment, only one multicast device needs to send query packets as a querier. This avoids redundancy. When the querier in the network segment fails, other devices in the same network segment need to take the role and process MLD protocol packets. During querier election, interface addresses of the devices are compared. The device with a smallest IP address is elected as the querier, as shown in Figure 1-2.

  a Device A and Device B consider themselves as the querier and send query packets to the local network segment.

  b They compare the source IPv6 address in the received packets with the address of their interfaces. The address of Device A is smaller. Therefore, Device A acts as the querier to periodically send query packets.

  c Device B fails in the election and starts a query keepalive timer. When the timer expires, Device B considers that the querier fails and starts to send query packets to initiate a new round of querier election.

Figure 1-2 Querier Election Diagram

- General group query and report

  The MLD querier periodically sends general group query packets to all hosts and multicast devices in the local network segment, and understands and maintains group membership based on the report packets replied by the member hosts. Figure 1-3 shows the general group query and report procedure.

  a The MLD querier Device A periodically sends general group query packets to the destination address FF02::1.

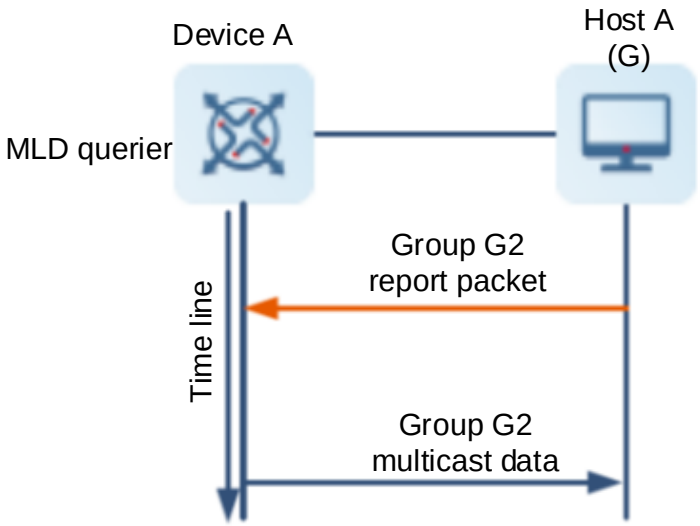
  b Upon receiving the general group query packets, Host A and Host B in the multicast group G start respective timers Timer-G-A and Timer-G-B.

  c The host whose timer expires first sends report packets destined for the multicast group G.

  If the timer Timer-G-A of Host A expires first, Host A sends report packets to the multicast group G. Upon receiving the report packets, Host B stops its timer and sends report packets in the network segment.

  d Upon receiving the report packets destined for the multicast group G from Host A, the MLD querier knows that there is member in the multicast group G. The multicast routing protocol generates an (*, G) entry. Upon receiving multicast data destined for the multicast group G, the MLD querier forwards the multicast data in the network segment.

Figure 1-3 General Group Query and Report Diagram



- Member join

  When a host tries to join a multicast group, it takes some time for the host to join the group if the host waits for a general group query packet from the querier and replies a report packet. If the host can proactively send a report packet to the MLD querier, the querier can immediately generate a multicast forwarding entry upon receiving the packet. If multicast devices in the group receive multicast data, the new host can quickly get multicast service. Figure 1-4 shows the new member join procedure.

  a Before receiving a general group query packet from Device A, Host A proactively sends a report packet destined for the multicast group G, to notify that Host A joins the multicast group G.

  b Upon receiving the report packet, the MLD querier Device A knows that there is a member in the multicast group G in the current network segment. The multicast routing protocol generates an (*, G) entry. Upon receiving multicast data destined for the multicast group G, the MLD querier forwards the multicast data in the network segment.

Figure 1-4 Member Join Diagram

- Member leave

  Upon receiving a leave packet from a member to plan to leave the multicast group G, the MLD querier sends a group-specific query packet to understand whether there is any other member existing in the group in the network segment. If not, the MLD querier deletes the corresponding membership to reduce redundant multicast traffic in the network and save bandwidth. Figure 1-5 shows the member leave procedure.

  a Host A sends a leave packet destined for all multicast devices in the local network segment to leave the multicast group G.

  b Upon receiving the leave packet, the MLD querier Device A sends a group-specific query packet destined for the multicast group G.

  c If there is any other member (for example, Host B) in the multicast group G, Host B sends a report packet for the multicast group G upon receiving the query packet. The MLD querier continues to maintain the membership of the multicast group G upon receiving the report packet. The (*, G) entry remains existent. Upon receiving multicast data destined for the multicast group G, the MLD querier forwards the multicast data in the network segment.

  d If there is no other member in the multicast group G, the querier receives no report packet for the multicast group G. After the timer expires, the (*, G) entry is deleted. Upon receiving multicast data destined for the multicast group G, the MLD querier does not forward the multicast data in the network segment.

Figure 1-5 Member Leave Diagram

1.1.3 Working Principles of MLDv2

1. Changes of MLDv2 from MLDv1

- In MLDv2, when you add a host to a group, you can specify the host to receive multicast data from specified sources. In MLDv1, you cannot specify sources for a host.
- In MLDv1, an MLDv1 packet can carry information of only one multicast group. In MLDv2, an MLDv2 packet can carry information of multiple multicast groups. This relieves the interaction problem of a great number of packets between hosts and the querier.

2. Types of MLDV2 Packets

- Query packets include general group query packet, group-specific query packet, and source-specific query packet (check whether members in a group receive multicast data from the specific source).
- Member report packets include multicast group and multicast source information. A source can be filtered in INCLUDE or EXCLUDE mode. (G, INCLUDE, (S1, S2...)) means to receive multicast data sent only from specified sources S1, S2, ... to the group G. (G, EXCLUDE, (S1, S2...)) means to reject multicast data sent from specified sources S1, S2, ... to the group G.

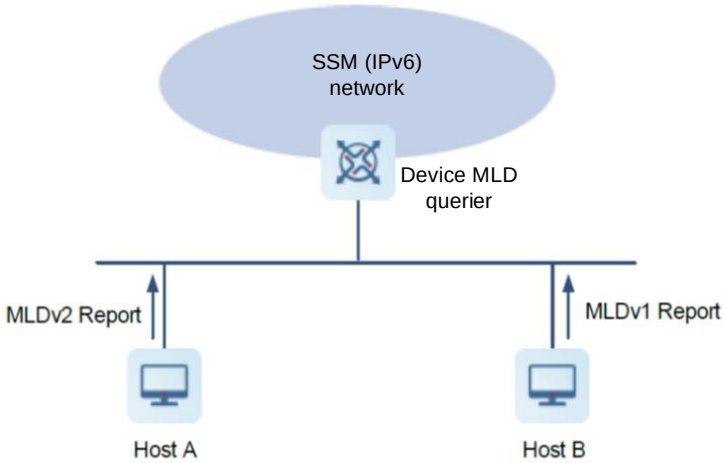
3. Working Mechanisms of MLDv2

Compared with MLDv1, MLDv2 supports you to select sources for a host to receive multicast data when you add the host.

- Specify sources to receive multicast data: You can specify sources for the host to receive multicast data when you add the host to a multicast group.
- Query a specified source: Upon receiving a report packet to modify the correspondence between multicast sources and groups from members, the MLD querier sends a specified source query packet. If you expect a member to receive multicast data from a specified source, configure a report packet. The MLD querier updates the source list of this group based on the report.

1.1.4 MLD SSM Mapping

In the source-specific multicast (SSM) model, a host must run MLDv2 if you want to specify source addresses for the host. If a host supports only MLDv1, a multicast source cannot be specified for the host. To enable a host that supports only MLDv1 to use the SSM service, you can enable the MLD SSM mapping function on the multicast device.



Based on the MLD SSM mapping mechanism, static SSM address mapping rules can be configured on the multicast device to convert the (*, G) information in MLDv1 report packets to (S, G) information so that the SSM service can be used by the host that supports only MLDv1.

In the SSM network shown in Figure 1-6, the MLD multicast device runs MLDv2, Host A supports only MLDv1, and Host B supports MLDv2. The MLD SSM mapping function can be enabled on the MLD querier to provide SSM service for Host A.

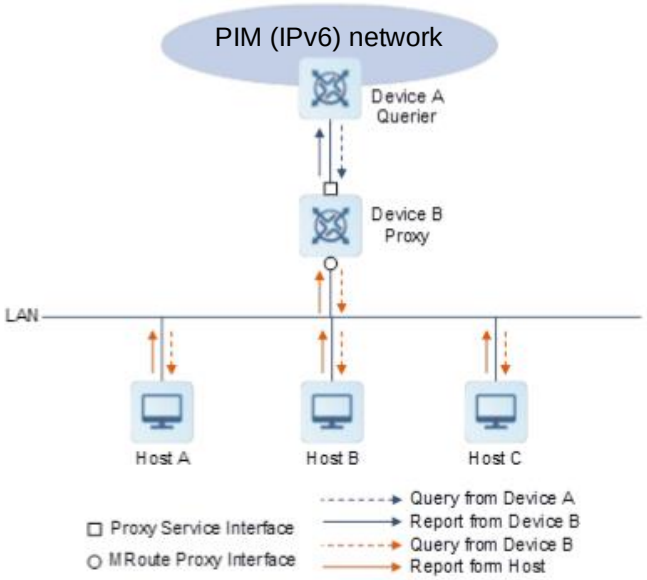
In this network, when the device receives an MLDv1 report packet from Host A, the device checks the address of the IPv6 multicast group G in the packet.

- If the multicast group G is not in the IPv6 SSM group address range, the ASM service is provided.
- If the multicast group G is in the IPv6 SSM group address range, whether the ASM service can be provided depends on the following situation:
  - If no MLD SSM mapping rule is configured on the device for the multicast group G, the SSM service cannot be provided and the packet is discarded.
  - If an MLD SSM mapping rule is configured on the device for the multicast group G, the (*, G) information in the MLDv1 report packet is mapped to (G, INCLUDE, (S1, S2)) and the SSM multicast service is provided.

Figure 1-6 Topology of MLD SSM Mapping

1.1.5 MLD Proxy

In some user scenarios, if you do not want devices connected to hosts to run complete multicast routing protocols, you can enable the MLD proxy function.



On the user side, the MLD proxy acts as a querier and periodically queries user information. On the route side, the MLD proxy acts a host and sends user information to a network when necessary. In this way, L2 multicast

flooding is suppressed, user information is more effectively obtained and controlled, and the protocol packets and network load are reduced to some extent.

Two types of MLD proxy interfaces are defined to facilitate understanding:

- MLD proxy service interface: This interface is responsible for behaviors of hosts. It receives query packets from uplink devices, replies report packets based on current group membership, and sends report or leave packets when the membership changes.
- MLD MRoute proxy interface: This interface is responsible for behaviors of the querier. It sends query packets, collects host information, and maintains membership.

Figure 1-7 Topology of MLD Proxy

1.1.6 Protocols and Standards

- RFC 2710: Multicast Listener Discovery (MLDv1) for IPv6
- RFC 3810: Multicast Listener Discovery Version 2 (MLDv2) for IPv6

1.2 Restrictions and Guidelines

- In an IPv6 network, all L3 devices must run the IPv6 PIM protocol before multicast forwarding entries can be established normally.
- Device interfaces must run MLDv2 before hosts supporting either MLD version can use the SSM service.
- A member host can be a PC or a set top box (STB), and it can normally receive multicast data by the multicast client software.

1.3 Configuration Task Summary

MLD configuration includes the following tasks:

(1) Configuring Basic Functions of MLD

(2) (Optional) Configuring an MLD Version

(3) Enabling Security Control for MLD Multicast. All the configuration tasks below are optional. Select the configuration tasks as required.

- Enabling Access Control for Multicast Groups
- Configuring the Maximum Number of Group Members

(4) Configuring MLD Querier Parameters. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Last Member Query Interval
- Configuring the Last Member Query Times
- Configuring the General Group Query Interval
- Configuring the Maximum Response Time of Query Packets
- Configuring the Other Querier Keepalive Time
- Configuring the Robustness Variable of the MLD Querier

(5) (Optional) Configuring Static MLD Groups

(6) (Optional) Configuring a Device Interface as a Simulated Host to Join a Group

(7) (Optional) Enabling the MLD Proxy Function

(8) (Optional) Enabling the SSM Mapping Function

1.4 Prerequisites

An IPv6 unicast routing protocol is configured to ensure that device nodes are reachable through IPv6 unicast routes.

1.5 Configuring Basic Functions of MLD

1.5.1 Overview

The multicast routing function is enabled on the local network and group information on the local network is collected so that member hosts can join multicast groups to receive multicast data packets.

1.5.2 Restrictions and Guidelines

- The IPv6 multicast routing function should be enabled on each multicast device on the local network unless otherwise specified.
- The PIM-SMv6 function should be enabled on interfaces connected to the local network unless otherwise specified.

1.5.3 Prerequisites

All PIM interfaces should be reachable through IPv6 unicast routes.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the IPv6 multicast routing function.

ipv6 mrouting-enable

The IPv6 multicast routing function is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(5) Enable the PIM-SMv6 function.

ipv6 pim sparse-mode

The PIM-SMv6 function on an interface is disabled by default.

1.6 Configuring an MLD Version

1.6.1 Overview

At present, there are two versions of MLD. Multicast devices running MLDv2 can identify MLDv1 packets. Multicast devices running MLDv1 cannot identify MLDv2 packets.

1.6.2 Restrictions and Guidelines

- After an MLD version is configured, MLD automatically restarts.
- The MLD version on a multicast device must be later than or equal to the MLD version on a host.
- It is recommended that an MLD version be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.

1.6.3 Prerequisites

Configuring Basic Functions of MLD.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure an MLD version.

ipv6 mld specify-version { **1** | **2** }

MLDv2 is running on an interface by default.

1.7 Enabling Security Control for MLD Multicast

1.7.1 Overview

- To prevent a host from joining an IPv6 multicast group, you can enable the function of filtering the MLD group on the interface directly connected to a network segment.
- To prevent a great number of hosts from joining an IPv6 multicast group and affecting interface performance of devices, you can configure the maximum number of members on the interface directly connected to a network segment.
- To prevent a great number of hosts from joining an IPv6 multicast group and affecting the overall performance of devices, you can configure the maximum number of members on the devices.

1.7.2 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Enabling Access Control for Multicast Groups
- Configuring the Maximum Number of Group Members

1.7.3 Prerequisites

Configuring Basic Functions of MLD.

1.7.4 Enabling Access Control for Multicast Groups

1. Overview

After enabling access control for multicast groups on an interface, you can control hosts from joining groups in the directly connected network segment. ACLs are used to limit the group address range. Report packets denied by the ACLs are discarded.

When MLDv2 is enabled, this command supports extended ACLs to precisely filter source record information in MLDv2 packets. If the received MLD report packets follow the format of (S1, S2, S3, ..., Sn, G), the corresponding ACL must be configured for filtering. S1, S2, S3, ..., Sn correspond to source addresses in ACL entries, and G corresponds to the destination address in the ACL entries.

2. Restrictions and Guidelines

It is recommended that access control be enabled on all multicast device interfaces directly connected to the local network unless otherwise specified.

3. Prerequisites

Before a multicast group address range is configured, ensure that the corresponding ACL is created and a multicast group range is specified. For details about ACL configuration, see *Configuring ACL*.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Enable access control for multicast groups.

ipv6 mld restricted-group *acl-name*

An interface allows hosts to join any group by default.

1.7.5 Configuring the Maximum Number of Group Members

1. Overview

To prevent a great number of hosts from joining an IPv6 multicast group, you can limit the number of members.

- In the global configuration mode, the number of members in an MLD group on a device is limited.
- In the interface configuration mode, the number of members in an MLD group on an interface is limited.

If the number of group members exceeds the interface limit or global limit, subsequent report packets are ignored.

If an exceptional list is configured, report packets in a specified range can be normally processed, and the records about these group members are not counted.

Interface and global limits can be configured separately. If the global limit is smaller than the interface limit, the global limit prevails.

2. Restrictions and Guidelines

It is recommended that the maximum number of group members be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.

It is recommended that the maximum number of group members be configured on multicast devices directly connected to the local network unless otherwise specified.

3. Prerequisites

- Before an exceptional list is configured, ensure that the corresponding ACL is created and an exceptional multicast group range is specified. For details about ACL configuration, see *Configuring ACL*.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the maximum number of MLD group members. Select one of the following to configure.

- Configure the maximum number of MLD group members on a device.

  ipv6 mld max-member-record *max-member-record* [**except** *acl-name*]

- Configure the maximum number of MLD group members on an interface.

  interface *interface-type interface-number*

  ipv6 mld max-member-record *max-member-record* [**except** *acl-name*]

By default, the maximum number of MLD group members on a device is **64000**, and that on an interface is **4000**.

1.8 Configuring MLD Querier Parameters

1.8.1 Overview

MLD maintains IPv6 membership by query packets and report packets. If multiple multicast devices exist in a network segment, only one multicast device needs to send query packets as a querier. IP addresses of multicast devices are compared. The device with the smallest address is elected as the querier. The querier periodically sends query packets to obtain local member information and ensure that a group has at least one host. If no host is available in a group, the group is deleted by the device.

The MLD querier work can be adjusted using multiple parameters. When the default parameter values are used, the querier can normally work. Network optimization can be implemented by adjusting querier parameter values to avoid excessive protocol packets and network congestion. Also, membership can be updated and maintained in time.

1.8.2 Restrictions and Guidelines

- It is recommended that querier parameters be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.
- In actual network deployment, to accurately, timely, and stably maintain group membership and avoid

non-queriers from initiating a new round of election, ensure that the following durations are arranged in ascending order: Maximum response time of general group query packet < Sending interval of general group query packet < Other querier keepalive time.

1.8.3 Prerequisites

Configuring Basic Functions of MLD.

1.8.4 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Last Member Query Interval
- Configuring the Last Member Query Times
- Configuring the General Group Query Interval
- Configuring the Maximum Response Time of Query Packets
- Configuring the Robustness Variable of the MLD Querier
- Configuring the Other Querier Keepalive Time

1.8.5 Configuring the Last Member Query Interval

1. Overview

Before a host leaves a multicast group, the host sends a leave packet. Upon receiving the leave packet, the querier continuously sends group-specific/source-specific query packets and waits for responses from hosts. This parameter specifies the query packet sending interval.

2. Restrictions and Guidelines

- It is recommended that this parameter be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.
- The unit of the last member query interval is 0.1 seconds. If the parameter value is 10, the actual sending interval is 1 second.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.

interface loopback *interface-number*

(4) Configure the last member query interval.

ipv6 mld last-member-query-period *interval*

The group-specific query packet sending interval is **1** second by default.

1.8.6 Configuring the Last Member Query Times

1. Overview

Before a host leaves a multicast group, the host sends a leave packet. Upon receiving the leave packet, the querier continuously sends specific group/source query packets and waits for responses from the host. This parameter specifies the query packet sending times.

2. Restrictions and Guidelines

It is recommended that this parameter be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the last member query times.

ipv6 mld last-member-query-number *count*

The group-specific query packet sending times is **2** by default.

1.8.7 Configuring the General Group Query Interval

1. Overview

The MLD querier periodically sends query packets to all hosts and multicast devices on the shared network. This parameter specifies the interval for sending query packets.

2. Restrictions and Guidelines

It is recommended that this parameter be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the general group query interval.

ipv6 mld query-period *interval*

The default interval for sending general group query packets is **125** seconds.

1.8.8 Configuring the Maximum Response Time of Query Packets

1. Overview

After the MLD querier sends query packets, member hosts reply upon receiving the query packets before the maximum response time expires. If no response is received after timeout, it is considered that no member exists in the group of the directly connected network segment and the group information is deleted.

2. Restrictions and Guidelines

It is recommended that this parameter be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*

- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the maximum response time of query packets.

ipv6 mld max-response-time *max-response-time*

The maximum response time of query packets is **10** seconds by default.

1.8.9 Configuring the Other Querier Keepalive Time

1. Overview

When a non-querier does not receive a query packet in the same network segment within a specified period, the non-querier considers there is only querier (itself) in the directly connected network segment and initiates a new round of querier election. This parameter specifies the timeout time for the non-queriers to wait for query packets.

2. Restrictions and Guidelines

It is recommended that this parameter be configured on all interfaces where MLD is enabled on the local network unless otherwise specified.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the other querier keepalive time.

ipv6 mld other-querier-timeout *timeout*

The keepalive time of other querier is **255** seconds by default.

1.8.10 Configuring the Robustness Variable of the MLD Querier

1. Overview

When the query packets sent by the querier are lost due to network instability, the query packets are retransmitted. The retransmission times are referred to as the robustness variable of the MLD querier.

In the event of packet loss, query packet retransmission occurs in either of the following situations:

- When the querier is started, it sends general group query packets.

- Upon receiving leave packets, the querier sends group-specific/source-specific query packets to check whether there are members existing in the specific multicast group.

2. Restrictions and Guidelines

It is recommended that this parameter be configured on all interfaces where MLD is enabled on the local network unless otherwise specified.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure the robustness variable of the MLD querier.

ipv6 mld robustness-variable *robustness*

The robustness variable of the MLD querier is **2** by default.

1.9 Configuring Static MLD Groups

1.9.1 Overview

In some application scenarios, a static multicast group may need to be configured on the interfaces connected to group members in the following cases:

1. The group members are stable and multicast data needs to be quickly and stably forwarded to member interfaces.

2. The group members cannot send report packets but need to receive certain multicast data. After the static multicast group is configured, the multicast devices consider that group members exist on these interfaces and forward multicast data to these interfaces.

1.9.2 Restrictions and Guidelines

A static multicast group must be manually configured on an interface connected to group members.

1.9.3 Prerequisites

Configuring Basic Functions of MLD.

1.9.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure a static MLD group.

ipv6 mld static-group-entries *ipv6-group-address*

No interface is added to any static multicast group by default.

1.10 Configuring a Device Interface as a Simulated Host to Join a Group

1.10.1 Overview

In some test scenarios, no host is available or can be added to a multicast group. In this case, you need to configure device interfaces to simulate hosts and add the hosts to a specific multicast group.

1.10.2 Restrictions and Guidelines

- An interface can be added to multiple groups at the same time.

1.10.3 Prerequisites

The PIM protocol must be configured and the IPv6 multicast routing function must be enabled on the interfaces to be configured as hosts.

1.10.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.

interface aggregateport *interface-number*

- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure a device interface as a host to join a group.

ipv6 mld add-to-join-group *ipv6-group-address*

No interface is added to any multicast group by default.

1.11 Enabling the MLD Proxy Function

1.11.1 Overview

The MLD router proxy function collects local member information. For a host, the MLD proxy functions as a router and sends query packets.

For the querier, the MLD proxy functions as a host and sends report packets.

1.11.2 Restrictions and Guidelines

- The MLD proxy service interface is configured on the interface of routers directly connected to the upstream devices unless otherwise specified.
- The MRoute proxy interface is configured on the interface of hosts directly connected to the downstream devices unless otherwise specified.
- A maximum of 32 proxy service interfaces can be configured on a device. After receiving MLD query packets, the proxy service interface sends report packets based on the MLD group member records.

1.11.3 Prerequisites

Configuring Basic Functions of MLD.

1.11.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Enable the MLD proxy service function.

ipv6 mld enable-proxy-service

The MLD proxy service function is disabled by default.

(5) Enable the MLD MRoute proxy function.

ipv6 mld enable-mrouting-proxy *interface-type interface-number*

The MRoute proxy function is disabled by default.

1.12 Enabling the SSM Mapping Function

1.12.1 Overview

MLDv2 supports source filtering while MLDv1 does not. However, the multicast devices provide the SSM mapping function to implement source filtering and enable MLDv1 hosts to use the SSM service. Multicast device interfaces run MLDv2. When receiving MLDv1 report packets, a multicast device adds the static mapping source address.

1.12.2 Restrictions and Guidelines

The SSM service must be enabled and the SSM group address range must be consistent on all multicast devices.

1.12.3 Prerequisites

- Configuring Basic Functions of MLD.
- Before a static mapping entry is configured, ensure that the corresponding ACL is created and a multicast group range is specified. For details about ACL configuration, see *Configuring ACL*.

1.12.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the SSM mapping function.

ipv6 mld ssm-policy enable

The SSM mapping function is disabled by default.

(4) (Optional) Configure a static mapping entry.

ipv6 mld ssm-policy static *acl-name ipv6-source-address*

No static mapping entry is configured by default.

1.13 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **cleanup** commands to clear information.

Caution

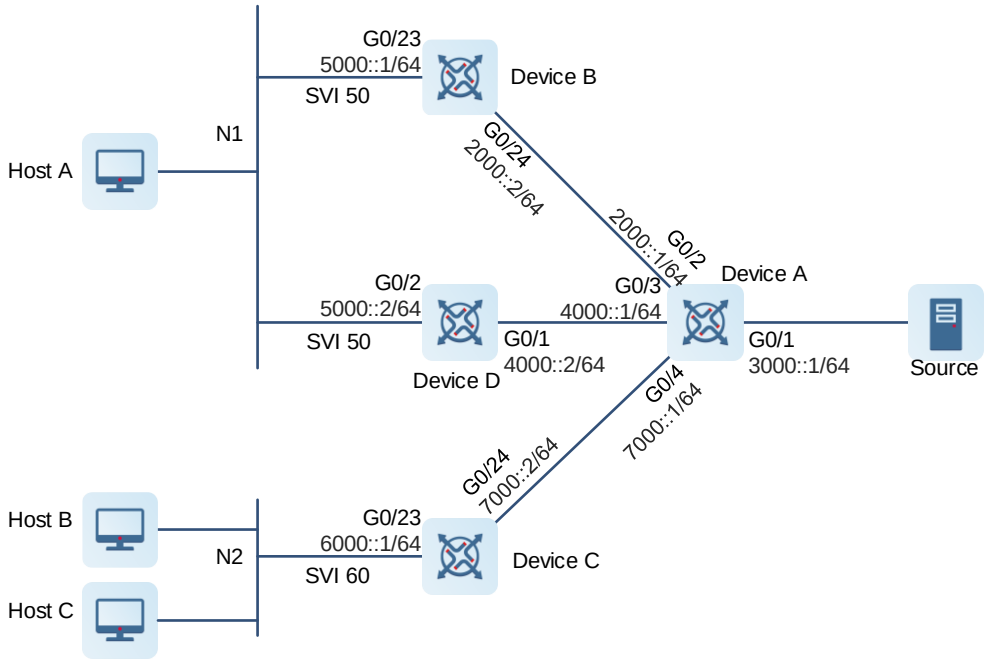
Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
cleanup ipv6 mld-cache dynamicgroup [*ipv6-group-address*] [*interface-type interface-number*]	Clears dynamic group member records in the MLD cache.
cleanup ipv6 mld-cache interface *interface-type interface-number*	Clears all MLD statistics and group member records on the interface.
display ipv6 mld-info groups [*ipv6-group-address* | *interface-type interface-number*] [**detail**]	Displays groups directly connected to the device and group information learned from MLD.
display ipv6 mld-info interface [*interface-type interface-number*]	Displays configurations of the interface.
display ipv6 mld-info ssm-mapping [*ipv6-group-address*]	Displays the SSM mapping information.
display debugging	Displays the MLD debugging switch status.
debugging ipv6 mld-info all	Debugs all MLD information.
debugging ipv6 mld-info decode	Debugs MLD packet resolution.
debugging ipv6 mld-info encode	Debugs MLD packet encoding.
debugging ipv6 mld-info events	Debugs MLD event information.
debugging ipv6 mld-info fsm	Debugs MLD event information.
debugging ipv6 mld-info tib	Debugs MLD state machine information.
debugging ipv6 mld-info warning	Debugs MLD alarms.

1.14 Examples

1.14.1 Configuring Basic Functions of MLD



1. Requirements

As shown in Figure 1-8, Host A, Host B, and Host C residing in shared networks N1 and N2 of IPv6 want to receive video information from the source in multicast mode. The static multicast group FF13::1 is configured on N1 shared network, and hosts on N2 shared network can join the multicast group FF14::1.

- OSPFv3 runs in the network to make unicast routes between any two nodes reachable.
- Device B and Device D are connected to the shared network N1 through SVI 50. The IPv6 address of Device B is smaller than the IPv6 address of Device D. Therefore, Device B acts as the querier, and Host A is the multicast information receiver in the shared network N1.
- Device C is connected to the shared network N2 through SVI 60, and Host B is the multicast information receiver in the shared network N2.
- Device B, Device C, and Device D are connected to other devices in the IPv6 PIM network through L3 interfaces.

2. Topology

Figure 1-8 Topology for Basic Functions of MLD

3. Notes

- Configure an IPv6 unicast routing protocol OSPFv3 on a multicast device and ensure that unicast routes are reachable to the Loopback interface.
- Enable the IPv6 multicast routing function on all multicast devices.
- Configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts,

and interfaces connected to sources.

- Configure a static multicast group on the interfaces of the devices on shared network N1.
- Enable the multicast group access control function on the interfaces of the devices on shared network N2.

4. Procedure

(1) Configure an IPv6 address for each interface and configure the unicast routing protocol.

Configure an IPv6 address for the interface of Device A and configure the OSPFv3 protocol to implement internetworking. Perform the same configuration on Device B, Device C, and Device D.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ipv6 router-protocol ospf 5050
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 address 3000::1/64
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 ospf 5050 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
DeviceA(cfg)# interface GigabitEthernet 0/2
DeviceA(cfg-if-GigabitEthernet 0/2)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/2)# ipv6 address 2000::1/64
DeviceA(cfg-if-GigabitEthernet 0/2)# ipv6 ospf 5050 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/2)# exit
DeviceA(cfg)# interface GigabitEthernet 0/3
DeviceA(cfg-if-GigabitEthernet 0/3)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/3)# ipv6 address 8000::1/64
DeviceA(cfg-if-GigabitEthernet 0/3)# ipv6 ospf 5050 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/3)# exit
DeviceA(cfg)# interface GigabitEthernet 0/4
DeviceA(cfg-if-GigabitEthernet 0/4)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/4)# ipv6 address 7000::1/64
DeviceA(cfg-if-GigabitEthernet 0/4)# ipv6 ospf 5050 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/4)# exit
DeviceA(cfg)# interface loopback 0
DeviceA(cfg-if-Loopback 0)# ipv6 address 1111::1/128
DeviceA(cfg-if-Loopback 0)# ipv6 ospf 5050 set-area 0
DeviceA(cfg-if-Loopback 0)# exit
```

(2) Enable the IPv6 multicast routing function on all devices, and configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts, and interfaces connected to sources.

Enable the IPv6 multicast routing function and configure the PIM-SMv6 protocol on Device A. Perform the same configuration on Device B, Device C, and Device D.

```
DeviceA(cfg)# ipv6 mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
DeviceA(cfg)# interface GigabitEthernet 0/2
```

```
DeviceA(cfg-if-GigabitEthernet 0/2)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/2)# exit
DeviceA(cfg)# interface GigabitEthernet 0/3
DeviceA(cfg-if-GigabitEthernet 0/3)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/3)# exit
DeviceA(cfg)# interface GigabitEthernet 0/4
DeviceA(cfg-if-GigabitEthernet 0/4)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/4)# exit
DeviceA(cfg)# interface loopback 0
DeviceA(cfg-if-Loopback 0)# ipv6 pim sparse-mode
DeviceA(cfg-if-Loopback 0)# exit
```

Configure an RP. Configure a C-BSR and a C-RP on Device A.

```
DeviceA(cfg)# ipv6 pim c-bsr Loopback 0
DeviceA(cfg)# ipv6 pim c-rp Loopback 0
```

(3) Configure a static multicast group on the interfaces of the devices on shared network N1.

Configure a static multicast group on SVI 50 of Device B, and set the static multicast group address to FF13::1. Perform the same configuration on Device D.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface VLAN 50
DeviceB (cfg-if-VLAN 50)# ipv6 mld static-group-entries ff13::1
DeviceB(cfg-if-VLAN 50)# exit
DeviceB(cfg)# interface GigabitEthernet 0/23
DeviceB(cfg-if-GigabitEthernet 0/23)# switch-port access vlan 50
DeviceB(cfg-if-GigabitEthernet 0/23)# exit
DeviceB(cfg)# interface TenGigabitEthernet 0/27
DeviceB(cfg-if-TenGigabitEthernet 0/27)# switch-port mode trunk
DeviceB(cfg-if-TenGigabitEthernet 0/27)# switch-port trunk native vlan 50
DeviceB(cfg-if-TenGigabitEthernet 0/27)# exit
```

(4) Enable the multicast group access control function on the interfaces of the devices on shared network N2.

Enable the multicast group access control function on SVI 60 of Device C, and add the hosts in network N2 to the multicast group FF14::1.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ipv6 access-control-list ipv6-group
DeviceC(cfg-ipv6acl)# permit ipv6 any host FF14::1
DeviceC(cfg-ipv6acl)# exit
DeviceC(cfg)# interface VLAN 60
DeviceC(cfg-if-VLAN 60)# ipv6 mld restricted-group ipv6-group
DeviceC(cfg-if-VLAN 60)# exit
```

5. Verification

Run the **display ipv6 mld-info interface** command to display MLD configuration of each device. Device B is taken as an example. Device B is the querier, because the IPv6 address of SVI 50 on Device B in the shared network N1 is smaller.

```
DeviceB# display ipv6 mld-info interface VLAN 50
Interface VLAN 50 (Index 4146)
 MLD Enabled, Active, Querier, Version 2 (default)
 Internet address is fe80::274:9cff:feee:53cb
 MLD interface max-member-record is 4000
 MLD interface has 0 group-record states
 MLD interface has 0 add-to-group records
 MLD interface has 1 static-group-entries records
 MLD activity: 10 joins, 1 leaves
 MLD query interval is 125 seconds
 MLD querier timeout is 255 seconds
 MLD max query response time is 10 seconds
 Last member query response interval is 10 (1/10s)
 Last member query count is 2
 Group Membership interval is 260
 Robustness Variable is 2
```

Run the **display ipv6 pim-info sparse-mode mroute** command to display the multicast routing entries on each device. The multicast routing entries on Device B are as follows:

```
DeviceB# display ipv6 pim-info sparse-mode mroute
IPv6 Multicast Routing Table
(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 0
(S,G,rpt) Entries: 0
FCR Entries: 0
REG Entries: 0

(*, ff13::1)
RP: 1111::1
RPF nbr: fe80::274:9cff:fe11:c9e7
RPF idx: GigabitEthernet 0/24

FCR:
```

Run the **display ipv6 mld-info groups** command to display the static multicast group FF13::1 that SVI50 joins on Device B and Device D.

```
DeviceB# display ipv6 mld-info groups
MLD Connected Group Membership
Group Address                 Interface        Uptime     Expires    Last Reporter
ff13::1                      VLAN 50           00:11:07   stopped    ::
```

Try to add a host to the multicast groups FF13::1 and FF14::1 through SVI 60, and run the **display ipv6 mld-info groups** command to display that the host joins in only the multicast group FF14::1 through SVI 60.

```
DeviceC# display ipv6 mld-info groups
MLD Connected Group Membership
Group Address                 Interface        Uptime     Expires    Last Reporter
ff14::1                      VLAN 60           00:01:03   00:03:51
fe80::274:9cff:feee:f49f
```

6. Configuration Files

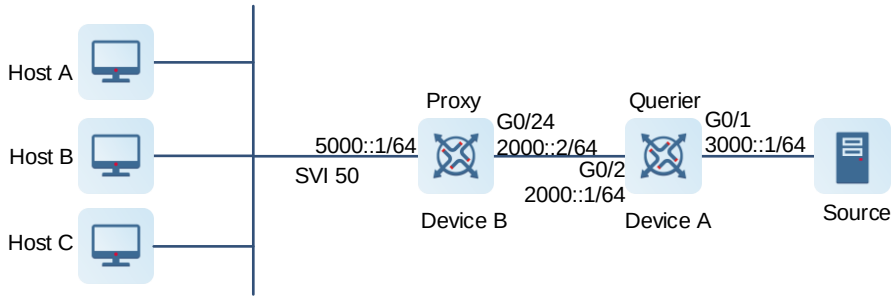
7. Common Errors

- The multicast routing function is not enabled on a multicast device.
- No multicast interface is available on the network.



1.14.2 Configuring the MLD Proxy Function

1. Requirements

As shown in Figure 1-9, the PIM-SMv6 protocol is configured in the network. Host A and Host B in the stub network receive multicast data from the source. The multicast group addresses are FF13::1 and FF14::1. The MLD proxy function is enabled on Device B to maintain membership and normal forwarding of multicast data.

2. Topology

Figure 1-9 Topology of the MLD Proxy

3. Notes

- Configure an IPv6 unicast routing protocol OSPFv3 on a multicast device and ensure that unicast routes are reachable to the Loopback interface.
- Enable the IPv6 multicast routing function on all multicast devices, and configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts, and interfaces connected to sources.
- Configure a proxy service interface.
- Configure an MRoute proxy interface.

4. Procedure

(1) Configure an IPv6 unicast routing protocol OSPFv3 on a multicast device and ensure that unicast routes are reachable to the Loopback interface.

Configure an IPv6 address for the interface of Device A and configure the OSPFv3 protocol to implement internetworking. Perform the same configuration on Device B.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ipv6 router-protocol ospf 5050
DeviceA(cfg)# interface GigabitEthernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 address 3000::1/64
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 ospf 5050 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
DeviceA(cfg)# interface GigabitEthernet 0/2
DeviceA(cfg-if-GigabitEthernet 0/2)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/2)# ipv6 address 2000::1/64
```

```
DeviceA(cfg-if-GigabitEthernet 0/2)# ipv6 ospf 5050 area 0
DeviceA(cfg-if-GigabitEthernet 0/2)# exit
DeviceA(cfg)# interface loopback 0
DeviceA(cfg-if-Loopback 0)# ipv6 address 1111::1/128
DeviceA(cfg-if-Loopback 0)# ipv6 ospf 5050 set-area 0
DeviceA(cfg-if-Loopback 0)# exit
```

(2) Enable the IPv6 multicast routing function on all multicast devices, and configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts, and interfaces connected to sources.

Enable the IPv6 multicast routing function and configure the PIM-SMv6 protocol on Device A. Perform the same configuration on Device B.

```
DeviceA(cfg)# ipv6 mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
DeviceA(cfg)# interface GigabitEthernet 0/2
DeviceA(cfg-if-GigabitEthernet 0/2)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/2)# exit
DeviceA(cfg)# interface loopback 0
DeviceA(cfg-if-Loopback 0)# ipv6 pim sparse-mode
DeviceA(cfg-if-Loopback 0)# exit
```

Configure an RP. Configure a C-BSR and a C-RP on Device A.

```
DeviceA(cfg)# ipv6 pim c-bsr Loopback 0
DeviceA(cfg)# ipv6 pim c-rp Loopback 0
```

(3) Configure a proxy service interface.

Configure GigabitEthernet 0/24 on Device B as a proxy service interface.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface GigabitEthernet 0/24
DeviceB(cfg-if-GigabitEthernet 0/24)# ipv6 mld enable-proxy-service
DeviceB(cfg-if-GigabitEthernet 0/24)# exit
```

(4) Configure an MRoute proxy interface.

Configure SVI 50 of Device B as an MRoute proxy interface.

```
DeviceB(cfg)# interface VLAN 50
DeviceB(cfg-if-VLAN 50)# ipv6 mld enable-mrouting-proxy GigabitEthernet 0/24
```

5. Verification

Run the **display ipv6 mld-info groups** command on Device B to display the proxy entries.

```
DeviceB# display ipv6 mld-info groups
MLD Connected Group Membership
Group Address                    Interface          Uptime     Expires    Last Reporter
ff13::1                          VLAN 50            00:03:24   00:04:14
fe80::274:9cff:feee:f49f
```

```
ff14::1                                  VLAN 50                 00:00:06   00:04:14
fe80::274:9cff:feee:54cb

MLD Proxy-server Connected Group Membership
Group Address                              Interface                Uptime
ff13::1                                  GigabitEthernet 0/24    00:03:24
ff14::1                                  GigabitEthernet 0/24    00:00:06
```

Run the **display ipv6 mld-info groups** command on Device A to display that addresses of members joining the multicast groups FF13::1 and FF14::1 are IPv6 addresses of the Device B proxies.

```
DeviceA# display ipv6 mld-info groups
MLD Connected Group Membership
Group Address                              Interface                Uptime      Expires     Last Reporter
ff13::1                                  GigabitEthernet 0/2     00:09:56   00:03:44
fe80::274:9cff:feee:53cb
ff14::1                                  GigabitEthernet 0/2     00:00:23   00:03:56
fe80::274:9cff:feee:53cb
```

6. Configuration Files

- Device A configuration file

```

```

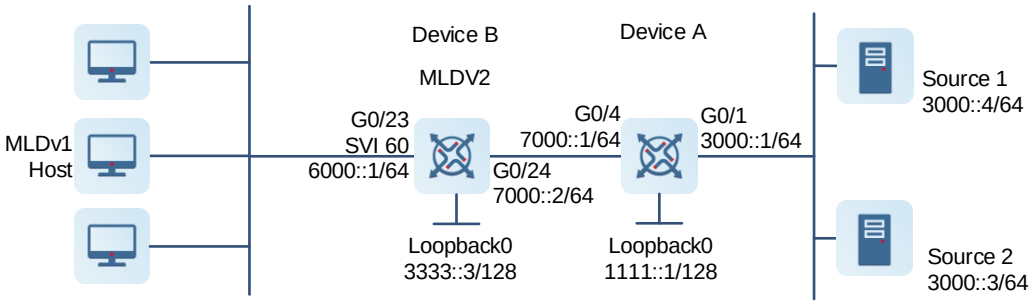
7. Common Errors

The basic functions of MLD are not enabled.



1.14.3 Configuring SSM Mapping

1. Requirements

As shown in Figure 1-10, the SSM model is used to provide multicast service in an IPv6 multicast network. The default SSM group address range in the network is FF3X::/32. Hosts run MLDv1 and do not support MLDv2. Hosts are expected to receive multicast packets from Source 2 and ignore multicast packets from Source 1.

2. Topology

Figure 1-10 Topology of SSM Mapping

3. Notes

- Configure an IPv6 unicast routing protocol OSPFv3 on a multicast device and ensure that unicast routes are reachable to the Loopback interface.
- Enable the IPv6 multicast routing function on all multicast devices, and configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts, and interfaces connected to sources.
- Configure an SSM group address range.
- Enable the SSM mapping function.
- Configure an SSM mapping static linked list.

4. Procedure

(1) Configure an IPv6 unicast routing protocol OSPFv3 on a multicast device and ensure that unicast routes are reachable to the Loopback interface.

Configure an IPv6 address for the interface of Device A and configure the OSPFv3 protocol to implement internetworking. Perform the same configuration on Device B.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ipv6 router-protocol ospf 5050
DeviceA(cfg)# interface GigabitEthernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 address 3000::1/64
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 ospf 5050 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
DeviceA(cfg)# interface GigabitEthernet 0/4
```

```
DeviceA(cfg-if-GigabitEthernet 0/4)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/4)# ipv6 address 7000::1/64
DeviceA(cfg-if-GigabitEthernet 0/4)# ipv6 ospf 5050 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/4)# exit
DeviceA(cfg)# interface loopback 0
DeviceA(cfg-if-Loopback 0)# ipv6 address 1111::1/128
DeviceA(cfg-if-Loopback 0)# ipv6 ospf 5050 set-area 0
DeviceA(cfg-if-Loopback 0)# exit
```

(2) Enable the IPv6 multicast routing function on all multicast devices, and configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts, and interfaces connected to sources.

Enable the IPv6 multicast routing function and configure the PIM-SMv6 protocol on Device A. Perform the same configuration on Device B.

```
DeviceA(cfg)# ipv6 mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
DeviceA(cfg)# interface GigabitEthernet 0/4
DeviceA(cfg-if-GigabitEthernet 0/4)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/4)# exit
DeviceA(cfg)# interface loopback 0
DeviceA(cfg-if-Loopback 0)# ipv6 pim sparse-mode
DeviceA(cfg-if-Loopback 0)# exit
```

Set the MLD version on SVI 60 connected to hosts to 2 on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface VLAN 60
DeviceB(cfg-if-VLAN 60)# ipv6 mld specify-version 2
DeviceB(cfg-if-VLAN 60)# exit
```

(3) Configure an SSM group address range.

Configure an SSM multicast address range on all devices. Take Device A as an example and perform the same configuration on Device B.

```
DeviceB(cfg)# ipv6 pim enable-ssm default
```

(4) Enable the SSM mapping function.

Enable the SSM mapping function on Device B.

```
DeviceB(cfg)# ipv6 mld ssm-policy enable
```

(5) Configure an SSM mapping static linked list.

Map the multicast addresses in FF34::/64 to Source 1 on Device B.

```
DeviceB(cfg)# ipv6 access-control-list map-acl
DeviceB(cfg-ipv6acl)# permit ipv6 any FF34::/64
DeviceB(cfg)# ipv6 mld ssm-policy static map-acl 3000::3
```

5. Verification

Display the SSM mapping information.

```
DeviceB# display ipv6 mld-info ssm-mapping
SSM Mapping : Enabled
Database      : Static mappings configured
```

Display multicast source information corresponding to the multicast group FF34::1.

```
DeviceB# display ipv6 mld-info ssm-mapping FF34::1
Group address: ff34::1
Database        : Static
Source list   : 3000::3
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ipv6 mrouting-enable
!
interface GigabitEthernet 0/1
 unset switch-port
 ipv6 address 3000::1/64
 ipv6 ospf 5050 set-area 0
 ipv6 pim sparse-mode
!
interface GigabitEthernet 0/4
 unset switch-port
 ipv6 address 7000::1/64
 ipv6 ospf 5050 set-area 0
 ipv6 pim sparse-mode
!
interface Loopback 0
 ipv6 address 1111::1/128
 ipv6 ospf 5050 set-area 0
 ipv6 pim sparse-mode
!
ipv6 router-protocol ospf 5050
 graceful-restart
!
ipv6 pim enable-ssm default
!
end
```

- Device B configuration file

```
hostname DeviceB
!
ipv6 access-control-list map-acl
```

```
 30 permit ipv6 any FF34::/64
!
ipv6 mrouting-enable
!
vlan range 1,60
!
interface GigabitEthernet 0/23
 switch-port access vlan 60
!
interface GigabitEthernet 0/24
 unset switch-port
 ipv6 address 7000::2/64
 ipv6 ospf 5050 set-area 0
 ipv6 pim sparse-mode
!
interface Loopback 0
 ipv6 address 3333::3/128
 ipv6 ospf 5050 set-area 0
 ipv6 pim sparse-mode
!
interface VLAN 60
 ipv6 address 6000::1/64
 ipv6 ospf 5050 area 0
 ipv6 pim sparse-mode
 ipv6 mld specify-version 2
!
ipv6 router-protocol ospf 5050
 graceful-restart
!
ipv6 mld ssm-policy enable
ipv6 mld ssm-policy static map-acl 3000::3
ipv6 pim enable-ssm default
!
end
```

7. Common Errors

- The basic functions of MLD are not enabled.
- The SSM service is not enabled.
- No SSM address range is configured.

1.15 Common Misconfigurations

- Basic functions of MLD are not configured on the proxy service interface.
- No SSM service address is configured when the SSM service is used.
- The SSM service address ranges on different multicast devices are inconsistent.

1.15.1 What Can I Do when On-demand Multicast Service Is Unavailable on Client

- Fault Symptom

  The multicast function is enabled. But I failed to use the on-demand multicast service through a client.

- Troubleshooting

  a Check whether the connection between the on-demand client and multicast server is normal.

  Run the **display ipv6 route** command to check for any entry of unicast route to the multicast source on the server. If no, configure a unicast routing protocol.

  b Check configuration on the devices.

  Run the **display ipv6 pim-info** { **dense-mode | sparse-mode** } **interface** command to check for PIM information on an interface. If no information about the interface is displayed, the PIM-SMv6 function is not enabled. Run the **ipv6 pim sparse-mode** command to enable the PIM-SMv6 function on the interface.

  c Check whether the multicast receiver normally joins the group.

  Run the **display ipv6 mld-info groups** command to check whether the host joins the corresponding multicast group on the multicast device residing in the same network segment as the host.

  d Check whether the multicast entries on the multicast source and receiver are normal.

  Run the **display ipv6 pim-info** { **dense-mode | sparse-mode** } command to check whether the multicast entries on the devices are normal.

1 Configuring PIM-SMv6

1.1 Introduction

The Protocol Independent Multicast (PIM) is an intra-domain multicast routing protocol that is independent from unicast routing protocols. Any unicast routing protocol, for example, static route, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF), can provide routing information for IP multicast. Multicast routing is independent of unicast routing, and simply uses unicast routing tables to generate multicast routing information. The Protocol Independent Multicast-Sparse Mode version 6 (PIM-SMv6) is used most widely, and applies to networks of any form, especially large networks where group members are scattered in a wide area. Compared with other intra-domain multicast routing protocols, PIM-SMv6 has irreplaceable advantages.

1.2 Principles

Suppose that not all hosts need to receive multicast data, PIM-SMv6 sends multicast data to hosts that require the multicast data.

A PIM multicast device provides multicast service in any-source multicast (ASM) and source-specific multicast (SSM) models. For groups in the SSM address range, the SSM model is used. For other groups, the ASM model is used. In the ASM model, a host joins a specified multicast group G without the multicast source S specified. In the SSM model, a host can join a specified multicast group G to receive multicast data from a specified source S.

1.2.1 ASM Model

1. Basic Principles

PIM-SMv6 in the ASM model is implemented as follows:

- A rendezvous point (RP) is used as a root of a rendezvous point tree (RPT) for transition. The designated router (DR) connected to a host sends a join message to the RP of a multicast group, and the multicast devices on the route create (*, G) entries hop by hop. Based on the entries, an RPT is created with the RP as the root.
- To send data to a multicast group, the source DR sends a register message to the RP to create an (S, G) entry on the RP. After the registration succeeds, the multicast source sends multicast data to the RP. After the multicast data arrives at the RP, it is copied and sent to the host via the RPT.

In the ASM model, the key mechanisms of PIM-SMv6 include PIM neighbor creation, DR election, RP, bootstrap router (BSR), multicast source registration, shortest path tree (SPT) switchover, and assertion.

2. PIMv6 Neighbor Creation

Neighbor relationship must be created between PIM multicast devices to form a PIM network, so that PIM control messages and multicast packets can be transmitted on the network. A Hello message is sent from a PIM interface. In the multicast packet with the Hello message encapsulated, the destination address is FF02::D (indicating all PIM multicast devices in the same network segment), the source address is the IP address of the PIM interface, and the time to live (TTL) value is 1. The Hello message is used to:

- Discover PIM neighbors.

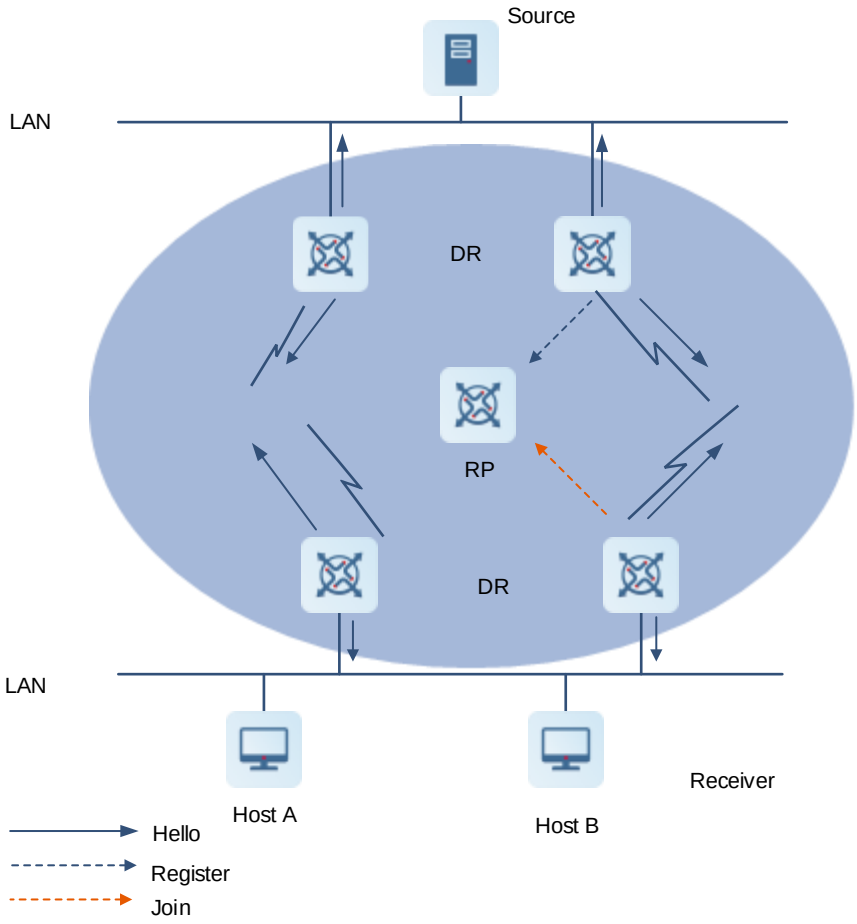
  PIM multicast devices in the same network segment receive the multicast packet with the destination address as FF02::D, obtain neighbor information, and create neighbor relationship. After the neighbor relationship is created, the PIM interfaces can receive and process other PIM packets and create multicast routing entries.

  When a PIM interface is enabled or detects a new neighbor, a Triggered-Hello-Delay message is used to generate a random time. Within the time, the interface sends Hello messages.

- Negotiate protocol parameters. The Hello message contains the following key parameters:
  - **DR Priority**: The priority of a multicast device for DR election. The device with a higher priority is selected.
  - **Holdtime**: The neighbor is considered reachable before timeout.
  - **Propagation Delay**: Duration between the time when a PIM device receives a prune packet and the time when the PIM device sends the prune packet to the uplink devices.
  - **Override-Interval**: The interval to override the prune.

- Maintain neighbor relationship.

  A Hello message is sent periodically between PIM multicast devices. If no new Hello message is received from a PIM neighbor within the hold time, this neighbor is considered unreachable and then removed from the neighbor list. Any change of PIM neighbors will cause change of the multicast topology in the network. If an uplink or downlink neighbor in a multicast distribution tree (MDT) is unreachable, multicast routes converge again and the MDT is reshaped.



3. DR Election

As shown in Figure 1-1, the source DR sends a register message to the RP. Member DRs send join messages to the RP and forward multicast data to members in a multicast group. In the network segment to which members and multicast source are connected, multiple PIM devices obtain IP addresses and DR priorities of neighbors based on the Hello messages sent between the PIM devices during PIM neighbor creation. The PIM device that is elected becomes a member DR or source DR. The election rules are as follows:

(1) The DR priorities are compared. The device with a higher priority is selected.

(2) If the DR priorities are the same or there is any neighbor in the shared network segment that does not support DR priority, the IP addresses of the devices are compared. The device with a larger IP address is selected.

Figure 1-1 Schematic Diagram of DR Election

4. BSR Election

In the PIM network, the BSR periodically generates bootstrap messages (BSMs) that include a series of candidate-RPs (C-RPs) and corresponding group addresses. The BSMs are sent in the entire domain hop by hop. All PIM multicast devices in the network receive the BSMs and record the C-RPs and corresponding group addresses.

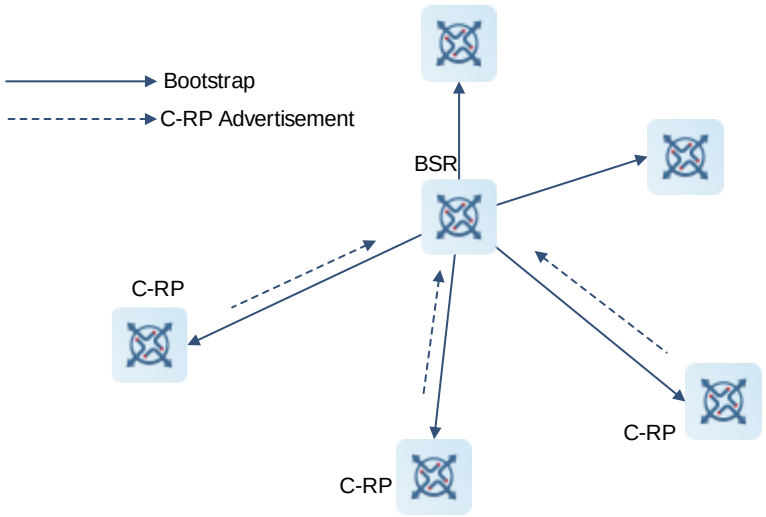
In the PIM-SMv6 domain, one or multiple candidate-BSRs (C-BSRs) are configured and the BSR is elected based on rules.

5. RP Election

In the PIMv6 network, the RP processes register messages of the source DR and join packets of group members. The process from the multicast source to members of the multicast group is divided into two sections: The SPT that uses the source DR as the root and the RP as the leaf, and the RPT that uses the RP as the root and member DRs as leaves. In the PIM-SMv6 network with the ASM model, the RP must act as a transition to create or forward data.

In the PIM network, an RP can serve one or more groups, and a group can be served by only one RP. In the PIM network, the RP can be configured as static or dynamic.

- Static RP



A static RP sets the RP address on each PIM multicast device to enable the entire PIMv6 network to know the RP address.

- Dynamic RP

  Multiple C-RPs can be configured in a PIM-SMv6 domain to elect an RP dynamically. These C-RPs add their own addresses and served multicast groups to advertisement packets and sent the packets to the BSR periodically in unicast mode. The BSR is elected from the configured C-BSRs based on rules. The BSR periodically generates BSMs that include a series of C-RPs and corresponding group addresses. The BSMs are sent in the entire domain. Each PIM device in the domain receives and saves these BSMs, and applies the same hash algorithms to compute and elect an RP for each group.

  - BSR election process: Initially, each C-BSR considers itself a BSR and sends a BSM throughout the network. The BSMs carry the C-BSR addresses and priorities. Upon receiving the BSMs, each PIM device compares the C-BSR addresses and priorities to elect the BSR.
  - RP election process: The C-RPs periodically send advertisement packets to the BSR in unicast mode to advertise the C-RP addresses, priorities, and addresses of the served groups. The BSR collects the information as RP-Set, encapsulates the information in a BSM, and sends the messages to each PIM device in the network. Upon receiving the RP-Set, the PIM devices in the network use the same algorithms for computation to obtain the RP that serves each group. Each PIM device obtains the RP position of each group. Figure 1-2 shows the schematic diagram of dynamic RP election.

Figure 1-2 Schematic Diagram of Dynamic RP Election

6. Multicast Source Registration

Figure 1-3 Schematic Diagram of Multicast Source Registration

As shown in Figure 1-3, when a multicast source sends data to a group, the source DR sends a register message to the RP so that the RP obtains the source information and a multicast packet and forwards the multicast packet to the members in the group. The forwarding process is described as follows:

(1) The multicast source sends a multicast packet to the source DR.

(2) The source DR encapsulates the multicast packet in a register message and sends the message to the RP in unicast mode.

(3) Upon receiving the register message, the RP decapsulates the message and forwards the multicast packet to the members in a group via the RPT. Meanwhile, the RP sends an (S, G) join packet to the source. The PIM devices on the route create (S, G) entries, and finally create an SPT from the source to the RP.

(4) The source DR S forwards multicast packets based on this SPT. The multicast data is sent to the RP in the form of multicast packets.

(5) Upon receiving multicast packets from the source, the RP discards the register message and sends a register-stop message to the source.

(6) Upon receiving the register-stop message, the source DR stops encapsulating the register message, forwards multicast packets via the SPT, and periodically sends a register-probe message to the RP.

(7) Upon receiving the register-probe message, the RP sends a register-stop message to the source DR and updates the (S, G) entries.

(8) Upon receiving the register-stop message, the source DR continues forwarding multicast packets via the SPT without encapsulating the register message.

7. RPT Construction

When a group member joins the network, the DR connecting to the group member sends a join packet to the RP. If a multicast source has sent a multicast packet to the RP, the multicast packet will be sent to the group member via the RPT.

The RPT construction procedure is as follows:

- When a member DR receives an MLD (*, G) INCLUDE Report packet, if the member DR is not an RP of the group G, the member DR sends a (*, G) join packet to the RP and the multicast devices on the route create the (*, G) entries hop by hop to generate an RPT that uses the RP as the root.
- During RPT construction, each PIM device checks the reverse path forwarding (RPF) when sending a join packet to the RP to find the unicast route to the RP. The outbound interface of the unicast route is an uplink interface, and the next hop of the unicast route is the RPF neighbor. The join packet is sent from the member DR to the RP.

8. SPT Switchover

In the PIM-SMv6 network of the ASM model, one or multiple multicast groups correspond to one RP. Before SPT switchover, all packets of multicast groups sent to the RP service must be transitioned by the RP. When the sending rate of multicast packets grows, the RP load is increased. To solve this problem, the PIM-SMv6 relieves the RP load by SPT switchover. SPT switchover can be triggered by the RP or a member DR.

- SPT switchover triggered by the RP

  After receiving a register message from the source DR, the RP decapsulates the register message, forwards the multicast packets in the message to the group members via the RPT, and sends an (S, G) join packet to the source DR. The PIM multicast devices on the route create (S, G) entries hop by hop to create an SPT from the RP to the source.

- SPT switchover triggered by a member DR

  a When receiving the first multicast packet from the RP, the member DR obtains the source address.

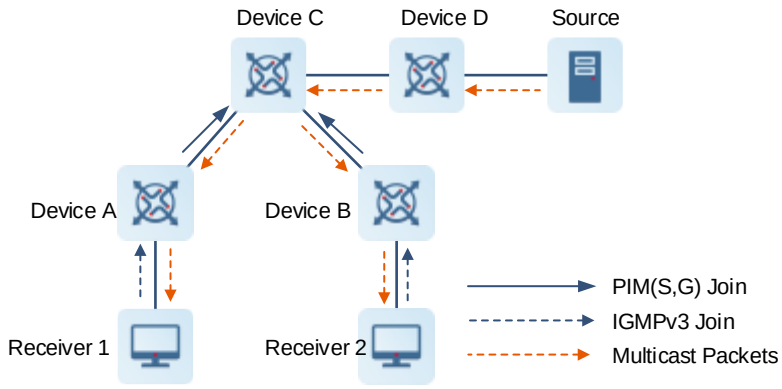
  b The member DR sends an (S, G) join packet to the source. The PIM devices on the route create (S, G) entries and create an SPT from the member DR to the source DR.

  c After the SPT is created, the member DR sends a prune packet to the RP hop by hop and removes the downlink interface from the (*, G) entries. After the pruning, the RP does not forward multicast packets to the member DR via the RPT.

  d The SPT from the member DR to the source DR does not pass the RP. The RP sends a prune packet to the source DR to remove the downlink interface from the (S, G) entries. After the pruning, the source DR does not forward packets to the RP via the original "RP-source DR" SPT.

1.2.2 SSM Model

1. Basic Principles



In the SSM model, members in a multicast group can specify to receive or reject data from a multicast source. The group members get to know the (S, G) entries of sources through access to the server or receiving advertisements. After understanding requirement of group members, the member DR sends a join packet to the source DR. This join packet is transmitted to the multicast source hop by hop to create an SPT from the source to the group members.

Note

- To implement the SSM model on IPv6, complete multicast interconnection through the PIM-SMv6 and configure MLDv2 to manage relationship between the hosts and devices.
- SSM model requirements: The hosts must know the addresses of multicast sources in advance using other network services so that the hosts can select multicast sources.

- On the devices that reside on the route from the hosts to the multicast source, the PIM-SMv6 and SSM functions must be enabled.

Figure 1-4 SSM Model

Caution

After the SSM function is enabled, the default group range of the SSM is FF3x::/32 (x cannot be 1 or 2). You can modify the group range of the SSM using commands.

In the SSM model, the key mechanisms of PIM-SMv6 include neighbor creation, DR election, and SPT creation.

2. PIMv6 Neighbor Creation

For more information about the PIMv6 neighbor creation mechanism in the SSM model, see the PIMv6 neighbor creation mechanism in the ASM model in 1.2.1 2. PIMv6 Neighbor Creation.

3. DR Election

For more information about the DR election mechanism in the SSM model, see the DR election mechanism in the ASM model in 1.2.1 3. DR Election.

4. SPT Construction

The SPT construction mechanism is as follows:

(1) The member DR learns through MLDv2 that a group member wants to receive data of a multicast source and sends an (S, G) join packet to the source hop by hop.

(2) The PIMv6 multicast devices on the route receive the (S, G) join packet and create the (S, G) entries, creating an SPT from the group member to the source.

(3) After the SPT is created, the multicast source distributes the multicast packets to the group member via the SPT.

1.2.3 Protocols and Standards

- RFC 4601: Protocol Independent Multicast-Sparse Mode (PIM-SM)
- RFC 5059: Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- RFC 3962: Protocol Independent Multicast-Dense Mode protocol

- RFC 4607: Source-Specific Multicast for IP

1.3 Restrictions and Guidelines

- Before PIM-SMv6 is enabled, enable the multicast routing and forwarding function in global configuration mode. Otherwise, multicast packets cannot be sent even if PIM-SMv6 is enabled.
- In the IPv6 multicast network, the PIM (IPv6) protocol must be run on all L3 devices. Otherwise, a forwarding route cannot be created.

1.4 Configuration Task Summary

The PIM-SMv6 configuration includes the following tasks:

(1) Enabling the PIM-SMv6 Function

(2) Configuring a model for PIM-SMv6. Select one of the following to configure:

- Configuring PIM-SMv6 in the ASM Model
- Configuring PIM-SMv6 in the SSM Model

(3) Configuring PIM-SMv6 Neighbor Parameters. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Neighbor Message Time Parameters
- Configuring Neighbor Tracking
- Configuring Neighbor Filtering

(4) (Optional) Configuring DR Priority

(5) Configuring Parameters of the Join/Prune Packets. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Join/Prune Packet Sending Interval
- Configuring the Prune Delay

(6) (Optional) Enabling PIM-SMv6 BFD Correlation

1.5 Enabling the PIM-SMv6 Function

1.5.1 Overview

Neighbor relationship must be created between PIM multicast devices to form a PIM-SMv6 network, so that PIM control messages and multicast packets can be transmitted on the network. The PIM-SMv6 function must be configured on all interfaces so that PIM neighbor creation, multicast entry creation, and multicast packet forwarding can be successful.

In a PIMv6 network, if you want an interface, for example, a stub network device interface connecting to hosts, to receive multicast packets without involving the PIMv6 network topology construction, you can set the interface to the PIM-SMv6 passive mode. After the PIM-SMv6 passive mode is configured, the interface does not process PIM packets. This improves device performance.

1.5.2 Restrictions and Guidelines

- The IPv6 multicast routing function must be enabled on each multicast device.

- The PIM-SMv6 function should be enabled on the following interfaces: interfaces interconnecting multicast devices, interfaces connecting the static RP, C-RP and C-BSRs, and interfaces connecting multicast sources or hosts.

1.5.3 Prerequisites

All PIM interfaces can be reached via IPv6 unicast routes.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable IPv6 multicast routing.

ipv6 mrouting-enable

The IPv6 multicast routing function is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(5) Enable the PIM-SMv6 function.

ipv6 pim sparse-mode

The PIM-SMv6 function is disabled by default.

(6) (Optional) Enable the PIM-SMv6 passive mode.

ipv6 pim sparse-mode passive

The PIM-SMv6 passive mode is disabled by default.

1.6 Configuring PIM-SMv6 in the ASM Model

1.6.1 Overview

The PIM-SMv6 network supports the multicast service in the ASM and SSM models. Either one model or two models can be configured.

PIM-SMv6 in the ASM model can provide hosts with multicast services of any source. A host joining a multicast group can receive multicast packets destined to this multicast group from any source.

If you require a PIMv6 network to support the multicast service in the ASM model, an RP must be configured. There are three methods to configure an RP:

- Configure a static RP.
- Configure a dynamic RP.
- Configure static and dynamic RPs. If static and dynamic RPs are available at the same time, dynamic RPs prevail.

1.6.2 Configuration Tasks

The PIM-SMv6 configuration in the ASM model includes the following tasks. Configure at least one RP, either dynamic or static. You can also configure both a static RP and a dynamic RP.

- Configuring a Static RP
- Configuring a Dynamic RP
  - Configuring C-BSRs and Related Parameters
  - Configuring C-RPs and Related Parameters
  - (Optional) Configuring Registration Parameters
- (Optional) Configuring the Last Hop Device to Switch over from the RPT to SPT

1.6.3 Prerequisites

In the PIM-SMv6 multicast network, all nodes are reachable via IPv6 unicast routes.

1.6.4 Configuring a Static RP

1. Overview

You can manually configure a static RP to prevent frequent packet interaction between the BSR and C-RPs or between the BSR and PIM multicast devices and avoid bandwidth occupation. If the multicast network is simple and small, you can configure a static RP.

2. Restrictions and Guidelines

- Static RPs must be configured on every multicast device.
- The multicast device selected as a static RP must boast high performance.
- You are advised to use the loopback interface as a static RP address.
- Static RPs configured on multicast devices should be consistent, including RP address and address range of the served groups.
- If multiple static RPs are configured to correspond to different addresses of groups, the RPs can implement load balancing.
- If multiple static RPs serve the same group, the static RP with a larger IPv6 address is selected first.
- You can use the control list to configure an RP to serve multiple (referencing an ACL) or all (not referencing an ACL) multicast groups. However, an RP can adopt only one configuration.

3. Prerequisites

Before an address range of a group is configured for an RP, ensure that the corresponding ACL is created and specify a multicast group range for the static RP to serve. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a static RP.

ipv6 pim static-rp-addr *ipv6-rp-address* [*acl-name*]

No static RP is configured by default.

1.6.5 Configuring C-BSRs and Related Parameters

1. Overview

In the PIM-SMv6 domain of the ASM model, a unique BSR must be available. The BSR collects and releases RP information.

- The BSR is elected from C-BSRs based on rules. The election rules are as follows:
  a The priorities of the C-BSRs are compared. The device with a higher priority is selected.
  b If the priorities are the same, the IP addresses are compared. The device with a larger IP address is selected.

  The winner is elected as the BSR in the domain and periodically sends BSMs in the domain. A BSM contains the BSR IP address, RP-Set and hash mask information. The hash mask is used for hash calculation during C-RP election. In the hold time of a BSM, if other C-BSRs do not receive the BSM from the BSR, the BSR is considered unreachable and a new round of BSR election is initiated.
- To avoid fraud by an illegitimate BSR, a BSR range can be specified on all PIM devices in the domain so that the PIM devices ignore a BSM that is sent from an illegitimate BSR.
- To limit BSM flooding, you can configure a BSR border on an interface. Upon receiving BSMs, this interface discards the BSMs without forwarding them. This limits the BSM flooding.

2. Restrictions and Guidelines

- C-BSRs must be configured on one or multiple multicast devices.
- The multicast devices selected as C-BSRs must boast high performance. The C-RPs and C-BSRs can reside on the same or different multicast devices.
- You are advised to use the loopback interface as a C-BSR address.
- If multiple C-BSRs are configured, they can implement redundancy backup.
- You are advised to configure a valid BSR address range on all PIM devices in the domain.
- A BSR border must be configured on the interface between domains.

3. Prerequisites

- Enabling the PIM-SMv6 Function.
- Before a valid BSR address range is configured on PIM devices, ensure that the corresponding ACL is created and specify a valid BSR range. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

a Enter the privileged EXEC mode.

privilege

b Enter the global configuration mode.

config-system terminal

c Configure C-BSRs and related parameters.

ipv6 pim c-bsr *interface-type interface-number* [*hash-mask-length* [*priority-value*]]

No C-BSR is configured by default.

(2) (Optional) Configure a valid BSR address range on all PIM devices.

ipv6 pim accept-bsr list *acl-name*

All BSMs are received by default.

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) (Optional) Configure a BSR border on the interface between PIM-SMv6 domains.

ipv6 pim bsr-boundary

No BSR border is configured by default.

If multiple domains exist, the BSR border must be configured on the interface between two domains.

1.6.6 Configuring C-RPs and Related Parameters

1. Overview

- After a multicast device is configured as a C-RP, the C-RP periodically sends an advertisement packet to the BSR in unicast mode. The packet includes the RP priority, advertisement packet hold time (greater than the interval of sending the advertisement packet), RP address, address of the served group, and prefix of the multicast address. Upon receiving the advertisement packet, the BSR collects the information in the packet as RP-Set in the advertisement packet hold time, encapsulates the information in a BSM, and sends the message to all PIM devices. Upon receiving the BSM from the BSR, the PIM devices in the domain apply the same algorithms for hash calculation to calculate the C-RP serving each multicast group. After the

advertisement packet hold time expires, if the BSR does not receive a next advertisement packet from the C-RP, this C-RP is considered unreachable.

- To prevent fraud by an illegitimate C-RP, a C-RP range can be specified on the BSR. If an advertisement packet comes from an illegitimate C-RP, the packet is ignored.
- The BSR can determine whether to receive an advertisement packet with the prefix of the multicast address being 0 from a C-RP. When the prefix of the multicast address is 0, this C-RP serves all multicast groups.
- When receiving the BSM from the BSR, each PIM multicast device in the domain applies rules to select the RP. The RP election rules are as follows:
  a The address of the multicast group that a host joins is compared with the mask length of the group address range that the C-RP serves. The device with the longest mask is selected.
  b If the addresses are consistent with the mask length, the priorities of the C-RPs are compared. The device with the smallest priority value is selected.
  c If the priorities are consistent, hash values are calculated and compared. The device with the largest hash value is selected.
  d If the hash values are the same, the IP addresses of the C-RPs are compared. The device with the largest IP address is selected.

2. Restrictions and Guidelines

- C-RPs must be configured on one or multiple multicast devices.
- The multicast devices selected as C-RPs must boast high performance. The C-RPs and C-BSRs can reside on the same or different multicast devices.
- You are advised to use the loopback interface as a C-RP address.
- If multiple C-RPs are configured to serve the same group, they can implement redundancy backup.
- If multiple C-RPs are configured to serve different groups, they can implement load balancing.
- A valid C-RP range can be configured on the BSR.
- To specify a group range for C-RPs to serve, you can add the ACL option to the **ip pim rp-candidate** command. The group range is calculated based on the permit access control entry (ACE), rather than the deny ACE.

3. Prerequisites

- Enabling the PIM-SMv6 Function.
- If the **group-acl** parameter is used to limit the range of groups served by the RP, ensure that the corresponding ACL is created and specify a multicast group range for the RP to serve. For more information about ACL configuration, see *Configuring ACL*
- Before a valid C-RP address range is configured on PIM BSRs, ensure that the corresponding ACL is created and specify a multicast group range for the static RP to serve. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

- Configure a C-RP and related parameters.
  a Enter the privileged EXEC mode.

privilege

b Enter the global configuration mode.

config-system terminal

c Configure a C-RP.

ipv6 pim c-rp *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval-seconds*] [**group-acl** *acl-name*]

No C-RP is configured by default.

- (Optional) Configure the BSR to receive C-RP advertisement packets with the prefix of the multicast address being 0. This C-RP serves all the multicast groups.

a Enter the privileged EXEC mode.

privilege

b Enter the global configuration mode.

config-system terminal

c Configure the BSR to receive advertisement packets from the C-RP that serves all multicast groups.

ipv6 pim accept-crp-with-null-group

The function for the BSR to receive advertisement packets from the C-RP that serves all multicast groups is disabled by default.

You are advised to enable this function on all C-BSRs.

- (Optional) Configure a valid C-RP range on the BSR.

a Enter the privileged EXEC mode.

privilege

b Enter the global configuration mode.

config-system terminal

c Configure a valid C-RP range.

ipv6 pim accept-crp list *acl-name*

The C-BSRs receive all external C-RP advertisement packets by default.

You are advised to enable this function on all C-BSRs.

- (Optional) Configure all PIM multicast devices to ignore RP priority and reselect an RP.

a Enter the privileged EXEC mode.

privilege

b Enter the global configuration mode.

config-system terminal

c Configure all PIM multicast devices to ignore the RP priority for RP election.

ipv6 pim ignore-rp-set-priority

If the address of the multicast group that a host joins is consistent with the mask length of the group address range that the C-RPs serve, the RP with the highest priority is selected by default.

You can configure each multicast device to ignore C-RP priority.

- (Optional) Configure static RP priority to be higher than dynamic RP priority on all PIM multicast devices.
  a Enter the privileged EXEC mode.

  privilege

  b Enter the global configuration mode.

  config-system terminal

  c Configure the static RP priority.

  ipv6 pim static-rp-preferred

  The dynamic RP priority is higher than the static RP priority by default.

  You can configure each multicast device to ignore dynamic RP priority.

1.6.7 Configuring Registration Parameters

1. Overview

When a multicast source sends multicast data, the data arrives at the source DR first. Upon receiving the multicast data, the source DR encapsulates the multicast data as a register message and sends the message to the RP. Related parameters of the register message are configured on the source DR and RP.

- You can configure the following parameters on the source DR:
  - RP reachability checking: Before sending a register message, the source DR determines whether the RP is reachable. If the RP is reachable, the message is sent. Otherwise, the message is not sent.
  - Limit on the rate of sending the register message: The rate of sending each register message in (S, G) status is limited. If multiple register messages in (S, G) status are sent from the same source, the rate of the register messages is limited to the product of *N* × Limit value.
  - Source address in the register message: The source address in the register message is the address of the DR interface connected to the multicast source by default. If a security policy is configured on the RP to filter out this address, the RP does not receive register messages from this source DR. In this case, you can specify a reachable source address as the source address of the register message.
  - Register suppression time: When the RP receives multicast packets sent by the multicast source via the SPT, the RP sends a register-stop message to the source DR. Within the register suppression time, the source DR stops encapsulating the register message and sends multicast packets to the RP via the SPT. After the register suppression time expires, if the source DR does not receive another register-stop message from the RP, the source DR continues to encapsulate the register message and send the message to the RP.
  - Null message detection time: Before the register suppression time expires, the RP receives a null message from the source DR, refreshes the local (S, G) entries, and sends a register-stop message to the source DR so that the source DR refreshes the register suppression timer. Otherwise, the source DR continues to encapsulate the register message and send multicast packets to the RP in the form of the register message.
- You can configure the following parameters on the RP:
  - (S, G) address range of source: Provide multicast services for hosts in the permitted multicast group in the ASM model. After this parameter is configured, the RP replies a register-stop message upon receiving data from an unauthorized source.

- Length of register message checksum: Adjust the calculation method of the register message checksum and calculate the checksum of the entire PIM protocol packets (including encapsulated multicast packets) or the checksum of PIM headers of separate register messages.
- Register message decapsulation and delivery to downlink interface: Configure this parameter on the RP to decapsulate the received register message and forward the multicast packets in the register message.
- Register message (S, G) entry timeout period: Configure this parameter to configure the timeout period of (S, G) entries. The (S, G) entries age if no packet is received within the register message timeout period.

2. Restrictions and Guidelines

- The source address in the specified register message must be reachable in unicast mode. You are advised to use the loopback interface of the source DR as the source address of the register message.
- If the **ip pimp-info rp-register-kat** command is not configured, modifying the register suppression time on the RP changes the (S, G) entry timeout period.
- Configuring a limit to the register message rate reduces the load of the source DR and RP. Only register messages under the limit are sent.
- The register-probe time cannot be greater than a half of the register suppression time. Otherwise, the configuration failed and an alarm is generated.
- The sum of the three times of register suppression time and the register-probe time does not exceed 65,535. Otherwise, the configuration failed and an alarm is generated.

3. Prerequisites

- Enabling the PIM-SMv6 Function.
- Before an (S, G) address range is configured for the source, if the **list** parameter is specified, ensure that the corresponding ACL is created and specify an (S, G) address range for the source. For more information about ACL configuration, see *Configuring ACL*
- Before an (S, G) address range is configured for the source, if the **route-map** parameter is specified, ensure that the corresponding route map is created and specify an (S, G) address range for the source. For more information about route map configuration, see *Configuring Routing Policies*.
- Before the register message checksum calculation is applied to entire packets, if the **group-acl** parameter is specified, ensure that the corresponding ACL is created and specify the register message checksum calculation to apply to the entire packets in a multicast group address range. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configure registration parameters on the source DR.

  a Enter the privileged EXEC mode.

  privilege

  b Enter the global configuration mode.

  config-system terminal

c Enable RP reachability checking on the source DR.

ipv6 pim register-rp-reachability

The RP reachability checking function is disabled by default.

d Limit the rate of sending register messages on the source DR.

ipv6 pim limit-register-rate *rate*

The sending rate of register messages is not limited by default.

e Configure a source address in the register messages on the source DR.

ipv6 pim register-source-addr { *ipv6-local-address* | *interface-type interface-number* }

The source IP address in the register messages is the address of the DR interface connected to the source by default.

f Configure the register suppression time on the source DR.

ipv6 pim register-suppression *suppression-time*

The default register suppression time is **60** seconds.

g Configure the null message detection time on the source DR.

ipv6 pim probe-interval *interval*

The default register-probe time is **5** seconds.

- Configure registration parameters on the RP.

a Enter the privileged EXEC mode.

privilege

b Enter the global configuration mode.

config-system terminal

c Configure the (S, G) address range for the source on the RP.

ipv6 pim restricted-register { **list** *acl-name* | **route-map** *route-map-name* } *

The (S, G) address range of register messages is not limited by default. The RP receives register messages with any (S, G) address.

You can configure to filter the source register message information on all C-RP or static RP multicast devices.

d Enable register message checksum calculation to be applied to the entire packets on the RP.

ipv6 pim register-checksum-wholepkt [**group-list** *acl-name*]

By default, the register message checksum of headers of only PIM packets and register messages, rather than the entire packets, is calculated.

If the **group-acl** parameter is not specified, this configuration applies to all group addresses.

e Configure the timeout period for the (S, G) entries created upon receiving the register message on the RP.

ipv6 pim rp-register-kat *interval*

By default, the timeout period for the (S, G) entries is the sum of three times of the register suppression time and the register-probe time.

You can configure the (S, G) entry timeout period on all C-RP or static RP multicast devices.

1.6.8 Configuring the Last Hop Device to Switch over from the RPT to SPT

1. Overview

If the multicast traffic in a network is heavy, the RP easily gets overloaded and then faulty. To relieve the RP load, you can initiate SPT switchover through the member DR. You can specify multicast groups to perform SPT switchover.

2. Prerequisites

- Enabling the PIM-SMv6 Function.
- Before an address range of a group is configured for SPT switchover, ensure that the corresponding ACL is created and specify a multicast group range for SPT switchover. For more information about ACL configuration, see *Configuring ACL*.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the SPT switchover function.

ipv6 pim spt-switching [**group-acl** *acl-name*]

The SPT switchover function is disabled by default.

If the **group-acl** parameter is not specified, all groups support SPT switchover.

1.7 Configuring PIM-SMv6 in the SSM Model

1.7.1 Overview

The PIM-SMv6 function in the SSM model can provide specified source services for hosts so that the hosts can determine to receive or reject multicast data of specified sources based on needs.

1.7.2 Restrictions and Guidelines

- If you require a PIM network to support the multicast service in the SSM model, the SSM function must be enabled.
- The SSM function must be enabled on each multicast device.
- The address range of SSM groups configured on all multicast devices must be consistent.
- MLDv2 or SSM mapping must be enabled.

1.7.3 Prerequisites

- In the multicast network, all nodes are reachable via IPv6 unicast routes.
- Enabling the PIM-SMv6 Function.
- Before an SSM group range is configured using an ACL, ensure that the corresponding ACL is created and specify an SSM multicast group range. For more information about ACL configuration, see *Configuring ACL*.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the SSM function.

ipv6 pim enable-ssm { **default** | **range** *acl-name* }

The SSM function is disabled by default.

1.8 Configuring PIM-SMv6 Neighbor Parameters

1.8.1 Overview

PIM multicast devices transmit Hello messages to discover neighbors, coordinate protocol parameters and maintain neighbor relationships.

1.8.2 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Neighbor Message Time Parameters
- Configuring Neighbor Tracking
- Configuring Neighbor Filtering

1.8.3 Prerequisites

- In the multicast network, all nodes are reachable via IPv6 unicast routes.
- Enabling the PIM-SMv6 Function.

1.8.4 Configuring the Neighbor Message Time Parameters

1. Overview

The neighbor message time parameters include hello message sending interval and hello message sending delay.

- The hello message sending interval can be configured, and the hello message hold time is 3.5 times the hello message sending interval. If no new hello message is received within the hello message hold time, the neighbor is considered unreachable.
- When the PIM interface is enabled or detects a new neighbor, random time is generated and it is referred to as hello message sending delay. Within the delay time, the interface sends hello messages out.

2. Restrictions and Guidelines

If the hello message hold time is greater than 65,535 seconds, the hello message sending interval is automatically set to 18,725 seconds.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Configure the neighbor message time parameters. Configure at least one of the tasks.

- Configure the hello message sending interval.

  ipv6 pim query-period *interval*

  The hello message is sent at an interval of **30** seconds by default.
- Configure the hello message sending delay.

  ipv6 pim triggered-hello-delay *delay*

  The default hello message sending delay is **5** seconds.

1.8.5 Configuring Neighbor Tracking

1. Overview

After the suppression capability of an interface is enabled, when a multicast device plans to send a join packet to an uplink multicast device but it receives a join packet sent from the neighbor to the uplink multicast device, this local multicast device suppresses its own join packet. If the suppression capability of the interface is disabled, the join packet can be sent. When the suppression capability of downlink hosts is disabled, an uplink device can determine the number of the downlink hosts based on the quantity of received join packets. This is neighbor tracking.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.

- **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Enable the neighbor tracking function.

ipv6 pim neighbor-tracking

The neighbor tracking function is disabled by default.

1.8.6 Configuring Neighbor Filtering

1. Overview

The neighbor filtering function can protect neighborhood. Controlling neighbors can strengthen PIM network security and limit the valid address range of neighbors. If a neighbor is filtered out based on an access filtering list, PIM-SMv6 does not create peer relationship with the neighbor or stops the peer relationship with this neighbor.

2. Prerequisites

Before an access filtering list is configured, ensure that the corresponding ACL is created and specify a valid neighbor address range. For more information about ACL configuration, see *Configuring ACL*.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Enable the neighbor filtering function.

ip pim peering-filter *acl-name*

The neighbor filtering function is disabled by default.

1.9 Configuring DR Priority

1.9.1 Overview

In a network segment shared by multicast sources and group members, multiple PIM multicast devices exist. The PIM multicast devices elect a DR based on neighbor messages. A device with the highest priority is selected. If the priorities are the same or some PIM devices do not support the DR priority function, the IP addresses are compared and the PIM multicast device with the largest IP address is selected. The selected PIM device functions as a DR, transmits protocol packets between the sources and members, and forwards multicast packets.

1.9.2 Prerequisites

- In the multicast network, all nodes are reachable via IPv6 unicast routes.
- Enabling the PIM-SMv6 Function.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Configure a DR priority in hello messages.

ipv6 pim dr-elected--priority *priority-value*

The default DR priority in hello messages is **1**.

1.10 Configuring Parameters of the Join/Prune Packets

1.10.1 Overview

A device sends a join packet to request an uplink device to forward multicast packets and sends a prune packet to request the uplink device to stop forwarding multicast packets. The request route is referred to as an RPT or SPT.

1.10.2 Restrictions and Guidelines

- The network administrator must ensure that the prune override interval is smaller than the join-prune packet hold time. Otherwise, a short interrupt may occur.
- When the PIM multicast device receives a prune message from an uplink interface, there are other downlink devices existent in the shared network segment. If this PIM multicast device still needs to receive multicast data, the PIM multicast device must send a prune override message to the uplink device within the override interval.

1.10.3 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Join/Prune Packet Sending Interval
- Configuring the Prune Delay

1.10.4 Prerequisites

Enabling the PIM-SMv6 Function.

1.10.5 Configuring Join/Prune Packet Sending Interval

1. Overview

A PIM device periodically sends the join/prune packet to an uplink device to update the forwarding status. The join packet is used to request data forwarding and the prune packet is used to stop data forwarding. Upon receiving the join/prune packet, the uplink device starts the join/prune packet hold time timer.

- If a join packet hold time timer expires, the PIM device is suppressed to forward multicast packets of the corresponding multicast group through the downlink interface.
- If a prune packet hold time timer expires, the PIM device is restored to forward the multicast packets of the corresponding multicast group through the downlink interface.

2. Restrictions and Guidelines

The join/prune packet sending interval must be smaller than the join/prune packet hold time. Generally, the join/prune packet hold time is 3.5 times the join/prune packet sending interval.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the join/prune packet sending interval.

ipv6 pim jp-timer *interval*

The join/prune packet is sent at an interval of **60** seconds by default.

1.10.6 Configuring the Prune Delay

1. Overview

Upon receiving a prune packet from a downlink device, the multicast device does not perform prune immediately and it waits for a period of time. This period of time is divided into two parts: The part from the time when the multicast device receives a prune message to the time when the multicast device sends the prune message to the uplink device is referred to as the propagation delay; the part from the time when the PIM device receives a prune packet to the time when the device continues to forward the multicast packets to a downlink device is referred to as the override interval. The period from the time when the multicast device receives a prune message to the time when the prune action is performed is the sum of the propagation delay and the override interval.

2. Restrictions and Guidelines

In the period from the time when the multicast device receives a prune message to the time when the prune action is performed, if the PIM device receives a prune override message from the downlink interface, the PIM device cancels pruning.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Configure the prune message propagation delay.

ipv6 pim propagation-delay *propagation-delay*

The default propagation delay of an interface is 500 ms.

(5) Configure the prune override interval.

ipv6 pim override-interval *override-interval*

The default prune override interval is 2500 ms.

1.11 Enabling PIM-SMv6 BFD Correlation

1. Overview

In some shared multicast network, PIM neighbor status change triggers re-initiation of some mechanisms, for example, DR election mechanism. Generally, a PIM neighbor triggers a new round of election after the neighborhood times out, causing multicast data interruption. PIM bidirectional forwarding detection (BFD) correlation can quickly detect link status and neighbor faults in a shared network segment and trigger a new round of DR election. This reduces multicast data transmission interrupt time and ensures reliability of the multicast network.

2. Restrictions and Guidelines

- If DR or assertion election is required in a multicast network, you are advised to enable PIM-SMv6 BFD correlation.
- The PIM BFD function must be enabled on the interconnection interface of the multicast devices.

3. Prerequisites

- In the network, all nodes are reachable via IPv6 unicast routes.
- Enabling the PIM-SMv6 Function.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 3 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*
- Enter the SVI configuration mode.
  - **interface vlan** *interface-number*
- Enter the loopback interface configuration mode.
  - **interface loopback** *interface-number*

(4) Enable PIM-SMv6 BFD correlation.

ipv6 pim bfd

PIM-SMv6 BFD correlation is disabled by default.

1.12 Monitoring

Run the display command to check the running status of a configured function to verify the configuration effect.

Run the cleanup commands to clear information.

Caution

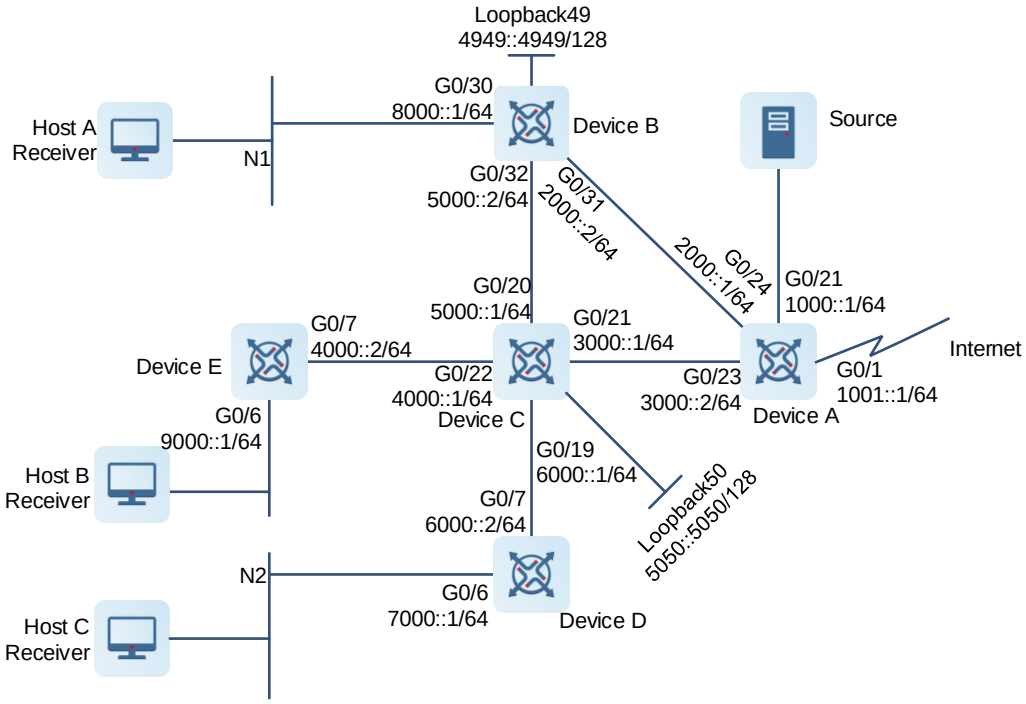
Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
cleanup ipv6 pim-info sparse-mode bsr rp-set *	Clears dynamic RP information.
cleanup ipv6 pim-info sparse-mode track	Resets the statistic start time and clears the counter of the PIMv6 packets.
display ipv6 pim-info sparse-mode bsr-router	Displays details about the BSR.
display ipv6 pim-info sparse-mode interface [*interface-type interface-number*] [**detail**]	Displays PIM-SMv6 information of an interface.
display ipv6 pim-info sparse-mode local-members [*interface-type interface-number*]	Displays local MLD information of a PIM-SMv6 interface.
display ipv6 pim-info sparse-mode mroute [*ipv6-group-or-source-address* [*ipv6-group-or-source-address*]]	Displays PIM-SMv6 routing information.
display ipv6 pim-info sparse-mode neighbor [**detail**]	Displays PIM-SMv6 neighbor information.
display ipv6 pim-info sparse-mode nexthop	Displays next hop information, including interface number, address, and metric value of a next hop.
display ipv6 pim-info sparse-mode embedded-rp mapping	Displays all RPs and the groups served by the RPs on the local device.
display ipv6 pim-info sparse-mode rp-group-hash *ipv6-group-address*	Displays RP information corresponding to a group address.
display ipv6 pim-info sparse-mode track	Displays the number of PIM packets sent and received since the statistic start time.

1.13 Configuration Examples

1.13.1 Configuring Basic Functions of PIM-SMv6 in the ASM Model



1. Requirements

As shown in Figure 1-5, the internal network is connected to the Internet. The PIM-SMv6 protocol is configured on each multicast device to provide ASM multicast services for hosts in networks N1 and N2 so that hosts

joining a multicast group can receive multicast data destined to this multicast group from any multicast source, including video-on-demand information.

2. Topology

Figure 1-5 PIM-SMv6 Multicast Network Topology in the ASM Model

3. Notes

- Configure IPv6 addresses and unicast routing protocols for multicast devices. The PIMv6 protocol in a multicast domain depends on unicast routing protocols. Normal communication of unicast routing lays a foundation of multicast routing. Ensure that each PIM node is reachable via unicast routes.
- Enable the IPv6 multicast function on all multicast devices. Enabling the multicast function is a prerequisite of PIM-SMv6 configuration.
- Enable the basic functions of PIM-SMv6 on all interfaces of the multicast devices. The other functions of PIM-SMv6 can be enabled only after the basic functions of PIM-SMv6 are enabled.
- Enable the MLD function on the interface connected to hosts so that the hosts can join or leave a multicast group by sending MLD messages. The multicast devices acting as leaf nodes maintain group membership based on the MLD protocol.
- Configure RPs. In the PIM-SMv6 network in the ASM model, the RP is a transitional station for forwarding multicast data. It is recommended that the multicast device with many traffic flows be configured as an RP, for example, device C in Figure 1-5.
- Configure a BSR border on the interface connected to the Internet. BSMs must be transmitted in the PIM-SMv6 domain within the border to improve the multicast controllability.

4. Procedure

(1) Configure IP addresses and enable unicast routing protocols on interfaces of different devices.

Configure an IPv6 address for the interface of Device A and configure the OSPFv3 protocol to implement internetworking.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ipv6 router-protocol ospf 4949
DeviceA(cfg-router)# exit
DeviceA(cfg)# interface gigabitEthernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 address 1001::1/64
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
DeviceA(cfg)# interface gigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/21)# ipv6 address 1000::1/64
DeviceA(cfg-if-GigabitEthernet 0/21)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)#interface gigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/23)# ipv6 address 3000::2/64
DeviceA(cfg-if-GigabitEthernet 0/23)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
DeviceA(cfg)# interface gigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/24)# ipv6 address 2000::1/64
DeviceA(cfg-if-GigabitEthernet 0/24)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
```

Configure IPv6 addresses on interfaces of device B, and configure the OSPFv3 protocol to implement internetworking.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6 router-protocol ospf 4949
DeviceB(cfg-router)# exit
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 address 8000::1/64
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/31)# ipv6 address 2000::2/64
DeviceB(cfg-if-GigabitEthernet 0/31)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/32)# ipv6 address 5000::2/64
```

```
DeviceB(cfg-if-GigabitEthernet 0/32)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface loopback 49
DeviceB(cfg-if-Loopback 49)# ipv6 address 4949::4949/128
DeviceB(cfg-if-Loopback 49)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-Loopback 49)# exit
```

Configure IPv6 addresses on interfaces of device C, and configure the OSPFv3 protocol to implement internetworking.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ipv6 router-protocol ospf 4949
DeviceC(cfg-router)# exit
DeviceC(cfg)# interface GigabitEthernet 0/19
DeviceC(cfg-if-GigabitEthernet 0/19)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/19)# ipv6    address 6000::1/64
DeviceC(cfg-if-GigabitEthernet 0/19)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/19)# exit
DeviceC(cfg)#interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 address 5000::1/64
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 address 3000::1/64
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface GigabitEthernet 0/22
DeviceC(cfg-if-GigabitEthernet 0/22)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/22)# ipv6 address 4000::1/64
DeviceC(cfg-if-GigabitEthernet 0/22)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/22)# exit
DeviceC(cfg)# interface loopback 50
DeviceC(cfg-if-Loopback 50)# ipv6 address 5050::5050/128
DeviceC(cfg-if-Loopback 50)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-Loopback 50)# exit
```

Configure IPv6 addresses on interfaces of device D, and configure the OSPFv3 protocol to implement internetworking.

```
DeviceD> privilege
DeviceD# config-system terminal
DeviceD(cfg)# ipv6 router-protocol ospf 4949
DeviceD(cfg-router)# exit
DeviceD(cfg)# interface GigabitEthernet 0/6
DeviceD(cfg-if-GigabitEthernet 0/6)# unset switch-port
DeviceD(cfg-if-GigabitEthernet 0/6)# ipv6 address 7000::1/64
```

```
DeviceD(cfg-if-GigabitEthernet 0/6)# ipv6 ospf 4949 set-area 0
DeviceD(cfg-if-GigabitEthernet 0/6)# exit
DeviceD(cfg)# interface GigabitEthernet 0/7
DeviceD(cfg-if-GigabitEthernet 0/7)# unset switch-port
DeviceD(cfg-if-GigabitEthernet 0/7)# ipv6 address 6000::2/64
DeviceD(cfg-if-GigabitEthernet 0/7)# ipv6 ospf 4949 set-area 0
DeviceD(cfg-if-GigabitEthernet 0/7)# exit
```

Configure IPv6 addresses on interfaces of device E, and configure the OSPFv3 protocol to implement internetworking.

```
DeviceE> privilege
DeviceE# config-system terminal
DeviceE(cfg)# ipv6 router-protocol ospf 4949
DeviceE(cfg-router)# exit
DeviceE(cfg)# interface GigabitEthernet 0/6
DeviceE(cfg-if-GigabitEthernet 0/6)# unset switch-port
DeviceE(cfg-if-GigabitEthernet 0/6)# ipv6 address 9000::1/64
DeviceE(cfg-if-GigabitEthernet 0/6)# ipv6 ospf 4949 set-area 0
DeviceE(cfg-if-GigabitEthernet 0/6)# interface GigabitEthernet 0/7
DeviceE(cfg-if-GigabitEthernet 0/7)# unset switch-port
DeviceE(cfg-if-GigabitEthernet 0/7)# ipv6 address 4000::2/64
DeviceE(cfg-if-GigabitEthernet 0/7)# ipv6 ospf 4949 set-area 0
DeviceE(cfg-if-GigabitEthernet 0/7)# exit
```

(2) Enable the multicast and PIM-SMv6 functions on all multicast devices, and enable the MLD function on all multicast devices connected to hosts.

Enable the multicast and PIM-SMv6 functions on device A.

```
DeviceA(cfg)# ipv6 mrouting-enable
DeviceA(cfg)# interface gigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface gigabitEthernet 0/23
DeviceA(cfg-if-GigabitEthernet 0/23)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/23)# exit
DeviceA(cfg)# interface gigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
```

Enable the IPv6 multicast, IPv6-SMv6, and MLD functions on device B.

```
DeviceB(cfg)# ipv6 mrouting-enable
DeviceB(cfg)# interface gigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface gigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# ipv6 pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface gigabitEthernet 0/32
```

```
DeviceB(cfg-if-GigabitEthernet 0/32)# ipv6 pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface loopback 49
DeviceB(cfg-if-Loopback 49)# ipv6 pim sparse-mode
DeviceB(cfg-if-Loopback 49)# exit
```

Enable the IPv6 multicast and PIM-SMv6 functions on device C.

```
DeviceC(cfg)# ipv6 mrouting-enable
DeviceC(cfg)# interface gigabitEthernet 0/19
DeviceC(cfg-if-GigabitEthernet 0/19)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/19)# exit
DeviceC(cfg)# interface gigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface gigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface gigabitEthernet 0/22
DeviceC(cfg-if-GigabitEthernet 0/22)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/22)# exit
DeviceC(cfg)# interface loopback 50
DeviceC(cfg-if-Loopback 50)# ipv6 pim sparse-mode
DeviceC(cfg-if-Loopback 50)# exit
```

Enable the IPv6 multicast, IPv6-SMv6, and MLD functions on device D.

```
DeviceD(cfg)# ipv6 mrouting-enable
DeviceD(cfg)# interface gigabitEthernet 0/6
DeviceD(cfg-if-GigabitEthernet 0/6)# ipv6 pim sparse-mode
DeviceD(cfg-if-GigabitEthernet 0/6)# exit
DeviceD(cfg)# interface gigabitEthernet 0/7
DeviceD(cfg-if-GigabitEthernet 0/7)# ipv6 pim sparse-mode
DeviceD(cfg-if-GigabitEthernet 0/7)# exit
```

Enable the IPv6 multicast, IPv6-SMv6, and MLD functions on device E.

```
DeviceE(cfg)# ipv6 mrouting-enable
DeviceE(cfg)# interface gigabitEthernet 0/6
DeviceE(cfg-if-GigabitEthernet 0/6)# ipv6 pim sparse-mode
DeviceE(cfg-if-GigabitEthernet 0/6)# exit
DeviceE(cfg)# interface gigabitEthernet 0/7
DeviceE(cfg-if-GigabitEthernet 0/7)# ipv6 pim sparse-mode
DeviceE(cfg-if-GigabitEthernet 0/7)# exit
```

(3) Configure RPs.

Note

There are two methods to configure RPs: dynamic RPs and static RPs. You can configure either or both types of RPs. If static and dynamic RPs are available at the same time, the dynamic RPs are preferred by default.

Configure dynamic RPs. One or multiple multicast devices in the PIM-SMv6 domain must be configured as C-RPs and C-BSRs. In this example, device B and device C are configured as C-RP and C-BSR. The address range of the served groups of the RP, as well as the interfaces of the C-RP and C-BSR are configured on device B and device C. The loopback interface is configured as the interface of the C-RP and C-BSR.

Configure C-RP and C-BSR and address range of the served groups of the RP on device B.

```
DeviceB(cfg)# ipv6 pim c-bsr loopback 49
DeviceB(cfg)# ipv6 access-control-list mcast-ipv6-list
DeviceB(cfg-ipv6acl)# permit ipv6 any ff13::/64
DeviceB(cfg)# ipv6 pim c-rp loopback 49 group-acl mcast-ipv6-list
```

Configure C-RP and C-BSR and address range of the served groups of the RP on device C.

```
DeviceC(cfg)# ipv6 pim c-bsr loopback 50
DeviceC(cfg)# ipv6 access-control-list mcast-ipv6-list
DeviceC(cfg-ipv6acl)# permit ipv6 any ff14::/64
DeviceC(cfg-stdacl)# exit
DeviceC(cfg)# ipv6 pim c-rp loopback 50 group-acl mcast-ipv6-list
```

Configure static RPs. The addresses of static RPs must be specified on all multicast devices.

Configure a static RP on device A.

```
DeviceA(cfg)# ipv6 pim static-rp-addr 5050::5050
```

Configure a static RP on device B.

```
DeviceB(cfg)# ipv6 pim static-rp-addr 5050::5050
```

Configure a static RP on device C.

```
DeviceC(cfg)# ipv6 pim static-rp-addr 5050::5050
```

Configure a static RP on device D.

```
DeviceD(cfg)# ipv6 pim static-rp-addr 5050::5050
```

Configure a static RP on device E.

```
DeviceE(cfg)# ipv6 pim static-rp-addr 5050::5050
```

(4) Configure a BSR border on the device A interface connected to the Internet.

```
DeviceA(cfg-if-GigabitEthernet 0/1)# ipv6 pim bsr-boundary
```

5. Verification

(1) Run the **display ipv6 pim-info sparse-mode interface** command to display the PIM-SMv6 running information on the interfaces.

The PIM-SMv6 running information on the interface of device A is as follows:

```
DeviceA# display ipv6 pim-info sparse-mode interface
Interface                                VIFindex Ver/     Nbr      DR
                                                  Mode     Count    Prior
GigabitEthernet 0/24                     3        v2/S     1        1
    Address          : fe80::2d0:f8ff:fe22:358d
    Global Address: 2000::1
    DR               : fe80::2d0:f8ff:feee:8c1f
```

```
GigabitEthernet 0/23                2          v2/S    1        1
      Address          : fe80::2d0:f8ff:fe22:358d
      Global Address: 3000::2
      DR               : this system
GigabitEthernet 0/21                1          v2/S    0        1
      Address          : fe80::2d0:f8ff:fe22:358d
      Global Address: 1000::1
      DR               : this system
```

The PIM-SMv6 running information on the interface of device B is as follows:

```
DeviceB# display ipv6 pim-info sparse-mode interface
Interface                           VIFindex Ver/     Nbr       DR
                                             Mode     Count     Prior
GigabitEthernet 0/31                2          v2/S    1        1
      Address          : fe80::2d0:f8ff:feee:8c1f
      Global Address: 2000::2
      DR               : this system
GigabitEthernet 0/32                3          v2/S    1        1
      Address          : fe80::2d0:f8ff:feee:8c1f
      Global Address: 5000::2
      DR               : this system
GigabitEthernet 0/30                1          v2/S    0        1
      Address          : fe80::2d0:f8ff:feee:8c1f
      Global Address: 8000::1
      DR               : this system
Loopback 49                           4          v2/S    0        1
      Address          : fe80::2d0:f8ff:feee:8c1f
      Global Address: 4949::4949
      DR               : this system
```

The PIM-SMv6 running information on the interface of device C is as follows:

```
DeviceC# display ipv6 pim-info sparse-mode interface
Interface                           VIFindex Ver/     Nbr       DR
                                             Mode     Count     Prior
GigabitEthernet 0/21                3          v2/S    1        1
      Address          : fe80::274:9cff:feee:f49f
      Global Address: 3000::1
      DR               : fe80::2d0:f8ff:fe22:358d
GigabitEthernet 0/22                4          v2/S    1        1
      Address          : fe80::274:9cff:feee:f49f
      Global Address: 4000::1
      DR               : this system
GigabitEthernet 0/20                2          v2/S    1        1
      Address          : fe80::274:9cff:feee:f49f
      Global Address: 5000::1
      DR               : fe80::2d0:f8ff:feee:8c1f
GigabitEthernet 0/19                1          v2/S    1        1
```

```
    Address          : fe80::274:9cff:feee:f49f
    Global Address: 6000::1
    DR               : this system
Loopback 50                          5          v2/S   0        1
    Address          : fe80::274:9cff:feee:f49f
    Global Address: 5050::5050
    DR               : this system
```

The PIM-SMv6 running information on the interface of device D is as follows:

```
DeviceD> privilege
DeviceD# display ipv6 pim-info sparse-mode interface
Interface                            VIFindex Ver/   Nbr     DR
                                              Mode   Count   Prior
GigabitEthernet 0/6                  1        v2/S   0       1
    Address          : fe80::274:9cff:fe11:c9e7
    Global Address: 7000::1
    DR               : this system
GigabitEthernet 0/7                  2        v2/S   1       1
    Address          : fe80::274:9cff:fe11:c9e7
    Global Address: 6000::2
    DR               : fe80::274:9cff:feee:f49f
```

The PIM-SMv6 running information on the interface of device E is as follows:

```
DeviceE# display ipv6 pim-info sparse-mode interface
Interface                            VIFindex Ver/   Nbr     DR
                                              Mode   Count   Prior
GigabitEthernet 0/6                  1        v2/S   0       1
    Address          : fe80::274:9cff:fec8:e27b
    Global Address: 9000::1
    DR               : this system
GigabitEthernet 0/7                  2        v2/S   1       1
    Address          : fe80::274:9cff:fec8:e27b
    Global Address: 4000::2
    DR               : fe80::274:9cff:feee:f49f
```

(2) Run the **display ipv6 pim-info sparse-mode bsr-router** command to display the election information of the BSRs.

The BSR election information on device A is as follows:

```
DeviceA# display ipv6 pim-info sparse-mode bsr-router
BSR address: 5050::5050
  Uptime:         00:05:28, BSR Priority: 64, Hash mask length: 126
  Expires:        00:01:54
  Role: Non-candidate BSR    Priority: 0, Hash mask length: 126
  State: Accept Preferred
```

The BSR election information on device B is as follows:

```
DeviceB# display ipv6 pim-info sparse-mode bsr-router
PIMv2 Bootstrap information
```

```
  BSR address: 5050::5050
  Uptime:         00:04:13, BSR Priority: 64, Hash mask length: 126
  Expires:        00:02:09
  Role: Candidate BSR    Priority: 64, Hash mask length: 126
  State: Candidate BSR

  Candidate RP: 4949::4949(Loopback 49)
    Advertisement interval 60 seconds
    Next Cand_RP_advertisement in 00:00:53
```

The BSR election information on device C is as follows:

```
DeviceC# display ipv6 pim-info sparse-mode bsr-router
PIMv2 Bootstrap information
This system is the Bootstrap Router (BSR)
  BSR address: 5050::5050
  Uptime:         00:04:25, BSR Priority: 64, Hash mask length: 126
  Next bootstrap message in 00:00:52
  Role: Candidate BSR    Priority: 64, Hash mask length: 126
  State: Elected BSR

  Candidate RP: 5050::5050(Loopback 50)
    Advertisement interval 60 seconds
    Next Cand_RP_advertisement in 00:00:44
```

The BSR election information on device D is as follows:

```
DeviceD# display ipv6 pim-info sparse-mode bsr-router
PIMv2 Bootstrap information
  BSR address: 5050::5050
  Uptime:         00:06:00, BSR Priority: 64, Hash mask length: 126
  Expires:        00:01:21
  Role: Non-candidate BSR    Priority: 0, Hash mask length: 126
  State: Accept Preferred
```

The BSR election information on device E is as follows:

```
DeviceE# display ipv6 pim-info sparse-mode bsr-router
PIMv2 Bootstrap information
  BSR address: 5050::5050
  Uptime:         00:06:23, BSR Priority: 64, Hash mask length: 126
  Expires:        00:01:58
  Role: Non-candidate BSR    Priority: 0, Hash mask length: 126
  State: Accept Preferred
```

(3) Run the **display ipv6 pim-info sparse-mode embedded-rp mapping** command to display the RP information on the multicast devices.

The RP information on device A is as follows:

```
DeviceA# display ipv6 pim-info sparse-mode embedded-rp mapping
PIM Group-to-RP Mappings
Group(s): ff13::/64
```

```
  RP: 4949::4949(Not self)
    Info source: 5050::5050, via bootstrap, priority 192
          Uptime: 03:10:58, expires: 00:01:32
Group(s): ff14::/64
  RP: 5050::5050(Not self)
    Info source: 5050::5050, via bootstrap, priority 192
          Uptime: 03:08:58, expires: 00:01:32
Group(s): ff00::/8, Static
    RP: 5050::5050(Not self), Static
          Uptime: 03:08:15
```

The RP information on device B is as follows:

```
DeviceB# display ipv6 pim-info sparse-mode embedded-rp mapping
PIM Group-to-RP Mappings
Group(s): ff13::/64
  RP: 4949::4949(Self)
    Info source: 5050::5050, via bootstrap, priority 192
          Uptime: 03:12:31, expires: 00:02:08
Group(s): ff14::/64
  RP: 5050::5050(Not self)
    Info source: 5050::5050, via bootstrap, priority 192
          Uptime: 03:10:26, expires: 00:02:08
Group(s): ff00::/8, Static
    RP: 5050::5050(Not self), Static
          Uptime: 03:09:35
```

The RP information on device C is as follows:

```
DeviceC# display ipv6 pim-info sparse-mode embedded-rp mapping
PIM Group-to-RP Mappings
Group(s): ff13::/64
  RP: 4949::4949(Not self)
    Info source: 4949::4949, via bootstrap, priority 192
          Uptime: 00:21:40, expires: 00:01:49
Group(s): ff14::/64
  RP: 5050::5050(Self)
    Info source: 4949::4949, via bootstrap, priority 192
          Uptime: 00:19:40, expires: 00:01:49
Group(s): ff00::/8, Static
    RP: 5050::5050(Self), Static
          Uptime: 00:18:52
```

The RP information on device D is as follows:

```
DeviceD# display ipv6 pim-info sparse-mode embedded-rp mapping
PIM Group-to-RP Mappings
Group(s): ff13::/64
  RP: 4949::4949(Not self)
    Info source: 4949::4949, via bootstrap, priority 192
          Uptime: 00:21:59, expires: 00:01:31
```

```
Group(s): ff14::/64
  RP: 5050::5050(Not self)
    Info source: 4949::4949, via bootstrap, priority 192
        Uptime: 00:19:59, expires: 00:01:31
Group(s): ff00::/8, Static
    RP: 5050::5050(Not self), Static
        Uptime: 00:19:09
```

The RP information on device E is as follows:

```
DeviceE# display ipv6 pim-info sparse-mode embedded-rp mapping
PIM Group-to-RP Mappings
Group(s): ff13::/64
  RP: 4949::4949(Not self)
    Info source: 4949::4949, via bootstrap, priority 192
        Uptime: 00:22:24, expires: 00:02:06
Group(s): ff14::/64
  RP: 5050::5050(Not self)
    Info source: 4949::4949, via bootstrap, priority 192
        Uptime: 00:20:24, expires: 00:02:06
Group(s): ff00::/8, Static
    RP: 5050::5050(Not self), Static
        Uptime: 00:19:31
```

(4) Run the **display ipv6 pim-info sparse-mode mroute** command to display the multicast routing tables of PIM-SMv6. The multicast source (1001:: 2/64) sends traffic to the multicast groups (FF14::1/64) and (FF13::1/64). Host A joins the multicast group (FF14::1/64), and host B joins the multicast group (FF13::1/64).

The routing table information on device A is as follows:

```
DeviceA# display ipv6 pim-info sparse-mode mroute
IPv6 Multicast Routing Table
(*,*,RP) Entries: 0
(*,G) Entries: 0
(S,G) Entries: 3
(S,G,rpt) Entries: 3
FCR Entries: 0
REG Entries: 3

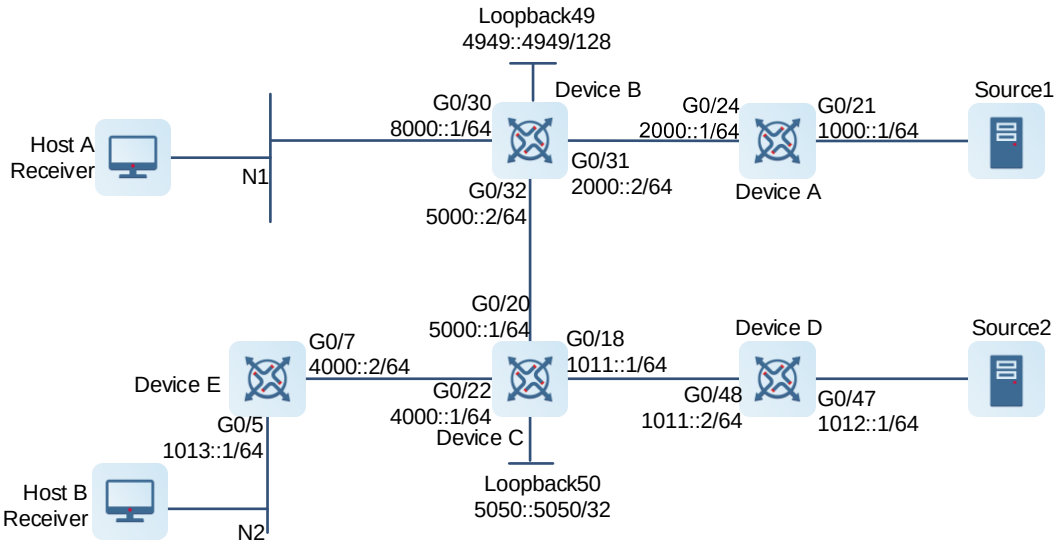
7. Common Errors

- The multicast routing function is not enabled on multicast devices.
- The multicast function is not enabled on any interface.
- No BSR border is configured between PIM-SMv6 domains.
- No RP is configured.
- No static RP is configured on a multicast device, or the configured static RP on this multicast device is not consistent with the configuration on other multicast devices.
- C-RPs are configured, but no C-BSR is configured.
- Static RP, C-RP or C-BSR is unreachable via unicast routes.



1.13.2 Configuring Basic Functions of PIM-SMv6 in the SSM Model

1. Requirements

As shown in Figure 1-6, the PIM-SMv6 protocol is enabled on multicast devices to provide SSM services for hosts in N1 and N2 so that the hosts can receive multicast data from specified multicast sources to the multicast group that the hosts join, for example, video-on-demand.

2. Topology

Figure 1-6 PIM-SMv6 Multicast Network Topology in the SSM Model

3. Notes

- Configure IPv6 addresses and unicast routing protocols for multicast devices. The PIMv6 protocol in a multicast domain depends on unicast routing protocols. Normal communication of unicast routing lays a foundation of multicast routing. Ensure that each PIMv6 node is reachable via unicast routes.
- Enable the multicast function on all multicast devices. Enabling the multicast function is a prerequisite of PIM-SMv6 configuration.

- Enable the basic functions of PIM-SMv6 on all interfaces of the multicast devices. The other functions of PIM-SMv6 can be enabled only after the basic functions of PIM-SMv6 are enabled.
- Enable the MLD function on the interface connected to hosts and set the MLD version to 2 so that the hosts can join or leave a multicast group by sending MLD messages based on the specified source. The multicast devices acting as leaf nodes maintain group membership based on the MLD protocol.
- Configure the same address range of SSM on all multicast devices. The SSM services provided by the multicast devices in the PIM-SMv6 domain are dedicated to specified groups, which realizes multicast controllability.

4. Procedure

(1) Configure IP addresses and enable unicast routing protocols on interfaces of different devices.

Configure IPv6 addresses and enable the OSPFv6 unicast routing protocol on interfaces of device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/21)# ipv6 address 1000::1/64
DeviceA(cfg-if-GigabitEthernet 0/21)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/24)# ipv6 address 2000::1/64
DeviceA(cfg-if-GigabitEthernet 0/24)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
```

Configure IPv6 addresses and enable the OSPFv6 unicast routing protocol on interfaces of device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 address 8000::1/64
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/31)# ipv6 address 2000::2/64
DeviceB(cfg-if-GigabitEthernet 0/31)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/32)# ipv6 address 5000::2/64
DeviceB(cfg-if-GigabitEthernet 0/32)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ipv6 address 4949::4949/128
```

```
DeviceB(cfg-if-Loopback 49)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-Loopback 49)# exit
```

Configure IPv6 addresses and enable the OSPFv6 unicast routing protocol on interfaces of device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface GigabitEthernet 0/18
DeviceC(cfg-if-GigabitEthernet 0/18)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/18)# ipv6 address 1011::1/64
DeviceC(cfg-if-GigabitEthernet 0/18)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/18)# exit
DeviceC(cfg)# interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 address 5000::1/64
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/22
DeviceC(cfg-if-GigabitEthernet 0/22)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/22)# ipv6 address 4000::1/64
DeviceC(cfg-if-GigabitEthernet 0/22)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/22)# exit
DeviceC(cfg)# interface Loopback 50
DeviceC(cfg-if-Loopback 50)# ipv6 address 5050::5050/128
DeviceC(cfg-if-Loopback 50)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-Loopback 50)# exit
```

Configure IPv6 addresses and enable the OSPFv6 unicast routing protocol on interfaces of device D.

```
DeviceD> privilege
DeviceD# config-system terminal
DeviceD(cfg)# interface GigabitEthernet 0/47
DeviceD(cfg-if-GigabitEthernet 0/47)# unset switch-port
DeviceD(cfg-if-GigabitEthernet 0/47)# ipv6 address 1012::1/64
DeviceD(cfg-if-GigabitEthernet 0/47)#    ipv6 ospf 4949 set-area 0
DeviceD(cfg-if-GigabitEthernet 0/47)# exit
DeviceD(cfg)# interface GigabitEthernet 0/48
DeviceD(cfg-if-GigabitEthernet 0/48)# unset switch-port
DeviceD(cfg-if-GigabitEthernet 0/48)# ipv6 address 1011::2/64
DeviceD(cfg-if-GigabitEthernet 0/48)# ipv6 ospf 4949 set-area 0
DeviceD(cfg-if-GigabitEthernet 0/48)# exit
```

Configure IPv6 addresses and enable the OSPFv6 unicast routing protocol on interfaces of device E.

```
DeviceE> privilege
DeviceE# config-system terminal
DeviceE(cfg)# interface GigabitEthernet 0/7
DeviceE(cfg-if-GigabitEthernet 0/7)# unset switch-port
DeviceE(cfg-if-GigabitEthernet 0/7)# ipv6 address 4000::2/64
DeviceE(cfg-if-GigabitEthernet 0/7)# ipv6 ospf 4949 set-area 0
DeviceE(cfg-if-GigabitEthernet 0/7)# exit
```

```
DeviceE(cfg)# interface GigabitEthernet 0/5
DeviceE(cfg-if-GigabitEthernet 0/5)# unset switch-port
DeviceE(cfg-if-GigabitEthernet 0/5)# ipv6 address 1013::1/64
DeviceE(cfg-if-GigabitEthernet 0/5)# ipv6 ospf 4949 set-area 0
DeviceE(cfg-if-GigabitEthernet 0/5)# exit
```

(2) Enable the multicast and PIM-SMv6 functions on all multicast devices, and enable the MLD function on all multicast devices connected to hosts.

Enable the IPv6 multicast and PIM-SMv6 functions on device A.

```
DeviceA(cfg)# ipv6 mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/21
DeviceA(cfg-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/21)# exit
DeviceA(cfg)# interface GigabitEthernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
```

Enable the IPv6 multicast, PIM-SMv6, and MLD functions on device B, and set the MLD version to 3.

```
DeviceB(cfg)# ipv6 mrouting-enable
DeviceB(cfg)# interface GigabitEthernet 0/30
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/30)# ipv6 mld specifiy-version 2
DeviceB(cfg-if-GigabitEthernet 0/30)# exit
DeviceB(cfg)# interface GigabitEthernet 0/31
DeviceB(cfg-if-GigabitEthernet 0/31)# ipv6 pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/31)# exit
DeviceB(cfg)# interface GigabitEthernet 0/32
DeviceB(cfg-if-GigabitEthernet 0/32)# ipv6 pim sparse-mode
DeviceB(cfg-if-GigabitEthernet 0/32)# exit
DeviceB(cfg)# interface Loopback 49
DeviceB(cfg-if-Loopback 49)# ipv6 pim sparse-mode
DeviceB(cfg-if-Loopback 49)# exit
```

Enable the IPv6 multicast and PIM-SMv6 functions on device C.

```
DeviceC(cfg)# ipv6 mrouting-enable
DeviceC(cfg)# interface GigabitEthernet 0/18
DeviceC(cfg-if-GigabitEthernet 0/18)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/18)# exit
DeviceC(cfg)# interface GigabitEthernet 0/20
DeviceC(cfg-if-GigabitEthernet 0/20)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/20)# exit
DeviceC(cfg)# interface GigabitEthernet 0/22
DeviceC(cfg-if-GigabitEthernet 0/22)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/22)# exit
DeviceC(cfg)# interface Loopback 50
DeviceC(cfg-if-Loopback 50)# ipv6 pim sparse-mode
DeviceC(cfg-if-Loopback 50)# exit
```

```
DeviceC(cfg)#
```

Enable the IPv6 multicast and PIM-SMv6 functions on device D.

```
DeviceD(cfg)# ipv6 mrouting-enable
DeviceD(cfg)# interface GigabitEthernet 0/47
DeviceD(cfg-if-GigabitEthernet 0/47)# ipv6 pim sparse-mode
DeviceD(cfg-if-GigabitEthernet 0/47)# exit
DeviceD(cfg)# interface GigabitEthernet 0/48
DeviceD(cfg-if-GigabitEthernet 0/48)# ipv6 pim sparse-mode
DeviceD(cfg-if-GigabitEthernet 0/48)# exit
```

Enable the IPv6 multicast, PIM-SMv6, and MLD functions on Device E, and set the MLD version to 3.

```
DeviceE(cfg)# ipv6 mrouting-enable
DeviceE(cfg)# interface GigabitEthernet 0/7
DeviceE(cfg-if-GigabitEthernet 0/7)# ipv6 pim sparse-mode
DeviceE(cfg-if-GigabitEthernet 0/7)# exit
DeviceE(cfg)# interface GigabitEthernet 0/5
DeviceE(cfg-if-GigabitEthernet 0/5)# ipv6 mld specifiy-version 2
DeviceE(cfg-if-GigabitEthernet 0/5)# ipv6 pim sparse-mode
DeviceE(cfg-if-GigabitEthernet 0/5)# exit
```

(3) Enable the SSM function and configure an address range of multicast groups on all multicast devices.

Set the address range of an SSM multicast group to FF33::/64 on device A.

```
DeviceA(cfg)# ipv6 access-control-list ipv6-ssm-list
DeviceA(cfg-ipv6acl)# permit ipv6 any FF33::/64
DeviceA(cfg-ipv6acl)#exit
DeviceA(cfg)# ipv6 pim enable-ssm range ipv6-ssm-list
```

Set the address range of an SSM multicast group to FF33::/64 on device B.

```
DeviceB(cfg)# ipv6 access-control-list ipv6-ssm-list
DeviceB(cfg-ipv6acl)# permit ipv6 any FF33::/64
DeviceB(cfg-ipv6acl)#exit
DeviceB(cfg)# ipv6 pim enable-ssm range ipv6-ssm-list
```

Set the address range of an SSM multicast group to FF33::/64 on device C.

```
DeviceC(cfg)# ipv6 access-list ipv6-ssm-list
DeviceC(cfg-ipv6acl)# permit ipv6 any FF33::/64
DeviceC(cfg-ipv6acl)#exit
DeviceC(cfg)# ipv6 pim enable-ssm range ipv6-ssm-list
```

Set the address range of an SSM multicast group to FF33::/64 on device D.

```
DeviceD(cfg)# ipv6 access-list ipv6-ssm-list
DeviceD(cfg-ipv6acl)# permit ipv6 any FF33::/64
DeviceD(cfg-ipv6acl)#exit
DeviceD(cfg)# ipv6 pim enable-ssm range ipv6-ssm-list
```

Set the address range of an SSM multicast group to FF33::/64 on device E.

```
DeviceE(cfg)# ipv6 access-list ipv6-ssm-list
DeviceE(cfg-ipv6acl)# permit ipv6 any FF33::/64
```

```
DeviceE(cfg-ipv6acl)#exit
DeviceE(cfg)# ipv6 pim enable-ssm range ipv6-ssm-list
```

5. Verification

(1) Run the **display ipv6 pim-info sparse-mode interface** command to display the PIM-SMv6 running information on the interfaces of each device.

The PIM-SMv6 running information on the interfaces of device A is as follows. The PIM-SM running information on the interfaces of devices B, C, D, and E is the same.

```
DeviceA> privilege
DeviceA# display ipv6 pim-info sparse-mode interface
Interface                                VIFindex Ver/     Nbr       DR
                                                  Mode     Count    Prior
GigabitEthernet 0/21                     2        v2/S     0        1
     Address          : fe80::2d0:f8ff:fe22:358d
     Global Address: 1000::1
     DR               : this system
GigabitEthernet 0/24                     3        v2/S     1        1
     Address          : fe80::2d0:f8ff:fe22:358d
     Global Address: 2000::1
     DR               : fe80::2d0:f8ff:feee:8c1f
```

(2) Run the **display ipv6 pim-info sparse-mode mroute** command to display the multicast routing tables of PIMv6. Host A needs to receive packets sent from the source (1000::2/64) and the source (1012::2/64) to the multicast group (FF33::100). Host B needs to receive packets sent from the source (1000::2/64) to the multicast group (FF33::100). The information output is as follows:

Run the **display ipv6 pim-info sparse-mode mroute** command to display the multicast routing tables of device A.

```
DeviceA> privilege
DeviceA# display ipv6 pim-info sparse-mode mroute

7. Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a multicast device.
- The SSM function is not enabled on a multicast device, or the SSM group address range on this multicast device is not consistent with the configuration on other multicast devices.
- The PIM-SMv6 function is not enabled on an interface, for example, the gateway interface connecting to hosts or a multicast source.
- The MLDv2 function is not enabled on an interface connected to hosts.

1 Configuring MLD Snooping

1.1 Introduction

Multicast Listener Discovery (MLD) snooping is a process of snooping protocol packets between an L3 multicast device and hosts to manage and control forwarding of IPv6 multicast traffic at the data link layer, implementing L2 multicast.

Generally, multicast packets need to pass through L2 switches, especially in some local area networks (LANs). As shown in Figure 1-1, the Protocol Independent Multicast (PIM) multicast device sends packets to hosts through an L2 switch. Because multicast group addresses cannot be learned on L2 devices, the packets will be broadcast in the VLAN. This wastes bandwidth and affects security. After the MLD snooping function is configured, the L2 switch can listen to MLD packets between hosts and the uplink PIM multicast device and establish L2 multicast forwarding entries to ensure that multicast data is forwarded only to specific hosts. This prevents multicast data from being broadcast in the L2 network.

Figure 1-1 Network Topology

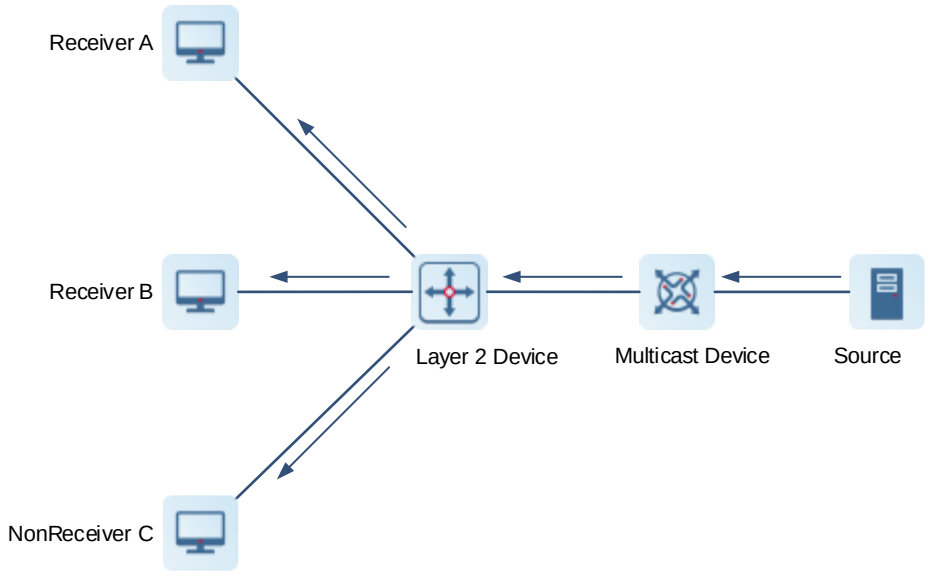
1.1.2 Principles

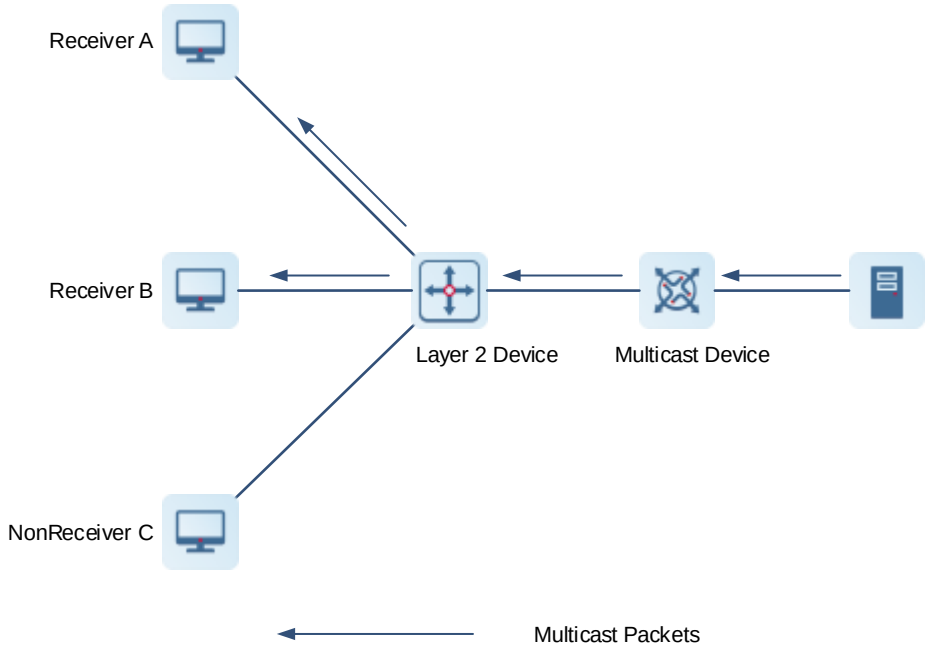
MLD snooping is a basic L2 multicast function that forwards and controls multicast data at the data link layer. By listening to and analyzing protocol packets between hosts and the L3 multicast device, the L2 device running

MLD snooping establishes and maintains L2 multicast forwarding entries to ensure on-demand forwarding of multicast data at the link layer.

As shown in Figure 1-2, when MLD snooping is not configured on the L2 device, IPv6 multicast packets are broadcast in the VLAN. As shown in Figure 1-3, when MLD snooping is enabled on the L2 device, IPv6 multicast packets are forwarded only to the member hosts of the multicast group. This prevents multicast data from being broadcast in the L2 network.

Figure 1-2 Multicast Data Transmission When MLD Snooping Is Disabled





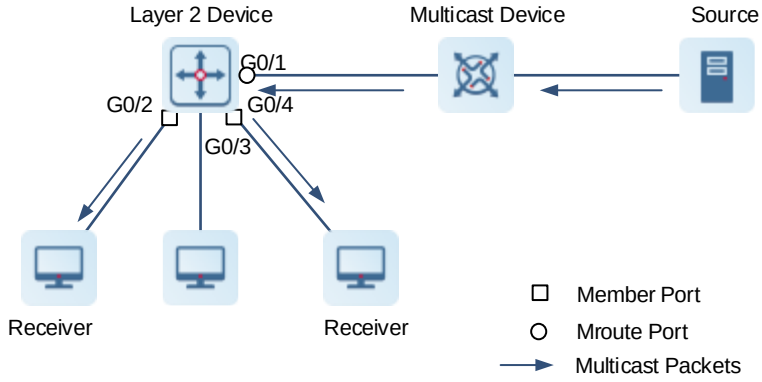


Figure 1-3 Multicast Data Transmission When MLD Snooping Is Enabled

1.1.3 Port Types

MLD snooping is enabled on a per-VLAN basis. MLD snooping ports are ports in a VLAN. The device running MLD snooping identifies ports in a VLAN as multicast router ports or member ports to manage and control forwarding of IP multicast data in the VLAN.

Figure 1-4 MLD Snooping Ports

- A multicast router port connects the L2 multicast device to an L3 multicast device, and indicates the direction of the multicast source. By listening to MLD packets, the L2 multicast device can automatically discover and maintain dynamic multicast router ports. You can also configure static multicast router ports.
- A member port connects the L2 multicast device to a host in a multicast group, and indicates the direction of a multicast group member. It is also called a listener port. By listening to MLD packets, the L2 multicast device can automatically discover and maintain dynamic member ports. You can also configure static member ports.

As shown in Figure 1-4, MLD snooping is enabled on the L2 multicast device, and the multicast data is received from a multicast router port and sent out from a member port.

1.1.4 Working Mechanism

A device running MLD snooping analyzes received MLD packets to discover and identify multicast router ports and member ports and establish and maintain MLD snooping forwarding entries. The device can identify and process the following types of MLD packets:

1. Query Packets

An L3 multicast device regularly sends an MLD general Query packet to all hosts and other multicast devices (with the address of FF02::1) in the local network segment to query the IPv6 multicast group members in this network segment. When receiving the MLD general Query packet, a multicast device forwards the packet through all ports in the VLAN except the one receiving the packet and processes the port receiving the packet as follows:

- Reset the aging timer of the port if the port is in the multicast router port list.
- Add the port to the multicast router port list if the port is not in the multicast router port list and start the aging timer of the port.
- When the L2 multicast device receives an MLD group-specific Query packet, it does not update the preceding timers.

2. Report Packets

When a member host receives a Query packet, the host will respond with a Report packet. If a host wants to join a multicast group, the host will proactively send a Report packet.

When receiving a Report packet, the device running MLD snooping forwards it to all multicast router ports in the VLAN, retrieves the address of the IPv6 multicast group that the host needs to join from the packet, and processes the port receiving the packet as follows:

- The device creates a forwarding entry for the IPv6 multicast group if no forwarding entry for the IPv6 multicast group exists, adds the port to the outbound port list as a dynamic member port, and starts the aging timer of the port.
- The device adds the port to the outbound port list as a dynamic member port and starts its aging timer if the forwarding entry of the IPv6 multicast group exists but the port is not contained in the outbound port list.
- The device resets the aging timer of the port if the forwarding entry of the IPv6 multicast group exists and the port is contained in the outbound port list.

3. Leave Packets

When a host leaves an IPv6 multicast group, it sends an MLD Leave packet (with the address of FF02::2) to notify the multicast device. When receiving a Leave packet, the device running MLD snooping performs the following actions in the VLAN:

- The device forwards the Leave packet through all multicast router ports.
- If the port receiving the Leave packet is a dynamic member port and the fast leave function is configured, the device immediately deletes the port from the MLD snooping forwarding entry of the corresponding multicast group. The port is no longer used as a dynamic member port of the group.
- If the port receiving the Leave packet is a dynamic member port but the fast leave function is not configured, the port status remains unchanged. When the aging timer of the port times out, the device deletes the port from the MLD snooping forwarding entry of the corresponding multicast group. The port is no longer used as a dynamic member port of the group.

1.1.5 Protocols and Standards

- RFC 4541: Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches

1.2 Configuration Task Summary

MLD snooping configuration includes the following tasks:

(1) Configuring Basic MLD Snooping Functions Select either of the following configuration tasks to configure.

- Configuring Basic MLD Snooping Functions in IVGL Mode
- Configuring Basic MLD Snooping Functions in SVGL Mode
- Configuring Basic MLD Snooping Functions in IVGL-SVGL Mode

(2) Configuring Protocol Packet Processing Parameters All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Static Multicast Router Port
- Configuring a Static Member Port

- Configuring Report Packet Suppression
- Configuring Port Fast Leave
- Configuring Dynamic Multicast Router Port Learning
- Configuring the Aging Time for Dynamic Multicast Router Ports
- Configuring the Aging Time for Dynamic Member Ports
- Configuring the Maximum Response Time for Query Packets

(3) Configuring Multicast Security Control All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Profile
- Configuring Multicast Group Filtering on a Port
- Configuring the Maximum Number of Multicast Groups That Can Be Dynamically Learned by a Port
- Configuring Source Port Check

(4) (Optional) Configuring QinQ Processing

1.3 Configuring Basic MLD Snooping Functions

1.3.1 Overview

The device running MLD snooping can provide independent or shared multicast services for user VLANs when operating in the following modes:

- Independent VLAN Group Learning (IVGL): provides independent multicast services for each user VLAN.
- Shared VLAN Group Learning (SVGL): provides shared multicast services for multiple user VLANs.
- IVGL-SVGL: provides both shared and independent multicast services for user VLANs.

1.3.2 Restrictions and Guidelines

- The SVGL mode and the IPv6 multicast function are mutually exclusive. If the IPv6 multicast function needs to be enabled on the device running MLD snooping, the device can operate only in IVGL mode.
- If the device running MLD snooping operates in SVGL or IVGL-SVGL mode, a profile must be defined to specify the multicast groups associated with the SVGL mode.

1.3.3 Configuration Tasks

Basic MLD snooping function configuration includes the following tasks. Please configure only one task.

- Configuring Basic MLD Snooping Functions in IVGL Mode
- Configuring Basic MLD Snooping Functions in SVGL Mode
- Configuring Basic MLD Snooping Functions in IVGL-SVGL Mode

Basic MLD snooping function configuration includes the following tasks.

1.3.4 Notes

The following table lists products supporting different basic MLD snooping functions.

Table 1-1 Products Supporting Different Basic MLD Snooping Functions

Function	Product Supporting the Function
Configuring Basic MLD Snooping Functions in IVGL Mode	S6980-64QC S6920-4C S6580-24DC8QC S6510-32CQ S6510-48VS8CQ S6250-48XS8CQ
Configuring Basic MLD Snooping Functions in SVGL Mode	S6980-64QC S6920-4C S6580-24DC8QC S6510-32CQ S6510-48VS8CQ S6250-48XS8CQ
Configuring Basic MLD Snooping Functions in IVGL-SVGL Mode	S6980-64QC S6920-4C S6580-24DC8QC S6510-32CQ S6510-48VS8CQ S6250-48XS8CQ

1.3.5 Configuring Basic MLD Snooping Functions in IVGL Mode

1. Overview

In IVGL mode, the device running MLD snooping provides independent multicast services for each user VLAN. Multicast traffic can be forwarded only in the belonged VLAN, and hosts can request multicast traffic only in the belonged VLAN.

2. Restrictions and Guidelines

- Unless otherwise specified, you are advised to enable MLD snooping globally on all L2 access devices connecting to hosts.
- After MLD snooping is enabled globally, it takes effect to all VLANs. You can disable MLD snooping on any VLAN. When the multicast service is disabled on a VLAN, the multicast services on other VLANs are not affected.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the IPv6 MLD snooping function and run the IVGL mode.

ipv6 mld snooping-mode ivgl

MLD snooping is disabled by default.

(4) (Optional) Disable MLD snooping on a specified VLAN.

unset ipv6 mld snooping-mode vlan *vlan-id*

After MLD snooping is enabled globally, it takes effect to all VLANs by default. If MLD snooping is disabled globally, it is ineffective on all VLANs.

You can disable MLD snooping on a VLAN only after MLD snooping is enabled globally.

1.3.6 Configuring Basic MLD Snooping Functions in SVGL Mode

1. Overview

In SVGL mode, the device running MLD snooping can provide shared multicast services for multiple user VLANs. Shared multicast services are usually used to provide the same video on demand (VOD) service for users in multiple VLANs. Compared with independent multicast services, shared multicast services save bandwidth.

VLANs for shared multicast services are classified into a shared VLAN and sub VLANs. Multicast traffic of multicast groups applied in SVGL mode on the shared VLAN is forwarded from the shared VLAN to sub VLANs, and hosts on sub VLANs request multicast traffic of multicast groups applied in SVGL mode from the shared VLAN.

2. Restrictions and Guidelines

- Multicast services can be shared among VLANs. After configuring the SVGL mode, you need to configure multicast groups applied in SVGL mode.
- Shared multicast services apply only to the shared VLAN and sub VLANs and use group addresses applied in SVGL mode.

3. Prerequisites

Before configuring multicast groups associated with the SVGL mode, ensure that the corresponding profile is created and a range of multicast groups that are permitted or denied by the filter is specified. For details about profile configuration, see 1.5.4 Configuring a Profile.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the IPv6 MLD snooping function and run the SVGL mode.

ipv6 mld snooping-mode svgl

MLD snooping is disabled by default.

(4) Configure multicast groups associated with the SVGL mode.

ipv6 mld snooping-mode svgl group-profile *profile-number*

No multicast group is associated with the SVGL mode by default.

(5) (Optional) Specify a shared VLAN.

ipv6 mld snooping-mode svgl shared-vlan *vlan-id*

The default shared VLAN in SVGL mode is VLAN 1.

1.3.7 Configuring Basic MLD Snooping Functions in IVGL-SVGL Mode

1. Overview

The IVGL-SVGL mode is also called the hybrid mode. In IVGL-SVGL mode, the device running MLD snooping can provide both shared and independent multicast services for user VLANs.

- In the shared VLAN and sub VLANs, shared multicast services apply to the multicast traffic of multicast groups applied in SVGL mode, and independent multicast services apply to other multicast traffic.
- In other VLANs (except the shared VLAN and sub VLANs), independent multicast services are provided.

2. Restrictions and Guidelines

- After configuring the IVGL-SVGL mode, you must specify the multicast groups associated with the SVGL mode.
- When a user VLAN is configured as a shared VLAN or sub VLAN, the user VLAN enjoys both shared and independent multicast services. When a user VLAN is configured as other VLANs, it enjoys only independent multicast services.

3. Prerequisites

Before configuring multicast groups associated with the SVGL mode, ensure that the corresponding profile is created and a range of multicast groups that are permitted or denied by the filter is specified. For details about profile configuration, see 1.5.4 Configuring a Profile.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the IPv6 MLD snooping function and run the IVGL-SVGL mode.

ipv6 mld snooping-mode ivgl-svgl

MLD snooping is disabled by default.

(4) (Optional) Specify a shared VLAN.

ipv6 mld snooping-mode svgl shared-vlan *vlan-id*

The default shared VLAN in SVGL mode is VLAN 1.

1.4 Configuring Protocol Packet Processing Parameters

1.4.1 Overview

By controlling protocol packet processing, an L2 multicast device can establish static or dynamic multicast forwarding entries. In addition, the device can adjust parameters to refresh dynamic multicast forwarding entries and MLD snooping membership quickly.

1.4.2 Restrictions and Guidelines

Configuring Basic MLD Snooping Functions Related configuration functions take effect only after basic MLD snooping functions are configured.

1.4.3 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Static Multicast Router Port
- Configuring a Static Member Port
- Configuring Report Packet Suppression
- Configuring Port Fast Leave
- Configuring Dynamic Multicast Router Port Learning
- Configuring the Aging Time for Dynamic Multicast Router Ports
- Configuring the Aging Time for Dynamic Member Ports
- Configuring the Maximum Response Time for Query Packets

1.4.4 Configuring a Static Multicast Router Port

1. Overview

A multicast router port is used to receive uplink multicast data and forward MLD Report and Leave packets. Static multicast router ports never age and can forward MLD Report and Leave packets to the uplink MLD querier stably.

2. Restrictions and Guidelines

- In SVGL mode, if no sub VLAN is configured, the configuration of static multicast router ports is valid only in the shared VLAN. In other VLANs, static multicast router ports can be configured but do not take effect. If sub VLANs are configured, the configuration of static multicast router ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static multicast router ports can be configured but do not take effect.
- In SVGL-IVGL mode, if no sub VLAN is configured, the configuration of static multicast router ports is valid in all VLANs. If sub VLANs are configured, the configuration of static multicast router ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static multicast router ports can be configured but do not take effect.
- In IVGL mode, the configuration of static multicast router ports is valid in all VLANs.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a static multicast router port.

ipv6 mld snooping-mode vlan *vlan-id* **multicast-router interface** *interface-type interface-number*

No static multicast router port is configured by default.

1.4.5 Configuring a Static Member Port

1. Overview

When a member port connecting to a member host is configured as a static member port, the host can receive multicast traffic from the specified multicast group no matter whether the host joins the multicast group. Static member ports never age.

2. Restrictions and Guidelines

- In SVGL mode, if no sub VLAN is configured, the configuration of static member ports is valid only in the shared VLAN. In other VLANs, static member ports can be configured but do not take effect. If sub VLANs are configured, the configuration of static member ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static member ports can be configured but do not take effect.
- In SVGL-IVGL mode, if no sub VLAN is configured, the configuration of static member ports is valid in all VLANs. If sub VLANs are configured, the configuration of static member ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static member ports can be configured but do not take effect.
- In IVGL mode, the configuration of static member ports is valid in all VLANs.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a static member port.

ipv6 mld snooping-mode vlan *vlan-id* **static-member** *ipv6-group-address* **interface** *interface-type interface-number*

No static member port is configured by default.

1.4.6 Configuring Report Packet Suppression

1. Overview

MLD Query and Report packets are exchanged periodically to maintain the group membership. When many hosts in a network join the same multicast group, many MLD packets will be sent to the MLD multicast device, which wastes network bandwidth and affects the performance of the MLD multicast device. Report packet suppression can optimize this situation.

When Report packet suppression is configured, the MLD multicast device forwards only the first Report packet from a specific VLAN for a multicast group to the multicast router port and suppresses subsequent Report

packets for the same multicast group during one query interval. This function helps reduce the number of packets in the network.

2. Restrictions and Guidelines

Only MLDv1 Report packets can be suppressed, and MLDv2 Report packets cannot be suppressed.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure Report packet suppression.

ipv6 mld snooping-mode suppress enable

Report packet suppression is disabled by default.

1.4.7 Configuring Port Fast Leave

1. Overview

When the port fast leave function is enabled and a port receives a Leave packet (including the MLDv1 Leave packet and MLDv2 Report packet of the INCLUDE type without carrying any source address), the port is directly deleted from the member port list of the corresponding multicast forwarding entry. When receiving group-specific Query packets and multicast data, the device does not forward the packets to this port.

2. Restrictions and Guidelines

The port fast leave function is applicable when only one host is connected to each port. This function helps save bandwidth and resources.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the port fast leave function.

ipv6 mld snooping-mode inf-fast-leave enable

The port fast leave function is disabled by default.

1.4.8 Configuring Dynamic Multicast Router Port Learning

1. Overview

In some test scenarios, a user host may send Query packets and PIMv6 neighbor messages. When the L2 device receives such Query packets or PIM neighbor messages, the L2 device will set the port receiving the packets as a dynamic multicast router port. All multicast packets in the VLAN will be forwarded to this port, and the host receives a large number of useless multicast packets. In addition, Query packets and PIMv6 neighbor messages sent by user hosts may affect the status of the L3 multicast routing protocol, such as the querier and

designated router (DR) election. In this case, you can disable dynamic multicast router port learning to resolve this problem and improve network security.

2. Restrictions and Guidelines

Disabling dynamic multicast router port learning and enabling a static multicast router port do not affect each other.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure dynamic multicast router port learning.

ipv6 mld snooping-mode [**vlan** *vlan-id*] **multicast-router learn**

Dynamic multicast router port learning is enabled by default.

1.4.9 Configuring the Aging Time for Dynamic Multicast Router Ports

1. Overview

A multicast router port is used to receive uplink multicast data and forward MLD Report and Leave packets. After enabling MLD snooping, an L2 device can dynamically learn multicast router ports to forward multicast packets for the uplink device. If a dynamic multicast router port does not receive a Query packet or neighbor message from the uplink device within the aging time due to unstable network or packet congestion, the L2 device will delete the dynamic multicast router port, which may cause multicast data interruption.

2. Restrictions and Guidelines

You can adjust the aging time of dynamic multicast router ports based on the network load. When the network load is heavy, set the aging time to a larger value. A too short aging time may cause dynamic multicast router ports to be added and deleted frequently, resulting in data interruption.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the aging time for dynamic multicast router ports.

ipv6 mld snooping-mode dyn-mr-aging-interval *dynamic-mroute-aging-interval*

The default aging time of dynamic multicast router ports is 300s.

1.4.10 Configuring the Aging Time for Dynamic Member Ports

1. Overview

When the device running MLD snooping receives an MLD Join packet from a host to join an IP multicast group, the device adds the port receiving the packet to the member port list and sets an aging time for the port. If the

port is already in the member port list, the device resets the aging timer of the port. If the timer times out, it is deemed that no user host receives multicast packets through this port, and the multicast device deletes the port from the MLD snooping member port list.

2. Restrictions and Guidelines

- You can adjust the aging time of dynamic member ports based on the network load. When the network load is heavy, set the aging time to a larger value. A too short aging time may cause dynamic member ports to be added and deleted frequently, resulting in data interruption.
- After this command is configured, the aging timer value of dynamic member ports is *host-aging-interval* for subsequent MLD Join packets. The aging time takes effect immediately after configuration and the started member port timers are updated.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the aging time for dynamic member ports.

ipv6 mld snooping-mode host-aging-interval *host-aging-interval*

The default aging time of dynamic member ports is 260s.

1.4.11 Configuring the Maximum Response Time for Query Packets

1. Overview

When hosts in the directly-connected network segment of the device serving as the MLD snooping querier receive a Query packet from the device, the hosts need to return a Report packet within the maximum response time. This function allows you to configure the maximum response time for Query packets on the device. If no host returns a Report packet within the maximum response time, the device considers that no group member exists in the directly-connected network segment and deletes the group information.

2. Restrictions and Guidelines

- When receiving an MLD general Query packet, the multicast device will update the aging timers of all member ports. The timer time is the maximum response time for Query packets. After the timer expires, the device regards that no group member receives multicast traffic through a port and deletes the port from the MLD snooping forwarding table.
- When receiving an MLD group-specific Query packet, the multicast device will start the aging timers of all member ports of the specific group. The timer time is the maximum response time for Query packets. After the timer expires, the device regards that no group member receives multicast traffic through a port and deletes the port from the MLD snooping forwarding table.
- For MLDv2 group-specific Query packets, the multicast device does not update the timers.
- The configured maximum response time for Query packets takes effect when the next Query packet is received.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the maximum response time for Query packets.

ipv6 mld snooping-mode max-response-time *max-response-time*

The maximum response time for Query packets is 10s by default.

1.5 Configuring Multicast Security Control

1.5.1 Overview

After multicast security control is configured, the device running MLD snooping can control the multicast service scope and load to prevent invalid multicast traffic and improve L2 multicast network security.

1.5.2 Prerequisites

Configuring Basic MLD Snooping Functions

1.5.3 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Profile
- Configuring Multicast Group Filtering on a Port
- Configuring the Maximum Number of Multicast Groups That Can Be Dynamically Learned by a Port
- Configuring Source Port Check

1.5.4 Configuring a Profile

1. Overview

A profile is used to define a range of multicast groups that permit or deny user access for reference by other functions.

- When the SVGL mode is enabled, a profile is used to define a range of multicast groups applied in SVGL mode.
- When multicast filtering is configured on a port, a profile is used to define a range of multicast groups that permit or deny user access through the port.
- When multicast filtering is configured on a VLAN, a profile is used to define a range of multicast groups that permit or deny user access on the VLAN.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a profile.

ipv6 mld group-profile *profile-number*

No profile is created by default.

(4) Define a range of multicast groups for a profile.

range *start-ipv6-address* [*end-ipv6-address*]

No multicast group range is defined for a profile by default.

Multiple multicast group ranges can be configured at the same time. If two multicast group ranges overlap, the ranges will be merged automatically.

(5) Configure the filtering action for a profile. The configuration steps below are mutually exclusive. Please configure only one task.

- Set the filtering action of a profile to Deny.

  deny

  If only the Deny action is configured and no multicast group range is configured, no group is denied. The effect is the same as permitting all groups.

- Set the filtering action of a profile to Permit.

  permit

  If only the Permit action is configured and no multicast group range is configured, no group is permitted. The effect is the same as denying all groups.

The Deny action is performed for a profile by default.

1.5.5 Configuring Multicast Group Filtering on a Port

1. Overview

Generally, the device running ports can join any multicast group. By configuring a range of multicast groups that permit or deny user access, you can customize the multicast service scope for users to guarantee the interest of operators and prevent invalid multicast traffic.

2. Restrictions and Guidelines

By applying a profile to a port, you can restrict the multicast groups that users can join on the port.

3. Prerequisites

Before configuring a range of multicast groups for a profile, ensure that the corresponding profile is created and a range of multicast groups that are permitted or denied by the filter is specified. For details about profile configuration, see 1.5.4 Configuring a Profile.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 2 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*

(4) Configure multicast group filtering on a port.

ipv6 mld snooping-mode group-filter *profile-number*

The multicast group filtering function is disabled on a port by default.

1.5.6 Configuring the Maximum Number of Multicast Groups That Can Be Dynamically Learned by a Port

1. Overview

If too much multicast traffic is requested concurrently, the multicast device will be severely burdened. Configuring the maximum number of multicast groups allowed for concurrent request can guarantee the bandwidth. You can limit the number of multicast groups allowed for concurrent request on a port.

2. Restrictions and Guidelines

Only dynamically learned multicast groups on a port are counted. Statically configured multicast groups are excluded.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.
  - **interface** *ethernet-type interface-number*
- Enter the Layer 2 link aggregation configuration mode.
  - **interface aggregateport** *interface-number*

(4) Configure the maximum number of multicast groups that can be dynamically learned by a port.

ipv6 mld snooping-mode max-member-record *max-groups-number*

The maximum number of multicast groups that can be dynamically learned by a port is 64,000 by default.

1.5.7 Configuring Source Port Check

1. Overview

The source port check function restricts users to receive only multicast traffic on multicast router ports to prevent users from sending invalid multicast traffic.

- After the source port check function is enabled, only multicast traffic received on multicast router ports is

valid. Multicast traffic received on other ports is invalid and will be discarded.

- When the source port check function is disabled, multicast traffic received on any port is valid.

2. Restrictions and Guidelines

- To restrict users to receive multicast traffic only on multicast router ports, configure this function.
- If no multicast router port exists after the source port check function is enabled, the device will discard received multicast traffic.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure source port check.

ipv6 mld snooping-mode source-inf validate

Source port check is disabled by default.

1.6 Configuring QinQ Processing

Note

This command is not supported by the S6980-64QC, or S6580-24DC8QC.

1.6.1 Overview

On a device with MLD snooping enabled and a dot1q-tunnel (QinQ) port configured, MLD snooping will process the MLD packets received on the QinQ port using the following two modes:

- Mode 1: Create multicast entries on the VLAN where the MLD packets are located. Forwarding MLD packets on the VLAN where these packets are located is called transparent transmission. For example, MLD snooping is enabled for a device, Port A on the device is designated as the QinQ port, the default VLAN of this port is VLAN 1, and Port A allows the passage of VLAN 1 and VLAN 10 packets. When an MLD Report packet is sent from VLAN 10 to Port A, MLD snooping establishes a multicast entry for VLAN 10 and forwards the MLD Report packet to the multicast router port of VLAN 10.
- Mode 2: Create multicast entries on the default VLAN of the QinQ port. Encapsulate the MLD packets with the VLAN tag of the default VLAN where the QinQ port is located and forward the packets within the default VLAN. For example, MLD snooping is enabled for a device, Port A on the device is designated as the QinQ port, the default VLAN of this port is VLAN 1, and Port A allows the passage of VLAN 1 and VLAN 10 packets. When an MLD Report packet is sent from VLAN 10 to Port A, MLD snooping establishes a multicast entry for VLAN 1, encapsulates the MLD Report packet with the tag of VLAN 1, and forwards the packet to the multicast router port of VLAN 1.

1.6.2 Restrictions and Guidelines

If the QinQ port needs to forward multicast packets on the VLANs specified by the VLAN IDs (VIDs) of the packets, transparent packet transmission needs to be configured on the QinQ port.

1.6.3 Prerequisites

- Configuring Basic MLD Snooping Functions.
- Configure basic QinQ functions. For details about QinQ configuration, see *Configuring QinQ*.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure transparent packet transmission on the QinQ port.

ipv6 mld snooping-mode tunnel

The function of transparent MLD packet transmission on the QinQ port is disabled by default.

1.7 Monitoring

Run the display command to check the running status of a configured function to verify the configuration effect.

Run the cleanup commands to clear information.

⚠ Caution

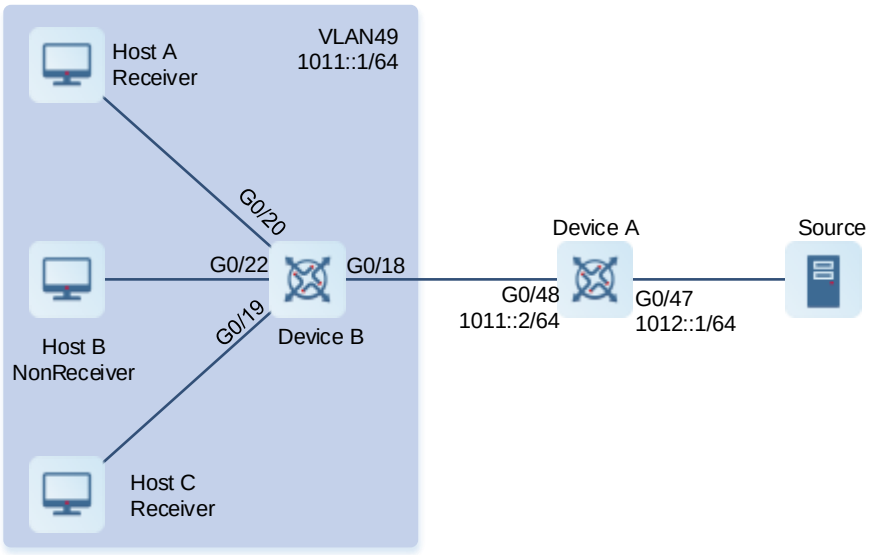
Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-2 Monitoring

Command	Purpose
cleanup ipv6 mld-cache snooping gda-table	Clears MLD snooping multicast forwarding entries.
cleanup ipv6 mld-cache snooping statistics	Clears MLD snooping statistics.
display ipv6 mld-info snooping	Displays the current MLD snooping mode.
display ipv6 mld-info snooping gda-table	Displays MLD snooping forwarding entries.
display ipv6 mld-info snooping statistics	Displays MLD snooping statistics.
display ipv6 mld-info snooping mrouter	Displays MLD snooping multicast router ports.
display ipv6 mld-info snooping interfaces [*interface-type interface-type interface-number*]	Displays MLD snooping interface information, interface filtering profile, and maximum number of multicast groups that can be dynamically learned by a port.

Command	Purpose
display ipv6 mld-info snooping vlan *vlan-id*	Displays multicast information about a single VLAN, on which MLD snooping is configured.
display ipv6 mld-info group-profile *profile-number*	Displays an MLD profile.

1.8 Configuration Examples



1.8.1 Configuring Basic MLD Snooping Functions in IVGL Mode

1. Requirements

In the multicast network shown in Figure 1-5, the router (Device A) connects to the user network through the switch (Device B), and MLD snooping is run on Device A. The multicast source sends data to multicast group FF14::10. There are three hosts (Host A, Host B, and Host C) in the network. Host A and Host C join multicast group FF14::10. Only Host A and Host B can receive multicast data that the multicast source sends to multicast group FF14::10.

2. Topology

Figure 1-5 Topology of Basic MLD Snooping Functions in IVGL Mode

3. Notes

Configure basic MLD snooping functions on Device B.

- Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and PIM-SMv6 related functions on Device A.

- Enable MLD snooping and run the IVGL mode on Device B.

4. Procedure

(1) Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IPv6 address and unicast routing protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 address 1012::1/64
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/48)# ipv6 address 1011::2/64
DeviceA(cfg-if-GigabitEthernet 0/48)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# ipv6 router-protocol ospf 4949
DeviceA(cfg-router)# exit
```

Configure the IPv6 address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# vlan 49
DeviceB(cfg-vlan)# exit
DeviceB(cfg)# interface vlan 49
DeviceB(cfg-if-VLAN 49)# ipv6 address 1011::1/64
DeviceB(cfg-if-VLAN 49)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-VLAN 49)# exit
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# interface GigabitEthernet 0/19
DeviceB(cfg-if-GigabitEthernet 0/19)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/19)# exit
DeviceB(cfg)# interface GigabitEthernet 0/20
DeviceB(cfg-if-GigabitEthernet 0/20)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/20)# exit
DeviceB(cfg)# interface GigabitEthernet 0/22
DeviceB(cfg-if-GigabitEthernet 0/22)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/22)# exit
DeviceB(cfg)# ipv6 router-protocol ospf 4949
DeviceB(cfg-router)# exit
```

(2) Enable multicast routing and PIM-SMv6 related functions on Device A.

```
DeviceA(cfg)# ipv6 mrouting-enable
```

```
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# ipv6 pim c-bsr GigabitEthernet 0/47
DeviceA(cfg)# ipv6 pim c-rp GigabitEthernet 0/47
```

(3) Enable MLD snooping and run the IVGL mode on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6 mld snooping-mode ivgl
```

5. Verification

Send packets from the multicast source (1012::2) to multicast group G (FF14::10). Enable Host A and Host C to join G.

Run the **display ipv6 mld-info snooping-mode gda-table** command on Device B to display the MLD snooping forwarding entry and check whether the member port list contains only GigabitEthernet 0/19 and GigabitEthernet 0/20.

```
DeviceB# display ipv6 mld-info snooping-mode gda-table
Multicast Switching Cache Table
  D: DYNAMIC
  S: STATIC
  M: MROUTE
(*, FF14::10, 49):
  VLAN(49) 3 OPORTS:
    GigabitEthernet 0/18(M)
    GigabitEthernet 0/19(M)
    GigabitEthernet 0/20(DM)
```

Run the **display ipv6 mld-info snooping-mode** command on Device B and check whether the MLD snooping working mode is IVGL.

```
DeviceB# display ipv6 mld-info snooping-mode
MLD-snooping mode: IVGL
Source port check: Disable
MLD Inf-Fast-Leave: Disable
MLD Report suppress: Disable
Query Max Response Time: 10 (Seconds)
Dynamic Mroute Aging Time: 300(Seconds)
Dynamic Host Aging Time: 260(Seconds)
MLD Snooping version: 1
MLD Tunnel: Disable

vlan 49
-------------
```

```
MLD Snooping state: Enabled
Multicast router learning mode: Enable
MLD Inf-Fast-Leave: Enabled
MLD VLAN Mode: STATIC
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ipv6 mrouting-enable
!
interface GigabitEthernet 0/47
 unset switch-port
 ipv6 address 1012::1/64
 ipv6 ospf 4949 set-area 0
 ipv6 pim sparse-mode
!
interface GigabitEthernet 0/48
 unset switch-port
 ipv6 address 1011::2/64
 ipv6 ospf 4949 set-area 0
 ipv6 pim sparse-mode
!
ipv6 pim c-bsr GigabitEthernet 0/47
ipv6 pim c-rp GigabitEthernet 0/47
!
```

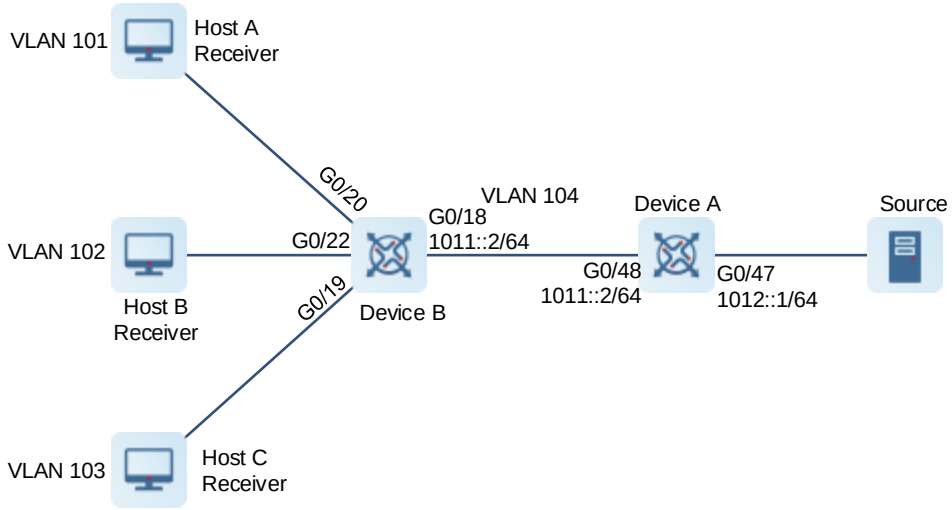
- Device B configuration file

```
hostname DeviceB
!
vlan range 1,49
!
interface GigabitEthernet 0/18
 switch-port access vlan 49
!
interface GigabitEthernet 0/19
 switch-port access vlan 49
!
interface GigabitEthernet 0/20
 switch-port access vlan 49
!
interface GigabitEthernet 0/22
 switch-port access vlan 49
!
interface VLAN 49
 ipv6 address 1011::1/64
```

```
 ipv6 ospf 4949 set-area 0
!
Ipv6 mld snooping-mode ivgl
!
```

7. Common Errors

- The working mode of MLD snooping is improper.



1.8.2 Configuring Basic MLD Snooping Functions in SVGL Mode

1. Requirements

In the multicast network shown in Figure 1-6, the router (Device A) connects to the user network through the switch (Device B), MLD snooping is run on Device A, and Device A directly connects to the multicast source. The multicast source sends data to multicast group FF14::10. Host A, Host B, and Host C are connected to VLAN 101, VLAN 102, and VLAN 103, respectively, and the three hosts join multicast group FF14::10. Host A, Host B, and Host C can receive multicast data that the multicast source sends to multicast group FF14::10.

2. Topology

Figure 1-6 Topology of Basic MLD Snooping Functions in SVGL Mode

3. Notes

Configure basic MLD snooping functions on Device B.

- Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and PIM-SMv6 related functions on Device A.
- Enable MLD snooping and run the SVGL mode on Device B.
- Configure the multicast groups associated with the MLD snooping SVGL mode on Device B and specify the shared VLAN and sub VLANs.

4. Procedure

(1) Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IP address and unicast routing protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 address 1012::1/64
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# vlan 104
DeviceA(cfg)# interface vlan 104
DeviceA(cfg-if-VLAN 104)# ipv6 address 1011::2/64
DeviceA(cfg-if-VLAN 104)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-VLAN 104)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# switch-port mode trunk
DeviceA(cfg-if-GigabitEthernet 0/48)# switch-port trunk native vlan 104
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# ipv6 router-protocol ospf 4949
DeviceA(cfg-router)# exit
```

Configure the IPv6 address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# vlan range 101-104
DeviceB(cfg-vlan-range)# exit
DeviceB(cfg)# interface VLAN 101
DeviceB(cfg-if-VLAN 101)# ipv6 address 1010::1/64
DeviceB(cfg-if-VLAN 101)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-VLAN 101)# exit
DeviceB(cfg)# interface VLAN 102
DeviceB(cfg-if-VLAN 102)# ipv6 address 1020::1/64
DeviceB(cfg-if-VLAN 102)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-VLAN 102)# exit
DeviceB(cfg)# interface VLAN 103
DeviceB(cfg-if-VLAN 103)# ipv6 address 1030::1/64
DeviceB(cfg-if-VLAN 103)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-VLAN 103)# exit
DeviceB(cfg)# interface VLAN 104
DeviceB(cfg-if-VLAN 104)# ipv6 address 1011::2/64
DeviceB(cfg-if-VLAN 104)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-VLAN 104)# exit
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port mode trunk
```

```
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port trunk native vlan 104
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# interface GigabitEthernet 0/19
DeviceB(cfg-if-GigabitEthernet 0/19)# switch-port access vlan 103
DeviceB(cfg-if-GigabitEthernet 0/19)# exit
DeviceB(cfg)# interface GigabitEthernet 0/20
DeviceB(cfg-if-GigabitEthernet 0/20)# switch-port access vlan 101
DeviceB(cfg-if-GigabitEthernet 0/20)# exit
DeviceB(cfg)# interface GigabitEthernet 0/22
DeviceB(cfg-if-GigabitEthernet 0/22)# switch-port access vlan 102
DeviceB(cfg-if-GigabitEthernet 0/22)# exit
DeviceB(cfg)# ipv6 router-protocol ospf 4949
DeviceB(cfg-router)# exit
```

(2) Enable multicast routing and PIM-SM related functions on Device A.

```
DeviceA(cfg)# ipv6 mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface vlan 104
DeviceA(cfg-if-VLAN 104)# ipv6 pim sparse-mode
DeviceA(cfg-if-VLAN 104)# exit
DeviceA(cfg)# ipv6 pim c-bsr GigabitEthernet 0/47
DeviceA(cfg)# ipv6 pim c-rp GigabitEthernet 0/47
```

(3) Enable MLD snooping and run the IVGL mode on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6 mld snooping-mode svgl
```

(4) Configure the multicast groups associated with the MLD snooping SVGL mode on Device B and specify the shared VLAN.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6 mld group-profile 1
DeviceB(cfg-profile)# permit
DeviceB(cfg-profile)# range ff13::1 ff14::fff
DeviceB(cfg-profile)# exit
DeviceB(cfg)# ipv6 mld snooping-mode svgl group-profile 1
DeviceB(cfg)# ipv6 mld snooping-mode svgl shared-vlan 104
```

5. Verification

Send packets from the multicast source (1012::2) to multicast group G (FF14::10). Enable Host A, Host B, and Host C to join G.

Run the **display ipv6 mld-info snooping gda-table** command on Device B to display the MLD snooping forwarding entry and check whether the member port list contains GigabitEthernet 0/19, GigabitEthernet 0/20, and GigabitEthernet 0/22.

```
DeviceB# display ipv6 mld-info snooping gda-table
Multicast Switching Cache Table
   D: DYNAMIC
   S: STATIC
   M: MROUTE
(*, FF14::10, 104):
   VLAN(104) 1 OPORTS:
      GigabitEthernet 0/18(M)

   VLAN(101) 1 OPORTS:
      GigabitEthernet 0/20(D)

   VLAN(103) 1 OPORTS:
      GigabitEthernet 0/19(D)

   VLAN(102) 1 OPORTS:
      GigabitEthernet 0/22(D)
```

Run the **display ipv6 mld-info snooping** command on Device B and check whether the MLD snooping working mode is SVGL.

```
DeviceB# display ipv6 mld-info snooping
MLD-snooping mode: SVGL
SVGL vlan: 104
SVGL profile number: 1
Source port check: Disable
MLD Fast-Leave: Disable
MLD Report suppress: Disable
Query Max Response Time: 10 (Seconds)
Dynamic Mroute Aging Time: 300(Seconds)
Dynamic Host Aging Time: 260(Seconds)
MLD Snooping version: 1
MLD Tunnel: Disable
```

6. Configuration Files

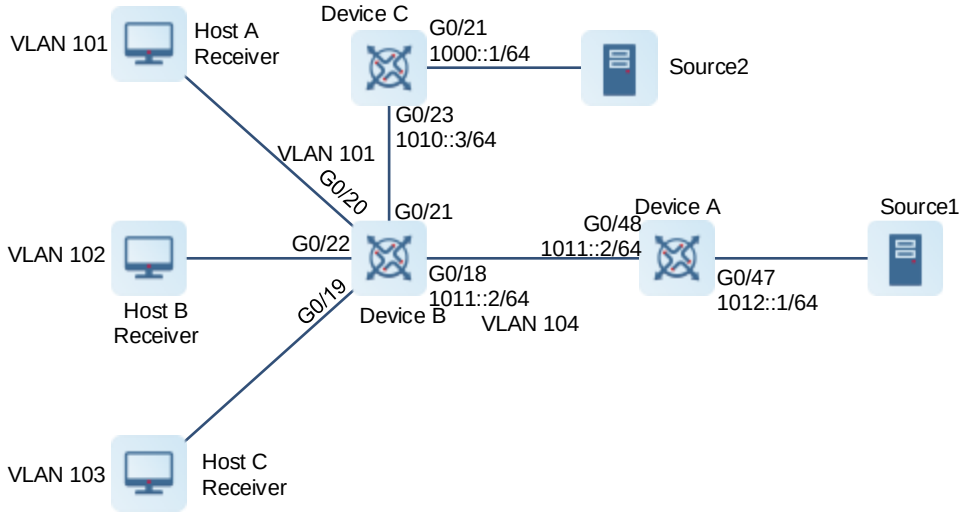
7. Common Errors

- The multicast groups associated with the SVGL mode are not configured.
- The address of the sent multicast traffic is not within the range of multicast groups associated with the SVGL mode.



1.8.3 Configuring Basic MLD Snooping Functions in IVGL-SVGL Mode

1. Requirements

In the multicast network shown in Figure 1-7, the routers (Device A and Device C) connect to the user network through the switch (Device B), MLD snooping is run on Device A and Device C, and Device A and Device C directly connect to the multicast sources. Multicast source 1 sends data to multicast group FF14::10, and multicast source 2 sends data to multicast group FF15::11. Host A, Host B, and Host C are connected to VLAN 101, VLAN 102, and VLAN 103, respectively. Host B and Host C join multicast group FF14::10, and Host A joins multicast groups FF14::10 and FF15::11. Host B and Host C can receive multicast data that source 1 sends to multicast group FF14::10, and Host A can receive multicast data that source 1 sends to multicast group FF14::10 and multicast data that source 2 sends to multicast group FF15::11. Host A, Host B, and Host C enjoy shared multicast services, and Host A also enjoy independent multicast services.

2. Topology

Figure 1-7 Topology of Basic MLD Snooping Functions in IVGL-SVGL Mode

3. Notes

Configure basic MLD snooping functions in IVGL-SVGL mode on Device B.

- Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and PIM-SMv6 related functions on Device A and Device C.
- Enable MLD snooping and run the IVGL-SVGL mode on Device B.
- Configure the multicast groups associated with the MLD snooping SVGL mode on Device B and specify the shared VLAN and sub VLANs.

4. Procedure

(1) Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IPv6 address and unicast routing protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 address 1012::1/64
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# vlan 104
DeviceA(cfg)# interface vlan 104
DeviceA(cfg-if-VLAN 104)# ipv6 address 1011::2/64
DeviceA(cfg-if-VLAN 104)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-VLAN 104)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
```

```
DeviceA(cfg-if-GigabitEthernet 0/48)# switch-port mode trunk
DeviceA(cfg-if-GigabitEthernet 0/48)# switch-port trunk native vlan 104
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# ipv6 router-protocol ospf 4949
DeviceA(cfg-router)# exit
```

Configure the IPv6 address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# vlan range 101-104
DeviceB(cfg-vlan-range)# exit
DeviceB(cfg)# interface VLAN 101
DeviceB(cfg-if-VLAN 101)# ipv6 address 1010::1/64
DeviceB(cfg-if-VLAN 101)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-VLAN 101)# exit
DeviceB(cfg)# interface VLAN 102
DeviceB(cfg-if-VLAN 102)# ipv6 address 1020::1/64
DeviceB(cfg-if-VLAN 102)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-VLAN 102)# exit
DeviceB(cfg)# interface VLAN 103
DeviceB(cfg-if-VLAN 103)# ipv6 address 1030::1/64
DeviceB(cfg-if-VLAN 103)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-VLAN 103)# exit
DeviceB(cfg)# interface VLAN 104
DeviceB(cfg-if-VLAN 104)# ipv6 address 1011::2/64
DeviceB(cfg-if-VLAN 104)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-VLAN 104)# exit
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port mode trunk
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port trunk native vlan 104
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# interface GigabitEthernet 0/19
DeviceB(cfg-if-GigabitEthernet 0/19)# switch-port access vlan 103
DeviceB(cfg-if-GigabitEthernet 0/19)# exit
DeviceB(cfg)# interface GigabitEthernet 0/20
DeviceB(cfg-if-GigabitEthernet 0/20)# switch-port access vlan 101
DeviceB(cfg-if-GigabitEthernet 0/20)# exit
DeviceB(cfg)# interface GigabitEthernet 0/21
DeviceB(cfg-if-GigabitEthernet 0/21)# switch-port access vlan 101
DeviceB(cfg-if-GigabitEthernet 0/21)# exit
DeviceB(cfg)# interface GigabitEthernet 0/22
DeviceB(cfg-if-GigabitEthernet 0/22)# switch-port access vlan 102
DeviceB(cfg-if-GigabitEthernet 0/22)# exit
DeviceB(cfg)# ipv6 router-protocol ospf 4949
DeviceB(cfg-router)# exit
```

Configure the IPv6 address and unicast routing protocol on Device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 address 1000::1/64
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface GigabitEthernet 0/23
DeviceC(cfg-if-GigabitEthernet 0/23)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/23)# ipv6 address 1010::3/64
DeviceC(cfg-if-GigabitEthernet 0/23)# ipv6 ospf 4949 set-area 0
DeviceC(cfg-if-GigabitEthernet 0/23)# exit
DeviceC(cfg)# ipv6 router-protocol ospf 4949
DeviceC(cfg-router)# exit
```

(2) Enable IPv6 multicast routing and PIM-SMv6 related functions on Device A and Device C.

Enable IPv6 multicast routing and PIM-SMv6 related functions on Device A.

```
DeviceA(cfg)# ipv6 mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface vlan 104
DeviceA(cfg-if-VLAN 104)# ipv6 pim sparse-mode
DeviceA(cfg-if-VLAN 104)# exit
DeviceA(cfg)# ipv6 pim c-bsr GigabitEthernet 0/47
DeviceA(cfg)# ipv6 pim c-rp GigabitEthernet 0/47
```

Enable multicast routing and PIM-SMv6 related functions on Device C.

```
DeviceC(cfg)# ipv6 mrouting-enable
DeviceC(cfg)# interface GigabitEthernet 0/21
DeviceC(cfg-if-GigabitEthernet 0/21)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/21)# exit
DeviceC(cfg)# interface GigabitEthernet 0/23
DeviceC(cfg-if-GigabitEthernet 0/23)# ipv6 pim sparse-mode
DeviceC(cfg-if-GigabitEthernet 0/23)# exit
```

(3) Enable MLD snooping and run the IVGL-SVGL mode on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6 mld snooping-mode ivgl-svgl
```

(4) Configure the multicast groups associated with the MLD snooping SVGL mode on Device B and specify the shared VLAN.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6 mld group-profile 1
DeviceB(cfg-profile)# permit
```

```
DeviceB(cfg-profile)# range ff13::1 ff14::fff
DeviceB(cfg-profile)# exit
DeviceB(cfg)# ipv6 mld snooping-mode svgl group-profile 1
DeviceB(cfg)# ipv6 mld snooping-mode svgl shared-vlan 104
```

5. Verification

Run the **display ipv6 mld-info snooping gda-table** command on Device B to display the MLD snooping forwarding entries and check whether the member port list of entry (*, FF14::10, 104) contains GigabitEthernet 0/22, GigabitEthernet 0/20, and GigabitEthernet 0/19 and the member port list of entry (*, FF15::11, 101) contains GigabitEthernet 0/20.

```
DeviceB# display ipv6 mld-info snooping gda-table
Multicast Switching Cache Table
  D: DYNAMIC
  S: STATIC
  M: MROUTE
(*, FF15::11, 101):
  VLAN(101) 2 OPORTS:
    GigabitEthernet 0/20(D)
    GigabitEthernet 0/21(M)

(*, FF14::10, 104):
  VLAN(104) 1 OPORTS:
    GigabitEthernet 0/18(M)

  VLAN(103) 1 OPORTS:
    GigabitEthernet 0/19(D)

  VLAN(102) 1 OPORTS:
    GigabitEthernet 0/22(D)

  VLAN(101) 1 OPORTS:
    GigabitEthernet 0/20(D)
```

Run the **display ipv6 mld-info snooping** command on Device B and check whether the MLD snooping working mode is IVGL-SVGL.

```
DeviceB# display ipv6 mld-info snooping
MLD-snooping mode: IVGL-SVGL
SVGL vlan: 104
SVGL profile number: 1
Source port check: Disable
MLD Fast-Leave: Disable
MLD Report suppress: Disable
Query Max Response Time: 10 (Seconds)
Dynamic Mroute Aging Time: 300(Seconds)
Dynamic Host Aging Time: 260(Seconds)
```

```

 graceful-restart
!
```

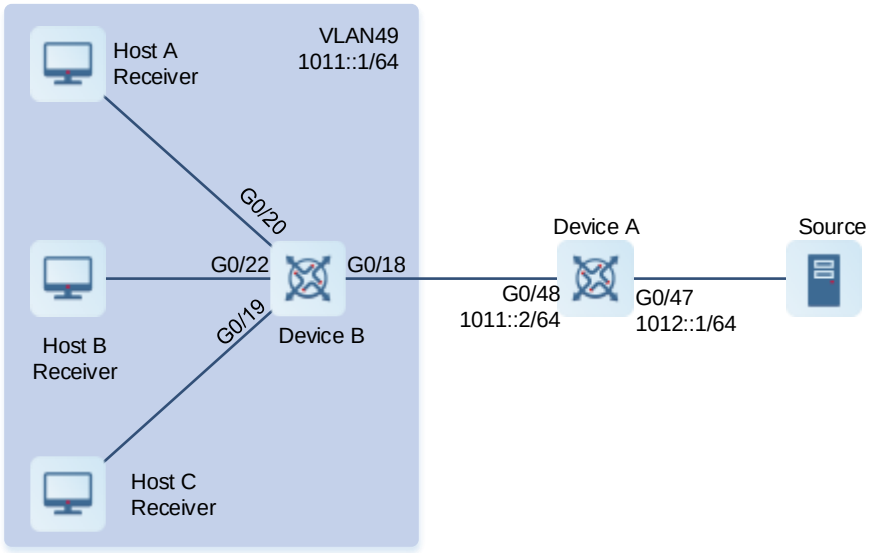
7. Common Errors

- The multicast groups associated with the SVGL mode are not configured.
- The address of sent multicast traffic is not within the range of multicast groups associated with the SVGL

mode.

- The multicast group addresses of multicast traffic in IVGL mode are within the multicast group range in SVGL mode. As a result, IVGL forwarding cannot be implemented.



1.8.4 Configuring Static Ports to Implement L2 Multicast

1. Requirements

In the multicast network shown in Figure 1-8, Host A, Host B, and Host C need to receive data that a multicast source sends to a specific multicast group stably. The router (Device A) connects to the user network through the L2 device (Device B). The static MLD multicast groups FF14::10 to FF14::12 are configured on the user-side port on Device A. Host A and Host B want to receive data of multicast group FF14::10 stably, and Host C wants to receive data of multicast group FF14::11.

2. Topology

Figure 1-8 Topology of Static Ports to Implement L2 Multicast

3. Notes

Configure MLD snooping static multicast router ports and member ports on Device B.

- Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and MLD static multicast groups on Device A.
- Enable MLD snooping on Device B.
- Configure static multicast router ports and member ports on Device B.

4. Procedure

(1) Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IPv6 address and unicast routing protocol on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 address 1012::1/64
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/48)# ipv6 address 1011::2/64
DeviceA(cfg-if-GigabitEthernet 0/48)# ipv6 ospf 4949 set-area 0
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# ipv6 router-protocol ospf 4949
DeviceA(cfg-router)# exit
```

Configure the IPv6 address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# vlan 49
DeviceB(cfg-vlan)# exit
DeviceB(cfg)# interface vlan 49
DeviceB(cfg-if-VLAN 49)# ipv6 address 1011::1/64
DeviceB(cfg-if-VLAN 49)# ipv6 ospf 4949 set-area 0
DeviceB(cfg-if-VLAN 49)# exit
DeviceB(cfg)# interface GigabitEthernet 0/18
DeviceB(cfg-if-GigabitEthernet 0/18)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/18)# exit
DeviceB(cfg)# interface GigabitEthernet 0/19
DeviceB(cfg-if-GigabitEthernet 0/19)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/19)# exit
DeviceB(cfg)# interface GigabitEthernet 0/20
DeviceB(cfg-if-GigabitEthernet 0/20)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/20)# exit
DeviceB(cfg)# interface GigabitEthernet 0/22
DeviceB(cfg-if-GigabitEthernet 0/22)# switch-port access vlan 49
DeviceB(cfg-if-GigabitEthernet 0/22)# exit
DeviceB(cfg)# ipv6 router-protocol ospf 4949
DeviceB(cfg-router)# exit
```

(2) Enable IPv6 multicast routing and PIM-SMv6 related functions on Device A.

```
DeviceA(cfg)# ipv6 mrouting-enable
DeviceA(cfg)# interface GigabitEthernet 0/47
DeviceA(cfg-if-GigabitEthernet 0/47)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/47)# exit
DeviceA(cfg)# interface GigabitEthernet 0/48
DeviceA(cfg-if-GigabitEthernet 0/48)# ipv6 mld static-group-entries ff14::10
DeviceA(cfg-if-GigabitEthernet 0/48)# ipv6 mld static-group-entries ff14::11
```

```
DeviceA(cfg-if-GigabitEthernet 0/48)# ipv6 mld static-group-entries ff14::12
DeviceA(cfg-if-GigabitEthernet 0/48)# ipv6 pim sparse-mode
DeviceA(cfg-if-GigabitEthernet 0/48)# exit
DeviceA(cfg)# ipv6 pim c-bsr GigabitEthernet 0/47
DeviceA(cfg)# ipv6 pim c-rp GigabitEthernet 0/47
```

(3) Enable MLD snooping functions on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6 mld snooping-mode ivgl
```

(4) Configure static multicast router ports and member ports on Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ipv6 mld snooping-mode vlan 49 static-member ff14::11 interface GigabitEthernet 0/19
DeviceB(cfg)# ipv6 mld snooping-mode vlan 49 static-member ff14::10 interface GigabitEthernet 0/22
DeviceB(cfg)# ipv6 mld snooping-mode vlan 49 static-member ff14::10 interface GigabitEthernet 0/20
DeviceB(cfg)# ipv6 mld snooping-mode vlan 49 multicast-router interface GigabitEthernet 0/18
```

5. Verification

Run the **display ipv6 mld-info snooping multicast-router** command and check whether the static router port is GigabitEthernet 0/18.

```
DeviceB# display ipv6 mld-info snooping multicast-router
Multicast Switching Mroute Port
  D: DYNAMIC
  S: STATIC
(*, *, 49):
  VLAN(49)   1 MROUTES:
    GigabitEthernet 0/18(DS)

(*, *, 101):
  VLAN(101)   1 MROUTES:
    GigabitEthernet 0/21(D)
```

Run the **display ipv6 mld-info snooping gda-table** command and check whether the static member ports of multicast group FF14::10 are GigabitEthernet 0/20 and GigabitEthernet 0/22 and the static member port of multicast group FF14::11 is GigabitEthernet 0/19.

```
DeviceB# display ipv6 mld-info snooping gda-table
Multicast Switching Cache Table
  D: DYNAMIC
  S: STATIC
  M: MROUTE
(*, FF14::10, 49):
  VLAN(49) 3 OPORTS:
    GigabitEthernet 0/18(M)
    GigabitEthernet 0/20(S)
```

```
      GigabitEthernet 0/22(S)

(*, FF14::11, 49):
   VLAN(49) 2 OPORTS:
      GigabitEthernet 0/18(M)
      GigabitEthernet 0/19(S)
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ipv6 mrouting-enable
!
interface GigabitEthernet0/47
 unset switch-port
 ipv6 address 1012::1/64
 ipv6 ospf 4949 set-area 0
 ipv6 pim sparse-mode
!
interface GigabitEthernet0/48
 unset switch-port
 ipv6 address 1011::2/64
 ipv6 ospf 4949 set-area 0
 ipv6 mld static-group-entries ff14::10
 ipv6 mld static-group-entries ff14::11
 ipv6 mld static-group-entries ff14::12
 ipv6 pim sparse-mode
!
Ipv6 router-protocol ospf 4949
 graceful-restart
!
ipv6 pim c-bsr GigabitEthernet 0/47
ipv6 pim c-rp GigabitEthernet 0/47
!
```

- Device B configuration file

```
hostname DeviceB
!
vlan range 1,49
!
interface GigabitEthernet 0/18
 switch-port access vlan 49
!
interface GigabitEthernet 0/19
 switch-port access vlan 49
```

```
!
interface GigabitEthernet 0/20
 switch-port access vlan 49
!
interface GigabitEthernet 0/22
 switch-port access vlan 49
!
interface VLAN 49
 ipv6 address 1011::1/64
 ipv6 ospf 4949 set-area 0
!
router-protocol ospf 49
 graceful-restart
!
ipv6 mld snooping-mode ivgl
!
ipv6 mld snooping-mode vlan 49 static-member FF14::11 interface GigabitEthernet 0/19
ipv6 mld snooping-mode vlan 49 static-member FF14::10 interface GigabitEthernet 0/22
ipv6 mld snooping-mode vlan 49 static-member FF14::10 interface GigabitEthernet 0/20
ipv6 mld snooping-mode vlan 49 multicast-router interface GigabitEthernet 0/18
!
```

7. Common Errors

- Basic MLD snooping functions are not configured or fail to be configured.

1 Configuring ACL

1.1 Introduction

1.1.1 Overview

The access control list (ACL) is also called access list or packet filtering in some documents. An ACL defines a series of "permit" or "deny" rule statements, and applies these rules to a device interface to control the data packets entering/leaving the interface, so as to improve the security of network devices.

Configuring ACL can guarantee network security, reliability, and stability, for example:

- Preventing packet attacks: An ACL can be configured to deny the attacks launched using the Internet Protocol (IP), Transmission Control Protocol (TCP), or Internet Control Message Protocol (ICMP) packets.
- Controlling network access: An ACL can be configured to restrict users to some services, for example, users are allowed to access only the WWW and email services, but not allowed to access other services such as telnet; some users are allowed to access services only within a given time period, or only certain hosts are allowed to access the network.
- Controlling network traffic: An ACL can be used together with quality of service (QoS) to guarantee prioritized services for some important data flows. For QoS configuration, see *Configuring QoS*.

1.1.2 Principles

1. Basic Concepts

- ACL

ACLs are classified into basic ACLs and dynamic ACLs.

Users can select a basic ACL or a dynamic ACL as needed. In general, a basic ACL can meet security requirements. However, attackers may counterfeit source addresses by using some software to spoof devices and access the network. Before users access the network, the dynamic ACL requires them to pass identity authentication, which makes it hard for attackers to access the network. Therefore, the dynamic ACL can be used in some sensitive areas to ensure network security.

Note

Spoofing devices by counterfeiting source addresses, namely, spoofing, is an inherent problem of all ACLs. Spoofing also occur on the dynamic ACL: Attackers may fake users' addresses to access the network during the effective access period after the users pass the identity authentication. This problem can be solved in two ways. One is to set shorter idle time of user access. The other is to use the IP Security (IPSec) encryption protocol to encrypt the network data, and ensure that all the data is encrypted when the data is transmitted to a device.

The ACL is generally configured on the following network devices:

- A device between an internal network and an external network (such as the Internet)

A device at the boundary of two networks

- A device connecting to a control port

- ACE

  An access control entry (ACE) is a statement containing the "permit" or "deny" action and filtering rules. Each ACE has a sequence number, which is automatically allocated by the device or manually configured. An ACL contains one or more ACEs. The ACL identifies and filters packets by using ACEs.

  The sequence of ACEs in an ACL determines the matching priority of the ACEs in the ACL. When processing packets, a network device performs rule matching in the ascending order of ACE sequence numbers. When finding a matched ACE, the network device stops matching subsequent ACEs.

  For example, create ACE 10 to deny all data flows.

```
10 deny ip any any
20 permit tcp 192.168.12.0 0.0.0.255 eq telnet any
```

  Since ACE 10 denies all the IP packets, the telnet packet from the host in the 192.168.12.0/24 network is denied even if it matches ACE 20. The reason is that, after finding that the packet matches the first ACE 10, the device stops matching the packet with the subsequent ACE 20.

  Here is another example: Create ACE 10 to permit all IPv6 data flows to pass through.

```
10 permit ipv6 any any
20 deny ipv6 host 200::1 any
```

  Since ACE 10 permits all IPv6 packets to pass through, the IPv6 packet sent from the host with IP address 200::1 can pass through even if it matches ACE 20. The reason is that, after finding that the packet matches the first ACE, the device stops matching the packet with the subsequent ACE 20.

- Step

  When the device automatically allocates sequence numbers to ACEs, the difference between two adjacent ACE sequence numbers is called a step. For example, if the step is set to 5, the device automatically allocates sequence numbers to ACEs in the ascending order of 5, 10, 15.... See the example below.

```
5 deny ip any any
10 permit tcp 192.168.12.0 0.0.0.255 eq telnet any
```

  After the step is changed, the ACE sequence numbers will be automatically rearranged based on the new step value. For example, when the step is changed to 10, the original ACE sequence numbers are changed from 5, 10, and 15 to 5, 15, and 25.

  A new ACE can be inserted between two ACEs by changing the step. For example, four ACEs are created, and the ACEs are manually numbered 1, 2, 3, and 4 in turn. To insert a new ACE after ACE 1, first change the step to 2 (then, the sequence numbers of the original four ACEs automatically change to 1, 3, 5, and 7), and then insert a manually configured ACE with sequence number 2.

- Filter field template

  Filter fields mean the fields used to identify and classify packets when an ACE is generated. A filter field template is a combination of such fields. An ACE identifies Ethernet packets by some fields in them, including:

  Layer 2 fields:

  - 48-bit source MAC address (the 48-bit source MAC address must be matched completely)
  - 48-bit destination MAC address (the 48-bit destination MAC address must be matched completely)

- 16-bit Layer 2 type field

Layer 3 fields:

- Source IP address field (all the source IP address values can be matched or a subnet can be used to define a type of flow)
- Destination IP address field (all the destination IP address values can be matched or a subnet can be used to define a type of flow)
- Protocol type field

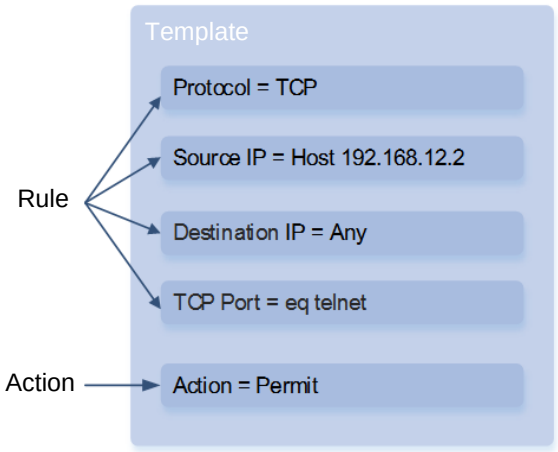
Layer 4 fields:

- You can define a TCP source port, destination port, or both for matching; you can also define the range of the source port or destination port for matching.
- You can define a User Datagram Protocol (UDP) source port, destination port, or both for matching; you can also define the range of the source port or destination port for matching.

For example, you can create an ACE to identify and classify packets based on their destination IP address field. You can also create another ACE to identify and classify packets based on their source IP address field and UDP source port field. These two ACEs use different filter field templates.

- Rules

Rules refer to the values of fields in an ACE filter field template. For example, an ACE reads as follows:



```
10 permit tcp host 192.168.12.2 any eq telnet
```

In this ACE, the filter field template is a collection of the following fields: source IP address field, destination IP address field, IP protocol field, and TCP destination port field. The corresponding values (namely, rules) are as follows: The source IP address is **Host 192.168.12.2**, the destination IP address is **Any** (namely, all the hosts), the IP protocol is **TCP**, and the TCP destination port is **Telnet**. See Figure 1-1.

- Action

Action is specified in ACE. The actions include permit and deny. Permit means that the traffic matching the rules can pass, and deny means that the traffic matching the rules is rejected.

Figure 1-1 Analysis of ACE: permit tcp host 192.168.12.2 any eq telnet

Note

- A filter field template can be a collection of Layer 3 fields and Layer 4 fields, or a collection of multiple Layer 2 fields. However, the filter field templates of the standard and extended ACLs cannot be a collection of Layer 2 and Layer 3 fields, or Layer 2 and Layer 4 fields, or Layer 2, Layer 3, and Layer 4 fields. To use a collection of Layer 2, Layer 3, and Layer 4 fields, you can use an expert extended ACL.
- Outbound ACLs to be associated with switch virtual interfaces (SVIs) can be IP standard, IP extended, MAC extended, or expert ACLs.
- If a destination MAC address is configured for matching in MAC extended and expert ACLs and such ACLs are applied in the outbound direction of an SVI, the ACEs containing the destination MAC address can be configured but fail to take effect. If you configure a destination IP address for matching in the IP extended and expert ACLs but the destination IP address is not within the subnet IP address range of the associated SVI, the configured ACLs do not take effect. For example, if VLAN 1 has an IP address 192.168.64.1 255.255.255.0 and an IP extended ACL is created, with the ACE **deny udp any 192.168.65.1 0.0.0.255 eq 255**, this ACL does not take effect when it is applied to the egress of VLAN 1. The cause is that the destination IP address is not within the subnet IP address range of VLAN 1. If the ACE is **deny udp any 192.168.64.1 0.0.0.255 eq 255**, the ACL takes effect because the destination IP address complies with the requirements.
- ACL resources (ternary content addressable memory (TCAM), keys, port groups, and ranges) are dynamically allocated resources. When services are delivered, the policy resource integration module allocates ACL resources based on the current status. ACL resources are first allocated to services accessed first. If ACL resources are insufficient for later accessed services, an ACL resource allocation failure occurs and a syslog error message is displayed. When data synchronization is triggered by device restart, hot swapping, or process restart, services may not be synchronized in their original time sequence. As a result, due to different time sequences of the services, no ACL resources are not allocated to services that should have ACL resources allocated. In this case, a syslog error message is displayed indicating insufficient ACL resources. You can delete related configuration to avoid data inconsistency.

Specification

- The outbound ACL acting on the physical port and Layer 3 aggregation port (AP) only supports matching well-known packets (unicast and multicast), but does not support matching unknown unicast packets, that is, the outbound ACL configured on a port does not take effect for the unknown packets or broadcast packets.
- When the input ACL, IEEE 802.1x, global IP and MAC address binding, port security, and IP source guard are all configured, the permit and default deny ACEs do not take effect but other deny ACEs take effect normally.
- When the input ACL and QoS are configured, the permit ACE does not take effect, but other deny ACEs take effect normally; the default deny ACE takes effect after the QoS entry.
- If an ACE is added to an ACL after the ACL is applied to the inbound direction of multiple SVIs, and the device is restarted after the configuration is saved, the ACLs configured on several SVIs may fail to take effect due to the hardware capacity causes.

Note

- When an expert ACL is configured and applied to the outbound direction of a port, if some ACEs in the ACL contain Layer 3 matching information (such as IP address and Layer 4 port), the non-IP packets received by the port cannot be subjected to the permit and deny ACEs of the ACL.
- When ACLs are applied, if an ACE in the ACLs (including the IP ACL and expert extended ACL) contains non-Layer 2 fields for matching (such as source IP (SIP) and destination IP (DIP)), the ACLs are ineffective for the tagged multiprotocol label switching (MPLS) packets.

2. IP ACL

IP ACL implements refined control over the IPv4 packets entering/leaving the device. You can deny or permit specific IPv4 packets destined to a network according to the actual needs, so as to control the access of IP users to network resources.

You can define a series of access rules in an IP ACL, and apply the ACL to the inbound or outbound direction of a port. You can also apply an IP ACL globally. When IPv4 packets enter or leave a device, the device determines whether to forward or block them by judging whether they match the rules.

To configure an IP ACL on a device, you must specify a unique name or number for each ACL to uniquely identify the ACL.

IP ACLs are classified into IP standard ACLs and IP extended ACLs. Table 1-1 lists the ranges of numbers that can be used for IP standard ACLs and IP extended ACLs.

Table 1-1 Number Ranges for IP Standard ACLs and IP Extended ACLs

Type	Number Range	Matching Field
IP standard ACL	1 to 99, 1300 to 1999	Source IP address
IP extended ACL	100 to 199, 2000 to 2699	● Source IP address ● Destination IP address ● IP protocol number ● Layer 4 source port ID or ICMP type ● Layer 4 destination port ID or ICMP code

The IP standard ACL controls the forwarding or blocking of packets based on the source IP address. The IP extended ACL controls the forwarding or blocking of packets by combining the matching fields in the table above.

A single ACL can use multiple independent ACL statements to define multiple rules, and all the statements use the same number or name so that the statements are bound to the same ACL.

Note

The ICMP code matching field in ACL rules is invalid for the ICMP packets with ICMP type 3. If the code field for matching ICMP packets is configured in an ACL rule, when ACL matching is performed on the ICMP packets with type 3 on the routers, the matching result may be different from the expected result.

One rule statement of denying all data flows is hidden at the end of each IP ACL. If a packet fails to match any rules, it will be denied. For example:

```
access-control-list 1 permit host 192.168.4.12
```

This ACL only permits the packets with source host address 192.168.4.12 to pass through, and denies the packets of the other hosts. The reason is that this ACL contains a rule statement at its end as follows:

```
access-control-list 1 deny any
```

Here is another example:

```
access-control-list 1 deny host 192.168.4.12
```

If an ACL contains the above statement only, the packets of all the hosts are denied wen passing through the port.

Caution

When defining an ACL, you must consider the route update packets. The rule statement of denying all data flows at the end of the ACL may result in blocking of all the route update packets.

The reflexive ACL automatically generates a temporary ACL according to the Layer 3 and Layer 4 information of the traffic originated from the internal network. A temporary ACL is created according to the following principles: The IP protocol number remains unchanged, the source IP address and destination IP address are strictly interchanged, and the TCP/UDP source port and destination port are strictly interchanged Only when the Layer 3 and Layer 4 information of the returned traffic strictly matches that in the temporary ACL previously created based on the outbound traffic, will the device permit the traffic to enter the internal network.

3. MAC Extended ACL

The MAC extended ACL implements refined control over the packets entering/leaving the device based on the Layer 2 information of the packets. You can deny or permit specific Layer 2 packets destined to a network according to the actual needs, so as to protect network resources against attacks or control the access of users to network resources.

You can define a series of access rules in a MAC extended ACL, and apply the ACL to the inbound or outbound direction of a port. When packets enter or leave a device, the device determines whether to forward or block them by judging whether they match the rules.

To configure a MAC extended ACL on a device, you must specify a unique name or number for each ACL to uniquely identify the ACL. Table 1-2 lists the range of numbers for the MAC extended ACLs.

Table 1-2 Number Range for MAC Extended ACLs

Type	Number Range	Matching Field
MAC extended ACL	700 to 799	● Source MAC address ● Destination MAC address ● Ethernet protocol type

The MAC extended ACL controls the forwarding or blocking of packets based on the source or destination MAC address and the Ethernet type of packets.

A single MAC extended ACL can use multiple independent ACL statements to define multiple rules, and all the statements use the same number or name so that the statements are bound to the same ACL.

Note

If a MAC extended ACL rule does not specify IPv6 packets, that is, the Ethernet type field is not defined or the defined Ethernet type field value is not 0x86dd, then the MAC extended ACL is not used to match IPv6 packets. If you need to match IPv6 packets, define an IPv6 ACL.

One rule statement of denying all data flows is hidden at the end of each MAC extended ACL. If a packet fails to match any rules, it will be denied. For example:

```
access-control-list 700 permit host 00d0.f800.0001 any
```

This ACL permits only the packets sent from the host with MAC address 00d0.f800.0001 to pass through, and denies the packets from all the other hosts. The reason is that this ACL contains a rule statement at its end as follows:

```
access-control-list 700 deny any any
```

4. Expert Extended ACL

An expert extended ACL implements refined control over the packets entering/leaving a device based on the Layer 2 and Layer 3 information of the packets. The expert extended ACL can be regarded as a combination and enhancement of the IP ACL and MAC extended ACL. An expert extended ACL can contain IP ACL rules and MAC extended ACL rules, and specify VLAN IDs for packet matching.

You can define a series of access rules in an expert extended ACL, and apply the ACL to the inbound or outbound direction of a port. When packets enter or leave a device, the device determines whether to forward or block them by judging whether they match the access rules.

To configure an expert extended ACL on a device, you must specify a unique name or number for each ACL to uniquely identify the ACL. Table 1-3 lists the range of numbers that can be used for expert extended ACLs.

Table 1-3 Number Range for Expert Extended ACLs

Type	Number Range	Matching Field
Expert extended ACL	2700 to 2899	● Source IP address ● Destination IP address ● IP protocol number ● Layer 4 source port ID or ICMP type ● Layer 4 destination port ID or ICMP code ● Source MAC address ● Destination MAC address ● Ethernet protocol type ● VLAN ID

The expert extended ACL controls the forwarding or blocking of packets by combining the matching fields in the table above.

A single expert extended ACL can use multiple independent ACL statements to define multiple rules, and all the statements must use the same number or name so that the statements are bound to the same ACL.

Note

If an expert extended ACL rule does not specify IPv6 packets, that is, the Ethernet type field is not defined or the defined Ethernet type field is not 0x86dd, then the expert extended ACL does not match IPv6 packets. If you need to match IPv6 packets, define an IPv6 ACL.

Specification

- The virtual extensible LAN (VXLAN) field in an expert extended ACL used for a data center product is used to match the inner packets of VXLAN. Therefore, you can apply an expert extended ACL in VXLAN mode to match the inner IP field of VXLAN.
- When a device needs to match VXLAN packets, you can specify the destination port ID of the VXLAN protocol to confirm VXLAN packets. You can also specify whether matched VXLAN packets carry tags. The **ip-flag** and **dscp** fields of VXLAN packets can be matched against ACLs

Specification

The UDF option in an expert extended ACL used for a data center product is a user-defined offset field for matching, in which users need to specify the protocol layer, offset value, data, and mask to be matched.

Note

The MPLS option in an expert extended ACL used for a data center product can provide the matching rules for the IPv4 field and tag field contained in MPLS packets.

One rule statement of denying all data flows is hidden at the end of each expert extended ACL. If a packet fails to match any rules, it will be denied. For example:

```
access-control-list 2700 permit 0x0806 any any any any any
```

This ACL only permits the packets with Ethernet type 0x0806 (namely, ARP) to pass through, and denies the packets of the other types. The reason is that this ACL contains a rule statement at its end as follows:

```
access-control-list 2700 deny any any any any
```

5. IPv6 ACL

The IPv6 ACL implements refined control over the IPv6 packets entering/leaving a device. You can deny or permit specific IPv6 packets destined to a network according to the actual needs, so as to control the access of IPv6 users to network resources.

You can define a series of access rules in an IPv6 ACL, and apply the ACL to the inbound or outbound direction of a port. When IPv6 packets enter or leave a device, the device determines whether to forward or block them by judging whether they match the rules.

To configure an ACL on a device, you must specify a unique name for the ACL of a protocol.

One rule statement of denying all IPv6 data flows is hidden at the end of each IPv6 ACL. If a packet fails to match any rules, it is denied. For example:

```
ipv6 access-control-list ipv6_acl
 10 permit ipv6 host 200::1 any
```

This ACL only permits the IPv6 packets coming from source host 200::1 to pass through, and denies the IPv6 packets from all the other hosts. The reason is that this ACL contains a rule statement at its end as follows:

```
deny ipv6 any any
```

6. ACL80

ACL80 is the expert advanced ACL, also known as user-defined ACL. ACL80 supports matching the specified bytes in the first 80 bytes of a packet by bit.

There are three elements in ACL80 matching: matching field content, matching field mask, and the start position (that is, the offset) of matching. The bits of the matching field content map to those of the matching field mask. The matching field content specifies the field value to be matched, and the matching field mask specifies whether the corresponding bits need to be matched. When a bit needs to be matched, the corresponding bit in the matching field mask must be set to **1**. If a bit in a matching field mask is set to **0**, the corresponding bit in the matching field content will not be matched regardless of the bit value in the matching field content. For example:

```
10 permit 00d0f8123456 ffffffffffff 0
20 deny 00d0f8654321 ffffffffffff 6
```

In ACE 10, the matching field content is 00d0f8123456, the matching field mask is ffffffffffff, and the offset is 0. This rule indicates that, if the destination MAC address of a packet is 00d0f8123456, the packet is permitted to be forwarded.

In ACE 20, the matching field content is 00d0f8654321, the matching field mask is ffffffffffff, and the offset is 6. This rule indicates that, if the source MAC address of a packet is 00d0f8654321, the packet is blocked.

You need to deeply understand the Layer 2 data frame structure so as to use the user-defined ACL correctly. Figure 1-2 shows the first 64 bytes of an Layer 2 data frame. In the figure, each letter represents one hexadecimal number and every two letters represent one byte.

Figure 1-2 First 64 Bytes of an Layer 2 Data Frame

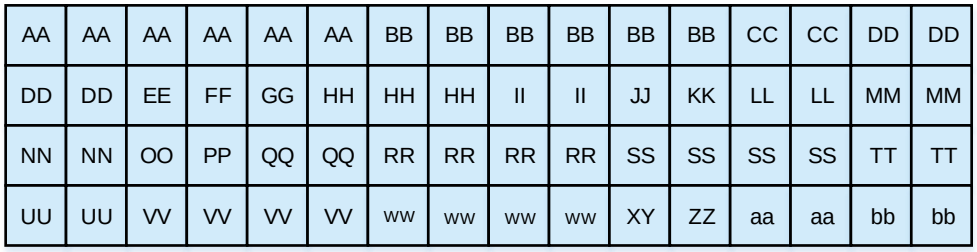


Table 1-4 lists the meaning and offset value of each letter.

Table 1-4 Meanings and Offset Values of Letters

Letter	Description	Offset	Letter	Description	Offset
A	Destination MAC address	0	O	TTL field	34
B	Source MAC address	6	P	Protocol number	35

Letter	Description	Offset	Letter	Description	Offset
C	VLAN tag field	12	Q	IP checksum	36
D	Data frame length field	16	R	Source IP address	38
E	Destination service access point (DSAP) field	18	S	Destination IP address	42
F	Source service access point (SSAP) field	19	T	TCP source port	46
G	Control field	20	U	TCP destination port	48
H	Org code field	21	V	Serial number	50
I	Encapsulated data type	24	W	Acknowledgment field	54
J	IP version No.	26	XY	IP header length and reserved bits	58
K	ToS field	27	Z	Reserved bits and flags bits	59
L	IP packet length	28	a	Windows size field	60
M	ID	30	b	Others	62
N	Flags field	32			

The offset of each field in the table is their offset in the IEEE 802.3 data frame containing the SNAP+Tag fields. The user-defined ACL extracts specific fields from the first 80 bytes of a data frame according to offsets listed in Table 1-5, and then compare the fields with the matching field masks so as to determine the matching field content. For example, if you permit all TCP packets to be forwarded, you can set the matching field content to **06**, the matching field mask to **ff**, and the offset to **35**. Create ACE 10 as follows:

```
10 permit 06 ff 35
```

Apply the ACL to the inbound or outbound direction of a port. When a packet enters or leaves a device, ACL80 extracts the content of the TCP protocol number field from the data frame, and then compares the content with the matching field content to find out all the matched TCP packets for forwarding.

7. Redirect ACL

Redirect ACL enables a device to redirect the packets matching the rules to a specified port for forwarding. Or the device obtains and analyzes the packets in specified ports.

Redirect ACL binds an ACL on an input port and specifies an output port. When the input interface receives a packet, it queries ACL rules bound to the port one by one. If the packet conforms to the characteristics described in a rule, it is forwarded from the output port specified by the policy.

Note

- Redirect ACL takes effect only in the inbound direction of a port.
- When a global redirect ACL is configured with a destination port. The port will not be affected by the global redirect ACL.

8. Global Security ACL

There are various virus packets in the network, and the identification characteristics of virus packets are the same or similar on each port. A port-based security ACL is often configured to filter out packets that comply with some characteristics (such as forged TCP attack packets) and prevent virus packets. You can create an ACL, add ACEs that match the characteristics of various virus packets, and apply the ACL to each port of a device to filter out virus packets.

When the port-based security ACL is used in the attack-defense scenarios such as virus filtering, there are much inconvenience.

- Ports must be configured one by one. Duplicate configuration, poor operating performance, and excessive consumption of ACL resources can occur.
- The access control function of the security ACL is weakened. Because the security ACL is used for virus filtering, the basic functions of the security ACL including restricting route updates and restricting network access become unavailable.

The global security ACL can be used for global anti-virus deployment and defense without affecting the port-based security ACL. A global security ACL can take effect on all the Layer 2 ports after one command is configured.

When both the global security ACL and port-based security ACL are configured, they take effect at the same time. The packets that match rules in the global security ACL will be directly filtered out as virus packets, and the packets that fail to match the rules of the global security ACL are still controlled by the port-based security ACL. To exempt some ports from the control of the global security ACL, disable the global security ACL function on these ports. When the global, port-based, and VLAN-based security ACLs are applied at the same time, the priority is port-based security ACL, VLAN-based security ACL, and global security ACL in the descending order.

To avoid misconfiguration of the global security ACL, the global security ACL disabling function is provided. If you disable the global security ACL function and then configure a global security ACL, the system prompts a configuration failure. If you have configured a global security ACL and then disable the global security ACL function, the system deletes all the current global security ACLs and displays a log prompt.

9. SVI Router ACL

An ACL applied to an SVI (namely, SVI ACL) takes effect for both the packets forwarded on Layer 2 in a VLAN and the inter-VLAN routed packets. As a result, different users in the same VLAN cannot make normal communication. The SVI router ACL function enables the ACL applied to an SVI to take effect only for the inter-VLAN routed packets.

The SVI router ACL function is disabled by default. The SVI ACL takes effect for the inter-VLAN Layer 3 forwarded packets and the intra-VLAN packets forwarded by bridges. After the SVI router ACL function is enabled, the SVI ACL is effective only for the inter-VLAN Layer 3 forwarded packets.

10. Packet Matching Logging

The packet matching logging is used to monitor the running status of ACL rules and provide necessary information for routine network maintenance and network optimization.

To better grasp the running status of ACL in the device, when adding ACEs, you can decide whether to specify the packet matching logging option as needed. If this option is specified, the matching logs are output when

ACEs match packets. ACL prints log information based on ACE, that is, the device periodically prints the ACEs that match packets and the number of matched packets. See the example below:

```
*Sep  9 16:23:06: %ACL-6-MATCH: ACL 100 ACE 10 permit icmp any any, match 78 packets, match 1000 bytes.
```

To reasonably control the quantity and frequency of log output, ACL allows configuring the log output interval.

Caution

- An ACL rule with the log option uses more hardware resources. If all the configured rules have the log option, the hardware policy capacity of the device is halved.
- The default output interval of packet matching logs is 0 minutes, that is, no ACL matching log is output. After specifying the log option when configuring ACL rules, you also need to configure the output interval, otherwise no matching log is output.
- For a rule with the log option, if no packet matches the rule within the specified time interval, no packet matching log related to the rule is output; if a packet matches the rule within the specified time interval, the packet matching log related to the rule is output after the time interval expires. The number of matched packets is the total number of packets matching the rule within the time interval, that is, the number of matched packets from the last log output to the current log output.

Specification

- The log option can be configured for the IP ACL and IPv6 ACL rules only.

11. Packet Matching Counting

For the needs of network management, you may want to know whether an ACL rule matches packets and the number of matched packets. ACL provides the rule-based packet matching counting function. You can enable or disable the packet matching counting function for all the rules in an ACL. When a packet matches a rule, the corresponding matching count increases accordingly. You can run the statistics clearing command for an ACL to clear the packet matching counts of all rules in the ACL and start new counting.

Caution

Enabling the packet matching counting function of ACL requires more hardware entries, and in extreme cases, halves the available hardware policy capacity of the device.

Specification

For IP ACL, MAC extended ACL, expert extended ACL, and IPv6 ACL, the packet matching counting function can be configured.

12. ACL Effective Time Range

If you need to control some flows within a specified time range, for example, disable chat tools during working hours, you can configure effective time ranges for ACEs to control the pass-through time of flows. The time ranges are classified into absolute time ranges and periodic time ranges.

An absolute time range indicates the time range from the specified start time to the end time. This time range does not occur cyclically nor has a period, for example, "12:00:00 on January 1, 2000 to 12:00:00 on January 1, 2001".

A periodic time range indicates a periodic time interval, for example, "8:00 on each Monday to 17:00 on each Friday".

For the configuration of time ranges, see *Configuring Time Range*.

13. Global Control Plane Security ACL

In some application scenarios, an ACL needs to be bound to restrict the source IP host to processing the initial packets in a TCP handshake, instead of conducting restriction after a TCP connection is established. The global control plane security ACL filters packets only through software. It not only reduces the hardware resource consumption but also meets the requirement for processing the initial TCP packets. If you apply a security ACL globally by running a control plane application command, the ACL takes effect on software only.

The global control plane security ACL takes effect on all Layer 2 ports. ACEs are not applied to hardware but only to software, which reduces the hardware resource consumption. During a TCP handshake, the software ACL checks initial TCP packets and filters out the TCP packets that match the ACL.

Note

- The global control plane security ACL is effective to software-based filtering and can be applied only to the inbound direction.
- The global control plane security ACL is not limited by the configuration of global ACL excluded ports. After the excluded ports are configured, the global control plane security ACL remains effective on the excluded ports.
- The global control plane security ACL takes effect on both Layer 2 ports and Layer 3 ports. That is, it can take effect on the following types of ports: access port, trunk port, hybrid port, Layer 3 Ethernet port, Layer 2 or Layer 3 aggregation port. It does not take effect on the SVIs or member ports of aggregation ports.
- The global control plane security ACL can be associated only with the IP standard ACL.

14. ACL hit-log

To allow users to know the content of packets matching ACEs, you can enable the device to output hit-logs. The hit-logs are output based on ACEs and packets, that is, the device outputs the information and number of hit-logs periodically.

```
Feb 23 22:46:53 s6510-2: %ACLD-6-HITLOG: acl(ext_acl) ace_sn(220) Permit igmp 112.112.0.21
(HundredGigabitEthernet 0/7)->100.11.11.134, (5) packet
Feb 23 22:46:57 s6510-2: %ACLD-6-HITLOG: acl(mac_acl) ace_sn(10) Permit udp
1234:1234:1234:1234:1234:1234:1234:1404(0) (HundredGigabitEthernet 0/7)->4100::123(0), (1) packet
Feb 23 22:46:59 s6510-2: %ACLD-6-HITLOG: acl(mac_acl) ace_sn(10) Permit packet 0000.0001.0106
(HundredGigabitEthernet 0/7)->ecb9.70b2.ae1c, (480) packet
```

There are three types of source and destination addresses of hit-logs: IPv4 address, IPv6 address, and MAC address.

To control output number and frequency of hit-logs, you can specify the output interval.

Warning

ACL hit-log is implemented based on the functions on the control plane and forwarding plane. Therefore, ACL must be applied on both the control plane and forwarding plane to activate hit-log configuration.

Note

- The default output interval of hit-logs is 1s, that it, up to 10 hit-logs are output per second. To enable log output, the output interval must be specified. To disable hit-log, set the output interval to 0.
- If the ACE containing the hit-log option does not match any packets within the specified interval, no hit-log will be output. If there are matched packets, the hit-log will be output when the interval expires.
- Hit-log is supported only on the switch.

15. ACL miss-log

If the packets match ACEs frequently, there are numerous hit-logs, which floods the CLI interface and affects performance. Furthermore, logs may be lost. Therefore, not all hit-logs are output.

The number of hit-logs that are not output is collected and output in the form of the miss-log.

The miss-logs are output periodically. The following example is for your reference:

```
Feb 23 22:46:53 s6510-2: %ACLD-6-MISSLOG: ACL logging rate-limited or missed 9652 packets
```

To control output number and frequency of miss-logs, you can specify the output interval.

To activate miss-log output, enable miss-log, hit-log, and ACL counter.

Note

- The default output interval of miss-logs is 1 min, that it, up to 1 miss-log is output per minute. To enable log output, the output interval must be specified. To disable miss-log, set the output interval to 0.
- Miss-log is supported by only the switch.

1.2 Configuration Task Summary

ACL configuration tasks are as follows.

To configure an ACL, select at least one of the following tasks to configure:

- Configuring an IP Standard ACL
- Configuring an IP Extended ACL
- Configuring a MAC Extended ACL
- Configuring an Expert Extended ACL
- Configuring an IPv6 ACL
- Configuring an Expert Advanced ACL (ACL80)
- Synchronizing All ACEs from Software to Hardware

1.3 Configuring an IP Standard ACL

1.3.1 Overview

This section describes how to create and apply an IP standard ACL to control the IPv4 packets entering/leaving a port. You can deny or permit specific IPv4 packets destined to a network so as to control the access of IP users to network resources.

1.3.2 Restrictions and Guidelines

- If a device needs to control users' access to network resources by checking the source IP addresses of packets, you can configure an IP standard ACL.
- The IP standard ACL can be configured on access, convergence, or core devices, depending on user distribution. The IP standard ACL takes effect only on the configured device, and does not affect the other devices in the network.

1.3.3 Configuration Tasks

IP standard ACL configuration includes the following tasks:

(1) Creating an IP Standard ACL

(2) Applying an IP Standard ACL

1.3.4 Creating an IP Standard ACL

1. Overview

This section describes how to create an IP standard ACL and configure rules.

2. Restrictions and Guidelines

- An IP standard ACL can contain no rules. When no rules are configured in an ACL, one rule statement of denying all data flows is hidden in the ACL to prohibit all IPv4 packets from entering the device.
- To make some ACL rules take effect at specified time or expire at specified time, for example, make an ACL effective within some time ranges in a week, configure an ACL rule with the **time-range** option.
- When configuring an ACL rule with the **time-range** option, configure the time range option. For the configuration of time ranges, see *Configuring Time Range*.
- For the hit-log function, see ACL hit-log and
- ACL miss-log for details. The ACE with the **log** option consumes more hardware resources. If all ACEs contain the **log** option, the hardware-based policy capacity will be cut by half.
- The default output interval of packet matching logs is 0 minutes, that is, no ACL matching log is output. After specifying the **log** option when configuring ACL rules, you also need to configure an output interval; otherwise no matching log is output.
- For a rule with the **log** option, if no packet is matched within the specified time interval, no packet matching log related to the rule is output; if a packet is matched within the specified time interval, the packet matching log related to the rule is output after the time interval expires. The number of matched packets is the total number of packets matching the rule within the time interval, that is, the number of matched packets from the last log output to the current log output.
- During the actual network maintenance, if many ACLs or rules are configured, but no remark is configured

for these ACLs or rules, it is difficult to distinguish the purposes of these ACLs or rules. Configuring remarks for ACLs or rules can help you understand the purpose of the ACLs.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an IP standard ACL and rules. Please configure only one task.

- Create a numerically indexed IP standard ACL and rules.

  access-control-list *acl-number* { **deny** | **permit** } { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *time-range-name*] [**hit-log**] [**log**]

  No IP standard ACL or rule is configured by default.

- Create a numerically indexed or named IP standard ACL and rules. Run the following commands in turn to create an IP standard ACL and rules.

  ip access-control-list standard { *acl-name* | *acl-number* }

  No IP standard ACL is configured by default.

  [*sequence-number*] { **deny | permit** } { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *time-range-name*] [**hit-log**] [**log**]

  There is an ACL rule of deny type in an IP standard ACL by default.

(4) (Optional) Configure an update interval for packet matching logs.

ip access-control-list log-output interval *time-value*

The default update interval is 0 minutes. That is, no ACL matching log is output.

(5) (Optional) Configure a remark for the ACL. Please configure only one task.

- Configure a remark for the numerically indexed IP standard ACL.

  access-control-list *acl-number* **list-comment** *text*

- Configure remarks for rules in the numerically indexed or named IP standard ACL.

  list-comment *text*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for rules in the IP standard ACL. Please configure only one task.

- Configure remarks for rules in the numerically indexed IP standard ACL.

  access-control-list *acl-number* **comment** *text*

- Configure remarks for rules in the numerically indexed or named IP standard ACL.

  comment *text*

No remark is configured for ACL rules by default.

(7) (Optional) Enable the packet matching counting function of an IP standard ACL.

ip access-control-list counter { *acl-name* | *acl-number* }

The packet matching counting function of an IP standard ACL is disabled by default.

(8) (Optional) Configure a step for rule sequence numbers in the IP standard ACL.

ip access-control-list resequence { *acl-name* | *acl-number* } *start-value step-value*

Both the start value and step of an IP standard ACL rule sequence numbers are **10** by default.

1.3.5 Applying an IP Standard ACL

1. Overview

Apply an IP standard ACL in the global configuration mode, interface configuration mode, or SVI configuration mode to make the IP standard ACL take effect.

2. Restrictions and Guidelines

Only one IP ACL, one MAC extended ACL, or one expert extended ACL can be applied to the inbound or outbound direction of a device port. Besides, an IPv6 ACL can be applied.

- Based on the user distribution, on the access, convergence, or core devices, in specified interface configuration mode, VXLAN interface configuration mode, or VLAN interface configuration mode, you can apply an IP standard ACL.
- Configuring the **in** or **out** option indicates that the IP standard ACL takes effect for the packets entering the device or those forwarded by the device.
- Configure the **counter-only** option to count the packets with some characteristics. The counting function takes effect only for permit rules but not for deny rules in an ACL.
- After an ACL is used as a **counter-only** ACL, the counting function cannot be globally enabled for the ACL, and the ACL cannot be applied globally or on the interface as a common ACL. That is, an ACL with the specified *acl-number* or *acl-name* cannot be used as a **counter-only** ACL and common ACL at the same time
- If the **control-plane** option is configured, the ACL is effective for software only so as to save hardware resources.
- If the **forward-plane** option is configured, the ACL is effective for hardware only.
- If the **forward-control-plane** option is configured, the ACL is effective for both software and hardware.
- The **port-counter** option indicates port-based packet counting.
- To apply the ACL with the **port-counter** option on all interfaces, the entries beyond the capacity may fail to be installed. The entries within the limit take effect normally while the entries beyond the limit are installed randomly on some ports.
- The **port-counter** option cannot be applied to member ports automatically. To count packets on member ports, apply the ACL to the member ports manually.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Apply an IP standard ACL globally.

ip access-apply { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane**] [**port-counter**]

No IP standard ACL is applied globally by default.

(4) Enter the interface configuration mode.

- Enter the Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan interface-*number*

(5) Apply an IP standard ACL to an interface.

ip access-apply { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane** | **priority**]

No IP standard ACL is applied to an interface by default.

1.4 Configuring an IP Extended ACL

1.4.1 Overview

This section describes how to create and apply an IP extended ACL to control the IPv4 packets entering/leaving a port. You can deny or permit specific IPv4 packets destined to a network so as to control the access of IP users to network resources.

1.4.2 Restrictions and Guidelines

- If a device needs to control users' access to network resources by checking the source IP addresses, destination IP addresses, protocol numbers, TCP/UDP source or destination port IDs of packets, you can configure an IP extended ACL.
- The IP extended ACL can be configured on access, convergence, or core devices, depending on user distribution. The IP extended ACL takes effect only on a configured device, but does not affect the other devices in the network.

1.4.3 Configuration Tasks

IP extended ACL configuration includes the following tasks:

(1) Creating an IP Extended ACL

(2) Applying an IP Extended ACL

1.4.4 Creating an IP Extended ACL

1. Overview

This section describes how to create an IP extended ACL and configure its rules.

2. Restrictions and Guidelines

- An IP extended ACL can contain no rules. When no rules are configured in an ACL, one rule statement of

denying all data flows is hidden in the ACL to prohibit all IPv4 packets from entering the device.

- To make some ACL rules take effect at specified time or expire at specified time, for example, make an ACL effective within some time ranges in a week, you can configure an ACL with the **time-range** option. If the specified *time-range-name* does not exist, the ACL takes effec.
- When configuring an ACL rule with the **time-range** option, see *Configuring Time Range*.
- For the hit-log function, see ACL hit-log and
- ACL miss-log for details
- Configuring an ACL rule with the **log** option consumes more hardware resources. If all the configured rules have the **log** option, the hardware policy capacity of the device is halved.
- The default output interval of packet matching logs is 0 minutes, that is, no ACL matching log is output. After specifying the **log** option when configuring ACL rules, you also need to configure an output interval; otherwise no matching log is output.
- For a rule with the **log** option, if no packet is matched within the specified time interval, no packet matching log related to the rule is output; if a packet is matched within the specified time interval, the packet matching log related to the rule is output after the time interval expires. The number of matched packets is the total number of packets matching the rule within the time interval, that is, the number of matched packets from the last log output to the current log output.
- During the actual network maintenance, if many ACLs or rules are configured, but no remark is configured for these ACLs or rules, it is difficult to distinguish the purposes of these ACLs or rules. Configuring remarks for ACLs or rules can help you understand the purpose of the ACLs.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an IP extended ACL and its rules. Please configure only one task.

- Create a numerically indexed IP extended ACL and its rules.

  access-control-list *acl-number* { **deny** | **permit** } *protocol* { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*] [**ecn** *ecn*]] [**fragment**] [**time-range** *time-range-name*] [**hit-log**] [**log**]

  No IP extended ACL or rule is configured by default.

- Create a numerically indexed or named IP extended ACL and its rules. Run the following commands in turn to configure an IP extended ACL and its rules.

  ip access-control-list extended { *acl-name* | *acl-number* }

  No IP extended ACL is configured by default.

  [*sequence-number*] { **deny** | **permit** } *protocol* { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host**

destination-ipv4-address | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*] [**ecn** *ecn*]] [**fragment**] [**time-range** *time-range-name*] [**hit-log**] [**log**]

There is an ACL rule of deny type in an IP extended ACL by default.

(4) (Optional) Configure an update interval for packet matching logs.

ip access-control-list log-output interval *time-value*

The default update interval is 0 minutes. That is, no ACL matching log is output.

(5) (Optional) Configure a remark for the IP extended ACL. Please configure only one task.

- Configure a remark for a numerically indexed IP extended ACL.

  access-control-list *acl-number* **list-comment** *comment text*

- Configure a remark for a numerically indexed or named IP extended ACL.

  list-comment *text*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for rules in the IP extended ACL. Please configure only one task.

- Configure remarks for rules in the numerically indexed IP extended ACL.

  access-control-list *acl-number* **comment** *text*

- Configure remarks for rules in the numerically indexed or named ACL.

  comment *text*

No remark is configured for ACL rules by default.

(7) (Optional) Enable the packet matching counting function of an IP extended ACL.

ip access-control-list counter { *acl-name* | *acl-number* }

The packet matching counting function of an IP extended ACL is disabled by default.

(8) (Optional) Configure the start value and the step for rule sequence numbers in the IP extended ACL.

ip access-control-list resequence { *acl-name* | *acl-number* } *start-value step-value*

Both the start value and step of IP extended ACL rule sequence numbers are **10** by default.

1.4.5 Applying an IP Extended ACL

1. Overview

Apply an IP extended ACL in the global configuration mode, interface configuration mode, or SVI configuration mode to make the IP extended ACL take effect.

2. Restrictions and Guidelines

Only one IP ACL, one MAC extended ACL, or one expert extended ACL can be applied to the inbound or outbound direction of a device port. Besides, an IPv6 ACL can be applied.

- Based on the user distribution, on the access, convergence, or core devices, in specified interface configuration mode, VXLAN interface configuration mode, or VLAN interface configuration mode, you can apply an IP extended ACL.
- Configuring the **in** or **out** option indicates that the ACL takes effect for the packets entering the device or those forwarded by the device.
- Configuring the **reflect** option enables the reflexive ACL.

- Configure the **counter-only** option to count the packets with some characteristics. The counting function takes effect only for permit rules but not for deny rules in an ACL.
- After an ACL is used as a **counter-only** ACL, the counting function cannot be globally enabled for the ACL, and the ACL cannot be applied globally or on ports as a common ACL. That is, ACLs with the same *acl-number* or *acl-name* cannot be used as a **counter-only** ACL and a common ACL at the same time.
- If the **control-plane** option is configured, the ACL is effective for software only so as to save hardware resources.
- If the **forward-plane** option is configured, the ACL is effective for hardware only.
- If the **forward-control-plane** option is configured, the ACL is effective for both software and hardware.
- The **port-counter** option indicates port-based packet counting.
- To apply the ACL with the **port-counter** option on all interfaces, the entries beyond the capacity may fail to be installed. The entries within the limit take effect normally while the entries beyond the limit are installed randomly on some ports.
- The **port-counter** option cannot be applied to member ports automatically. To count packets on member ports, apply the ACL to the member ports manually.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Apply an IP extended ACL globally.

ip access-apply { *acl-name* | *acl-number* } { **in** | **out** } [**control**-**plane** | **forward-control-plane** | **forward-plane**] [**port-counter**]

No IP extended ACL is applied globally by default.

(4) Enter the interface configuration mode.

- Enter the Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the aggregate interface configuration mode.
  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan interface-*number*

(5) Apply an IP extended ACL to an interface.

ip access-apply { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane** | **priority**]

No IP extended ACL is applied to an interface by default.

1.5 Configuring a MAC Extended ACL

1.5.1 Overview

This section describes how to create and apply a MAC extended ACL to control the Layer 2 packets entering/leaving a port. You can deny or permit specific Layer 2 packets destined to a network so as to control the access of users to network resources based on the Layer 2 packet headers.

1.5.2 Restrictions and Guidelines

- If a device needs to control users' access to network resources based on the Layer 2 packet information (such as the MAC addresses of users' PCs), you can configure a MAC extended ACL.
- The MAC extended ACL can be configured on access, convergence, or core devices, depending on user distribution. The MAC extended ACL takes effect only on the configured device, but does not affect other devices in the network.

1.5.3 Configuration Tasks

MAC extended ACL configuration includes the following tasks:

(1) Creating a MAC Extended ACL

(2) Applying a MAC Extended ACL

1.5.4 Creating a MAC Extended ACL

1. Overview

This section describes how to create a MAC extended ACL and configure its rules.

2. Restrictions and Guidelines

- An MAC extended ACL can contain no rules. When no rules are configured in an ACL, one rule statement of denying all data flows is hidden in the ACL to prohibit all Ethernet Layer 2 packets from entering the device.
- To make some ACL rules take effect at specified time or expire at specified time, for example, make an ACL effective within some time ranges in a week, you can configure an ACL with the **time-range** option. If the specified *time-range-name* does not exist, the ACL takes effect.
- When configuring an ACL rule with the **time-range** option, configure the time range option. For the configuration of time ranges, see *Configuring Time Range*.
- For the hit-log function, see ACL hit-log and
- ACL miss-log for details.
- During the actual network maintenance, if many ACLs or rules are configured, but no remark is configured for these ACLs or rules, it is difficult to distinguish the purposes of these ACLs or rules. Configuring remarks for ACLs or rules can help you understand the purpose of the ACLs.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a MAC extended ACL and its rules. Please configure only one task.

- Create a numerically indexed MAC extended ACL and its rules.

  access-control-list *acl-number* { **deny** | **permit** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]] [**time-range** *time-range-name*] [**hit-log**]

  No MAC extended ACL or rule is configured by default.

- Create a numerically indexed or named MAC extended ACL and its rules. Run the following commands in turn to configure a MAC extended ACL and its rules.

  mac access-control-list extended { *acl-name* | *acl-number* }

  No MAC extended ACL is configured by default.

  Run the command to configure a MAC extended ACL and enter the MAC extended ACL configuration mode.

  [*sequence-number*] { **deny** | **permit** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]] [**time-range** *time-range-name*] [**hit-log**]

  There is an ACL rule of deny type in a MAC extended ACL by default.

(4) (Optional) Configure a remark for the ACL. Please configure only one task.

- Configure a remark for the numerically indexed ACL.

  access-control-list *acl-number* **list-comment** *text*

- Configure remarks for rules in the numerically indexed or named ACL.

  list-comment *text*

No remark is configured for an ACL by default.

(5) (Optional) Configure remarks for ACL rules. Please configure only one task.

- Configure remarks for rules in the numerically indexed ACL.

  access-control-list *acl-number* **comment** *text*

- Configure remarks for rules in the numerically indexed or named ACL.

  comment *text*

No remark is configured for ACL rules by default.

(6) (Optional) Enable the packet matching counting function of a MAC extended ACL.

mac access-control-list counter { *acl-name* | *acl-number* }

The packet matching counting function of a MAC extended ACL is disabled by default.

(7) (Optional) Configure the start value and the step for rule sequence numbers in the MAC extended ACL.

mac access-control-list resequence { *acl-name* | *acl-number* } *start-value step-value*

Both the start value and step of MAC extended ACL rule sequence numbers are **10** by default.

1.5.5 Applying a MAC Extended ACL

1. Overview

Apply a MAC extended ACL in the global configuration mode, interface configuration mode, or SVI configuration mode to make the MAC ACL take effect.

2. Restrictions and Guidelines

Only one IP ACL, one MAC extended ACL, or one expert extended ACL can be applied to the inbound or outbound direction of a device port. Besides, an IPv6 ACL can be applied.

- Based on the user distribution, on the access, convergence, or core devices, in specified interface configuration mode, VXLAN interface configuration mode, or VLAN interface configuration mode, you can apply a MAC extended ACL.
- Configuring the **in** or **out** option indicates that the ACL takes effect for the packets entering the device or those forwarded by the device.
- onfigure the **counter-only** option to count the packets with some characteristics. The counting function takes effect only for permit rules but not for deny rules in an ACL.
- After an ACL is used as a **counter-only** ACL, the counting function cannot be globally enabled for the ACL, and the ACL cannot be applied globally or on ports as a common ACL. That is, an ACL with the specified *acl-number* or *acl-name* cannot be used as a **counter-only** ACL and common ACL at the same time .
- If the **control-plane** option is configured, the ACL is effective for software only so as to save hardware resources.
- If the **forward-plane** option is configured, the ACL is effective for hardware only.
- If the **forward-control-plane** option is configured, the ACL is effective for both software and hardware.
- The **port-counter** option indicates port-based packet counting.
- To apply the ACL with the **port-counter** option on all interfaces, the entries beyond the capacity may fail to be installed. The entries within the limit take effect normally while the entries beyond the limit are installed randomly on some ports.
- The **port-counter** option cannot be applied to member ports automatically. To count packets on member ports, apply the ACL to the member ports manually.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Apply a MAC extended ACL globally.

mac access-apply { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **forward-control-plane** | **forward-plane**] [**port-counter**]

No MAC extended ACL is applied globally by default.

(4) Enter the interface configuration mode.

- Enter the Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the aggregate interface configuration mode.
  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan interface-*number*

(5) Apply a MAC extended ACL to an interface.

mac access-apply { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only**| **forward-control**-**plane** | **forward-plane**]

No MAC extended ACL is applied to an interface by default.

1.6 Configuring an Expert Extended ACL

1.6.1 Overview

This section describes how to create and apply an expert extended ACL to control the packets entering/leaving the port. You can deny or permit specific packets destined to a network.

1.6.2 Restrictions and Guidelines

- If a device needs to control users' access to network resources by using IP ACL rules, MAC extended ACL rules, and VLANs in a mixed manner, you can configure an expert extended ACL.
- You can configure an expert extended ACL on an access, convergence, or core device based on the distribution of users. The configuration takes effect only on a configured device, but does not affect other devices in the network.

1.6.3 Configuration Tasks

Expert extended ACL configuration includes the following tasks:

(1) Creating an Expert Extended ACL

(2) Applying an Expert Extended ACL

1.6.4 Creating an Expert Extended ACL

1. Overview

This section describes how to create an expert extended ACL and configure its rules.

2. Restrictions and Guidelines

- An expert extended ACL can contain no rules. When no rules are configured in an ACL, one rule statement of denying all data flows is hidden in the ACL to prohibit all packets from entering the device.
- To make some ACL rules take effect at specified time or expire at specified time, for example, make an ACL effective within some time ranges in a week, , you can configure an ACL with the **time-range** option. If the specified *time-range-name* does not exist, the ACL takes effect.
- When configuring an ACL rule with the **time-range** option, configure the time range option. For the configuration of time ranges, see *Configuring Time Range*.

- For the hit-log function, see ACL hit-log and
- ACL miss-log for details.
- MPLS packets support matching labels from Layer 1 to Layer 6, for example, **permit mpls exp** 0 1 2 3 4 5 6 7 is used to match the EXP values in label 1 to label 6 from left to right respectively (the label closest to the Layer 2 header is in Layer 1). Another example is **permit mpls exp any** 1, which means that only the EXP value of Layer 2 labels is matched.

- During the actual network maintenance, if many ACLs or rules are configured, but no remark is configured for these ACLs or rules, it is difficult to distinguish the purposes of these ACLs or rules. Configuring remarks for ACLs or rules can help you understand the purpose of the ACLs.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an expert extended ACL and its rules. Please configure only one task.

- Create a numerically indexed expert extended ACL and its rules.

  access-control-list *acl-number* { **deny** | **permit** } [*protocol* | [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]]] [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source*-mac-*address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*] [**ecn** *ecn*]] [**fragment**] [[**udf** *udf-id header pos value mask*]] [**time-range** *time-range-name*] [**hit-log**]

  No expert extended ACL or rule is configured by default.

- Create a numerically indexed or named expert extended ACL and its rules. Run the following commands in turn to configure an expert extended ACL and its rules.

  expert access-control-list extended { *acl-name* | *acl-number* }

  No expert extended ACL is configured by default.

  Run the command to configure an expert extended ACL and enter the expert extended ACL configuration mode.

  [*sequence-number*] { **deny** | **permit** } [*protocol* | [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]]] [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source*-mac-*address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*] [**ecn** *ecn*]] [**fragment**] [[**udf** *udf-id header pos value mask*]] [**time-range** *time-range-name*] [**hit-log**]

  There is an ACL rule of deny type in an expert extended ACL by default.

- Create a numerically indexed expert extended ACL and MPLS packet matching rules.

access-control-list *acl-number* { **deny** | **permit** } **mpls {** *source-ipv4-address source-ipv4-wildcard* **|** **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [**hit-log**]

No expert extended ACL or is configured by default.

- Create a numerically indexed or named expert extended ACL. Run the following commands in turn to configure an expert extended ACL.

  expert access-control-list extended { *acl-number* | *acl-name* }

  No expert extended ACL is configured by default.

  No expert extended ACL is configured by default.

- Create a numerically indexed or named expert extended ACL and MPLS label matching rules. Run the following commands in turn to configure an expert extended ACL and MPLS label matching rules.

  expert access-control-list extended { *acl-name* | *acl-number* }

  No expert extended ACL is configured by default.

  Run the command to configure an expert extended ACL and enter the expert extended ACL configuration mode.

  [*sequence-number*] { **deny** | **permit** } { **vxlan | vxlan-ignore-dport** } *protocol* { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**eq** *port*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [**eq** *port*] [**tagged**] [**udp-dport** *dport*] [**ip-flag** *flag*] [**dscp** *dscp*] [**time-range** *time-range-name*] [**hit-log**]

  There is an ACL rule of deny type in an expert extended ACL by default.

(4) Create an expert extended ACL and VXLAN inner 5-tuple rules.

- Run the following commands in turn to configure an expert extended ACL and VXLAN inner 5-tuple rules.

  expert access-control-list extended { *acl-number* | *acl-name* }

  No expert extended ACL is configured by default.

  Run the command to configure an expert extended ACL and enter the expert extended ACL configuration mode.

  [*sn*] { **permit** | **deny** } [**vxlan | vxlan-ignore-dport**] *protocol* { *source-ipv4-address source-ip–wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [**tagged**] [**udp-dport** *dport*] [**time-range** *time-name*]] [**hit-log**]

(5) (Optional) Configure a remark for the ACL. Please configure only one task.

- Configure a remark for the numerically indexed ACL.

  access-control-list *acl-number* **list-comment** *comment*

- Configure remarks for rules in the numerically indexed or named ACL.

  list-comment *comment*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for ACL rules. Please configure only one task.

- Configure remarks for rules in the numerically indexed ACL.

access-control-list *acl-number* **comment** *comment*

- Configure remarks for rules in the numerically indexed or named ACL.

  comment *comment*

No remark is configured for ACL rules by default.

(7) (Optional) Configure the start value and the step for rule sequence numbers in the expert extended ACL.

expert access-control-list resequence { *acl-name* | *acl-number* } *start-value step-value*

Both the start value and step of an expert ACL rule sequence numbers are **10** by default.

1.6.5 Applying an Expert Extended ACL

1. Overview

Apply an expert extended ACL in the global configuration mode, interface configuration mode, or SVI configuration mode to make the expert extended ACL take effect.

2. Restrictions and Guidelines

Only one IP ACL, one MAC extended ACL, or one expert extended ACL can be applied to the inbound or outbound direction of a device port. Besides, an IPv6 ACL can be applied.

- Configuring the **in** or **out** option indicates that the ACL takes effect for the packets entering the device or those forwarded by the device.
- Configuring the **reflect** option enables the reflexive ACL.
- Configure the **counter-only** option to count the packets with some characteristics. The counting function takes effect only for permit rules but not for deny rules in an ACL.
- After an ACL is used as a **counter-only** ACL, the counting function cannot be globally enabled for the ACL, and the ACL cannot be applied globally or on ports as a common ACL. That is, ACLs with the same *acl-number* or *acl-name* cannot be used as a **counter-only** ACL and a common ACL at the same time.
- If the **control-plane** option is configured, the ACL is effective for software only so as to save hardware resources.
- If the **forward-plane** option is configured, the ACL is effective for hardware only.
- If the **forward-control-plane** option is configured, the ACL is effective for both software and hardware.
- The **port-counter** option indicates port-based packet counting.
- To apply the ACL with the **port-counter** option on all interfaces, the entries beyond the capacity may fail to be installed. The entries within the limit take effect normally while the entries beyond the limit are installed randomly on some ports.
- The **port-counter** option cannot be applied to member ports automatically. To count packets on member ports, apply the ACL to the member ports manually.
- The rule for matching the IP field of MPLS packets in an expert extended ACL cannot be applied in the outbound direction, namely, it does not take effect after applied.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Apply an expert extended ACL globally.

expert access-apply { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane**] [**port-counter**]

No expert extended ACL is applied globally by default.

(4) Enter the interface configuration mode.

- Enter the Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the aggregate interface configuration mode.
  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan interface-*number*

(5) Apply an expert extended ACL to an interface.

expert access-apply { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only**| **forward-control-plane** | **forward-plane** | **priority**]
