No expert extended ACL is applied to an interface by default.

1.7 Configuring an IPv6 ACL

1.7.1 Overview

This section describes how to create and apply an IPv6 ACL to control the IPv6 packets entering/leaving the port. You can deny or permit specific IPv6 packets destined to a network so as to control the access of IPv6 users to network resources.

1.7.2 Restrictions and Guidelines

- To control IPv6 users' access to network resources, configure an IPv6 ACL.
- You can configure an IPv6 ACL on an access, convergence, or core device based on the distribution of users. The IPv6 ACL takes effect only on the local device, but does not affect other devices in the network.

1.7.3 Configuration Tasks

IPv6 ACL configuration includes the following tasks:

(1) Creating an IPv6 ACL

(2) Applying an IPv6 ACL

1.7.4 Creating an IPv6 ACL

1. Overview

This section describes how to create an IPv6 ACL and configure its rules.

2. Restrictions and Guidelines

- You cannot specify the name of an IPv6 ACL but its number.
- An IPv6 ACL can contain no rules. When no rules are configured in an ACL, one rule statement of denying all data flows is hidden in the IPv6 ACL to prohibit all IPv6 packets except ND packets from entering the device.
- To make some ACL rules take effect at specified time or expire at specified time, for example, make an ACL effective within some time ranges in a week, you can configure an ACL with the **time-range** option. If the specified *time-range-name* does not exist, the ACL takes effect.
- When configuring an ACL rule with the **time-range** option, configure the time range option. For the configuration of time ranges, see *Configuring Time Range*.
- For the hit-log function, see ACL hit-log and
- ACL miss-log for details.
- Configuring an ACL rule with the **log** option consumes more hardware resources. If all the configured rules have the **log** option, the hardware policy capacity of the device is halved.
- The default output interval of packet matching logs is 0 minutes, that is, no ACL matching log is output. After specifying the **log** option when configuring ACL rules, you also need to configure an output interval; otherwise no matching log is output.
- For a rule with the **log** option, if no packet is matched within the specified time interval, no packet matching log related to the rule is output; if a packet is matched within the specified time interval, the packet matching log related to the rule is output after the time interval expires. The number of matched packets is the total number of packets matching the rule within the time interval, that is, the number of matched packets from the last log output to the current log output.
- During the actual network maintenance, if many ACLs or rules are configured, but no remark is configured for these ACLs or rules, it is difficult to distinguish the purposes of these ACLs or rules. Configuring remarks for ACLs or rules can help you understand the purpose of the ACLs.
- Before configuring a step for ACL rule sequence numbers, you must first configure an ACL.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an IPv6 ACL and enter the IPv6 ACL configuration mode.

ipv6 access-control-list *acl-name*

No IPv6 ACL is configured by default.

(4) Configure IPv6 ACL rules. Please configure only one task.

- Configure IPv6 ACL rules of TCP or UDP.

  [*sn*] { **permit** | **deny** } [*protocol* { *source-ipv6-prefix* / *prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } { { *destination-ipv6-prefix* / *prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** } [*op dstport* | **range** *lower upper*]] [**cos** *value* [**inner** *value*]] [{ **any** | **host** *source-mac-address* |

source-mac-address source-mac-wildcard } { **any** | **host** *destination–mac-address* | *destination-mac-address destination-mac-wildcard* }] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**vid** *vlan-id*] [**time-range** *time-name*] [**hit-log**] [**log**]

- Configure IPv6 ACL rules of protocols other than TCP or UDP.

  [*sn*] { **permit** | **deny** } [*protocol* { *source-ipv6-prefix* / *prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } { *destination-ipv6-prefix* / *prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** }] [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination–mac-address* | *destination–mac-address destination-mac-wildcard* }] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**vid** *vlan-id*] [**time-range** *time-name*] [**log**] [**hit-log**]

(5) (Optional) Configure a remark for the ACL.

list-comment *comment*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for ACL rules.

comment *comment*

No remark is configured for ACL rules by default.

(7) (Optional) Configure an update interval of packet matching logs.

ipv6 access-control-list log-output interval *time*

The default update interval of packet matching logs is 0 minutes, that is, no ACL matching log is output.

(8) (Optional) Enable the packet matching counting function of an IP extended ACL.

ip access-control-list counter { *acl-name* | *acl-number* }

The packet matching counting function of an IP extended ACL is disabled by default.

(9) (Optional) Configure the start value and the step for rule sequence numbers in the IPv6 extended ACL.

ipv6 access-control-list resequence *acl-name start-value step-value*

Both the start value and step of an IPv6 ACL rule sequence numbers are **10** by default.

1.7.5 Applying an IPv6 ACL

1. Overview

Apply an IPv6 ACL in the global configuration mode, interface configuration mode, or SVI configuration mode to make the IPv6 ACL take effect.

2. Restrictions and Guidelines

- Based on the user distribution, on the access, convergence, or core devices, in specified interface configuration mode, VXLAN interface configuration mode, or VLAN interface configuration mode, you can apply an IPv6 ACL.
- Configuring the **in** or **out** option indicates that the ACL takes effect for the packets entering the device or those forwarded by the device.
- Configuring the **reflect** option enables the reflexive ACL.

- Configure the **counter-only** option to count the packets with some characteristics. The counting function takes effect only for permit rules but not for deny rules in an ACL.
- After an ACL is used as a **counter-only** ACL, the counting function cannot be globally enabled for the ACL, and the ACL cannot be applied globally or on ports as a common ACL. That is, an ACL with the specified *acl-number* or *acl-name* cannot be used as a **counter-only** ACL and common ACL at the same time.
- If the **control-plane** option is configured, the ACL is effective for software only so as to save hardware resources.
- If the **forward-plane** option is configured, the ACL is effective for hardware only.
- If the **forward-control-plane** option is configured, the ACL is effective for both software and hardware.
- The **port-counter** option indicates port-based packet counting.
- To apply the ACL with the **port-counter** option on all interfaces, the entries beyond the capacity may fail to be installed. The entries within the limit take effect normally while the entries beyond the limit are installed randomly on some ports.
- The **port-counter** option cannot be applied to member ports automatically. To count packets on member ports, apply the ACL to the member ports manually.
- Neither of the ACE used for matching the IP field of MPLS packets and the ACE used for matching the label field of MPLS packets in an IPv6 ACL can be applied in the outbound direction, namely, it does take effect after applied.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Apply an Ipv6 standard ACL globally.

ipv6 access-apply { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane**] [**port-counter**]

No Ipv6 standard ACL is applied globally by default.

(4) Enter the interface configuration mode.

- Enter the interface configuration mode.

  interface *interface-type interface-number*

- Enter the aggregate interface configuration mode.
  interface aggregateport *interface-number*

- Enter the VLAN interface configuration mode.

  interface vlan *vlan-id*

(5) Apply an IPv6 ACL to an interface.

ipv6 traffic-filter *acl-name* { **in** | **out** } [**counter-only** | **control-plane** | **forward-control-plane** | **forward-plane** | **priority**]

No IPv6 ACL is applied to an interface by default.

1.8 Configuring an Expert Advanced ACL (ACL80)

1.8.1 Overview

When the fixed matching fields of the IP standard ACL, IP extended ACL, MAC extended ACL, expert extended ACL, and IPv6 ACL all fail to meet requirements, you can configure an expert advanced ACL (ACL80) to define the packet fields to be matched.

1.8.2 Restrictions and Guidelines

- You can configure an ACL80 on an access, convergence, or core device based on the distribution of users. The ACL80 takes effect only on the configured device, but does not affect other devices in the network.

1.8.3 Configuration Tasks

The ACL80 configuration includes the following tasks:

(1) Creating an ACL80

(2) Applying an ACL80

1.8.4 Creating an ACL80

1. Overview

This section describes how to create an ACL80 and configure its rules.

2. Restrictions and Guidelines

- An ACL80 supports matching Ethernet II packets, IEEE 802.2 LLC SNAP packets, and IEEE 802.2 packets. If the values of the DSAP field to the Control field to be matched are AAAA03, IEEE 802.2 SNAP packets are matched. If the values of the DSAP field to the Control field to be matched are E0E003, IEEE 802.2 LLC packets are matched. If an ACL80 tries to match Ethernet II packets, you cannot set the values of the DSAP field to the Control field.
- Due to hardware, currently ACL80 cannot implement random byte matching for the first 80 bytes of packets, but only supports matching the fields of the destination MAC address, source MAC address, VLAN ID, ETYPE, IP protocol number, source IPv4 address, destination IPv4 address, source port, destination port, ICMP_TYPE, ICMP_CODE, and PPPOE_IPTYPE in packets.
- When an ACL80 matches IP, ARP, and other information, the encapsulated data type and data type mask need to be configured first, that is, the field with offset 24 needs to be configured first, and the mask needs to be set to all Fs. For example, to allow the packets with the source IP address 192.168.1.2 to pass through, run the **permit 0800 FFFF 24 C0A80102 FFFFFFFF 38** command.
- An ACL80 can contain no rules. When no rules are configured in an ACL, one rule statement of denying all data flows is hidden in the ACL to prohibit all packets from entering the device.
- During the actual network maintenance, if many ACLs or rules are configured, but no remark is configured for these ACLs or rules, it is difficult to distinguish the purposes of these ACLs or rules. Configuring remarks for ACLs or rules can help you understand the purpose of the ACLs.
- For the hit-log function, see ACL hit-log and
- ACL miss-log for details.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an expert advanced ACL and enter the expert advanced ACL configuration mode.

expert access-control-list advanced *acl-name*

No expert advanced ACL is configured by default.

(4) (Optional) Configure rules in the expert advanced ACL.

[*sequence-number*] { **deny** | **permit** } *hex hex-mask offset* [**hit-log**]

No expert advanced ACL is configured.

(5) (Optional) Configure a remark for the ACL.

list-comment *text*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for ACL rules.

comment *text*

No remark is configured for ACL rules by default.

1.8.5 Applying an ACL80

1. Overview

Apply an ACL80 in the global configuration mode, interface configuration mode, SVI configuration mode, or VXLAN configuration mode to make the ACL80 take effect.

2. Restrictions and Guidelines

- Configuring the **in** or **out** option indicates that the ACL takes effect for the packets entering the device or those forwarded by the device.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the aggregate interface configuration mode.
  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan interface-*number*

- Enter the VXLAN configuration mode.

  vxlan *vni-number*

(4) Apply an expert advanced ACL to an interface.

expert access-apply { *acl-name* | *acl-number* } { **in** | **out** }

No expert advanced ACL is applied to an interface by default.

1.9 Configuring a Redirect ACL

1.9.1 Overview

This section describes how to configure the ACL-based redirection function on a specified port or globally, to redirect the matched packets entering the port or all the ports to a specified port for forwarding.

1.9.2 Restrictions and Guidelines

- You can configure the ACL-based redirection function on an access, aggregation, or core device based on the distribution of users. The configuration takes effect only on the local device, but does not affect other devices in the network.
- The ACL-based redirection function can be configured on the Layer 2 Ethernet interface and the Layer 2 aggregate interface only.
- The packet to be redirected must be an Layer 2 forwarded packet (that is, if a packet is forwarded from VLAN 2 to VLAN 3, it cannot be redirected), and the destination port of redirection must be in the same VLAN as the source port.
- If no rule is configured in an ACL, the ACL-based redirection function is unavailable.

1.9.3 Prerequisite

You must configure an ACL first to enable the ACL-based redirection function.

1.9.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

- Configure a redirect ACL.

  global redirect destination interface *interface-type interface-number* **acl** { *acl-name* | *acl-number* } **in**

  No redirect ACL is configured by default.

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(4) Configure a redirect ACL. Please configure only one task.

redirect destination interface *interface-type interface-number* **acl** { *acl-name* | *acl-number* } **in**

No redirect ACL is configured on a port by default.

1.10 Configuring a Global Security ACL

1.10.1 Overview

Disable the global security ACL function to forbid configuring global security ACLs.

1.10.2 Prerequisite

You must configure an ACL first to enable the global security ACL function.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Disable the global security ACL function.

global access-apply disable

The global security ACL function is enabled by default.

1.11 Configuring an SVI Router ACL

1.11.1 Overview

The SVI router ACL function can be configured to enable the ACL applied to an SVI to take effect only for the inter-VLAN routed packets.

1.11.2 Prerequisite

To implement this function, first configure an ACL.

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an SVI router ACL.

svi router-acls enable

1.12 Synchronizing All ACEs from Software to Hardware

1.12.1 Overview

When the entry capacity of the device software is greater than that supported by the hardware, no ACE can be added. When the entry capacity of the device software drops below that supported by the hardware, the ACEs that fail to be added before will not be added again. This command can be used to refresh the configuration to trigger the re-adding of ACEs, thus synchronizing ACEs from software to hardware.

1.12.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Synchronize all ACEs from software to hardware.

acl ref synchronize all

1.13 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

⚠ Caution

Running the **cleanup** commands may interrupt services due to loss of important information.

Run the **debugging** command to output debugging information.

⚠ Caution

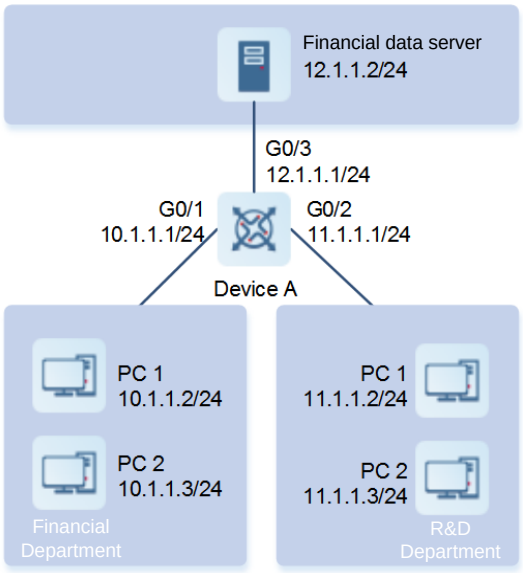
The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-5 ACL Monitoring

Command	Purpose
display access-control-lists [*acl-name* | *acl-number*] [**summary**] [**port-counter** [**interface** *interface-type interface-number*] [**in** | **out**]]	Displays a basic ACL.
display redirect [**interface {** *interface-type interface-number* | **vlan** *vlan-id* }]	Displays the redirection entries bound to a specified port. If no port is specified, the redirection entries bound to all the ports are displayed.

Command	Purpose
display access-apply [**interface {** *interface-type interface-number* | **vlan** *vlan-id* }]	Displays the configuration of an ACL applied to a port.
display ip access-apply [**interface** { *interface-type interface-number* | **vlan** *vlan-id* }]	Displays the configuration of an IP standard ACL and an extended ACL applied to a port.
display mac access-apply [**interface** *interface-type interface-number* | **vlan** *vlan-id* | **wlan** *wlan-id*]	Displays the configuration of a MAC extended ACL applied to a port.
display expert access-apply [**interface** { *interface-type interface-number* | **vlan** *vlan-id* }]	Displays the configuration of an expert extended ACL applied to a port.
display ipv6 traffic-filter [**interface {** *interface-type interface-number* }]	Displays the configuration of an IPv6 ACL applied to a port.
display acl res [**dev** *dev-number* [**slot** *slot-number*]]	Displays information about all ternary content-addressable memory (TCAMs) or a specified TCAM.
display acl capability	Displays device capability.
display svi router-acls state	Checks whether an ACL applied to an SVI takes effect on Layer 2 and Layer 3 networks.
display acl res detail [**dev** *dev-num* [**slot** *slot-num*]]	Displays usage details about all TCAMs or a specified TCAM.
cleanup acl res	Clears historical peak information of TCAM resource usage.
cleanup counters access-control-list [*acl-name* | *acl-number*]	Clears the number of packets matching an ACL.
cleanup access-control-list counters [*acl-name* | *acl-number*]	Clears the number of packets matching ACL deny rules.
debugging acl acld event	Debugs the ACL running process.
debugging acl acld client-show	Displays ACL client information.
debugging acl acld acl-show	Displays ACLs created on all ACL clients.

1.14 Examples



1.14.1 Configuring an IP Standard ACL

1. Requirements

An IP standard ACL needs to be configured to prevent the departments other than the financial department from accessing the financial data server.

2. Topology

Figure 1-3 Configuring a Standard IP ACL

3. Notes

- Configure an IP standard ACL on device A and add access rules.
- Apply the IP standard ACL to the outbound direction of the port connected to the financial data server on device A.

4. Procedure

(1) Configure an IP standard ACL and add access rules.

On device A, configure an IP standard ACL and add access rules.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip access-control-list standard 1
DeviceA(cfg-stdacl)# permit 10.1.1.0 0.0.0.255
DeviceA(cfg-stdacl)# deny 11.1.1.1 0.0.0.255
DeviceA(cfg-stdacl)# exit
```

(2) Apply the IP standard ACL to a port.

On device A, apply the IP standard ACL to the outbound direction of the port connected to the financial data server.

```
DeviceA(cfg)# interface gigabitethernet 0/3
DeviceA(cfg-if-GigabitEthernet 0/3)# ip access-apply 1 out
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA# display access-control-lists

ip access-control-list standard 1
10 permit 10.1.1.0 0.0.0.255
20 deny 11.1.1.0 0.0.0.255

DeviceA# display access-apply
ip access-apply 1 out
Applied On interface GigabitEthernet 0/3
```

Ping the financial data server from a PC of the R&D department and confirm that the ping operation fails.

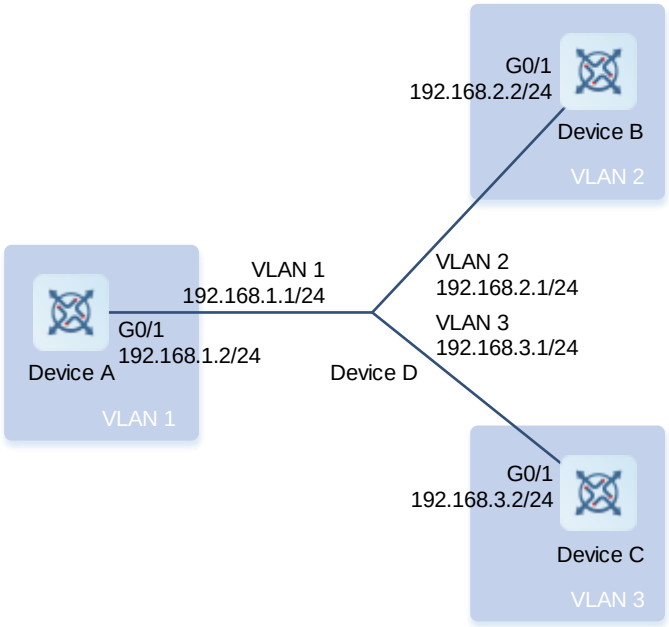
Ping the financial data server from a PC of the financial department and confirm that the ping operation succeeds.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
ip access-control-list standard 1
 10 permit 10.1.1.0 0.0.0.255
 20 deny 11.1.1.0 0.0.0.255
!
interface GigabitEthernet 0/1
 unset switch-port
 ip address 10.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
 unset switch-port
 ip address 11.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/3
 unset switch-port
 ip access-apply 1 out
 ip address 12.1.1.1 255.255.255.0
!
```

1.14.2 Configuring an IP Extended ACL



1. Requirements

Device A (VLAN 1), device B (VLAN 2), and device C (VLAN 3) are directly connected to device 4, which functions as the gateway of all the hosts. Requirement 1: The ping operation fails between VLAN 2 and VLAN 3,

but succeeds between VLAN 1 and VLAN 2, and between VLAN 1 and VLAN 3. Requirement 2: The DHCP packets of VLAN 1 and VLAN 2 are unreachable to each other, but the communication using other protocols is normal. Requirement 3: The host in VLAN 1 cannot to access VLAN 3 through telnet or SSH, but the communication using other protocols is normal.

2. Topology

Figure 1-4 Configuring an Extended IP ACL

3. Notes

- On device D, configure an IP extended ACL and add an access rule of filtering out packets received by UDP port 67 or 68 to meet requirement 2. On device C, configure an IP extended ACL and add an access rule of filtering out packets received by ACL ports 23 and 22 to meet requirement 3.
- On device A, apply the IP extended ACL to VLAN 1 interface, VLAN 2 interface, and VLAN 3 interface. On device C, apply the IP extended ACL to the line connected to the device D.

4. Procedure

(1) Configure IP addresses for all the device ports (omitted).

(2) Configure an IP extended ACL and add access rules.

On device D, configure an IP extended ACL and add access rules.

```
DeviceD> privilege
DeviceD# config-system terminal
DeviceD(cfg)# ip access-control-list extended inter_vlan_access1
DeviceD(cfg-extacl)# deny udp any eq bootps any eq bootpc
DeviceD(cfg-extacl)# deny udp any eq bootpc any eq bootps
DeviceD(cfg-extacl)# comment //Deny DHCP packets.
DeviceD(cfg-extacl)# permit ip any any
DeviceD(cfg-extacl)# comment //Permit the communication using other packets.
```

```
DeviceD(cfg-extacl)# exit
DeviceD(cfg)# ip access-control-list extended inter_vlan_access2
DeviceD(cfg-extacl)# deny ip 192.168.2.0 0.0.0.255 192.168.3.0 0.0.0.255
DeviceD(cfg-extacl)# comment //Deny the mutual access between VLAN 2 and VLAN 3.
DeviceD(cfg-extacl)# deny udp any eq bootpc any eq bootps
DeviceD(cfg-extacl)# deny udp any eq bootps any eq bootpc
DeviceD(cfg-extacl)# comment //Deny DHCP packets.
DeviceD(cfg-extacl)# permit ip any any
DeviceD(cfg-extacl)# comment //Permit the communication using other packets.
DeviceD(cfg-extacl)# exit
DeviceD(cfg)# ip access-control-list extended inter_vlan_access3
DeviceD(cfg-extacl)# deny ip 192.168.3.0 0.0.0.255 192.168.2.0 0.0.0.255
DeviceD(cfg-extacl)# comment //Deny the mutual access between VLAN 2 and VLAN 3.
DeviceD(cfg-extacl)# permit ip any any
DeviceD(cfg-extacl)# comment //Permit the communication using other packets.
DeviceD(cfg-extacl)# exit
```

On device C, configure an IP extended ACL and add access rules.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ip access-control-list extended access_deny
DeviceC(cfg-extacl)# deny tcp 192.168.1.0 0.0.0.255 eq telnet any eq telnet
DeviceC(cfg-extacl)# comment //Deny VLAN 1 access to VLAN 3 through telnet.
DeviceC(cfg-extacl)# deny tcp 192.168.1.0 0.0.0.255 eq 22 any eq 22
DeviceC(cfg-extacl)# comment //Deny VLAN 1 access to VLAN 3 through SSH.
DeviceC(cfg-extacl)# exit
```

(3) Apply the IP extended ACLs.

On device D, apply the IP extended ACL to the corresponding ports.

```
DeviceD(cfg)# interface vlan 1
DeviceD(cfg-if-VLAN 1)# ip access-apply inter_vlan_access1 in
DeviceD(cfg-if-VLAN 1)# exit
DeviceD(cfg)# interface vlan 2
DeviceD(cfg-if-VLAN 2)# ip access-apply inter_vlan_access2 in
DeviceD(cfg-if-VLAN 2)# exit
DeviceD(cfg)# interface vlan 3
DeviceD(cfg-if-VLAN 3)# ip access-apply inter_vlan_access3 in
DeviceD(cfg-if-VLAN 3)# exit
```

On device C, apply the IP extended ACL to the line connected to the switch.

```
hostC(cfg)# line vty 0
hostC(cfg-line)# access-class access_deny in
hostC(cfg-line)# exit
```

5. Verification

(1) Verify the connectivity.

The ping operation succeeds between VLAN 1 and VLAN 2, and between VLAN 1 and VLAN 3.

```
DeviceA# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/8/10 ms
DeviceA#
DeviceA# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/8/10 ms
```

The ping operation fails between VLAN 2 and VLAN 3.

```
DeviceB# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
   < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5)
```

(2) The host in VLAN 1 cannot access VLAN 3 through telnet.

```
DeviceA# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/8/10 ms
DeviceA#
DeviceA# telnet 192.168.3.2
Trying 192.168.3.2, 23...
% Destination unreachable; gateway or host down
```

6. Configuration Files

- Device D configuration file

```
hostname DeviceD
!
vlan 1
!
vlan 2
!
vlan 3
!
ip access-control-list extended inter_vlan_access1
 10 deny udp any eq bootps any eq bootpc
 20 deny udp any eq bootpc any eq bootps
 comment //Deny DHCP packets.
 30 permit ip any any
```

```
 comment //Permit the communication using other packets.
!
ip access-control-list extended inter_vlan_access2
 10 deny ip 192.168.2.0 0.0.0.255 192.168.3.0 0.0.0.255
 comment //Deny the mutual access between VLAN 2 and VLAN 3.
 20 deny udp any eq bootpc any eq bootps
 30 deny udp any eq bootps any eq bootpc
 comment //Deny DHCP packets.
 40 permit ip any any
 comment //Permit the communication using other packets.
!
ip access-control-list extended inter_vlan_access3
 10 deny ip 192.168.3.0 0.0.0.255 192.168.2.0 0.0.0.255
 comment //Deny the mutual access between VLAN 2 and VLAN 3.
 20 permit ip any any

1.14.3 Configuring a MAC Extended ACL

1. Requirements

A MAC extended ACL needs to be configured to restrict the resources accessible to visitors.

2. Topology

Figure 1-5 Configuring an Extended MAC ACL

3. Notes

- On device A, configure a MAC extended ACL and add access rules. The PCs in the visitor area are allowed to access the Internet and the company's internal public server, but are not allowed to access the company's financial data server, that is, the PCs are prohibited from accessing the server with MAC address 00e0.f800.000d.
- On device A, apply the MAC extended ACL to the inbound direction of a port connected to the visitor area.

4. Procedure

(1) Configure a MAC extended ACL and add access rules.

On device A, configure a MAC extended ACL and add access rules.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# mac access-control-list extended 700
DeviceA(cfg-macacl)# deny any host 00e0.f800.000d
DeviceA(cfg-macacl)# permit any any
DeviceA(cfg-macacl)# exit
```

(2) Apply the MAC extended ACL to a port.

On device A, apply the ACL to the inbound direction of the port connected to the visitor area.

```
DeviceA(cfg)# interface gigabitethernet 0/2
DeviceA(cfg-if-GigabitEthernet 0/2)# mac access-apply 700 in
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA# display access-control-lists
mac access-control-list extended 700
10 deny any host 00e0.f800.000d etype-any
20 permit any any etype-any
DeviceA# display access-apply
mac access-apply 700 in
Applied On interface GigabitEthernet 0/2
```

Ping the financial data server from a visitor PC and confirm that the ping operation fails.

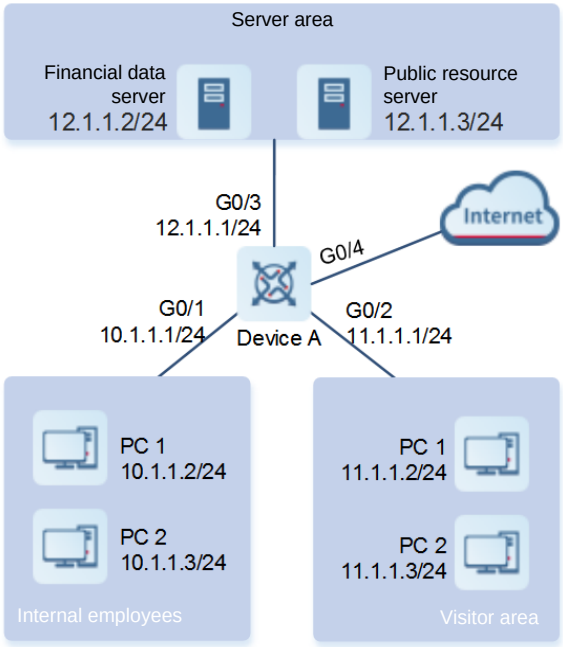
Ping the public resource server from a visitor PC and confirm that the ping operation succeeds.

Access the Internet through a visitor PC, for example, access www.baidu.com, and confirm that the home page can be opened.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
mac access-control-list extended 700
 10 deny any host 00e0.f800.000d
 20 permit any any
!
interface GigabitEthernet 0/1
 unset switch-port
 ip address 10.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
 unset switch-port
 mac access-apply 700 in
 ip address 11.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/3
 unset switch-port
 ip address 12.1.1.1 255.255.255.0
!
```



1.14.4 Configuring an Expert Extended ACL

1. Requirements

An expert extended ACL needs to be configured to restrict the resources accessible to visitors. Visitors cannot access the PCs of internal employees or the financial data server of the company, but can access the public resource server and Internet.

2. Topology

Figure 1-6 Configuring an Extended Expert ACL

3. Notes

- On device A, configure an expert extended ACL and add access rules, including:
  - Prohibiting the hosts in the visitor area from sending packets destined to the network segment of internal employees' PCs.
  - Prohibiting visitors from accessing the financial data server.
  - Permitting all the other packets to pass through.
- On device A, apply the ACL to the inbound direction of the port connected to the visitor area.

4. Procedure

(1) Configure an expert extended ACL and add access rules.

On device A, configure an expert extended ACL and add access rules.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# expert access-control-list extended 2700
DeviceA(cfg-expaclcfg-expacl)# deny ip any any 10.1.1.0 0.0.0.255 any
DeviceA(cfg-expacl)# deny ip any any host 12.1.1.2 any
DeviceA(cfg-expacl)# permit any any any any
DeviceA(cfg-expacl)# exit
```

(2) Apply the expert extended ACL to a port.

On device A, apply the ACL to the inbound direction of the port connected to the visitor area.

```
DeviceA(cfg)# interface gigabitethernet 0/2
```

```
DeviceA(cfg-if-GigabitEthernet 0/2)# expert access-apply 2700 in
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA(cfg)# display access-control-lists
expert access-control-list extended 2700
  10 deny ip any any 192.168.1.0 0.0.0.255 any
20 deny ip any any host 10.1.1.1 any
30 permit ip any any any any

DeviceA(cfg)# display access-apply
expert access-apply 2700in
Applied On interface GigabitEthernet 0/2
```

Ping the financial data server from a visitor PC and confirm that the ping operation fails.

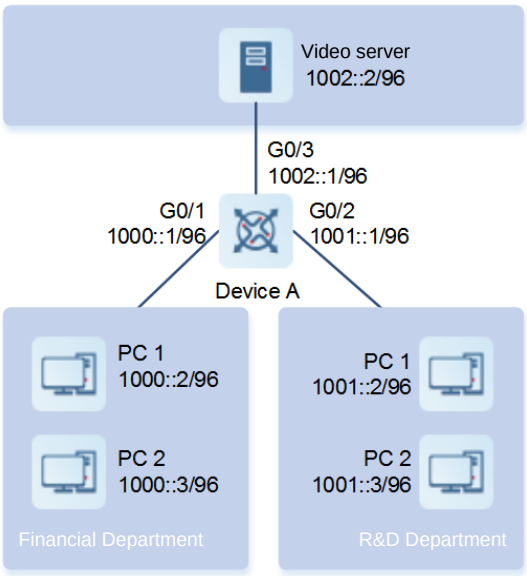
Ping the public resource server from a visitor PC and confirm that the ping operation fails.

Ping the internal employee gateway 192.168.1.1 from a visitor PC and confirm that the ping operation fails.

Access the Internet through a visitor PC, for example, access www.baidu.com, and confirm that the home page can be opened.

6. Configuration Files

Device A configuration file



```
hostname DeviceA
!
expert access-control-list extended 2700
  10 deny ip any any 10.1.1.0 0.0.0.255 any
  20 deny ip any any host 12.1.1.2 any
  30 permit ip any any any any
!
interface GigabitEthernet 0/1
  unset switch-port
  ip address 10.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
  unset switch-port
  expert access-apply 2700 in
  ip address 11.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/3
  unset switch-port
  ip address 12.1.1.1 255.255.255.0
!
```

1.14.5 Configuring an IPv6 ACL

1. Requirements

An IPv6 ACL needs to be configured to prevent hosts in the R&D department from accessing the video server.

2. Topology

Configuring an IPv6 ACL

3. Notes

- On device A, configure an IPv6 ACL and add access rules, including:
  - Prohibiting access to the IPv6 address of the video server.
  - Permitting all the IPv6 packets to pass through.
- On device A, apply the IPv6 ACL to the inbound direction of the port connected to the R&D department.

4. Procedure

(1) Configure an IPv6 ACL and add access rules.

On device A, configure an IPv6 ACL and add access rules.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ipv6 access-control-list dev_deny_ipv6video
DeviceA(cfg-ipv6acl)# deny ipv6 any host 1002::2
DeviceA(cfg-ipv6acl)# permit ipv6 any any
DeviceA(cfg-ipv6acl)# exit
```

(2) Apply the IPv6 ACL to a port.

On device A, apply the ACL to the inbound direction of the port connected to the R&D department.

```
DeviceA(cfg)# interface gigabitethernet 0/2
DeviceA(cfg-if-GigabitEthernet 0/2)# ipv6 access-apply dev_deny_ipv6video in
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA(cfg)# display access-control-lists

ipv6 access-control-list dev_deny_ipv6video
10 deny ipv6 any host 200::1
20 permit ipv6 any any

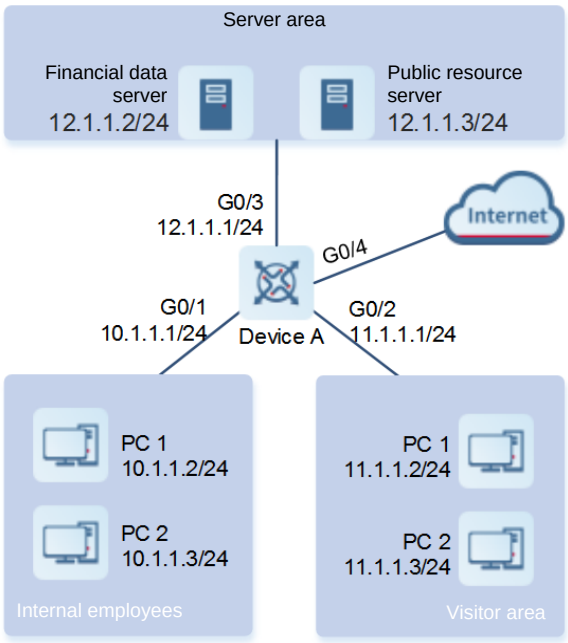
DeviceA(cfg)# display access-apply
ipv6 access-apply dev_deny_ipv6video in
Applied On interface GigabitEthernet 0/2
```

Ping the video server from a PC in the R&D department and confirm that the ping operation fails.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
ipv6 access-control-list dev_deny_ipv6video
 10 deny ipv6 any host 1002::2
 20 permit ipv6 any any
!
interface GigabitEthernet 0/1
 unset switch-port
 ipv6 address 1000::1/96
!
interface GigabitEthernet 0/2
 unset switch-port
 ipv6 access-apply dev_deny_ipv6video in
 ipv6 address 1001::1/96
!
interface GigabitEthernet 0/3
 unset switch-port
 ipv6 address 1002::1/96
!
```



1.14.6 Configuring an ACL80

1. Requirements

An ACL80, namely, an expert advanced ACL needs to be configured to restrict the resources accessible by visitors. Visitors cannot access the PCs of internal employees or the financial data server of the company, but can access the public resource server and Internet.

2. Topology

Figure 1-7 Configuring an ACL80

3. Notes

- On device A, configure an expert advanced ACL and add access rules, including:
  - Prohibiting the hosts in the visitor area from sending packets destined to the network segment of internal employees' PCs.
  - Prohibiting visitors from accessing the financial data server.
  - Permitting all the other packets to pass through.
- On device A, apply the ACL to the inbound direction of the port connected to the visitor area.

4. Procedure

(1) Configure an expert advanced ACL and add access rules.

On device A, configure an expert advanced ACL and add access rules.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# expert access-control-list advanced acl80-guest
DeviceA(cfg-expadvacl)# deny 0800 FFFF 24 0A0101 FFFFFF 42
DeviceA(cfg-expadvacl)# deny 0800 FFFF 24 0C010102 FFFFFFFF 42
DeviceA(cfg-expadvacl)# permit 0806 FFFF 24
DeviceA(cfg-expadvacl)# permit 0800 FFFF 24
DeviceA(cfg-expadvacl)# exit
```

(2) Apply the expert advanced ACL to a port.

On device A, apply the ACL80 to the inbound direction of the port connected to the visitor area.

```
DeviceA(cfg)# interface gigabitethernet 0/2
DeviceA(cfg-if-GigabitEthernet 0/2)# expert access-apply acl80-guest in
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA(cfg)# display access-control-lists
expert access-control-list advanced sss
 10 deny 0800 FFFF 24 0A0101 FFFFFF 42
 20 deny 0800 FFFF 24 0C010102 FFFFFFFF 42
 30 permit 0806 FFFF 24
 40 permit 0800 FFFF 24

expert access-apply acl80-guest in
Applied On interface GigabitEthernet 0/2
```

Ping the financial data server from a visitor PC and confirm that the ping operation fails.

Ping the public resource server from a visitor PC and confirm that the ping operation succeeds.

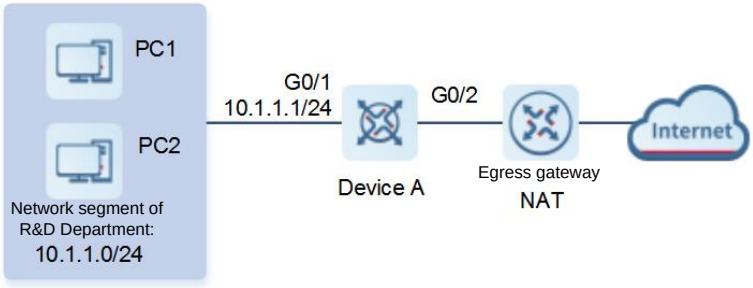
Ping the internal employee gateway 192.168.1.1 from a visitor PC and confirm that the ping operation fails.

Access the Internet through a visitor PC, for example, access www.baidu.com, and confirm that the home page can be opened.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
expert access-control-list advanced acl80-guest
 10 deny 0800 FFFF 24 0A0101 FFFFFF 42
 20 deny 0800 FFFF 24 0C010102 FFFFFFFF 42
 30 permit 0806 FFFF 24
 40 permit 0800 FFFF 24
!
interface GigabitEthernet 0/1
 unset switch-port
 ip address 10.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
 unset switch-port
 expert access-apply 2700 in
 ip address 11.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/3
 unset switch-port
 ip address 12.1.1.1 255.255.255.0
!
```



1.14.7 Configuring ACL Rules Based on Time Range

1. Requirements

ACL rules based on time range need to be configured to permit the R&D department to access the Internet only from 12:00 to 13:30 every day.

2. Topology

Figure 1-8 Configuring ACL Rules Based on Time Ranges

3. Notes

- Configure a time range on device A and add the time range entry from 12:00 to 13:30 every day.
- On device A, configure an IP standard ACL and add access rules, including:
  - Permitting packets from the source IP network segment 10.1.1.0/24 and associating the rule with the time range named access-internet.
  - Denying packets from the source IP network segment 10.1.1.0/24. This rule indicates that the Internet access is rejected beyond the time range.
  - Permitting packets from network segment addresses other than the R&D network segment addresses.
- On device A, apply the ACL to the inbound direction of the port connected to the R&D department.

4. Procedure

(1) Configure a time range.

Configure a time range on device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# time-range access-internet
DeviceA(cfg-timerange)# periodic daily 12:00 to 13:30
DeviceA(cfg-timerange)# exit
```

(2) Configure an IP standard ACL and add access rules.

On device A, configure an IP standard ACL and add access rules.

```
DeviceA(cfg)# ip access-control-list standard ip_std_internet_acl
DeviceA(cfg-stdacl)# permit 10.1.1.0 0.0.0.255 time-range access-internet
DeviceA(cfg-stdacl)# deny 10.1.1.0 0.0.0.255
DeviceA(cfg-stdacl)# permit any
```

```
DeviceA(cfg-stdacl)# exit
```

(3) Apply the IP standard ACL to a port.

On device A, apply the ACL to the inbound direction of the port connected the R&D department.

```
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# ip access-apply ip_std_internet_acl in
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA# display time-range

time-range entry: access-internet (inactive)
   periodic Daily 12:00 to 13:30

DeviceA# display access-control-lists

ip access-control-list standard ip_std_internet_acl
 10 permit 10.1.1.0 0.0.0.255 time-range access-internet (inactive)
 20 deny 10.1.1.0 0.0.0.255
 30 permit any

DeviceA# display access-apply
ip access-apply ip_std_internet_acl in
Applied On interface GigabitEthernet 0/1
```

During the effective period of the time range (12:00 to 13:30), visit the home page of www.baidu.com from a PC in the R&D department, and confirm that it can be accessed.

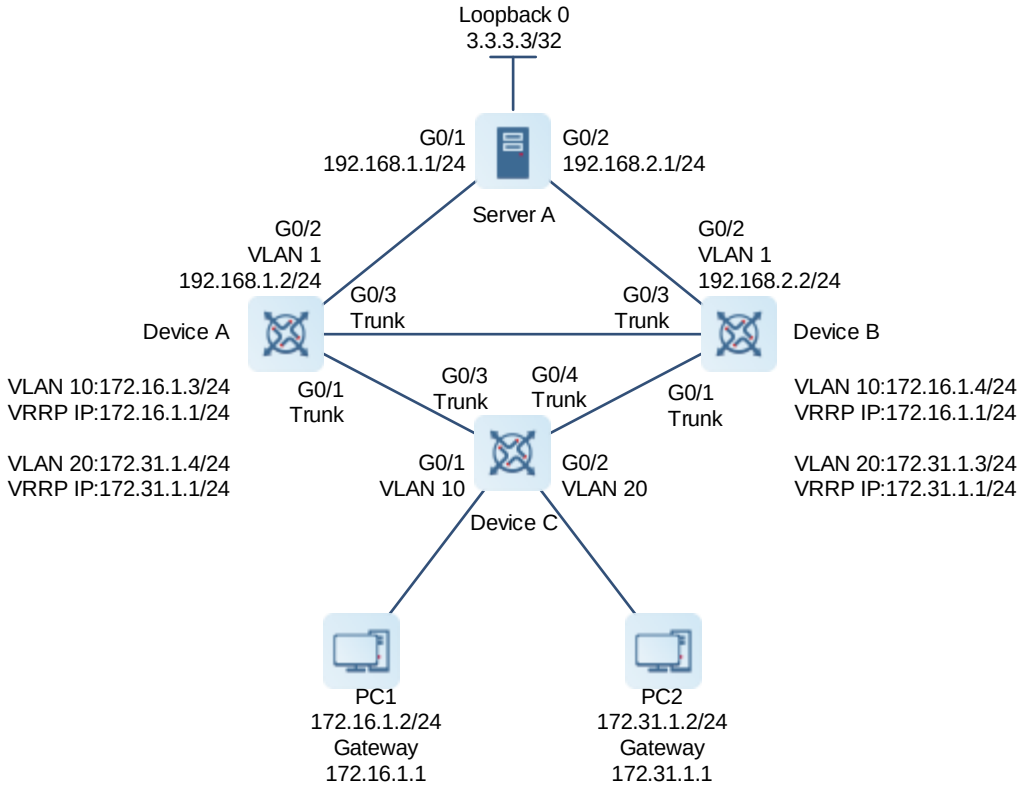
During the ineffective period (time beyond 12:00 to 13:30), visit the home page of www.baidu.com from a PC in the R&D department, and confirm that it cannot be accessed.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
ip access-control-list standard ip_std_internet_acl
 10 permit 10.1.1.0 0.0.0.255 time-range access-internet
 20 deny 10.1.1.0 0.0.0.255
 30 permit any
!
time-range access-internet
 periodic daily 12:00 to 13:30
!
interface GigabitEthernet 0/1
 unset switch-port
 ip access-apply ip_std_internet_acl in
 ip address 10.1.1.1 255.255.255.0
```

!



1.14.8 Configuring an SVI Router ACL

1. Requirements

Only Layer 3 communication between hosts in the scenario of a VRRP with multiple VLANs. Configure an ACL that only permits the access between hosts any denies the access request from other network segments.

2. Topology

Figure 1-9 Configuring an SVI Router ACL

3. Notes

- Device A and device B form a VRRP scenario. Both PC 1 and PC 2 are connected to device C.
- Configure STP to remove loops among device A, device B and device C.
- Use an SVI address as the gateway of PC 1 and PC 2.
- Configure an ACL that permits only the access between hosts and denies the access request from other network segments. Apply the ACL to the SVI. In this case, device A and device B are both hosts in the VRRP group.
- After the **svi router-acls enable** command is configured. Device A and device B in the VRRP group serve as a host and a backup respectively. VRRP returns to normal.

4. Procedure

(1) Configure a VLAN.

The configurations on device A, device B, device C and device D are the same. The following example configures a VLAN on device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# vlan 10
DeviceA(cfg-vlan)# exit
DeviceA(cfg)# vlan 20
DeviceA(cfg-vlan)# exit
```

(2) Configure a VRRP group.

Configure VRRP on device A.

```
DeviceA(cfg)# interface VLAN 10
DeviceA(cfg-if-VLAN 10)# ip address 172.16.1.3 255.255.255.0
DeviceA(cfg-if-VLAN 10)# vrrp-config 10 ip 172.16.1.1
DeviceA(cfg-if-VLAN 10)# vrrp-config 10 priority 120
DeviceA(cfg-if-VLAN 10)# exit
DeviceA(cfg)# interface VLAN 20
DeviceA(cfg-if-VLAN 20)# ip address 172.31.1.4 255.255.255.0
DeviceA(cfg-if-VLAN 20)# vrrp-config 20 ip 172.31.1.1
```

Configure VRRP on device B.

```
DeviceB(cfg)# interface VLAN 10
DeviceB(cfg-if-VLAN 10)# ip address 172.16.1.4 255.255.255.0
DeviceB(cfg-if-VLAN 10)# vrrp-config 10 ip 172.16.1.1
DeviceB(cfg-if-VLAN 10)# exit
DeviceB(cfg)# interface VLAN 20
DeviceB(cfg-if-VLAN 20)# ip address 172.31.1.3 255.255.255.0
DeviceB(cfg-if-VLAN 20)# vrrp-config 20 ip 172.31.1.1
DeviceB(cfg-if-VLAN 20)# vrrp-config 20 priority 120
DeviceB(cfg-if-VLAN 20)# exit
```

(3) Configure STP to remove loops.

The configurations on device A, device B, device C and device D are the same. The following example configures STP on device A.

```
DeviceA(cfg)# stp
```

(4) Configure an ACL.

The configurations on device A and device B are the same. The following example configures an ACL on device A.

```
DeviceA(cfg)# ip access-control-list standard 10
DeviceA(cfg-stdacl)# permit host 3.3.3.3
DeviceA(cfg-stdacl)# deny any
DeviceA(cfg-stdacl)# exit
```

(5) Apply an ACL to an SVI.

The configurations on device A and device B are the same. The following example applies an ACL to an interface of device A.

```
DeviceA(cfg)# int vlan 20
DeviceA(cfg-if-VLAN 20)# ip access-apply 10 in
```

(6) Configure the **svi router-acls enable** command on device A.

The configurations on device A and device B are the same. The following example configures the **svi router-acls enable** command on device A.

```
DeviceA(cfg)# svi router-acls enable
```

5. Verification

Check the VRRP status on device A.

```
DeviceA# display-config
Interface      Grp  Pri  timer   Own  Pre  State    Master addr     Group addr
VLAN 10        10   120  3.53    -    P    Master   172.16.1.3      172.16.1.1
VLAN 20        20   100  3.60    -    P    Backup   172.31.1.3      172.31.1.1
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
vlan 1
!
vlan 10
!
vlan 20

!
```

1.14.9 Configuring the ACL Packet Counting Function

1. Requirements

When you apply an ACL, you can configure the **counter-only** option to count the packets with some characteristics. The following example counts the ICMP packets discarded by the PC ping gateway and locate the discarded packets.

2. Topology

Figure 1-10 Configuring ACL Packet Counting

3. Notes

- Apply ACLs to both inbound and outbound directions of G0/1 and G0/2 on the device. You need to configure four ACLs on the device to match the ICMP packets from the PC to the gateway and from the gateway to the PC.
- Apply ACLs to both inbound and outbound directions of G0/1 on the gateway. You need to configure two ACLs on the gateway to match the ICMP packets from the PC to the gateway and from the gateway to the PC.
- Configure the **counter-only** option when you apply an ACL.
- The function only counts the packets matching the permit rule in the ACL and does not count those matching the deny rule.

4. Procedure

(1) Configure an ACL.

Configure four ACLs on the device to match the ICMP packets from the PC to the gateway and from the gateway to the PC.

```
Device> privilege
Device# config-system terminal
Device(cfg)# ip access-control-list extend 100
Device(cfg-extacl)# permit icmp host 10.10.10.1 host 10.10.10.254
Device(cfg-extacl)# exit
Device(cfg)# ip access-control-list extend 101
Device(cfg-extacl)# permit icmp host 10.10.10.254 host 10.10.10.1
Device(cfg-extacl)# exit
Device(cfg)# ip access-control-list extend 102
Device(cfg-extacl)# permit icmp host 10.10.10.1 host 10.10.10.254
Device(cfg-extacl)# exit
Device(cfg)# ip access-control-list extend 103
Device(cfg-extacl)# permit icmp host 10.10.10.254 host 10.10.10.1
Device(cfg-extacl)# exit
```

Configure two ACLs on the gateway to match the ICMP packets from the PC to the gateway and from the gateway to the PC.

```
Gateway> privilege
Gateway #config-system terminal
Gateway(cfg)# ip access-control-list extend 100
Gateway(cfg-extacl)# permit icmp host 10.10.10.1 host 10.10.10.254
Gateway(cfg-extacl)# exit
Gateway(cfg)# ip access-control-list extend 101
Gateway(cfg-extacl)# permit icmp host 10.10.10.254 host 10.10.10.1
Gateway(cfg-extacl)# exit
```

(2) Apply ACLs.

Apply ACLs to both inbound and outbound directions of the interconnected interface, G0/1, on the gateway and the device.

```
DeviceA(cfg)# interface VLAN 10
DeviceA(cfg-if-VLAN 10)# ip address 172.16.1.3 255.255.255.0
DeviceA(cfg-if-VLAN 10)# vrrp-config 10 ip 172.16.1.1
DeviceA(cfg-if-VLAN 10)# vrrp-config 10 priority 120
DeviceA(cfg-if-VLAN 10)# exit
DeviceA(cfg)# interface VLAN 20
DeviceA(cfg-if-VLAN 20)# ip address 172.31.1.4 255.255.255.0
DeviceA(cfg-if-VLAN 20)# vrrp-config 20 ip 172.31.1.1
```

Apply ACLs to both inbound and outbound directions of the interconnected interface, G0/2, on the gateway and the device.

```
Device# config-system terminal
Device(cfg)# interface gigabitEthernet 0/2
Device(cfg-if-GigabitEthernet 0/2)# ip access-apply 103 in counter-only
Device(cfg-if-GigabitEthernet 0/2)# ip access-apply 102 out counter-only
Device(cfg-if-GigabitEthernet 0/2)# exit
```

Apply ACLs to both inbound and outbound directions of the interconnected interface, G0/1, on the device and the PC.

```
Device# config-system terminal
Device(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-GigabitEthernet 0/1)# ip access-apply 100 in counter-only
Device(cfg-if-GigabitEthernet 0/1)# ip access-apply 101 out counter-only
Device(cfg-if-GigabitEthernet 0/1)# exit
```

5. Verification

Send a total of 15 ICMP packets three times from the PC ping gateway address, 10.10.10.254. Display the count of ICMP packets on the device and the gateway respectively. Display the count of ICMP packets on the device.

```
Device# display access-control-list
ip access-control-list extended 100
    10 permit ip host 10.10.10.1 host 10.10.10.254 (55 packets matches, 98008 bytes matches, 0:00:23 ago )
```

```
ip access-control-list extended 101
    10 permit ip host 10.10.10.254 host 10.10.10.1 (55 packets matches, 98008 bytes matches, 0:00:23 ago )
ip access-control-list extended 102
    10 permit ip host 10.10.10.1 host 10.10.10.254 (55 packets matches, 98008 bytes matches, 0:00:23 ago )
ip access-control-list extended 103
    10 permit ip host 10.10.10.254 host 10.10.10.1 (55 packets matches, 98008 bytes matches, 0:00:23 ago )
```

Display the count of ICMP packets on the gateway.

```
Gateway# display access-control-list
ip access-control-list extended 100
    10 permit ip host 10.10.10.1 host 10.10.10.254 (55 packets matches, 98008 bytes matches, 0:00:23 ago )
ip access-control-list extended 101
    10 permit ip host 10.10.10.254 host 10.10.10.1 (55 packets matches, 98008 bytes matches, 0:00:23 ago )
```

Analyze the count of ICMP packets and locate the discarded packets

15 packets are received in the inbound direction of the interconnected interface, G0/1, of the device and the PC. (ACL 100 is applied to the device.)

15 packets are sent from the outbound direction of the interconnected interface, G0/2, of the device and the gateway. (ACL 102 is applied to the device.)

15 packets are received in the inbound direction of the interconnected interface, G0/1, of the gateway and the device. (ACL 100 is applied to the gateway.)

15 packets are sent from the outbound direction of the interconnected interface, G0/1, of the gateway and the device. (ACL 101 is applied to the gateway.)

10 packets are received in the inbound direction of the interconnected interface, G0/2, of the device and the gateway. (ACL 103 is applied to the device.)

The packets were discarded in the link between the device and the gateway.

6. Configuration Files

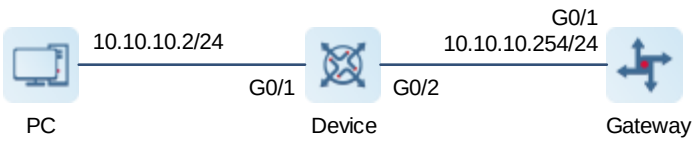
- Device configuration file

```
hostname Device
!
ip access-control-list extended 100
 10 permit icmp host 10.10.10.1 host 10.10.10.254
!
ip access-control-list extended 101
 10 permit icmp host 10.10.10.254 host 10.10.10.1
!
ip access-control-list extended 102
 10 permit icmp host 10.10.10.1 host 10.10.10.254
!
ip access-control-list extended 103
 10 permit icmp host 10.10.10.254 host 10.10.10.1
!
interface GigabitEthernet 0/1
 ip access-apply 100 in counter-only
```

```
 ip access-apply 101 out counter-only
!
interface GigabitEthernet 0/2
 ip access-apply 103 in counter-only
 ip access-apply 104 out counter-only
!
```

- Gateway configuration file

```
hostname Gateway
!
ip access-control-list extended 100
 10 permit icmp host 10.10.10.1 host 10.10.10.254
!
ip access-control-list extended 101
 10 permit icmp host 10.10.10.254 host 10.10.10.1
!
interface GigabitEthernet 0/1
 ip access-apply 100 in counter-only
 ip access-apply 101 out counter-only
 ip address 10.10.10.254 255.255.255.0
!
```



1.14.10 Configuring Hit-Log Output

1. Requirements

If the ACL contains the **hit-log** option, the number of packets with the specified feature is collected and output in the form of a hig-log. The following example counts the ICMP packets permitted by the standard ACL in a Ping operation and identifies the packet content.

2. Topology

Figure 1-11 Configuring Hit-Log Output

3. Notes

- Create a standard ACL named **std_acl**.
- Apply **ACL std_acl** in the ingress direction of interface G0/1.
- Enable **ACL std_acl** with counter.
- The output interval of hit-logs and of miss-logs are greater than 0s and 0 min respectively.

4. Procedure

(2) Configure the ACL.

Configure an ACL to permit ICMP packets from the PC to the gateway.

```
Device> privilege
Device# config-system terminal
Device(cfg)# ip access-control-list standard std_acl
Device(cfg-extacl)# permit any hit-log
Device(cfg-extacl)# exit
```

(3) Apply the ACL.

Apply the ACL in the ingress direction of interface G0/1.

```
Device(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-GigabitEthernet 0/1)# ip access-apply std_acl in
Device(cfg-if-GigabitEthernet 0/1)# exit
```

(4) Enable ACL counter.

Enable ACL counter.

```
Device(cfg)# ip access-control-list counter std_acl
```

(5) Configure the intervals of hit-logs and of miss-logs respectively.

Set the intervals of hit-logs and of miss-logs to 5s and 1 min respectively.

```
Device(cfg)# global access-control-list hit-log interval 5
Device(cfg)# global access-control-list miss-log interval 1
```

5. Verification

Ping the gateway IP address 10.10.10.254 from a PC and send a total of 600000 ICMP packets in 70s. Enable syslog on the device and verify hit-log and miss-log output.

```

1 Configuring QoS

1.1 Introduction

1.1.1 Overview

Quality of service (QoS) can meet users' requirements for different applications and different levels of service quality. It allocates and schedules resources based on users' requirements and provides different levels of service quality for different packets.

On a traditional IP network, a device treats all the packets in the same way, in which the device processes packets based on their arrival time according to the queuing strategy of first in first out (FIFO), and transmits the packets to the destination on a best-effort basis. When the network bandwidth is abundant, all the packets are properly processed; when the network is congested, all the packets may be discarded.

QoS assigns a transmission priority to the packets of a type to highlight the importance of the packets. Then, the devices provide special transmission services for these packets according to forwarding policies for different priorities, congestion avoidance, and other mechanisms. With QoS, a device processes real-time and important packets preferentially, processes non-real-time and common packets with lower priorities and even discards the packets upon network congestion.

QoS enhances the network performance predictability, effectively allocates network bandwidth, and reasonably utilizes network resources.

1.1.2 Principles

1. Basic Concepts

- DiffServ model

  The differentiated services (DiffServ) model classifies all packets transmitted on a network into different types. The classification information related to QoS priority marking is recorded in some fields of Layer 2 or Layer 3packets, for example, the PRI field of IEEE 802.1Q frames, type of service (ToS) field of IPv4 packets, traffic class (TC) field of IPv6 packets, and the MPLS experimental bits (EXP) field of multiprotocol label switching (MPLS) packets.

  In the network of DiffServ model, the classification information of packets can be assigned by hosts or other network devices or based on different application policies or different packet contents. A device applies the same transmission service policy to packets containing the same classification information and applies different transmission service policies to packets containing different classification information. Based on the classification information carried by packets, a device may provide different transmission priorities for different packets, reserve bandwidth for a kind of packets, discard certain packets with lower priorities, or take some other actions.

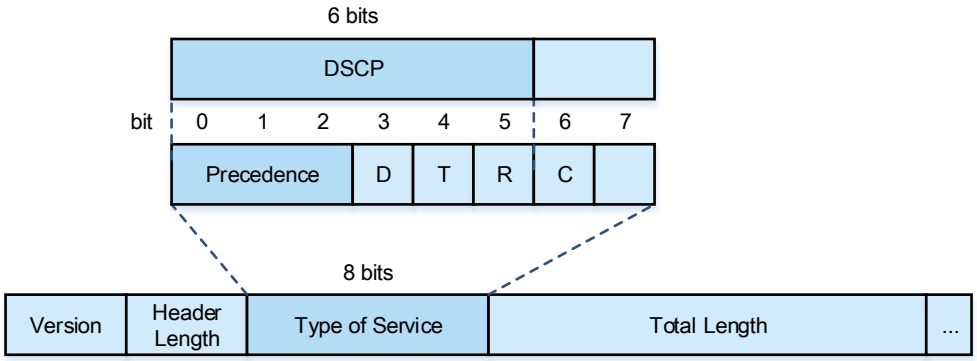
- PRI field of the IEEE 802.1q frames

  The PRI field of IEEE 802.1Q frames (namely, the IEEE 802.1p priority) is located in the header of an Layer 2 packet containing an IEEE 802.1Q tag header, as shown in Figure 1-1.

Figure 1-1 Format of an Layer 2 Frame with an IEEE 802.1Q Tag Header

The 4-byte IEEE 802.1Q tag header contains the 2-byte tag protocol identifier (TPID) and 2-byte tag control information (TCI). TCI contains the 3-bit PRI field, as shown in Figure 1-2.

Figure 1-2 PRI Field of the IEEE 802.1q Frames

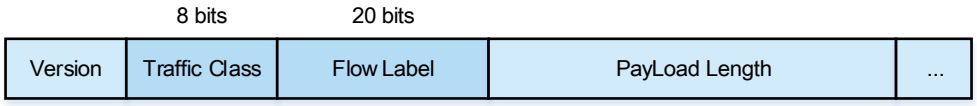


The PRI field represents eight priorities for packet transmission, and the priority values from high to low are 7, 6, ..., 1, and 0. The IEEE 802.1p priority is applicable to scenarios where Layer 3 headers do not need to be analyzed and QoS needs to be implemented only at Layer 2.

- ToS field of the IPv4 packets

  IPv4 packets use the ToS field in the IP header to indicate the priority of the packets, as shown in Figure 1-3.

Figure 1-3 ToS Field in the IP Header



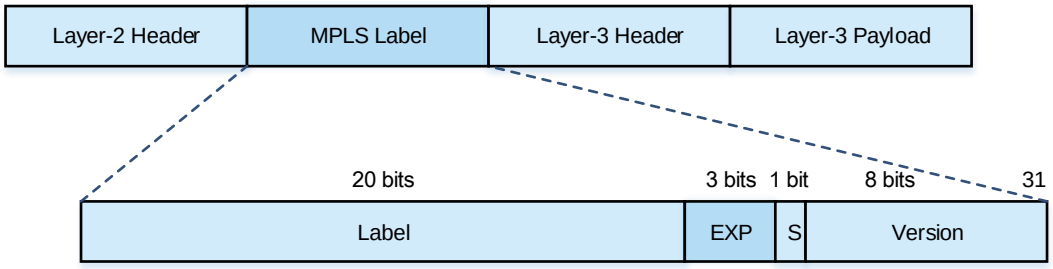
The ToS field contains eight bits, of which the first three bits are the IP PRE (precedence) field and represent eight priorities for packet transmission, with the priority values from high to low being 7, 6, ..., 1, and 0.

RFC 2474 redefines the ToS field of the IP header, in which the first 6 bits (bits 0 to 5) represent the differentiated services code point (DSCP). DSCP is used to classify packets into a maximum of 64 different categories.

- ToS field of the IPv6 packets

  IPv6 packets use the TC field in the IPv6 header to indicate the packet priority, as shown in Figure 1-4Figure 1-4.

Figure 1-4 TC Field in the IPv6 Header



The TC field contains eight bits and provides the same function as the ToS field of IPv4 packets. The first six bits of the TC field indicate DSCP.

- EXP field of the MPLS packets

  MPLS packets use the EXP field in the label to indicate the packet priority, as shown in Figure 1-5.

Figure 1-5 EXP Field in the MPLS Label

The EXP field contains three bits, which represent eight priorities for packet transmission, and the priority values from high to low are 7, 6, ..., 1, and 0. Since the EXP field has the same length as the priority field (IP PRE) of IP packets, one-to-one mapping can be formed between them.

- CoS

  The class of service (CoS) is used to determine the packet queue number when an interface sends packets. The CoS values are 7, 6, ..., 1, and 0 from high to low.

2. Traffic Classification

Traffic classification identifies packets with certain characteristics according to rules. It is the prerequisite and basis for providing differentiated network services. Traffic classification is classified into simple traffic classification and complex traffic classification.

- Simple traffic classification

  Simple traffic classification classifies packets only based on the priorities carried in packets (for example, the PRI value of IEEE 802.1q frames, IP PRE or DSCP value of IP packets, TC value of IPv6 packets, and the EXP value of MPLS packets). Simple traffic classification implements the mapping from the priority to

the CoS of the device based on whether an interface is configured to trust the priority tag carried in uplink packets.

- Complex traffic classification

  Complex traffic classification classifies packets based on the priorities carried in packets or by identifying packets meeting certain characteristics according to access control list (ACL) rules.

  A QoS policy based on complex traffic classification associates the complex traffic classification with relevant traffic behaviors to form a policy, which is then applied to an interface to take effect. A QoS policy comprises three elements: class, traffic behavior, and policy.

  - A class comprises the class name and class rule. A class defines the matching rules of traffic classification to classify packets.
  - A traffic behavior defines the action to be taken for the classified packets, including modifying the packet priority (also known as priority re-marking) and monitoring traffic.
  - A policy comprises the policy name, and the binding relationship between a class and a traffic behavior. A policy binds a specified class and a traffic behavior and is applied to one or more interfaces to take effect.

The policy-based binding between multiple traffic classes and behaviors is as shown in Figure 1-6.

Figure 1-6 Policy-Based Binding Between Multiple Traffic Classes and Behaviors

- QoS logical interface group

  You can specify a series of interfaces (aggregation ports or Ethernet interfaces) as a QoS logical interface group, and associate a policy with the logical interface group for QoS processing. For example, the rate limiting function of a traffic behavior enables the packets complying with the rate limiting conditions to share the bandwidth limited by the policy on all the interfaces in the same logical interface group.

3. Priority Mapping

Priorities are used to identify the scheduling weights or forwarding priority of packets. Different priority types are defined for different packet types: IEEE 802.1q frames use the IEEE 802.1p priority, IP packets use the IP PRE or DSCP, and MPLS packets use the EXP priority, and so on.

After a packet enters a device interface, the packet priority is mapped to the CoS according to the trust mode configured for the interface. Table 1-1 shows the mappings between trust mode configured for an interface and the priorities.

Table 1-1 Interface Trust Mode and Priority Mapping

Interface Trust Mode	Priority Mapping
Untrusted	● No priority carried in packets is trusted. ● All packets received from an interface use the IEEE 802.1p value configured for the interface. ● The CoS values are obtained from the 802.1p-to-DSCP mapping table and DSCP-to-CoS mapping table. Packets are sent to queues based on their CoS values. ● If an IEEE 802.1Q tagged packet is sent from an egress, the packet priority is changed to the corresponding CoS value.
Trusting 802.1p	● If a packet received by an interface is an IEEE 802.1Q tagged packet, the carried IEEE 802.1p value is directly used. If a packet does not carry any tag, the IEEE 802.1p value configured for the interface is used. ● The CoS values are obtained from the 802.1p-to-DSCP mapping table and DSCP-to-CoS mapping table. Packets are sent to queues based on their CoS values. ● If an IEEE 802.1Q tagged packet is sent from an egress, the packet priority is changed to the corresponding CoS value.
Trusting DSCP	● If a packet received from an interface is a non-IP packet, it is processed in the same way of trusting 802.1p. If the received packet is an IP packet, the CoS value is obtained from the DSCP-to-CoS mapping table based on the DSCP value of the packet. Packets are sent to queues based on their CoS values. ● If an MPLS header needs to be encapsulated into a packet, the EXP value is changed according to the DSCP-to-EXP mapping table.
Trusting IP PRE	● If a packet received from an interface is a non-IP packet, it is processed in the same way of trusting 802.1p. If the received packet is an IP packet, the CoS value is obtained from the IP PRE-to-DSCP mapping table and DSCP-to-CoS mapping table based on the IP PRE value of the packet. Packets are sent to queues based on their CoS values.
Trusting EXP	● If a packet received from an interface is a non-MPLS packet, it is processed in the same way of trusting 802.1p. If the received packet is an MPLS packet, the CoS value is obtained from the EXP-to-CoS mapping table based on the EXP value of the packet. Packets are sent to queues based on their CoS values. ● After an MPLS header is decapsulated, the DSCP value is changed according to the EXP-to-DSCP mapping table.

4. Traffic Policing

Traffic policing supervises the rate of the specific traffic, limits the rate within a reasonable range, and discards the traffic out of the limit or re-marks the priority. Traffic policing adopts the committed access rate (CAR)

technology to control traffic. CAR uses the single-rate single-token bucket algorithm to judge whether the rate of each packet exceeds the specified traffic limit.

- Single-rate single token bucket

  The single-rate single token bucket contains two parameters: **CIR** and **CBS**.

  - Committed information rate (CIR): Indicates the rate at which a token is added to a token bucket.
  - Committed burst size (CBS): Indicates the capacity of a token bucket.

  The single-rate single token bucket adds tokens to a token bucket at a fixed rate (namely, CIR). When the number (that is, CBS) of tokens in a token bucket reaches the capacity of the token bucket, the excess tokens are discarded. When the device processes packets, it takes tokens out of the token bucket, with the number same as the size of packets (in bytes). When the number of tokens is sufficient, the packets can be forwarded. When the number of tokens is insufficient, the packets are discarded or the priorities of some packets are re-marked before forwarding.

- CAR processing

  CAR uses a token bucket to measure the packets passing through an interface, and implements the preset policing action based on the measurement results. These actions include:

  - Forwarding: Packets within the traffic limit are normally forwarded.
  - Discarding: Packets out of the traffic limit are discarded. The packets out of the total traffic limit of an interface are directly discarded.
  - Changing the priority and forwarding: The priorities of the packets out of the traffic limit are changed and then the packets are forwarded.

5. Congestion Management

When the receiving rate of packets exceeds the sending rate, congestion occurs on the sending interface. If no sufficient buffer is provided to store these packets, packet loss may occur. The congestion management mechanism determines the sending order of packets based on their local priorities. The congestion management function controls congestion and improves the local priorities of packets for some important data. When congestion occurs, the packets of higher priorities are sent first to ensure that key services are provided in time.

Congestion management adopts the queue scheduling mechanism. The processing is as follows:

(1) After each packet undergoes the QoS processing in a device, it obtains a CoS value finally.

(2) The device allocates the packets to the corresponding sending queues according to the CoS values.

(3) The outbound interface selects the packets in a queue for sending according to various queue scheduling policies (such as SP, RR, WRR, DRR, WFQ, SP+WRR, SP+DRR, and SP+WFQ).

- SP scheduling policy

  In strict-priority (SP) scheduling, packets are scheduled strictly based on their queue priorities from high to low. Before sending a packet, check whether there is a packet to be sent in a high-priority queue. If there is, send it. If not, check whether there is a packet to be sent in the next-level queue, and so on.

  The weakness of SP scheduling is that, when congestion occurs, if the packets in a higher priority queue exist for a long time, the packets in a lower priority queue have no opportunity of being scheduled.

- RR scheduling policy

  Round robin (RR) scheduling uses the round robin method to schedule multiple queues. Only one packet in a queue is processed each time.

- WRR scheduling policy

  The weighted round robin (WRR) scheduling solves the problem that weight cannot be set for RR scheduling. WRR scheduling also adopts the round robin method to schedule multiple queues. The number of packets in a queue processed each time is proportional to the weight of the queue. RR scheduling is equivalent to WRR scheduling with the weight 1.

  However, WRR scheduling fails to schedule the services with low delay requirements in time.

- DRR scheduling policy

  The deficit round robin (DRR) scheduling is similar to WRR scheduling, but implements scheduling based on the number of packet bytes, instead of the number of packets.

  However, DRR scheduling fails to schedule the services with low delay requirements in time.

- WFQ scheduling policy

  Weighted fair queuing (WFQ) scheduling fixes the problem that the queues using WRR scheduling have no fixed egress bandwidth. WFQ scheduling allocates an egress bandwidth to queues based on the queue weight, and different queues can have the opportunity of fair scheduling.

- SP+WRR scheduling policy

  SP scheduling is configured for one or more sending queues, and the other queues are scheduled in the WRR mode. Among SP queues, only after all the packets in an SP queue with a higher priority are sent, can the packets in an SP queue with a next higher priority be sent. Among SP and WRR queues, only after the packets in all SP queues are sent, can the packets in WRR queues be sent.

- SP+DRR scheduling policy

  SP scheduling is configured for one or more sending queues, and the other queues are scheduled in the DRR mode. Among SP queues, only after all the packets in an SP queue with a higher priority are sent, can the packets in an SP queue with a next higher priority be sent. Among SP and DRR queues, only after the packets in all SP queues are sent, can the packets in DRR queues be sent.

- SP+WFQ scheduling policy

  SP scheduling is configured for one or more sending queues, and the other queues are scheduled in the WFQ mode. Among SP queues, only after all packets in an SP queue with a higher priority are sent, can the packets in an SP queue with a next higher priority be sent. Among SP and WFQ queues, only after the packets in all SP queues are sent, can the packets in WFQ queues be sent.

6. Congestion Avoidance

Congestion avoidance monitors the usage of the outbound interface queues, and eliminates the network overload by actively discarding packets and adjusting the network traffic when network congestion occurs. Congestion avoidance avoids congestion by effectively monitoring the network traffic load, forecasting the occurrence of congestion, and discarding packets. Discarding policies include tail-drop, discarding based on random early detection (RED) results, and discarding based on weighted random early detection (WRED) results.

- Tail-drop

  Traditional packet loss policies use the tail-drop method. Tail-drop is effective for all traffic and cannot distinguish service levels. When congestion occurs, data packets at the tail of a queue are discarded until the congestion is removed.

- RED and WRED

The hosts running Transmission Control Protocol (TCP) decreases the rate of sending packets to respond to massive packet loss. After congestion is removed, the hosts increase the rate of sending packets. Tail-drop may cause TCP global synchronization. Namely, when a queue discards multiple TCP packets simultaneously, multiple TCP connections enter the congestion avoidance and slow startup state simultaneously. In this case, the tail is dropped, and the traffic is reduced and adjusted. When congestion is removed, traffic peaks appear. The process repeats constantly, the network traffic goes up and down suddenly, and the line traffic always fluctuates between the lowest traffic and the full traffic. When TCP global synchronization occurs, the connection bandwidth cannot be fully used, which causes a bandwidth waste.

To avoid this circumstance, you can use the RED or WRED packet discarding policy. The policy provides a mechanism for discarding packets at random and avoiding TCP global synchronization. When packets of a TCP connection are discarded and the remaining packets of the TCP connection are sent at a lower rate, packets of other TCP connections are still sent at higher rates. There are always some TCP connections whose packets are sent at higher rates, which increases the utilization of line bandwidth.

When WRED is used, you can set the lower threshold and maximum discarding probability for a queue. When the length of a queue is smaller than the lower threshold, no packets are discarded. When the queue length is between the lower threshold and higher threshold, WRED starts to discard packets randomly and sets a maximum discarding probability. A longer queue leads to a higher discarding probability. When the length of a queue is greater the higher threshold, packets are discarded at the maximum discarding probability.

Different from RED, WRED uses priorities to distinguish discarding policies. RED is a special case of WRED. When all the CoS values of an interface are mapped to the same lower and higher thresholds, WRED becomes RED.

1.2 Configuration Task Summary

QoS configuration includes the following tasks:

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Traffic Classification
- Configuring Priority Mapping
- Configuring the Interface Rate Limit
- Configuring Congestion Management
- Configuring Congestion Avoidance
- Configuring the QoS Global Policy
- Disabling the Packet Priority Change
- Configuring the Queue Display and Configuration Mode

1.3 Configuring Traffic Classification

1.3.1 Overview

Traffic classification uses certain rules to identify the packets with certain characteristics. You can define the binding between multiple traffic classes and traffic behaviors to form policies and apply the policies to interfaces to realize traffic classification and processing.

1.3.2 Configuration Tasks

Traffic classification configuration includes the following tasks:

(1) Configuring a Class

(2) Configuring a Policy

(3) Applying a Policy

(4) (Optional) Configuring a Logical Interface Group

1.3.3 Configuring a Class

1. Overview

This section describes how to create a class, and defines class matching rules in class configuration mode.

2. Restrictions and Guidelines

- A class name comprises a maximum of 31 characters.
- Run the **match-rule** command to define a class matching rule.
- When setting the matching rule of a class to ACL matching, you need to create an ACL and ACL rules first.
- The new rule will overwrite the previous one and the device will only keep the latest rule. A notification will be prompted when a new rule is configured

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a class and enter the class configuration mode.

cmap-create *class-map-name*

No class is configured by default.

(4) Define a matching rule for the class. Configure at least one of the tasks.

- Set the matching rule of the class to ACL matching.

  match-rule access-apply { *acl-name* | *acl-number* }

  Numerically indexed ACLs or named ACLs are supported.

- Set the matching rule of the class to matching the PRE priorities of IP packets.

  match-rule ip precedence *precedence-value-list*

  Multiple IP PRE values can be matched at the same time. The value range of IP PRE is from 0 to 7.

- Set the matching rule of the class to matching the DSCP priorities of IP packets.

  match-rule ip dscp *dscp-value-list*

  Multiple DSCP values can be matched at the same time. The value range of DSCP priority is from 0 to 63.

No class matching rules are defined by default.

1.3.4 Configuring a Policy

1. Overview

This section describes how to create a policy, and bind classes and traffic behaviors in the policy configuration mode.

2. Restrictions and Guidelines

- A policy name comprises a maximum of 31 characters.
- When multiple classes are associated with the same policy, you are not advised to match the same flow with multiple classes; otherwise the traffic behavior bound to a class is performed on the flow randomly, and, when the device restarts, the traffic behavior bound to a class is also performed on the flow randomly.
- The **set** command is used to modify the priority tag of a specified packet, such as IEEE 802.1p and DSCP.
- The **police** command is used to limit the bandwidth of the specified traffic and configure the processing action on traffic beyond the limit, for example, discarding the traffic out of the limit, or modifying the CoS or DSCP value.
- The **drop** command is used to drop all the identified streams. To configure other traffic behaviors, you must delete this traffic behavior.
- The **unset police** or **unset apply acl** command may fail to take effect for the applied QoS flow policy configuration due to insufficient FP resources. The configuration will not rolled back automatically. In this case, you need to restore the **no** action manually. You are advised to cancel the application before changing the action and then apply the application again after.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a policy and enter the policy configuration mode.

policy-create *policy-map-name*

No policy is configured by default.

(4) Associate a class and enter the policy class configuration mode.

cmap *class-map-name*

No class is associated with a policy by default.

(5) Bind the class to a traffic behavior. Configure at least one of the tasks.

- Bind the class to the traffic behavior of modifying the IEEE 802.1p,and DSCP values.

  set { **cos** *new-cos* [**priority**] | **ip dscp** *new-dscp* [**with cos** *new-cos* **priority**] }

- Bind the class to the traffic behavior of limiting the bandwidth and processing packets beyond the limit.

  police *rate-bps burst-byte* [**exceed**-**action** { **cos** *new-cos* [**none**-**tos**] | **drop** | **dscp** *new-dscp* }]

- Bind the class to the traffic behavior of discarding packets.

  drop

A class is not bound to any traffic behavior by default.

This command can be configured only when a class associated with a policy is not bound to any traffic behavior. Namely, after a class associated with a policy is bound to the traffic behavior of discarding packets, you need to first delete the binding and then bind the class to other traffic behaviors.

(6) Enable ACL filtering to filter out packets matching the deny rule.

apply acl

(7) Enable policy statistics.

statistics enable

1.3.5 Applying a Policy

1. Overview

This section describes how to apply a configured policy to a specified interface to make the policy take effect.

2. Restrictions and Guidelines

- A policy can be applied globally or to an interface.
- If a policy is applied globally, the policy is applied to all interfaces which can be configured with policies.
- Configuring the **input** option applies a policy to the input direction of an interface.
- Configuring the **output** option applies a policy to the output direction of an interface.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

- Apply a policy in global configuration mode.

  apply-policy { **input** | **output** } *policy-map-name*

  No policy is applied globally by default.

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(4) Apply a policy on the interface.

apply-policy { **input** | **output** } *policy-map-name*

No policy is applied to an interface by default.

1.3.6 Configuring a Logical Interface Group

1. Overview

This section describes how to associate a configured policy with a logical interface group.

2. Restrictions and Guidelines

- A maximum of 128 logical interface groups can be created.
- In global configuration mode, run the **virtual-group** command to create a logical interface group and enter the logical interface group configuration mode.
- In interface configuration mode, run the **virtual-group** command to add the interface to a specified logical interface group. If the logical interface group is not created, this command creates the logical interface group and adds the interface to the group.
- The following types of interfaces cannot be added to a logical interface group:
  - Member interface of an aggregation port
  - VSL member interface

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

- Create a logical interface group

  virtual-group *virtual-group-number*

  No logical interface group is defined by default.

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport interface *-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface ethernet-type interface-number

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(4) Add the interface to a logical interface group.

virtual-group *virtual-group-number*

An interface is not added to any logical interface group by default.

(5) Return to the global configuration mode.

exit

(6) Enter the logical interface group configuration mode.

virtual-group *virtual-group-number*

(7) Apply a policy to the logical interface group.

apply-policy { **input** | **output** } *policy-map-name*

1.4 Configuring Priority Mapping

1.4.1 Overview

Priority mapping can be implemented based on the trust mode configured for an interface.

1.4.2 Configuration Tasks

Priority marking and mapping configuration includes the following tasks:

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Trust Mode
- Configuring Mappings

1.4.3 Configuring the Trust Mode

1. Overview

- You can set various priorities for packets according to the trust mode configured for an interface.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Ethernet interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface *ethernet-type interface-number*

(4) Configure the trust mode for the interface. Please configure only one task.

- Configure trusting IEEE 802.1p.

  mls qos trust cos

- Configure trusting DSCP.

  mls qos trust dscp

- Configure trusting IP PRE.

mls qos trust ip-precedence

An interface is in untrusted mode by default.

(5) (Optional) Configure the IEEE 802.1p value for the interface.

mls qos cos *cos-value*

The default IEEE 802.1p value of an interface is **0**.

1.4.4 Configuring Mappings

1. Overview

This section describes how to configure mappings.

2. Restrictions and Guidelines

- Run the **mls qos map cos-dscp** command to configure the mappings from IEEE 802.1p values to DSCP values.
- Run the **mls qos map dscp-cos** command to configure the mappings from DSCP values to CoS values.
- Run the **mls qos map ip-precedence-dscp** command to configure the mappings from IP PRE values to DSCP values.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure mappings. Configure at least one of the tasks.

- Configure the IEEE 802.1p-to-DSCP mappings.

  mls qos map cos-dscp *dscp-value-list*

  The IEEE 802.1p values 0 to 7 are mapped to the DSCP values 0, 8, 16, 24, 32, 40, 48, and 56 respectively by default.

- Configure the DSCP-to-CoS mappings.

  mls qos map dscp-cos *dscp-value*&<1-8> **to** *cos-value*

  DSCP values 0 to 7 are mapped to CoS 0, DSCP values 8 to 15 are mapped to CoS 1, DSCP values 16 to 23 are mapped to CoS 2, DSCP values 24 to 31 are mapped to CoS 3, DSCP values 32 to 39 are mapped to CoS 4, DSCP values 40 to 47 are mapped to CoS 5, DSCP values 48 to 55 are mapped to CoS 6, and DSCP values 56 to 63 are mapped to CoS 7 by default.

- Configure the IP PRE-to-DSCP mappings.

  mls qos map ip-precedence-dscp *dscp-value-list*

  The IP PRE values 0 to 7 are mapped to the DSCP values 0, 8, 16, 24, 32, 40, 48, and 56 respectively by default.

1.5 Configuring the Interface Rate Limit

1.5.1 Overview

This section describes how to configure traffic limit for an interface.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Ethernet interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(4) Configure traffic limit for the interface. Configure at least one of the tasks.

- Configure the rate limit for the traffic in the input direction of an interface.

  speed-limit input *rate-value burst-value*

- Configure the rate limit for the traffic in the output direction of an interface.

  speed-limit output *rate-value burst-value*

No traffic limit is configured for an interface by default.

1.6 Configuring Congestion Management

1.6.1 Overview

This section describes how to control congestion. The priorities of important data packets can be raised so that they are sent first when congestion occurs, thereby ensuring that key services are provided in time.

1.6.2 Configuration Tasks

The congestion management configuration includes the following tasks:

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the CoS-to-Queue Mappings
- Configuring the Scheduling Policy and Round Robin Weights for Output Queues
- Configuring Bandwidth for a Queue

- Enabling ECN for a Queue
- Configuring Cumulative ECN Counter
- Configuring the ECT Mark Type

1.6.3 Notes

Table 1-2 Products Supporting Congestion Management Functions

Function	Product
Configuring Cumulative ECN Counter	Supported by the S6580-48CQ8QC and S6580-24DC8QC
Configuring the ECT Mark Type	Supported by the S6580-48CQ8QC and S6580-24DC8QC

1.6.4 Configuring the CoS-to-Queue Mappings

1. Overview

This section describes how to configure the CoS-to-queue mappings so that packets can enter various output queues based on their CoS values.

2. Restrictions and Guidelines

- Run the **priority-queue cos-map** command to configure the CoS-to-queue mappings.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the CoS-to-queue mappings.

priority-queue cos-map *qid cos-value* &<1-8>

The CoS values 0 to 7 are mapped to the queues 1 to 8 respectively by default.

1.6.5 Configuring the Scheduling Policy and Round Robin Weights for Output Queues

1. Overview

This section describes how to configure the scheduling policy and round robin weights for output queues.

2. Restrictions and Guidelines

- Run the **priority-queue** command to set the scheduling policy to SP scheduling.
- Run the **mls qos scheduler sp** command to set the scheduling policy to SP scheduling for output queues.
- Run the **mls qos scheduler rr** command to set the scheduling policy to RR scheduling for output queues.

- Run the **mls qos scheduler wrr** command to set the scheduling policy to WRR scheduling based on the packet quantity for output queues.
- Run the **mls qos scheduler drr** command to set the scheduling policy to WRR scheduling based on the packet size for output queues.
- Run the **mls qos scheduler wfq** command to set the scheduling policy to WFQ scheduling for output queues.
- Run the **drr-queue bandwidth** command to configure the round robin weight for the DRR scheduling policy of output queues. A higher weight means that more packet bytes can be sent.
- Run the **wrr-qos-queue bandwidth** command to configure the round robin weight for the WRR scheduling policy of output queues. A higher weight means longer output time. The configurable weight range depends on the product.
- Run the **wfq-queue bandwidth** command to configure the round robin weight for the WFQ scheduling policy of output queues. A higher weight means that more packet bytes can be sent.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the scheduling policy for output queues. Please configure only one task.

- Set the scheduling policy to SP scheduling.

  priority-queue

- Configure the scheduling policy for global output queues.

  mls qos scheduler { **drr** | **rr** | **sp** | **wfq** | **wrr** }

  The default scheduling policy of global output queues is **WRR**.

- Configure the scheduling policy for interface output queues. Run the following commands in turn to configure the scheduling policy for interface output queues.

  interface *interface-type interface-number*

  mls qos scheduler { **drr** | **rr** | **sp** | **wfq** | **wrr** }

  No scheduling policy is configured on an interface by default.

(4) Configure the round robin weight for the scheduling policy of output queues. Please configure only one task.

- Configure the round robin weight for the scheduling policy of global output queues.

  { **drr-queue** | **wfq-queue** | **wrr-qos-queue** } **bandwidth** *weight-value-list*

  The default round robin weight ratio of global queues is **1:1:1:1:1:1:1:1**.

- Configure the round robin weight for the scheduling policy of interface output queues. Run the following commands in turn to configure the round robin weight for the scheduling policy of interface output queues.

  interface *interface-type interface-number*

  { **drr-queue** | **wfq-queue** | **wrr-qos-queue** } **bandwidth** *weight-value-list*

  The default round robin weight ratio of interface queues is **1:1:1:1:1:1:1:1**.

1.6.6 Configuring Bandwidth for a Queue

1. Overview

This section describes how to configure the minimum guaranteed bandwidth and maximum limited bandwidth for a queue.

2. Restrictions and Guidelines

- This command can be configured globally or on an interface, depending on the product.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the L2 or L3 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

(4) Configure the minimum guaranteed bandwidth and maximum limited bandwidth for a queue.

qos queue *queue-id* **bandwidth** { **maximum** *bandwidth* | **minimum** *bandwidth* }

No minimum guaranteed bandwidth or maximum limited bandwidth is configured for a queue by default.

1.6.7 Enabling ECN for a Queue

1. Overview

With combination of the WRED technology and explicit congestion notification (ECN) technology, a terminal can perceive network congestion and notify the source device of the congestion. Upon receiving the notification, the source device reduces the packet sending rate to prevent congestion aggravation.

2. Restrictions and Guidelines

- Both the ECN and WRED functions must be configured before the ECN function is enabled for a queue.
- After the ECN function is enabled for a queue (namely, the ECN field in packets is set to **01** or **10**), when queue congestion occurs, the device changes the ECN field to **CE** (**11**), instead of discarding packets randomly according to the WRED template.
- After the ECN function is enabled for a queue, the device sets the ECN field to **CE** only when the packet rate reaches the lower discarding threshold specified in the WRED template.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the global WRED function.

queueing wred

The WRED function is disabled by default.

(4) (Optional) Configure a sampling interval for collecting statistics on the packets discarded by WRED and packets marked by ECN.

qos wred-ecn statistics sample-period *period-value*

A sampling interval for collecting statistics is configured by default.

(5) Enter the Layer 2 or Layer 3 Ethernet interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface *ethernet-type interface-number*

(6) Enable the ECN function for a queue.

qos queue *queue-id* **ecn**

The ECN function is disabled for an interface queue by default.

1.6.8 Configuring Cumulative ECN Counter

Note

This function is supported by only the S6580-48CQ8QC, and S6580-24DC8QC.

1. Overview

The device counts new ECN-marked packets by default. Some products support cumulative ECN-marked packet counting.

2. Restrictions and Guidelines

- ECN statistics will be cleared when the counter mode is changed.
- If you run the **unset qos queue** *queue-id* **ecn** command to disable the ECN function for a queue, the interface still counts the cumulative number of ECN-marked packets. Run the **display qos wred-ecn statistics** command to display the cumulative number.

3. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Configure cumulative ECN counter.
qos wred-ecn statistics mode ecn-total

Cumulative ECN counter is not configured by default.

1.6.9 Configuring the ECT Mark Type

Note

This function is supported by only the S6580-48CQ8QC and S6580-24DC8QC.

1. Overview

The chips need to be specified with the ECN Capable Transport (ECT) mark value for packet counting. Parameters **ect0** and **ect1** correspond to value **10** and **01** respectively. If not specified, the parameter is subject to the chip.

2. Restrictions and Guidelines

N/A

3. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Configure ECN Capable Transport (ECT) mark type.
qos ecn remark type { **ect0** | **ect1** }

No ECT mark type is not configured by default.

1.7 Configuring Congestion Avoidance

1.7.1 Overview

Congestion avoidance monitors the usage of queues in an outbound interface and eliminates the network overload by actively discarding packets and adjusting the network traffic in the case of network congestion.

1.7.2 Configuration Tasks

Congestion avoidance configuration includes the following tasks:

(1) Enabling the WRED Function

(2) (Optional) Configuring Higher and Lower Threshold Values

(3) (Optional) Configuring the Sampling Interval

1. Overview

You can configure the sampling interval for the WRED discarding function to affect the calculation result of the average queue length.

2. Restrictions and Guidelines

- When packets are forwarded, WRED determines the discarding probability based on the average queue length of the egress queue. When the queue length is between the lower threshold and the higher threshold, WRED starts to discard packets randomly. A longer queue leads to a higher discarding probability but the probability cannot be higher than the maximum discarding probability. When the queue length is greater than the higher threshold, packets are discarded at the maximum discarding probability.

- To make the sampling interval effective, you need to first configure the WRED discarding function on an interface. Namely, the sampling interval can be configured only after the higher threshold and lower threshold for WRED to discard packets are configured on an interface.
- The sampling interval ranges from 8 μs to 512 μs. The sampling interval can affect the calculation result of the average queue length.
- Use this command together with the sampling weight configuration command to precisely adjust the WRED discarding function.

3. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Configure the sampling interval.
wrr-queue random-detect sample-period *period-value*

No sampling interval is configured by default.

(4) Configuring the Sampling Weight

(5) (Optional) Configuring the CoS-to-Threshold Mappings

1.7.3 Enabling the WRED Function

1. Overview

This section describes how to configure WRED as the packet discarding policy.

2. Restrictions and Guidelines

The default packet discarding policy is tail-drop.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the WRED function.

queueing wred

The WRED function is disabled by default.

1.7.4 Configuring Higher and Lower Threshold Values

1. Overview

This section describes how to configure the higher and lower threshold values for WRED.

2. Restrictions and Guidelines

- When the packet length of a queue is smaller than the lower threshold, no packets are discarded. When the queue length is between the lower threshold and the higher threshold, WRED starts to discard packets randomly.
- Because the maximum value of the configuration range is equal to the current higher threshold, you need to pay attention to the configured higher threshold when configuring the lower threshold.
- The threshold for WRED to discard packets can be configured in the unit of percentage or cell. The final configuration prevails.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Ethernet interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface *ethernet-type interface-number*

(4) Configure a lower threshold value. Please configure only one task.

- Configure a lower threshold value in percentage.

  wrr-qos-queue random-detect min-threshold *queue-id threshold*&<1-2>

  The queue value range is from 1 to 8. The value range of the lower threshold value is from 1 to the set value of the higher threshold.

- Configure a lower threshold value in the unit of cell.

  wrr-qos-queue random-detect min-threshold cell *queue-id cell-value*&<1-2>

  The queue value range is from 1 to 8. The value range of the lower threshold is from 1 to the set value of the higher threshold. The default threshold value depends on the product.

(5) The threshold value is configured in percentage by default. Configure a higher threshold value. Please configure only one task.

- Configure a higher threshold value in percentage.

  wrr-qos-queue random-detect max-threshold *queue-id threshold*&<1-2>

  The queue value range is from 1 to 8. The value range of the higher threshold is from the set value of the lower threshold to the maximum value allowed for the higher threshold value.

- Configure a higher threshold value in the unit of cell.

wrr-qos-queue random-detect max-threshold cell *queue-id cell-value*&<1-2>

The queue value range is from 1 to 8. The value range of the higher threshold is from the set value of the lower threshold to the maximum value allowed for the higher threshold value.

The threshold value is configured in percentage by default.

1.7.5 Configuring the Maximum Discarding Probability

1. Overview

When the packet length in a queue is between the lower threshold and the higher threshold, you can configure the maximum probability for discarding packets at random.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 2 or Layer 3 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

(4) Configure the maximum discarding probability.

wrr-qos-queue random-detect probability *queue-id probability*&<1-2>

The maximum discarding probability is not configured by default.

1.7.6 Configuring the Sampling Interval

4. Overview

You can configure the sampling interval for the WRED discarding function to affect the calculation result of the average queue length.

5. Restrictions and Guidelines

- When packets are forwarded, WRED determines the discarding probability based on the average queue length of the egress queue. When the queue length is between the lower threshold and the higher threshold, WRED starts to discard packets randomly. A longer queue leads to a higher discarding probability but the probability cannot be higher than the maximum discarding probability. When the queue length is greater than the higher threshold, packets are discarded at the maximum discarding probability.
- To make the sampling interval effective, you need to first configure the WRED discarding function on an interface. Namely, the sampling interval can be configured only after the higher threshold and lower threshold for WRED to discard packets are configured on an interface.
- The sampling interval ranges from 8 μs to 512 μs. The sampling interval can affect the calculation result of the average queue length.
- Use this command together with the sampling weight configuration command to precisely adjust the WRED discarding function.

6. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Configure the sampling interval.
wrr-queue random-detect sample-period *period-value*

No sampling interval is configured by default.

1.7.7 Configuring the Sampling Weight

1. Overview

You can configure the sampling weight for the WRED discarding function to affect the calculation result of the average queue length.

2. Restrictions and Guidelines

- When packets are forwarded, WRED determines the discarding probability based on the average queue length of the egress queue. When the queue length is between the lower threshold and the higher threshold, WRED starts to discard packets randomly. A longer queue leads to a higher discarding probability but the probability cannot be higher than the maximum discarding probability. When the queue length is greater than the higher threshold, packets are discarded at the maximum discarding probability.
- The sampling weight indicates the weight factor of sampled data updates. A larger sampling weight indicates a longer update interval of the average queue length and a larger average queue length.
- To make the sampling weight effective, you need to first configure the WRED discarding function on an interface. Namely, the sampling weight must be configured after the higher threshold and lower threshold are configured for the WRED discarding function on an interface.
- Use this command together with the sampling interval configuration command to precisely adjust the WRED discarding function.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Ethernet interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface *ethernet-type interface-number*

(4) Configure the sampling weight.

wrr-qos-queue random-detect sample-weight *queue-id weight*-value

No sampling weight is configured by default.

1.7.8 Configuring the CoS-to-Threshold Mappings

1. Overview

This section describes how to configure the CoS-to-threshold mappings.

2. Restrictions and Guidelines

- Multiple threshold groups can be configured for the lower threshold and maximum discarding probability.
- By configuring the mappings from CoS values and threshold groups, you can select the effective threshold group mapped to a CoS, for example, you can map CoS 0 to threshold group 1, and CoS 1 to threshold group 2.
- If the packets of CoS values 0 and 1 are all added to queue 1 for scheduling, the packets of CoS 0 are processed based on the lower threshold and maximum discarding probability in group 1, and the packets of CoS 1 are processed based on the lower threshold and maximum discarding probability in group 2.
- When all the CoS values are mapped to the same threshold group, the enabled WRED becomes RED.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the CoS-to-threshold mappings.

wrr-qos-queue cos-map *threshold-id cos*&<1-8>

All the CoS values are mapped to the threshold in group 1 by default.

1.8 Configuring the QoS Global Policy

Note

This function is supported by only theS6980-64QC, S6580-48CQ8QC, and S6580-24DC8QC.

1.8.1 Overview

Enabling the QoS global policy enables some QoS policies by default, for example, changing the DSCP value of L2 flows.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the global QoS policy.

mls qos enable

1.9 Disabling the Packet Priority Change

1.9.1 Overview

When a packet is sent out of a device, the priority of the packet is changed to the priority configured on the device. You can disable packet priority change, that is, the priority of a packet sent out of a device is the same as that when the packet is sent to the device.

1.9.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Disable packet priority change.

mls qos remark disable

1.10 Configuring the Queue Display and Configuration Mode

1.10.1 Overview

After the queue display and configuration mode is configured, the display range of all queues on the device becomes 0-7 or 1-8.

1.10.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the queue display and configuration mode.

qos-queue compatible { enable | disable }

1.11 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

⚠ Caution

Running the **cleanup** commands may interrupt services due to loss of important information.

Run the **debugging** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-3 QoS Monitoring

Command	Purpose
display cmap-create [*class-map-name*]	Displays the traffic classification information.
display policy-create [*policy-map-name* [**cmap** *class-map-name*]]	Displays the QoS policy information.
display policy-create interface *interface-type interface-number*	Displays information about a policy applied to an interface.
display policy-create statistics { **interfaces** *interface-type interface-number* **| global** } [**cmap** *class-map-name*] { **input** | **output** }	Displays policy statistics.
display virtual-group { *virtual-group-number* | **summary** }	Displays information about a logical interface group.
display mls qos virtual-group { *virtual-group-number* | **policers** }	Displays information about a policy applied to a logical interface group.
display mls qos maps { **cos-dscp** | **dscp-cos** | **ip-prec-dscp** }	Displays various mappings.
display mls qos speed-limit [**interface** *interface-type interface-number*]	Displays the rate limit information of an interface.
display mls qos queueing [**interface** *interface-type interface-number*]	Displays information about the QoS queues, scheduling policies, and round robin weights.
display mls qos scheduler [**interface** *interface-type interface-number*]	Displays the scheduling policy information of an output queue.
display mls qos develop { status | **capacity** | **mstat** | **features | istat | intf_status }**	Displays QoS-related internal information.
display queueing wred interface *interface-type interface-number*	Displays the WRED configuration.
display mls qos interface { *interface-type interface-number* | **policers** }	Displays the QoS information of an interface.
display qos bandwidth [**interface** *interface-type interface-number*]	Displays information about the queue bandwidth.

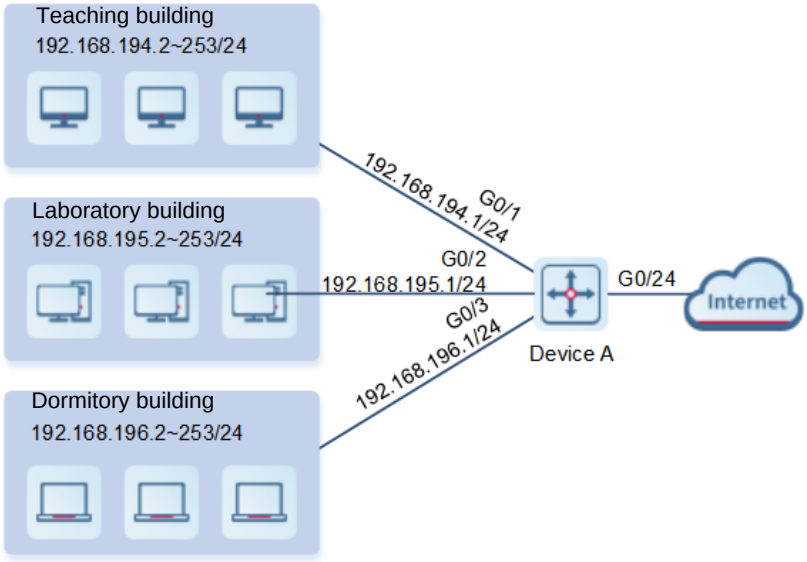
Command	Purpose
display qos res [**dev** *dev-number* [**slot** *slot-number*]]	Displays QoS resource usage of the current device.
display qos wred-ecn statistics [**interface** *interface-type interface-number*]	Displays statistics on the packets discarded by WRED and the packets marked by ECN.
cleanup qos res	Clears historical peak values of QoS resource usage.
cleanup qos wred-ecn statistics	Clears statistics on packets discarded by WRED and packets marked by explicit congestion notification (ECN).
cleanup policy-create statistics [{ **interfaces** *interface-type interface-number* **| global** } [**cmap** *class-map-name*]] { **input** | **output** }	Clears policy statistics.
debugging qos lib [**event** | **message**]	Debugs the QoS library.
debugging qos server [**event** | **message**]	Debugs the QoS communication server.
debugging qos mls	Debugs QoS user command processing.
debugging qos vmsup	Debugs VMSUP configurations.

1.12 Configuration Examples

1.12.1 Configuring the Interface Rate Limit and Priority Re-marking

1. Requirements

To meet the service requirements of normal teaching, a school puts forwards the following requirements:



- Controlling the Internet access traffic of the school within 100 Mbps and discarding the packets out of the limit.
- Controlling the egress traffic of the dormitory building within 50 Mbps and discarding the packets out of limit.
- Controlling the rate of packets with DSCP priority 7 sent from laboratory building within 20 Mbps and discarding the packets out of limit..
- Controlling the egress traffic of the teaching building within 30 Mbps and discarding the packets out of limit.

Note

The school connects to the Internet through G0/24 of device A, and G0/1, G0/2, and G0/3 of device A connect to the teaching building (192.168.194.2~253/24), laboratory building (192.168.195.2~253/24), and dormitory building (192.168.196.2~253/24) respectively.

2. Topology

Figure 1-7 Configuring the Interface Rate Limit and Priority Re-marking

3. Notes

(1) For Internet access traffic on the outbound interface, configure the egress traffic limit on interface G0/24 of device A, and set the bandwidth limit to 100 Mbps and burst traffic limit to 256 Kbps.

(2) For the dormitory building, configure the ingress traffic limit on interface G0/3 of device A, and set the bandwidth limit to 50 Mbps and burst traffic limit to 256 Kbps.

(3) For the teaching building, configure the ingress traffic limit on interface G0/1 of device A, and set the bandwidth limit to 50 Mbps and burst traffic limit to 256 Kbps.

(4) For the laboratory building, create the class **cmap_dscp7** to match DSCP priority 7, create the policy **pmap_shiyan**, associate **cmap_dscp7** with the policy, bind the traffic behavior and set the bandwidth limit to 20 Mbps, apply **pmap_shiyan** to interface G0/2, and configure the interface to trust DSCP.

4. Procedure

(1) Configure IP addresses for interfaces (omitted).

(2) Configure rate limits for the interfaces.

For Internet access traffic on the outbound interface, configure the egress traffic limit on interface G0/24.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitethernet 0/24
DeviceA(cfg-if-GigabitEthernet 0/24# speed-limit output 102400 256
DeviceA(cfg-if-GigabitEthernet 0/24)# exit
```

For the dormitory building, configure the ingress traffic limit on interface G0/3.

```
DeviceA(cfg)# interface gigabitethernet 0/3
DeviceA(cfg-if-GigabitEthernet 0/3# speed-limit input 51200 256
DeviceA(cfg-if-GigabitEthernet 0/3)# exit
```

For the teaching building, configure the ingress traffic limit on interface G0/1.

```
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1# speed-limit input 30720 256
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
```

(3) Configure traffic classification.

For the laboratory building, configure a class, traffic behavior, and policy.

```
DeviceA(cfg)# cmap-create cmap_dscp7
DeviceA(cfg-cmap)# match-rule ip dscp 7
DeviceA(cfg-cmap)# exit
DeviceA(cfg)# policy-create pmap_shiyan
DeviceA(cfg-policymap)# cmap cmap_dscp7
DeviceA(cfg-pmap-c)# police 20480 128 exceed-action drop
DeviceA(cfg-pmap-c)# exit
DeviceA(cfg-policymap)# exit
```

Apply the policy to an interface and configure the interface to trust DSCP.

```
DeviceA(cfg)# interface gigabitethernet 0/2
DeviceA(cfg-if-GigabitEthernet 0/2# apply-policy input pmap_shiyan
DeviceA(cfg-if-GigabitEthernet 0/2)# mls qos trust dscp
DeviceA(cfg-if-GigabitEthernet 0/2)# exit
```

5. Verification

Check whether the interface rate limits are successfully configured.

```
DeviceA# display mls qos speed-limit
Interface: GigabitEthernet 0/1
   rate limit input Kbps = 30720 burst = 256
Interface: GigabitEthernet 0/3
   rate limit input Kbps = 51200 burst = 256
Interface: GigabitEthernet 0/24
   rate limit output Kbps = 102400 burst = 256
```

Check whether the class is successfully created.

```
DeviceA# display cmap-create cmap_dscp7

 Class Map cmap_dscp7
    Match ip dscp 7
```

Check whether the policy is successfully created.

```
DeviceA# display policy-create pmap_shiyan

 Policy Map pmap_shiyan
     Class cmap_dscp7
        police 20480 128 exceed-action drop
```

Check whether the policy is applied to the interface successfully.

```
DeviceA# display mls qos interface gigabitethernet 0/2
Interface: GigabitEthernet 0/2
```

```
Ratelimit input:
Ratelimit output:
Attached input    policy-map: pmap_shiyan
Attached output policy-create:
Default trust: dscp
Default cos: 0
```

6. Configuration Files

Device A configuration file

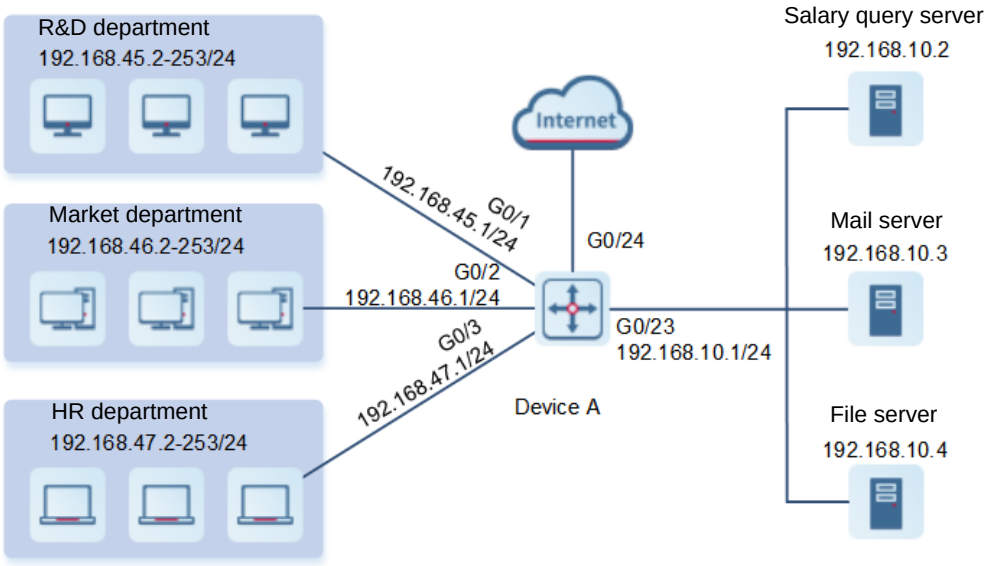
```
hostname DeviceA
!
cmap-create cmap_dscp7
  match-rule ip dscp 7
!
policy-create pmap_shiyan
  cmap cmap_dscp7
    police 20480 128 exceed-action drop
!
interface GigabitEthernet 0/1
  ip address 192.168.194.1 255.255.255.0
  speed-limit input 30720 256
!
interface GigabitEthernet 0/2
  ip address 192.168.195.1 255.255.255.0
  apply-policy input pmap_shiyan
  mls qos trust dscp
!
interface GigabitEthernet 0/3
  ip address 192.168.196.1 255.255.255.0
  speed-limit input 51200 256
!
interface GigabitEthernet 0/24
  speed-limit output 102400 256
!
```

1.12.2 Configuring Queue Scheduling and Congestion Avoidance

1. Requirements

Priority re-marking and queue scheduling need to be configured to meet the following requirements:

- When the R&D department and market department access the servers, the priorities of the server packets are as follows: packets destined for the mail server > packets destined for the file server > packets destined for the salary query server.
- No matter when the HR management department accesses the Internet or servers, device A processes the corresponding packets with the highest priority.
- Network congestion often occurs during operation of device A. WRR queue scheduling must be used to schedule IP packets from the R&D and market departments to access the mail database, file database, and



salary query database based on the ratio of 6:2:1.

Note

The R&D department (192.168.45.2~253/24), market department (192.168.46.2~253/24), and HR department (192.168.47.2~253/24) are connected to interfaces G0/1, G0/2, and G0/3 of device A respectively; the salary query server (192.168.10.2/24), mail server (192.168.10.3/24), and file server (192.168.10.4/24) are connected to interface G0/23 of device A.

2. Topology

Figure 1-8 Configuring Queue Scheduling and Congestion Avoidance

3. Notes

(1) On device A, create ACLs to filter packets used for accessing servers, create classes, and associate the classes with these ACLs.

(2) Create policies to associate with the classes and specify the IEEE 802.1p values for the packets accessing various servers in the policies: Set the IEEE 802.1p value to 4 for the packets accessing the mail server, to 3 for the packets accessing the file server, and to 2 for the packets accessing the salary query server. Apply the policies to the inbound interfaces connected to the R&D and market departments and configure the interfaces to trust IEEE 802.1p.

(3) Assign the highest priority 7 to the IEEE 802.1p value of the interface connected to the HR department, to ensure that packets from the HR department are sent with the highest priority.

(4) Set the scheduling policy to WRR for output queues and set the round robin weight to 1:1:1:2:6:1:1:0 for the queues. This means that SP scheduling is used for packets of the HR department, and the packets for accessing the mail database, file database, and salary query database from the R&D and market departments are scheduled based on the ratio of 6:2:1.

(5) Enable the WRED function.

(6) Set the lower thresholds to 10 and 20 for queue 2 of interface G0/2.

(7) Set the higher thresholds to 60 and 90 for queue 2 of interface G0/2.

(8) Set the maximum discarding probabilities to 60 and 80 for queue 2 of interface G0/2.

4. Procedure

(1) On device A, configure ACLs to filter packets used for accessing the servers and add ACL rules.

Configure the ACL for matching packets used for accessing the salary query server as well as ACL rules.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip access-control-list extended salary
DeviceA(cfg-extacl)# permit ip any host 192.168.10.2
DeviceA(cfg-extacl)# exit
```

Configure the ACL for matching packets used for accessing the mail server as well as ACL rules.

```
DeviceA(cfg)# ip access-control-list extended mail
DeviceA(cfg-extacl)# permit ip any host 192.168.10.3
DeviceA(cfg-extacl)# exit
```

Configure the ACL for matching packets used for accessing the file server as well as ACL rules.

```
DeviceA(cfg)# ip access-control-list extended file
DeviceA(cfg-extacl)# permit ip any host 192.168.10.4
DeviceA(cfg-extacl)# exit
```

(2) Configure classes on device A.

Associate a class named salary with the ACL rule for matching packets used for accessing the salary query server.

```
DeviceA(cfg)# cmap-create salary
DeviceA(cfg-cmap)# match-rule access-apply salary
DeviceA(cfg-cmap)# exit
```

Associate a class named mail with the ACL rule for matching packets used for accessing the mail server.

```
DeviceA(cfg)# cmap-create mail
DeviceA(cfg-cmap)# match-rule access-apply mail
DeviceA(cfg-cmap)# exit
```

Associate a class named file with the ACL rule for matching packets used for accessing the file server.

```
DeviceA(cfg)# cmap-create file
DeviceA(cfg-cmap)# match-rule access-apply file
DeviceA(cfg-cmap)# exit
```

(3) Configure policies on device A.

Configure the policy named toserver to access the server.

```
DeviceA(cfg)# policy-create toserver
DeviceA(cfg-policymap)#
```

Associate the class named salary with a traffic behavior.

```
DeviceA(cfg-policymap)# cmap salary
DeviceA(cfg-pmap-c)# set cos 2
DeviceA(cfg-pmap-c)# exit
```

Associate the class named mail with a traffic behavior.

```
DeviceA(cfg-policymap)# cmap mail
DeviceA(cfg-pmap-c)# set cos 4
DeviceA(cfg-pmap-c)# exit
```

Associate the class named file with a traffic behavior.

```
DeviceA(cfg-policymap)# cmap file
DeviceA(cfg-pmap-c)# set cos 3
DeviceA(cfg-pmap-c)# exit
DeviceA(cfg-map)# exit
```

(4) Apply policies on device A.

Apply a policy to the interface connected to the R&D department.

```
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# apply-policy input toserver
DeviceA(cfg-if-GigabitEthernet 0/1)# mls qos trust cos
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
```

Apply a policy to the interface connected to the market department.

```
DeviceA(cfg)# interface gigabitethernet 0/2
DeviceA(cfg-if-GigabitEthernet 0/2)# apply-policy input toserver
DeviceA(cfg-if-GigabitEthernet 0/2)# mls qos trust cos
DeviceA(cfg-if-GigabitEthernet 0/2)# exit
```

(5) On device A, configure the 802.1p field for an interface.

Configure the highest priority for the 802.1p field for the interface connected to the HR department.

```
DeviceA(cfg)# interface gigabitethernet 0/3
DeviceA(cfg-if-GigabitEthernet 0/3)# mls qos cos 7
DeviceA(cfg-if-GigabitEthernet 0/3)# exit
```

(6) On device A, configure a scheduling policy for output queues.

Set the scheduling policy to WRR for output queues.

```
DeviceA(cfg)# wrr-qos-queue bandwidth 1 1 1 2 6 1 1 0
DeviceA(cfg)# mls qos scheduler wrr
```

(7) Configure congestion avoidance on device A.

Enable the WRED function.

```
DeviceA(cfg)# queueing wred
```

Configure the higher and lower threshold values and maximum discarding probability.

```
DeviceA(cfg)# interface gigabitethernet 0/2
DeviceA(cfg-if-GigabitEthernet 0/2)# wrr-qos-queue random-detect min-threshold 2 10 20
DeviceA(cfg-if-GigabitEthernet 0/2)# wrr-qos-queue random-detect max-threshold 2 60 90
DeviceA(cfg-if-GigabitEthernet 0/2)# wrr-qos-queue random-detect probability 2 60 80
```

Configure the CoS-to-threshold mappings.

```
DeviceA(cfg)# wrr-qos-queue cos-map 2 0 1 2 3
DeviceA(cfg)# exit
```

5. Verification

Check whether ACLs are successfully created.

```
DeviceA# display access-lists

ip access-control-list extended file
 10 permit ip any host 192.168.10.4

ip access-control-list extended mail
 10 permit ip any host 192.168.10.3

ip access-control-list extended salary
 10 permit ip any host 192.168.10.2
```

Check whether the classes are successfully associated with the ACLs.

```
DeviceA# display cmap-create

 Class Map salary
    Match access-apply salary
 Class Map mail
    Match access-apply mail
 Class Map file
    Match access-apply file
```

Check whether policies are successfully created, and whether the classes and traffic behaviors are successfully bound.

```
DeviceA# display policy-create

 Policy Map toserver
     Class mail
        set cos 4
     Class file
        set cos 3
     Class salary
        set cos 2
```

Check whether a policy is successfully applied to interface GigabitEthernet 0/1.

```
DeviceA# display mls qos interface gigabitethernet 0/1
Interface: GigabitEthernet 0/1
Ratelimit input:
Ratelimit output:
Attached input    policy-map: toserver
Attached output policy-create:
Default trust: cos
Default cos: 0
```

Check whether a policy is successfully applied to interface GigabitEthernet 0/2.

```
DeviceA# display mls qos interface gigabitethernet 0/2
```

```
Interface: GigabitEthernet 0/2
Ratelimit input:
Ratelimit output:
Attached input    policy-map: toserver
Attached output policy-create:
Default trust: cos
Default cos: 0
```

Check whether a policy is successfully applied to interface GigabitEthernet 0/3.

```
DeviceA# display mls qos interface gigabitethernet 0/3
Interface: GigabitEthernet 0/3
Ratelimit input:
Ratelimit output:
Attached input    policy-create:
Attached output policy-create:
Default trust: none
Default cos: 7
```

Check whether the 802.1p value is successfully configured for the interface and whether the scheduling policy and the round robin weight are successfully configured.

```
DeviceA# display mls qos queueing
Cos-queue map:

1 Configuring MMU

1.1 Introduction

1.1.1 Overview

The memory management unit (MMU) is a technology for allocating the chip buffers reasonably. This technology makes devices better deal with all kinds of burst flows.

Flows are not always steady and various burst flows exist in the network. When the network flow is steady and the bandwidth is sufficient, all the data flows are processed properly. When burst flows exist in the network, data flows may be discarded even if the average flow rate does not exceed the bandwidth. Data packets are stored in the buffers of a device before being forwarded. Normally, data packets in the buffers will be forwarded in microseconds. When a burst flow arises, if the instantaneous rate of the burst flow is out of the processing capacity of the device, the data packets that cannot be processed in time are piled up in the buffers and packet loss takes place once the buffers are insufficient. In this case, the MMU technology can used to reasonably configure buffers and allocate different buffer sizes to services, with a view to optimizing the network.

1.1.2 Principles

1. Basic Concepts

- Cell

  Cell is a buffer unit, namely, the minimum unit for the device to store packets. The size of each cell varies with the device. One packet can use multiple cells, while one cell can be used by only one packet.

- Port group

  All the ports that physically belong to the same switching chip and the same core (some chips are multi-core chips) are called a port group. All devices implement buffer management in port groups. For example, card M18000_40XS_CB has two single-core switching chips, so it has two port groups. The first 20 ports of the card belong to port group 1 and the last 20 ports belong to port group 2.

- Buffer slice

  The buffer of a port group may be divided into multiple buffer blocks, and each buffer block is called a buffer slice. Slice is the minimum unit for independent buffer management. Each buffer slice is managed independently, and a port queue may use one or more buffer slices.

- Guaranteed buffer

  A guaranteed buffer is also called an exclusive buffer. This part of buffer is distributed based on each port queue. The guaranteed buffer of a queue can be used by this queue only. A fixed number of guaranteed buffers are allocated to each queue by default. This part of buffer enables a queue to normally forward packets at the line rate under the stable flow.

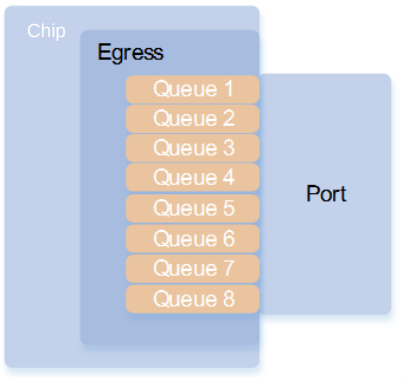
- Shared buffer

  In the total buffer of a port group, the remaining part obtained after the guaranteed buffer of each port queue is deducted is the total shared buffer. The shared buffer is available to all the queues. A shared buffer threshold can be set for each queue. This threshold restricts the maximum number of shared buffers

that can be used by a queue. When the sum of shared buffers configured for queues in a port group exceeds the total shared buffers of the port group, the "first-come first-served" buffer occupancy mechanism is adopted.

- Service pool

  In addition to the guaranteed buffer, each port queue can use shared buffers. The shared buffers are uniformly stored in the service pool for management. One buffer slice may have multiple service pools. After using its own guaranteed buffer, each queue can request a shared buffer from the service pool within the shared buffer threshold, and the mechanism of "first-request, first-served" is adopted for the service pool. One queue can use the shared buffer of only one service pool according to the mapping configuration.



- Priority group (PG)

  PG is the abbreviation of priority group. For the sake of better and flexible buffer management, a chip offers eight PG objects in the ingress direction to implement independent buffer management. Packets are configured with different priorities (for example, 0 to 7) and can be mapped to different PG objects or one PG so that different buffer allocation schemes are provided for packets with different priorities.

- Egress queues

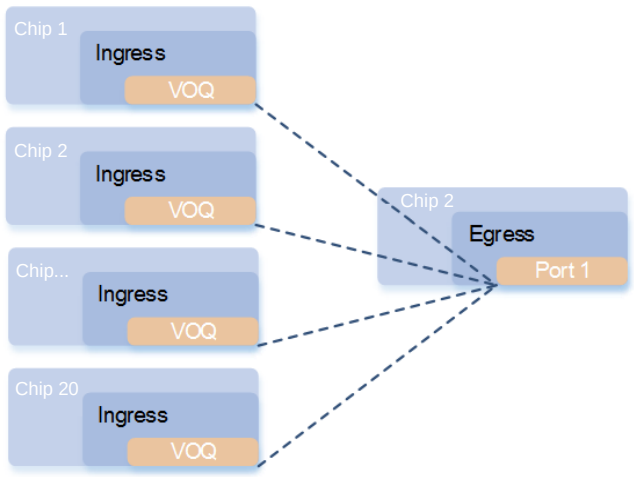
  Egress queues of a port are classified into unicast queues and multicast queues (the number of queues depends on the product). Logically, a switching chip is divided into the ingress direction and egress direction. The egress queues are in the egress direction of a switching chip. Before packets are sent out of a device, they need to be queued at the egress queues, as shown in Figure 1-1.

Figure 1-1 Egress Queues

Currently, there are three types of egress queue models:

- There are eight unicast queues and eight multicast queues at the egress. The known unicast packets enter the unicast queues, and all the other packets enter the multicast queues.
- There are eight unicast queues and four multicast queues at the egress. The known unicast packets enter the unicast queues, and all the other packets enter the multicast queues.
- There are only eight queues at the egress, with unicast and multicast queues not differentiated. The queues are managed as unicast queues in the device.

Caution



A device that supports egress queue buffer management does not support VOQ queue buffer management.

- VOQ

  VOQ is the abbreviation of virtual output queue. Logically, a switching chip is divided into the ingress direction and egress direction. A VOQ is in the ingress direction of a switching chip. Before packets are sent out of a device, they need to be queued at the VOQs. Each egress is mapped to one VOQ group (containing eight prioritized queues) on each core in all the chips where input ports are located.

  Suppose that a chassis device is capable of housing 10 line cards and each line card has 2 single-core chips, there are 20 switching chips in total. Taking port 1 on chip 2 as an example, in such a switching system, each of the 20 switching chips has one VOQ group in the ingress direction that maps to port 1 on chip 2. For example, a packet enters the device through chip 20 and is destined for port 1 on chip 2. This packet must be queued in the VOQ (on chip 20) mapped to port 1 on chip 2, as shown in Figure 1-2.

Figure 1-2 VOQs

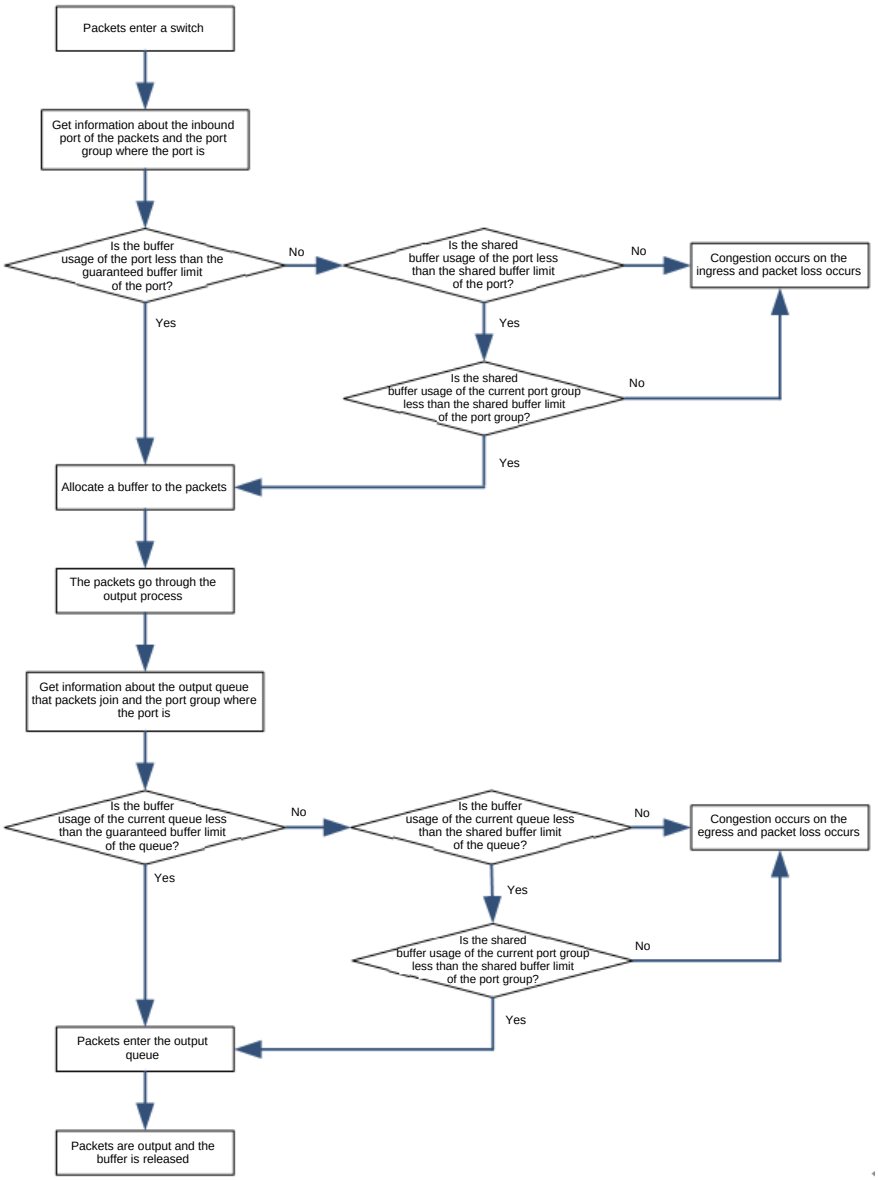
Caution

A device that supports VOQ buffer management does not support egress queue buffer management.

- Global multicast queue

  A global multicast queue refers to the multicast queue shared by all the ports in a port group, and is different from the multicast queue owned by a single physical port.

Caution



Only the device that supports VOQ buffer management supports global queue buffer management.

2. Buffer Adjustment

Users can adjust the buffer allocation of a chip so that the queue of each service has a different buffer size available, services are treated differently, and services of different priorities are provided.

In terms of hardware, the buffer is managed in the input direction and output direction. Figure 1-3 shows the processing mechanism.

Figure 1-3 Buffer Processing Mechanism

During buffer management, the buffer size is adjusted to the maximum value in the input direction to prevent packet loss in the input direction, and packet loss takes place in the output direction. Therefore, buffer adjustment is not allowed in the input direction, and a CLI command is available for buffer adjustment in the output direction only, including the guaranteed buffer and shared buffer of queues. Buffer adjustment allocates different buffer sizes to queues based on the guaranteed buffer threshold and shared buffer threshold configured for the queues.

3. Status Monitoring

Status monitoring monitors the buffer usage and the queue packet forwarding and discarding by using statistical methods, with a view to providing data support for network optimization and reasonable buffer configuration.

Status monitoring adopts the polling mode to periodically read, from a chip, the buffer usage information and information about packets forwarded/discarded by queues, and analyzes the information so as to display the device operating status.

- Monitoring buffer occupancy in the egress direction

  The information about the guaranteed buffer, shared buffer, and service pool buffer occupancy of queues in the egress direction is regularly collected. The data can be displayed via a CLI command, in MIB mode, or other methods.

- Monitoring packet forwarding and discarding of the egress queues

  The information about the quantities and bytes of packets forwarded and discarded by queues in the egress direction is regularly collected, and the forwarding rate is also calculated. The data can be displayed via a CLI command, in MIB mode, or other methods.

- Sampling interval for status monitoring data

  Status monitoring data is sampled at a fixed interval, which can be configured based on user requirements.

4. Exception Detection

The exception detection function monitors the packet forwarding and discarding of each queue, and displays alarms when the buffer occupancy exceeds the threshold or queue packets are lost.

Exception detection adopts the polling mode to periodically read device buffer occupancy information and the number of packets forwarded by queues, and displays alarms through system logs based on the current configuration. When the buffer utilization of a queue exceeds the alarm threshold, a system log alarm is printed to alert users.

1.2 Configuration Task Summary

MMU configuration includes the following tasks:

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Buffer Adjustment
- Configuring Status Monitoring
- Configuring Exception Detection

1.3 Configuring Buffer Adjustment

1.3.1 Overview

The buffer adjustment function aims to adjust the objects (such as queues) managed based on chip buffers.

1.3.2 Restrictions and Guidelines

- Configuration on an interface can be made on a physical port only.
- You are advised to configure buffer adjustment when there is no traffic on the device; otherwise the configuration may cause temporary interruption of service traffic.

1.3.3 Configuration Tasks

Buffer adjustment configuration includes the following tasks:

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Guaranteed Buffer for a Queue
- Configuring a Shared Buffer for a Queue
- Configuring a Guaranteed Buffer for an Ingress PG
- Configuring a Shared Buffer for an Ingress PG
- Configuring a Flow Control Threshold for an Ingress PG
- Configuring a Flow Control Threshold Offset for an Ingress PG
- Configuring Headroom Buffer Space for an Ingress PG
- Configuring the Global Headroom Buffer Threshold
- Configuring Cut-

1.3.4 Notes

Table 1-1 Products Supporting Buffer Adjustment Functions

Function	Product Supporting the Function
Configuring Cut-	Supported by the S6520-64CQ, S6510-48VS8CQ, S6510-32CQ, S6510-4C, and S6250-48XS8CQ

1.3.5 Configuring a Guaranteed Buffer for a Queue

1. Overview

This section describes how to configure a guaranteed buffer for a queue so that the queue uses this part of buffer exclusively.

2. Restrictions and Guidelines

- The *queue-id* &<1-n> parameter means that up to *n* queue numbers can be configured. Whether this parameter is supported and the value range of this parameter depend on the actual product version.
- The configuration is displayed when the **display current-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Ethernet interface configuration mode.

interface *ethernet-type interface-number*

(4) Configure a guaranteed buffer for queues.

mmu queue-guarantee { **output** { **multicast** | **unicast** } } [*queue-id*&<1-n>] **set** *value*

No guaranteed buffer is configured for a queue by default.

1.3.6 Configuring a Shared Buffer for a Queue

1. Overview

This section describes how to configure a shared buffer for a queue so as to control the size of the shared buffer that can be used by the queue.

2. Restrictions and Guidelines

- The *queue-id*&<1-n> parameter means that up to *n* queue numbers can be configured.
- The configuration is displayed when the **display current-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Ethernet interface configuration mode.

interface *ethernet-type interface-number*

(4) Configure a shared buffer for queues.

mmu queue-threshold { **output** { **multicast** | **unicast** } } [*queue-id*&<1-n>] **set** { *threshold* | **cell** *value* }

No shared buffer is configured for a queue by default.

1.3.7 Configuring a Guaranteed Buffer for an Ingress PG

1. Overview

This section describes how to configure a guaranteed buffer for an ingress priority group (PG) so that the PG uses the buffer exclusively.

2. Restrictions and Guidelines

- The *pg-id* &<1-n> parameter indicates that up to *n* queues can be configured.
- The configuration is displayed when the **display current-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure a guaranteed buffer for an ingress PG.

mmu **pg-guarantee pg** [*pg*-id&<1-n>] set *value*

No guaranteed buffer is configured for an ingress PG by default.

1.3.8 Configuring a Shared Buffer for an Ingress PG

1. Overview

This section describes how to configure a shared buffer for an ingress PG so as to control the size of the shared buffer that can be used by the ingress PG.

2. Restrictions and Guidelines

- The *pg-id*&<1-n> parameter indicates up to *n* queues can be configured.
- The configuration is displayed when the **display current-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure a shared buffer for an ingress PG.

mmu ingress-threshold pg [*pg-id*&<1-n>] **set** *threshold*

No shared buffer is configured for an ingress PG by default.

1.3.9 Configuring a Flow Control Threshold for an Ingress PG

1. Overview

This section describes how to configure a flow control threshold for an ingress PG and adjust the flow control threshold of the ingress based on the PG.

2. Restrictions and Guidelines

- Whether this function is supported depends on the actual product version.
- The configuration takes effect only when flow control or PFC is enabled on a port.
- The configuration is displayed when the **display current-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 2 or Layer 3 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

(4) Configure a flow control threshold for an ingress PG.

mmu xoff-threshold pg [*pg-id&<1-n>*] **set** *threshold*

No flow control threshold is configured for an ingress PG by default.

1.3.10 Configuring a Flow Control Threshold Offset for an Ingress PG

1. Overview

This section describes how to configure the flow control threshold offset for an ingress PG to adjust the interval for restoring the PG from the XOFF state to the XON state.

2. Restrictions and Guidelines

- The configuration takes effect only when flow control/PFC is enabled.
- The configuration is displayed when the **display current-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure a flow control threshold offset for an ingress PG.

mmu xon-threshold-offset pg [*pg-id&<1-n>*] **set** *threshold*

No flow control threshold offset is configured for an ingress PG by default.

1.3.11 Configuring Headroom Buffer Space for an Ingress PG

1. Overview

This section describes how to configure headroom buffer space for an ingress PG to adjust the headroom buffer space that can be used by the PG.

2. Restrictions and Guidelines

- The configuration takes effect only when flow control/PFC is enabled.
- The configuration is displayed when the **display current-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure a flow control headroom buffer threshold for a specified ingress PG.

mmu headroom-threshold pg [*pg-id&<1-n>*] **set** *threshold*

No headroom buffer space is configured for an ingress PG by default.

1.3.12 Configuring the Global Headroom Buffer Threshold

1. Overview

This section describes how to configure the global headroom buffer threshold to control the headroom buffer space reserved for a PG.

2. Restrictions and Guidelines

The configuration is displayed when the **display current-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a flow control headroom buffer threshold for ingress PGs.

mmu pg-headroom set *value*

No global headroom buffer threshold is configured by default.

1.3.13 Configuring Cut-Through

Note

This function is supported by only the S6520-64CQ, S6510-48VS8CQ, S6510-32CQ, S6510-4C, and S6250-48XS8CQ.

1. Overview

This section describes how to enable the cut-through function to reduce the packet forwarding latency.

2. Restrictions and Guidelines

After the function is enabled, chips determine whether to forward packets in cut-through mode based on the actual condition. For example, the cut-through function is unavailable upon congestion.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure the cut-through mode.

mmu cut-through

The cut-through function is disabled by default.

1.4 Configuring Status Monitoring

1.4.1 Overview

This section describes how to collect statistics on and monitor the buffer usage and queue packet forwarding and discarding so as to provide guidance for buffer adjustment configuration.

1.4.2 Restrictions and Guidelines

Configuration on an interface can be made on a physical port only.

1.4.3 Configuration Tasks

The status monitoring configuration includes the following tasks:

All the following configuration tasks are optional. Select the configuration tasks as required.

- Configuring the Monitoring Data Sampling Period
- Configuring the Slice ID Numbering Mode
- Configuring Buffer Statistics Tracking

1.4.4 Configuring the Monitoring Data Sampling Period

1. Overview

This section describes how to configure the monitoring data sampling period. The device samples and reports data based on the configured interval.

2. Restrictions and Guidelines

- The separate buffer statistics or packet statistics sampling period has a higher priority than the monitoring data sampling period.
- The configuration is displayed when the **display current-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the monitoring data sampling period.

mmu sample-period { { **buffer-counter | queue-counter** } *counter* **| set value** }

No monitoring data sampling period is configured by default.

1.4.5 Configuring the Slice ID Numbering Mode

1. Overview

This section describes how to configure the slice ID numbering mode to control slice IDs to start from 1 or 0.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the slice ID numbering mode.

mmu slice-id compatible

No slice ID numbering mode is configured by default.

1.4.6 Configuring Buffer Statistics Tracking

1. Overview

Configure buffer statistics tracking to record the buffer usage peak value.

2. Restrictions and Guidelines

- The device works in the current-use-count mode by default. After the max-use-count mode is configured, features in the current-use-count will not be active, such as some MMU-gRPC triggered events.

3. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Configure buffer statistics tracking.
mmu buffer-statistics-tracking max-use-count

The device works in the current-use-count mode without recording the buffer usage peak value by default.

1.5 Configuring Exception Detection

1.5.1 Overview

The exception detection function is used to analyze the data about device buffer and forwarding status, and generate an alarm when an exception occurs.

1.5.2 Configuration Tasks

Exception detection configuration includes the following tasks:

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Buffer Usage Alarm Threshold for a PG
- Configuring an Alarm Threshold for the Buffer Utilization of a Queue

- Configuring a Buffer Utilization Alarm Threshold for a Port
- Enabling or Disabling the Packet Loss Alarm Function for Queues Globally
- Enabling or Disabling the Packet Loss Alarm Function for Queues in an Interface
- Configuring the Packet Loss Alarm Frequency
- Disabling the MMU-HA Function
- Disabling the MMU-HA Restart Function

1.5.3 Configuring a Buffer Usage Alarm Threshold for a PG

1. Overview

This section describes how to configure a buffer usage alarm threshold for PGs. When the buffer usage of a PG exceeds the threshold, a log alarm is generated.

2. Restrictions and Guidelines

- To prevent frequent log refreshing, the alarm logs of the same PG are printed once in 30s at most. The maximum printing interval depends on the configured sampling period.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the buffer utilization alarm threshold for a PG.

mmu usage-warn-limit set *threshold*

The default buffer utilization alarm threshold is **0**, indicating that no alarm is reported.

This configuration takes effect on all port groups or buffer slices.

1.5.4 Configuring an Alarm Threshold for the Buffer Utilization of a Queue

1. Overview

When the buffer utilization of a queue exceeds the configured value, a system log alarm is printed.

2. Restrictions and Guidelines

- The *queue-id* &<1-n> parameter means that up to *n* queue numbers can be configured.
- To prevent frequent log refreshing, the alarm logs of the same queue are printed once in 30s at most. The maximum printing interval depends on the configured sampling period.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 2 or Layer 3 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

(4) Configure a buffer utilization alarm threshold for a queue.

mmu usage-warn-limit { **multicast** | **unicast** } [*queue-id*&<1-n>] **set** *threshold*

The default buffer utilization alarm threshold is **0**, indicating that no alarm is reported.

1.5.5 Configuring a Buffer Utilization Alarm Threshold for a Port

1. Overview

When the buffer utilization of all the queues on a port exceeds the configured value, a system log alarm is printed.

2. Restrictions and Guidelines

- The *queue-id* &<1-n> parameter means that up to *n* queue numbers can be configured.
- To prevent frequent log refreshing, the alarm logs of the same port are printed once in 30s at most. The maximum printing interval depends on the configured sampling period.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 2 or Layer 3 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

(4) Configuring a buffer utilization alarm threshold for a port.

mmu usage-warn-limit { **pg-headroom** | **priority-group** } [*pg-id&<1-n>*] **set** *value*

The default buffer utilization alarm threshold is **0**, indicating that no alarm is reported.

1.5.6 Enabling or Disabling the Packet Loss Alarm Function for Queues Globally

1. Overview

You can enable or disable the packet loss alarm function for queues globally to control the packet loss alarm function of all interface queues.

2. Restrictions and Guidelines

- The *queue-id* &<1-n> parameter indicates that up to *n* queues can be assigned with IDs.
- If this command is configured in both interface configuration mode and global configuration mode, the command configuration in interface configuration mode has a higher priority than that in global configuration mode.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable or disable the packet loss alarm function for queues globally.

mmu queue-loss-warn { **multicast** | **unicast** } [queue-id&<1-n>] { **on** | **off** }

The packet loss alarm function is disabled by default.

1.5.7 Enabling or Disabling the Packet Loss Alarm Function for Queues in an Interface

1. Overview

You can enable or disable the packet loss alarm function for queues in an interface to control the packet loss alarm function of the interface. The priority of this command is higher than that in global configuration mode.

2. Restrictions and Guidelines

- The *queue-id* &<1-n> parameter indicates that up to *n* queues can be assigned with IDs.
- If this command is configured in both interface configuration mode and global configuration mode, the command configuration in interface configuration mode has a higher priority than that in global configuration mode.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Enable or disable the packet loss alarm function for queues in an interface.

mmu queue-loss-warn { **multicast** | **unicast** } [*queue-id*&<1-n>] { **on** | **off** }

The packet loss alarm function of an interface is disabled by default.

1.5.8 Configuring the Packet Loss Alarm Frequency

1. Overview

You can configure the packet loss alarm frequency so that packet loss alarms are generated N times within the period (T).

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the packet loss alarm frequency.

mmu queue-loss-warn frequency cycle *value1* **times** *value2*

Packet loss alarms are generated 30 times within 60 seconds by default.

1.5.9 Disabling the MMU-HA Function

1. Overview

This section describes how to disable the MMU high availability (MMU-HA) function globally.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Disable the MMU-HA function.

mmu ha disable

The MMU-HA function is enabled by default.

1.5.10 Disabling the MMU-HA Restart Function

1. Overview

This section describes how to disable the MMU-HA restart function. After the function is disabled, the system still detects whether the MMU buffer is suspended.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Disable the MMU-HA restart function.

mmu ha reset disable

The MMU-HA restart function is enabled by default.

1.6 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

⚠ Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-2 MMU Monitoring

Command	Purpose
display [**mmu**] **queue-counter** [**interface** *interface-type interface-number* [**slot** *slot-id*] | **multicast**]	Displays the packet statistics of a queue.
display [**mmu**] **queue-buffer** [**interface** *interface-type interface-number* [**slot** *slot-id*] | **multicast**]	Displays the buffer utilization information of a queue.
display [mmu] pg-buffer [**interface** *interface-type interface-number*]	Displays the buffer usage information of a PG.
display mmu buffer-mode	Displays the current buffer mode.
display mmu buffer-config interface *interface-type interface-number* [**slot** *slot-id*]	Displays the difference between the buffer configuration conducted by users and the actually effective buffer configuration.
display mmu buffer-config queue-threshold cell interface *interface-type interface-number* [**slot** *slot-id*]	Displays the difference between the static buffer threshold configured by users and the actually effective buffer configuration.
display [**mmu**] **priority-group buffer-statistics** [**interface** *interface-type interface-number* | **total**]	Displays the buffer usage information of a PG on a specified port.
display [**mmu**] **ingress-queue buffer-statistics { interface** *interface-type interface-number* | **total }** [**slot** *slot-id*]	Displays the ingress queue buffer statistics.
display [**mmu**] **egress-queue buffer-statistics** [**interface** *interface-type interface-number* | **total**]	Displays the buffer usage information of queues in the outbound direction.
display [**mmu**] **ingress-queue traffic-statistics interface** *interface-type interface-number* [**slot** *slot-id*]	Displays the ingress queue traffic statistics.
display [**mmu**] **egress-queue traffic-statistics interface** *interface-type interface-number*	Displays traffic statistics in the outbound direction.
display [**mmu**] **{ priority-group | egress-queue } buffer-statistics total**	Displays the global buffer usage information of PGs and queues in both inbound and outbound directions.
display [**mmu**] **ingress-queue traffic-statistic multicast** [**slot** *slot-id*]	Displays global multicast traffic statistics.
display [**mmu**] **ingress-queue buffer-statistics multicast** [**slot** *slot-id*]	Displays the global multicast buffer usage information.
cleanup [**mmu**] **queue-counter** [**interface** *interface-type interface-number*]	Clears the packet statistics of a queue.
cleanup [**mmu**] **queue-buffer peaked** [**interface** *interface-type interface-number*]	Clears the historical buffer utilization peak values of a queue.

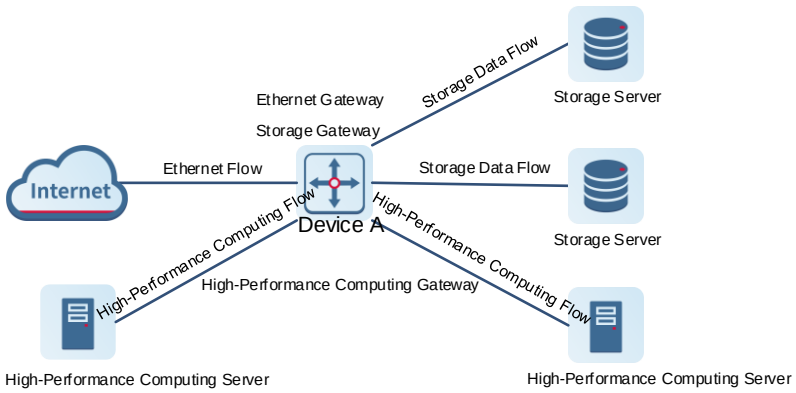
Command	Purpose
cleanup mmu usage-warn-count	Clears the count of all buffer alarms.
cleanup queue-buffer usage-warn-count	Clears the count of buffer alarms of a queue.

1.7 Configuration Examples

1.7.1 Configuring Ingress PG-based Buffer Application Based on Ingress PGs

1. Requirements

An enterprise needs to ensure no packet loss on the storage data flow in the data center network.
A traditional data center uses three types of networks to carry different flows to meet different traffic requirements, as shown in the following topology.



There are mainly three types of flows:

- Storage data flow: No packet loss is allowed.
- High-performance computing flow: A low latency is required.
- Ethernet flow: Certain packet loss and delay are allowed.

With the expansion of data centers, the Ethernet is used to carry all of three different types of flows, and additional mechanisms are defined to enable the Ethernet to meet the requirements of the types of network traffic. In addition, the priority-based flow control (PFC) mechanism based on ingress PGs is used to meet the requirements of no packet loss on the storage data flow and no impact on the other two types of flows when the three types of flows coexist on the Ethernet.

2. Topology

Figure 1-4 Configuring Ingress PG-based Buffer Application

3. Notes

- Map the remote direct memory access (RDMA) traffic to a PG.
- Enable the PFC function on the PG to ensure that no packet loss occurs on the traffic of this priority.

- Configure the XON and XOFF thresholds for the PG so that flow control frames can be generated.
- Configure sufficient headroom buffer space for the PG to buffer packets on the lines at the interval between effective flow control periods.
- For PFC-disabled PGs, the shared buffer threshold of the PGs should be higher than the buffer threshold of egress queues to ensure no packet loss on the ingress.
- For PFC-enabled PGs, the XOFF buffer threshold of the PGs should be lower than the buffer threshold of the egress to trigger the PFC function.
- You need to adjust values based on the network environment. Values provided in this section are merely examples for reference.

4. Procedure

(1) Configure a guaranteed buffer for an ingress PG.

Configure a guaranteed buffer for an ingress PG on the storage flow service port of device A.

```
DeviceA# config-system terminal
DeviceA(cfg)# interface list gigabitethernet 0/1-20
DeviceA(cfg-if-list)# mmu pg-guarantee pg 3 set 10
DeviceA(cfg-if-list)# exit
```

(2) Configure a flow control threshold for the ingress PG.

Configure the flow control threshold for the ingress PG on the storage flow service port of device A.

```
DeviceA# config-system terminal
DeviceA(cfg)# interface list gigabitethernet 0/1-20
DeviceA(cfg-if-list)# mmu xoff-threshold pg 3 set 20
DeviceA(cfg-if-list)# exit
```

(3) Configure a flow control threshold offset for the ingress PG.

Configure a flow control threshold offset for the ingress PG on the storage flow service port of device A.

```
DeviceA# config-system terminal
DeviceA(cfg)# interface list gigabitethernet 0/1-20
DeviceA(cfg-if-list)# mmu xon-threshold-offset pg 3 set 16
DeviceA(cfg-if-list)# exit
```

(4) Configure a headroom buffer for the ingress PG.

Configure a headroom buffer for the ingress PG on the storage flow service port of device A.

```
DeviceA# config-system terminal
DeviceA(cfg)# interface list gigabitethernet 0/1-20
DeviceA(cfg-if-list)# mmu headroom-threshold pg 3 set 300
DeviceA(cfg-if-list)# exit
```

5. Verification

On device A, verify that the command configuration for the interface GigabitEthernet 0/1 is correct.

```
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# display this-config
```

```
Building configuration...
!
 mmu pg-guarantee pg 3 set 10
 mmu xoff-threshold pg 3 set 20
 mmu xon-threshold-offset pg 3 set 16
 mmu headroom-threshold pg 3 set 300
```

6. Configuration Files

Device A configuration file

The configurations of the interface GigabitEthernet 0/1 to the interface GigabitEthernet 0/20 are exactly the same, and therefore only the configuration of GigabitEthernet 0/1 is provided below.

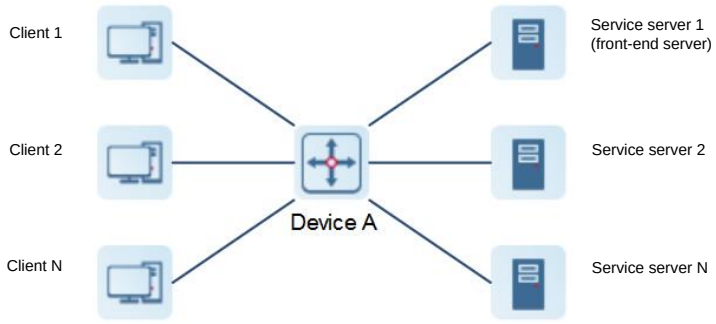
```
hostname DeviceA
!
interface GigabitEthernet 0/1
 mmu pg-guarantee pg 3 set 10
 mmu xoff-threshold pg 3 set 20
 mmu xon-threshold-offset pg 3 set 16
 mmu headroom-threshold pg 3 set 300
!
```

1.7.2 Configuring Egress Queue-based Large Buffer Application

1. Requirements

An enterprise needs a buffer large enough for the net disk service to avoid packet loss occurring in the service flow.

As shown in the following figure, device A is connected to 5 clients and 35 service servers, and 15 service servers are virtualized as 15 front-end servers.



The main service flow is as follows:

- A client sends a request packet to a front-end server.
- The front-end server sends the received request packet to a service server.
- After receiving the request packet, the service server sends a response packet to the front-end server.
- After receiving the response packet, the front-end server sends it to the client.
- The client receives the response packet, indicating that a session is created successfully.
- A many-to-one flow transmission mode exists in this service model:
- The request flows of multiple clients are sent to one front-end server.
- The request flows of multiple front-end servers are sent to one service server.
- The response flows of multiple service servers are sent to one front-end server.
- The response flows of multiple front-end servers are sent to one client.

These flows are basically transmitted through device A, which can easily lead to network congestion. Such a problem can be fixed by configuring a large buffer on the device.

2. Topology

Figure 1-5 Configuring Egress Queue-based Large Buffer Application

3. Notes

- On all the service ports (namely, the ports connecting to clients and servers), set the shared buffer to 100% for the queues where the service is.
- On all the service ports, set the guaranteed buffer to the minimum size for queues not in use.
- On all the ports not in use, set the guaranteed buffer to the minimum size for all the queues.

4. Procedure

(1) Configure a shared buffer.

On device A, set a shared buffer for queues on all the service ports.

```
DeviceA> enabel
DeviceA# config-system terminal
DeviceA(cfg)# interface list gigabitethernet 0/1-40
DeviceA(cfg-if-list)# mmu queue-threshold output unicast 1 set 100
DeviceA(cfg-if-list)# mmu queue-threshold output multicast 1 set 100
DeviceA(cfg-if-list)# exit
```

(2) Configure a guaranteed buffer.

On device A, set a guaranteed buffer for queues on all the service ports.

```
DeviceA# config-system terminal
DeviceA(cfg)# interface list gigabitethernet 0/1-40
DeviceA(cfg-if-list)# mmu queue-guarantee output unicast 2 3 4 5 6 7 8 set 1
DeviceA(cfg-if-list)# mmu queue-guarantee output multicast 2 3 4 5 6 7 8 set 1
DeviceA(cfg-if-list)# exit
```

On device A, set a guaranteed buffer for queues on all the ports not in use.

```
DeviceA(cfg)# interface list gigabitethernet 0/41-48
DeviceA(cfg-if-list)# mmu queue-guarantee output unicast set 1
DeviceA(cfg-if-list)# mmu queue-guarantee output multicast set 1
DeviceA(cfg-if-list)# exit
```

5. Verification

On device A, verify that the command configuration for interface GigabitEthernet 0/1 is correct.

```
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# display this-config

Building configuration...
!
 mmu queue-threshold output unicast 1 set 100
 mmu queue-threshold output multicast 1 set 100
 mmu queue-guarantee output unicast 2 set 1
 mmu queue-guarantee output unicast 3 set 1
 mmu queue-guarantee output unicast 4 set 1
 mmu queue-guarantee output unicast 5 set 1
 mmu queue-guarantee output unicast 6 set 1
 mmu queue-guarantee output unicast 7 set 1
 mmu queue-guarantee output unicast 8 set 1
 mmu queue-guarantee output multicast 2 set 1
 mmu queue-guarantee output multicast 3 set 1
 mmu queue-guarantee output multicast 4 set 1
 mmu queue-guarantee output multicast 5 set 1
 mmu queue-guarantee output multicast 6 set 1
 mmu queue-guarantee output multicast 7 set 1
 mmu queue-guarantee output multicast 8 set 1
```

6. Configuration Files

Device A configuration file

The configuration of interface GigabitEthernet 0/1 to interface GigabitEthernet 0/40 is exactly the same, and therefore only the configuration of GigabitEthernet 0/1 is provided below. The configuration of interface GigabitEthernet 0/41 to interface GigabitEthernet 0/48 is exactly the same, and therefore only the configuration of GigabitEthernet 0/41 is provided below.

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 mmu queue-threshold output unicast 1 set 100
 mmu queue-guarantee output unicast 2 set 1
 mmu queue-guarantee output unicast 3 set 1
 mmu queue-guarantee output unicast 4 set 1
 mmu queue-guarantee output unicast 5 set 1
 mmu queue-guarantee output unicast 6 set 1
 mmu queue-guarantee output unicast 7 set 1
 mmu queue-guarantee output unicast 8 set 1
 mmu queue-threshold output multicast 1 set 100
 mmu queue-guarantee output multicast 2 set 1
 mmu queue-guarantee output multicast 3 set 1
 mmu queue-guarantee output multicast 4 set 1
 mmu queue-guarantee output multicast 5 set 1
 mmu queue-guarantee output multicast 6 set 1
```

```
  mmu queue-guarantee output multicast 7 set 1
  mmu queue-guarantee output multicast 8 set 1
!
interface gigabitEthernet 0/41
  mmu queue-guarantee output unicast 1 set 1
  mmu queue-guarantee output unicast 2 set 1
  mmu queue-guarantee output unicast 3 set 1
  mmu queue-guarantee output unicast 4 set 1
  mmu queue-guarantee output unicast 5 set 1
  mmu queue-guarantee output unicast 6 set 1
  mmu queue-guarantee output unicast 7 set 1
  mmu queue-guarantee output unicast 8 set 1
  mmu queue-guarantee output multicast 1 set 1
  mmu queue-guarantee output multicast 2 set 1
  mmu queue-guarantee output multicast 3 set 1
  mmu queue-guarantee output multicast 4 set 1
  mmu queue-guarantee output multicast 5 set 1
  mmu queue-guarantee output multicast 6 set 1
  mmu queue-guarantee output multicast 7 set 1
  mmu queue-guarantee output multicast 8 set 1
!
```

1 Configuring AAA

1.1 Introduction

1.1.1 Overview

Authentication, authorization and accounting (AAA) is a network security management mechanism, which provides basic authentication, authorization, and accounting (billing) services for users who access networks. The content of AAA is described as follows:

- Authentication service: Identifies users before they access networks to check whether the users have access permissions.
- Authorization service: Classifies user permissions to grants different access permissions to users.
- Accounting service: Records users' usage of network resources. The statistical data can be used for analysis and billing.

AAA boasts strong flexibility and controllability, scalability, standardized authentication, and supports multiple backup systems. Compared with simple access control functions provided by devices such as local username authentication and line password-based authentication, AAA provides a higher level of security protection and therefore becomes the overriding access control method.

1.1.2 Principles

1. Basic Concepts

- Security method

  A security method refers to the method used to implement authentication, authorization, and accounting services. Security methods can be classified into AAA authentication methods, AAA authorization methods, and AAA accounting methods by service type.

  Based on the service provider, service methods can be further classified into service methods providing no security management, service methods providing security management through a local device, and service methods providing security management through a remote server. For details, see 1.1.2 3. AAA Authentication, 1.1.2 4. AAA Authorization, and 1.1.2 5. AAA Accounting.

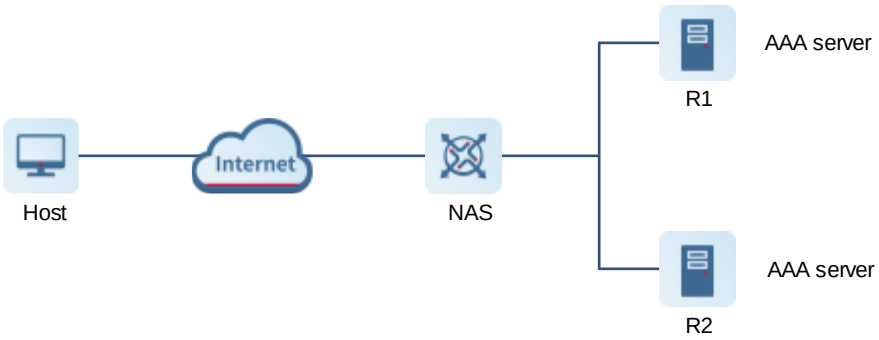
- Method list

  Method lists are classified into authentication method lists, authorization method lists, and accounting method lists based on the AAA service type. Each method list provides multiple security methods for this type of AAA service, to ensure that alternative methods are available if one method is unavailable.

  A method list contains one or more security methods. The sequence for the methods to take effect is subject to the sequence of security methods defined in the list, that is, a method defined earlier takes effect earlier. If a method fails to respond during AAA service provision, a device switches to the next method until all methods in the method list are tried. If a method returns a failure or all methods fail to respond, the process stops and the device cannot provide the security service for users.

Caution

A device tries the next method only when no response is received from the previous method. For example, if a method denies user access during identity authentication, the identity authentication process ends and the device does not switch to other identity authentication methods.



- AAA server group

  An AAA server is a device that provides remote AAA security services for users.

  An AAA server group is a collection of one or more AAA servers of the same type and provides security services for users as a security method.

2. AAA Basic Architecture

Figure 1-1 Topology of a Typical AAA Network

As shown in Figure 1-1, a typical AAA network consists of hosts (users), a network access server (NAS), and an AAA server (remote server). AAA uses the client/server (C/S) structure. A host sends an AAA request to the NAS as a client. After receiving the request, the NAS requests the AAA security services from the AAA server as a client and provides network access permissions for the host based on the returned result.

- Main roles

  Host: A host is a device that requests network access permissions and usually refers to a user.

  NAS: A NAS responds to hosts' network access requests and manages the hosts by using security methods provided by an AAA server.

  AAA server: An AAA server provides security methods for the NAS.

- Brief process of typical AAA services

  a Configure a method list and enable the AAA security services on the NAS. The method list provides three security methods: R1 server, R2 server, and local username database (with the effective sequence from left to right). Host-related identity information has been configured in the three methods.

  b After a host connects to the NAS through a network, the NAS provides the AAA security services for the host by using a method in the method list. According to the sequence that the methods take effect, the NAS requests the security services from R1 first.

  c If R1 responds to the NAS successfully, the NAS provides network access permissions for the host based on security information provided by R1. If R1 does not respond, the NAS switches the security

method and requests the security services from R2, and so on until all methods in the method list are used up.

Note

An AAA server can use a Remote Authentication Dial-In User Service (RADIUS) or Terminal Access Controller Access-Control System Plus (TACACS+) server. Unless otherwise specified in this document, the RADIUS server is used as the AAA server. For details about TACACS+, see *Configuring TACACS*.

3. AAA Authentication

AAA authentication checks information (username and password) about a user who requests the access service, to determine whether the user has the network access permission.

- AAA authentication methods

  AAA authentication methods are classified into authentication exemption, local authentication, and remote server group authentication based on the method provider.

  - Authentication exemption

    User legitimacy is not checked. This method is used only when users are very trustworthy. You are not advised to use this method.

  - Local authentication

    Local authentication uses the database on the NAS to manage user information (such as usernames, passwords, and attributes) and identify user identities.

  - Remote server group authentication

    This authentication method uses the user database on the remote server to manage user data and identify user identities. It can achieve multi-device centralized authentication with large capacity and high reliability. A remote server group supports RADIUS servers and TACACS+ servers.

- AAA authentication types

  AAA authentication is classified into login authentication, enable authentication, and File Transfer Protocol (FTP) authentication based on the user access mode.

  - Login authentication

    This authentication verifies user identities when the users log in to the command line interface (CLI) of the NAS through Secure Shell (SSH), telnet, or FTP.

  - Enable authentication

    After users log in to the NAS CLI, this authentication verifies the users' identity information before their CLI execution permissions are elevated, that is, users are authenticated before they enter the privileged EXEC mode.

  - FTP authentication

    FTP authentication is especially used for FTP users. If no FTP authentication method is configured, login authentication is used to authenticate FTP users.

4. AAA Authorization

AAA authorization is used to manage services available to users and control network access permissions of access users. After the AAA authorization service is enabled, users can use only permitted services and are granted permissions in their permitted scopes.

- AAA authorization methods

  AAA authorization methods are classified into direct authorization, local authentication, and remote server group authentication based on the method provider.

  - Direct authorization

    Direct authorization provides default permissions that the access device allows users to use. It is used only when users are very trustworthy.

  - Local authorization

    Configure attribute authorization for local users on the NAS, which completes the authorization.

  - Remote server group authorization

    Configure user attribute authorization on the remote server. The NAS completes authorization by means of a remote server group. When all servers in a remote server group fail, you can configure local authorization or direct authorization as an alternative method.

- AAA authorization types

  AAA authorization is classified into EXEC authorization, command authorization, config-commands authorization, console authorization, and network authorization based on the permission type.

  - EXEC authorization

    EXEC authorization grants different privilege levels (0–15) to users when the users log in to the NAS CLI.

    EXEC authorization is usually used in conjunction with login authentication. After login authentication and EXEC authorization are configured on the same line, if a user passes login authentication but fails in EXEC authorization, the user cannot open the CLI.

  - Command authorization

    Command authorization grants authorization to commands after users log in to the NAS CLI.

    When a user enters a command and attempts to run it, AAA sends the command to the security server. If the security server allows this command, the command is executed. Otherwise, the command is not executed and a command execution denial message is displayed.

  - Config-commands authorization

    This authorization grants authorization to commands in configuration modes (including the global configuration mode and sub-modes).

  - Console authorization

    This authorization grants authorization to commands to be executed by users who log in through the console.

    The system can differentiate users who log in through the console from those who log in through other terminals. You can enable or disable command authorization for users who log in through the console. If command authorization is disabled for users who log in through the console, the command authorization method list that has been applied to the console line no longer takes effect.

- Network authorization

  Network authorization grants available network services to users, such as traffic, bandwidth, and timeout services.

  Network authorization is based on authentication. Network authorization is available only for authenticated users. The RADIUS or TACACS+ server grants permissions to authenticated users by returning a series of attributes.

5. AAA Accounting

AAA accounting is used to record users' usage of network resources to implement billing, auditing, and tracking functions.

The accounting service starts accounting after a user passes authentication and records the user's network access activities. It stops accounting when the user logs out, and generates a network resource access report for the user.

- AAA accounting methods

  AAA accounting methods are classified into no accounting, local accounting, and remote server group accounting based on the method provider.

  - No accounting

    Accounting is not performed on users.

  - Local accounting

    Local accounting is completed by the NAS, which collects statistics on and limits the number of local user connections. The fee calculation function is unavailable.

  - Remote server group accounting

    Accounting is performed by a remote server. You can configure local accounting as an alternative method to avoid an accounting failure occurring when all servers in a remote server group fail.

- AAA accounting types

  AAA accounting can be classified into EXEC accounting, command accounting, and network accounting based on the accounting content.

  - EXEC accounting

    Accounting is both performed when users log in to and log out of the NAS CLI.

  - Command accounting

    Command accounting is used to record commands run by a user after the user logs in to the NAS CLI from a terminal.

  - Network accounting

    Network accounting is used to record information about sessions of users who access the network.

6. Multi-Domain AAA

In multi-domain AAA, users are assigned to different domains and independent security methods are defined for each domain so that users in different domains use different security methods.

In a multi-domain environment, you can configure a separate AAA method list for each domain on the NAS. Therefore, users with the same attribute can be assigned to the same domain for the ease of management.

- Basic principles of AAA service based on domain names
  a A user submits identity authentication information to the NAS.
  b The NAS resolves the domain name in the identity authentication information.
  c The NAS checks whether the domain name is defined. If no, the NAS refuses to provide security services. If yes, the NAS makes further judgment.
  d If no method list is defined for the domain name, the NAS refuses to provide security services. If a method list is defined, the NAS provides security services.
- Username forms

  A username can be expressed in four forms. In the usernames below, "domain-name" indicates a domain name.
  - userid@domain-name
  - domain-name\userid
  - userid.domain-name
  - userid

  In the preceding username forms, the username form (userid) with no domain name uses the default domain name (**default**).
- Domain name matching

  If the username of an authenticated user carries domain information but the domain is not configured on the NAS, the NAS cannot provide AAA services for the user.

  Exact match is adopted to match domain names carried in usernames with those configured on the NAS. For example, if domain.com and domain.com.cn are configured on the NAS and a username is expressed in the form of aaa@domain.com, the NAS determines that the user belongs to domain.com rather than domain.com.cn.

1.2 Restrictions and Guidelines

- Before configuring any AAA function, run the **aaa-config new-pattern** command to enable the AAA security services. Otherwise, no command can be configured.
- AAA authentication, authorization, and accounting are three independent processes. You can use only the authentication service without authorization or accounting.
- The basic methodology and process of configuring the AAA authentication, authorization, or accounting services are as follows:
  a Enable AAA security services.
  b Determine the required AAA security service type based on the scenario.
  c Configure an AAA method list for the security service type.
  d In a corresponding mode, apply an AAA method list to make it take effect (methods do not need to be applied for some security services. For details, see specific configuration tasks).

  If this step is not configured, methods configured in step C do not take effect but the default method is used.
- Configure user information before configuring security methods.

- To use the remote server group method, configure user data on remote servers. For details about how to configure user data, see the operation instructions of the remote servers.
- To use the local method, configure local user data on the local device. For details about local users, see *Configuring Basic Management*.

1.3 Configuration Task Summary

AAA configuration includes the following tasks:

(1) (Optional) Configuring an AAA Server Group

(2) Configuring AAA Authentication

- Configuring Basic Features of AAA Authentication
- (Optional) Configuring AAA Authentication Logging

(3) (Optional) Configuring AAA Authorization

- Configuring Basic Features of AAA Authorization
- (Optional) Configuring the Function of Caching Command Authorization Results
- (Optional) Configuring the Function of Allowing Users to Log in to the Slave Device

(4) (Optional) Configuring AAA Accounting

- Configuring Basic Features of AAA Accounting
- (Optional) Configuring a Policy for User Accounting Start Failures

(5) (Optional) Configuring Domain-Based AAA Services

1.4 Configuring an AAA Server Group

1.4.1 Overview

AAA usually uses the remote server group method to provide AAA services for users. This method provides more flexible and rich security services than the local method.

1.4.2 Restrictions and Guidelines

- One or more servers can be added to each server group.
- Both RADIUS and TACACS+ support server group configuration. The configuration procedure below uses RADIUS as an example. For details about a TACACS+ server group, see *Configuring TACACS*.
- When configuring the authentication, authorization, and accounting method lists, you can specify different server groups for them.
- In a custom server group, only servers in the default server group can be specified and applied.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an AAA custom server group.

aaa-config server-group server rds *group-name*

No server group is configured by default.

The name of a server group cannot be set to a predefined keyword "radius" or "tacacs+".

(4) Add an AAA server group member.

server { *ipv4-address* | *ipv6-address* } [**authentication-port** *auth-port* | **accounting-port** *acct-port*] *

No AAA server group member is added to a server group by default.

(5) (Optional) Specify a VRF instance for the AAA server group.

ip vrf binding *vrf-name*

No VRF instance is specified for an AAA server group by default.

When a server group in a specified VRF instance is used, the source IP address used by the device to communicate with a remote server needs to be acquired from the VRF instance. If you run the **ip radius-mode source-interface** command to specify the source interface of request packets, the IP address obtained from this source interface is prior to that acquired from the VRF instance.

(6) Configure the MGMT interface for the AAA server group.

ip oob [**via mgmt** *mgmt-number*]

An AAA server group uses MGMT 0 by default.

1.5 Configuring Basic Features of AAA Authentication

1.5.1 Overview

AAA authentication is used to verify user identities. After AAA authentication is configured, users can access network resources only after passing the authentication specified in security methods in the method list.

1.5.2 Restrictions and Guidelines

- After AAA authentication is configured, if no authentication method is configured and the default authentication method does not exist, users can log in through the console without authentication but other types of access users need to pass local authentication.
- If multiple methods are defined in the method list, when a method fails to respond, the device switches to the next method. The execution sequence of methods is the sequence of methods configured in the method list. If a method responds and returns a failure, the device does not switch to the next method.
- If you have passed login authentication (except the authentication exemption method) when logging in to the CLI, the device records the username, and then uses the username for authentication when Enable authentication is performed. You do not need to enter the username again but the entered password must match the username. If login authentication fails or the authentication exemption method is used when you log in to the CLI, the username will not be recorded, and you need to enter the username for authentication in the further Enable authentication.
- The authentication exemption method allows any user to access network resources without authentication. You are not advised to use this method. Only in some special cases (all access users are trustworthy and no network failure caused by authentication system problems is allowed), this method can be used as an alternative method when the device receives no response in the remote server group authentication and

local authentication.

1.5.3 Configuration Tasks

Configure basic features of AAA authentication. Select at least one of the following tasks to configure.

- Configuring Login Authentication
- Configuring Enable Authentication
- Configuring FTP Authentication

1.5.4 Configuring Login Authentication

1. Overview

After login authentication is configured, access users who log in through SSH, telnet, or FTP need to be authenticated before accessing network resources.

2. Restrictions and Guidelines

A configured login authentication method must be applied to a line that needs login authentication. Otherwise, the method does not take effect.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable AAA security services.

aaa-config new-pattern

The AAA security services are disabled by default.

(4) Configure a login authentication method list.

aaa-config authentication line-login { *list-name* | **default** } *method*&<1-4>

No login authentication method list is configured by default.

(5) (Optional) Configure the maximum number of consecutive failed login attempts.

aaa-config lock authentication times *max-attempts*

(6) The default maximum number of consecutive failed login attempts is **3**. **0** indicates that the number of consecutive failed login attempts is not limited.

(7) (Optional) Configure the user lockout duration.

aaa-config lock authentication lockout-time *lockout-time*

After the number of login attempts of a user exceeds the configured number of consecutive failed login attempts, the user is locked out for 10 minutes by default.

(8) Enter the configuration mode of a specified line.

line { **console** | **vty** } *first-line* [*last-line*]

(9) Apply the login authentication method list to the line.

line-login authentication { *list-name* | **default** }

The default login authentication method list applied to a line is the default method list.

1.5.5 Configuring Enable Authentication

1. Overview

After Enable authentication is configured and a user logs in to the NAS CLI through a terminal, the user must be authenticated before running the **enable** command to enter the privileged EXEC mode.

1. Restrictions and Guidelines

After an Enable authentication method list is configured, the Enable authentication function takes effect automatically.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable AAA security services.

aaa-config new-pattern

The AAA security services are disabled by default.

(4) Configure an Enable authentication method list.

aaa-config authentication enable reset *method*&<1-4>

No Enable authentication method list is configured by default.

1.5.6 Configuring FTP Authentication

1. Overview

After FTP authentication is configured, FTP users need to pass FTP authentication upon login.

2. Restrictions and Guidelines

If the AAA FTP security service is enabled on a device, users must perform FTP authentication through AAA.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable AAA security services.

aaa-config new-pattern

The AAA security services are disabled by default.

(4) Enable the FTP server function.

ftp-server enable

The FTP server function is disabled by default.

(5) Configure an FTP authentication method list.

aaa-config authentication ftp { *list-name* | **default** } *method*&<1-4>

No FTP authentication method list is configured by default.

(6) Configure FTP to use AAA accounts for login authentication.

ftp-server authentication { *list-name* | **default** }

FTP does not support login authentication on AAA accounts by default.

1.6 Configuring AAA Authentication Logging

1.6.1 Overview

The device generates logs when an AAA user passes authentication. If a large number of users go online concurrently, the device generates considerable logs, which may degrade the device performance or cause frequent screen refreshing. In this case, you can disable the logging function or restrict the logging rate.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure AAA authentication logging. Please configure only one task.

- Disable AAA authentication logging.

  unset aaa-config log enable

  AAA authentication logging is enabled by default.

- Configure the rate of AAA authentication logging.

  aaa-config log speed-limit *rate-limit*

  Five AAA authentication logs are printed per second by default.

1.7 Configuring Basic Features of AAA Authorization

1.7.1 Overview

AAA authorization is used to manage services available to users and control network use permissions of access users. After the basic features of AAA authorization are enabled, users can use only the permitted services and are granted permissions in their permitted scopes.

1.7.2 Restrictions and Guidelines

- EXEC authorization is usually used together with login authentication. Authentication and authorization can use different methods and different servers, and the authentication and authorization results of the same user may be different. If a user passes login authentication but fails in EXEC authorization, the user cannot open the CLI.

- When configuring command authorization, specify the command level, which is used as the default level of commands. For example, if a command is visible to users above level 14, the default level of the command is 14.
- EXEC authorization and command authorization need to be applied to a line so that they take effect.
- Command authorization is unavailable when role-based access control (RBAC) is enabled. For details about RBAC, see *Configuring RBAC*.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an AAA authorization method. Configure at least one of the tasks.

- Configure an EXEC authorization method list to authorize permitted users to open the CLI.

  aaa-config aaa-authorization execute { *list-name* | **default** } *method*&<1-4>

  No EXEC authorization method list is configured by default.

- Configure a command authorization method list to authorize permitted users to run a command.

  aaa-config aaa-authorization cmd *level* { *list-name* | **default** } *method*&<1-4>

  No command authorization method list is configured by default.

- Configure a network authorization method list to authorize permitted users to access network services.

  aaa-config aaa-authorization net { *list-name* | **default** } *method*&<1-4>

  No network authorization method list is configured by default.

- Grant authorization to all commands in configuration modes.

  aaa-config aaa-authorization config-mode-commands

  The authorization for commands in configuration modes is disabled by default.

- Enable command authorization for users who log in through the console. You can enable command authorization for users who log in through the console and users who log in through other terminals separately.

  aaa-config aaa-authorization console

  Command authorization is disabled for users who log in through the console by default.

(4) (Optional) Enter the configuration mode of a specified line.

line { **console** | **vty** } *first-line* [*last-line*]

(5) (Optional) Apply the authorization method to the specific line. Please configure only one task.

- Apply the EXEC authorization method to the specific line.

  aaa-authorization execute { *list-name* | **default** }

  EXEC authorization is disabled by default.

- Apply the command authorization method to the specific line.

  aaa-authorization cmd *level* { *list-name* | **default** }

The command authorization function is disabled by default.

1.8 Configuring the Function of Caching Command Authorization Results

1.8.1 Overview

After this function is configured, the device locally caches command authorization results returned by the AAA server. For subsequent commands with the level same as the cached authorized commands, command authorization can be performed based on the locally cached results.

1.8.2 Restrictions and Guidelines

Authorization results in the local cache apply only to the current session and commands of the current level. The authorization of other sessions or commands of other levels are performed by the remote server and local authorization can be performed only after their results are cached locally.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the function of caching command authorization results.

aaa-config command-author cache

The function of caching command authorization results is disabled by default.

1.9 Configuring the Function of Allowing Users to Log in to the Slave Device

1.9.1 Overview

The function of allowing users to log in to the slave device is used to control whether a user is allowed to log in to the console of the slave device.

1.9.2 Restrictions and Guidelines

- The **aaa-config new-pattern** command must be configured first.
- The configuration remains valid unless the function is disabled explicitly on the master device.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable AAA security services.

aaa-config new-pattern

The AAA security services are disabled by default.

(4) Disable the function of allowing users to log in to the console of the slave device.

unset aaa-config slave-login allow

The function of allowing users to log in to the console of the slave device is enabled by default.

1.10 Configuring Basic Features of AAA Accounting

1.10.1 Overview

AAA accounting is used to record users' usage of network resources, login and logout processes, and command execution information.

1.10.2 Restrictions and Guidelines

- EXEC accounting is performed only on users who pass login authentication and log in to the NAS. When login authentication is not configured or the authentication exemption method is adopted, EXEC accounting is not performed.
- If accounting start is not performed on a user upon login, accounting stop will not be performed when the user logs out.
- The remote server group method used in the command accounting function supports only the TACACS+ protocol.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an AAA accounting method. Configure at least one of the tasks.

- Configure an EXEC accounting method list.

  aaa-config aaa-accounting execute { *list-name* | **default** } **start-and-stop** *method*&<1-4>

  NO EXEC accounting method list is configured by default.

  A configured EXEC accounting method list must be applied to a line so that it takes effect.

- Configure a command accounting method list.

  aaa-config aaa-accounting cmd *level* { *list-name* | **default** } **start-and-stop** *method*&<1-4>

  No command accounting method list is configured by default.

  A configured command accounting method list must be applied to a line so that it takes effect.

- Configure a network accounting method list.

  aaa-config aaa-accounting net { *list-name* | **default** } **start-and-stop** *method*&<1-4>

  No network accounting method list is configured by default.

(4) (Optional) Enable the accounting update function.

aaa-config accounting update

Accounting update is disabled by default.

After this function is configured, the device updates accounting information periodically. This function helps improve the accounting accuracy. You are advised to configure it.

(5) (Optional) Configure the accounting update interval.

aaa-config accounting update time *interval*

The default accounting update interval is **5** minutes.

It is recommended that the accounting update interval not be configured unless otherwise specified.

(6) Apply the accounting method. Please configure only one task.

- Enter the line configuration mode and apply the EXEC accounting method. Run the following commands in sequence:

  line { **console** | **vty** } *first-line* [*last-line*]

  aaa-accounting execute { *list-name* | **default** }

  A line is associated with the default method list by default.

- Enter the line configuration mode and apply the command accounting method. Run the following commands in sequence:

  line { **console** | **vty** } *first-line* [*last-line*]

  aaa-accounting cmd [*accounting-commands-level*] { *list-name* | **default** }

  A line is associated with the default method list by default.

1.11 Configuring a Policy for User Accounting Start Failures

1.11.1 Overview

After this function is configured, the user status is online or offline if the accounting start fails.

1.11.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the user online/offline status after the accounting start fails.

aaa-config accounting start-fail { **offline** | **online** }

The user online/offline status after an accounting start failure is not configured by default.

1.12 Configuring Domain-Based AAA Services

1.12.1 Overview

The domain-based AAA services classify users into different domains and the domains use different security methods to provide AAA services.

1.12.2 Restrictions and Guidelines

- The device supports a maximum of 32 domains.
- After the domain-based AAA services are enabled, if information of a user does not carry domain information, the user is assigned to the default domain **reset**. A method list for the **reset** domain must be configured on the device. Otherwise, users without domain information cannot use AAA services.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable domain-based AAA services.

aaa-config domain enable

The domain-based AAA services are disabled by default.

(4) Create a domain and enter the domain configuration mode.

aaa-config domain { *domain-name* | **default** }

No domain is configured by default.

(5) Configure an authentication method list for the AAA domain.

authentication { **dot1x** | **enable** | **line-login** } { *list-name* | **default** }

The default authentication method list used in an AAA domain is the default method list.

(6) Configure an accounting method list for the AAA domain.

accounting { **cmd** | **execute** | **net** } { *list-name* | **default**}

The default accounting method list used in an AAA domain is the default method list.

(7) Configure an authorization method list for the AAA domain.

aaa-authorization { **cmd** | **execute** | **net** } { *list-name* | **default** }

The default authorization method list used in an AAA domain is the default method list.

(8) (Optional) Set the domain status.

state { **active** | **block** }

A configured domain is active by default.

(9) (Optional) Configure whether usernames carry domain name information.

username-format { **with-domain** | **without-domain** }

Usernames carry domain name information during interaction between the NAS and the server by default.

(10) (Optional) Configure a limit on the number of users supported in the domain.

access-limit *access-limit-number*

No limit on the number of users supported in a domain is configured by default.

1.13 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

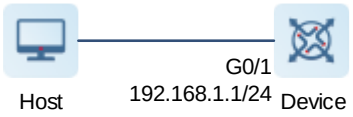
⚠ Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-1 AAA Monitoring

Command	Purpose
display aaa-info accounting update	Displays accounting update information.
display aaa-info capability	Displays display AAA capabilities.
display aaa-info domain [**reset** | *domain-name*]	Displays information about a configured domain.
display aaa-info lockout	Displays lockout parameter configuration in the current login authentication.
display aaa-info group	Displays all AAA server groups.
display aaa-info methodlists	Displays all AAA method lists.
display aaa-info user { **all** | **by-id** *session-id* | **by-name** *user-name* | **lockout** }	Displays AAA user information.
cleanup aaa-config user lock list { **all** | **user-name** *user-name-id* }	Clears the list of locked users.

1.14 Configuration Examples



1.14.1 Configuring Local Login Authentication and Local EXEC Authorization

1. Requirements

You can use local login authentication and local EXEC authorization together to control the permissions of users who log in to the device. In this method, you need to configure accounts and their permissions only in the local user database of the device, to control user permissions with no need to use an authentication server.

2. Topology

Figure 1-2 Topology of Local Login Authentication and Local EXEC Authorization

3. Notes

- Enable AAA security services on the device.
- Add accounts to the local user database of the device.
- Create an authentication method list and an authorization method list.
- Apply the authentication method and authorization method to a specific line.

4. Procedure

Enable AAA security services.

```
Device> privilege
Device# config-system terminal
Device(cfg)# aaa-config new-pattern
```

Add accounts **host1** and **host2** to the local user database of the device and configure account permissions.

```
Device(cfg)# user-account host1 privilege 15 password password1
Device(cfg)# user-account host2 privilege 4 password password2
```

Create a login authentication method list named **login-method**, in which the authentication method is local authentication, and create an EXEC authorization method list named **exec-method**, in which the authorization method is local authorization.

```
Device(cfg)# aaa-config authentication line-login login-method native
Device(cfg)# aaa-config authorization execute exec-method native
```

Apply the authentication method list and authorization method list to a line.

```
Device(cfg)# line vty 0 35
Device(cfg-line)# line-login authentication login-method
Device(cfg-line)# aaa-authorization execute exec-method
```

5. Verification

Run the **display aaa-info methodlists** command on the device to display configured method lists.

```
Device# display aaa-info methodlists

Authentication methodlists:
aaa-config authentication line-login login-method native

Accounting methodlists:

Authorization methodlists:
aaa-config aaa-authorization execute exec-method native
```

Log in to the device through telnet by using client software (such as PuTTY or Xshell) and verify that different users have different account permissions.

- Log in to the device as user **host1** and check that the privilege level of the user is 15.

```
User Access Verification

Username:host1
Password:password1

Device# display privilege
Current privilege level is 15
```

- Log in to the device as user **host2** and check that the privilege level of the user is 4.

```
User Access Verification

Username:host2
Password:password2

Device# display privilege
Current privilege level is 4
```

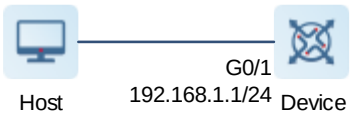
6. Configuration Files

```
!
user-account host1 privilege 15 password password1
user-account host2 privilege 4 password password2
!
aaa-config new-pattern
!
aaa-config authorization execute exec-method native
aaa-config authentication line-login login-method native
!
line vty 0 35
 aaa-authorization execute exec-method
 line-login authentication login-method
!
end
```

7. Common Errors

- No authentication method list and authorization method list are applied to a specific line.
- No account is configured in the local user database.

1.14.2 Configuring Enable Authentication



1. Requirements

Users can have execution permissions with a privilege level of 0 to 15. After Enable authentication is configured, users must be authenticated when running the **privilege** command to switch the permission to a higher level.

As shown in Figure 1-3, when both local authentication and Enable password authentication are configured on the device, local authentication is preferred. If local authentication is invalid, privilege cipher authentication is used.

2. Topology

Figure 1-3 Topology of Enable Authentication

3. Notes

- Enable AAA security services on the device.
- Configure the local user database and Enable password.
- Configure an Enable authentication method list.

Note

Only one Enable authentication method list can be defined. Therefore, you do not need to define the name of the Enable authentication method list. After the default method list is configured, the Enable authentication function takes effect automatically.

4. Procedure

Enable AAA security services.

```
Device> privilege
Device# config-system terminal
Device(cfg)# aaa-config new-pattern
```

Add account **host1** to the local user database and set the privilege level of the account to **15**.

```
Device(cfg)# user-account host1 privilege 15 password password1
```

Set the password to **enpassword1** for privilege level 15 in Enable authentication.

```
Device(cfg)# privilege safe-cipher level 15 enpassword1
```

Configure an Enable authentication method list, in which local authentication is prior to Enable password authentication.

```
Device(cfg)# aaa-config authentication enable default native enable
```

5. Verification

Log in to the device as user **host1** and check that the privilege level of the user is 15.

```
User Access Verification

Username:host1
Password:password1
```

```
Device# display privilege
Current privilege level is 15
```

Switch the privilege level to 4 and verify that no password is required for authentication.

```
Device# privilege 4
Device# display privilege
Current privilege level is 4
```

Switch the privilege level to 15 and verify that identity authentication is needed. Local authentication has a higher priority. Therefore, you can enter the password of **host1** (**password1**) for authentication to successfully switch the privilege level to 15.

```
Device# privilege 15
Password:password1

Device# display privilege
Current privilege level is 15
```

6. Configuration Files

```
!
user-account host1 privilege 15 password password1
!
aaa-config new-pattern
!
aaa-config authentication enable default native enable
!
privilege safe-cipher 5 $1$7b8Y$v6u11F23p9y3vwp6
!
end
```

1.14.3 Configuring Command Authorization

1. Requirements

Command authorization needs to be configured for login users so that users who log in to the device through terminals can only use commands in their authorized scopes.

2. Topology

Figure 1-4 Topology of Command Authorization

3. Notes

- Enable AAA security services on the device.
- Configure an IP address and a shared key for the TACACS+ server on the device.

- Configure the login authentication method list and command authorization method list on the device.
- Configure to-be-authenticated users and authorized command scopes on the TACACS+ server.
- Apply the authentication method and authorization method to a specific line.

4. Procedure

(1) On the TACACS+ server, add login users, configure authorized command scopes, and configure the server to provide AAA services for the device. (The configuration is omitted here. For the configuration of the TACACS+ server, use the operation manual of the server.)

(2) Enable AAA security services.

```
Device> privilege
Device# config-system terminal
Device(cfg)# aaa-config new-pattern
```

(3) Configure the IP address and shared key of the TACACS+ server (the IP address is set to **10.110.1.2** and shared key to **sharekey** in this example).

```
Device(cfg)# tacplus-server host 10.110.1.2 share-key sharekey
```

(4) Configure a login authentication method list named **login-method**, in which TACACS+ server authentication is prior to local authentication.

```
Device(cfg)# aaa-config authentication line-login login-method server-group tacacs+ native
```

(5) Add the account **host1** to the local user database and configure the account permissions.

```
Device(cfg)# user-account host1 privilege 15 password password1
```

(6) Configure a command authorization method list named **command-method** for level-15 commands. In this list, TACACS+ server authorization is prior to local authorization.

```
Device(cfg)# aaa-config authorization cmd 15 command-method server-group tacacs+ native
```

(7) Apply the authentication method list and authorization method list to a line.

```
Device(cfg)# line vty 0 35
Device(cfg-line)# line-login authentication login-method
Device(cfg-line)# aaa-authorization execute command-method
```

5. Configuration Files

```
!
aaa new-model
!
aaa authentication login login-method group tacacs+ local
aaa authorization commands 15 command group tacacs+ local
!
tacacs-server host 10.110.1.2 key 7 $10$062$/SJrCPEEZKM=$
!
username host1 privilege 15 password 7 $10$247$knWuVat9D+rHyNk=$
!
line vty 0 35
 login authentication login-method
 authorization exec command-method
!
```

6. Common Errors

- The shared key configured on the TACACS+ server is different from that configured on the device.
- A command authorization configuration error occurs on the TACACS+ server.

1.14.4 Configuring Network Authorization

1. Requirements

Network authorization needs to be configured to grant available network services to users, such as the traffic, bandwidth, and timeout services.

2. Topology

Figure 1-5 Topology of Network Authorization

3. Notes

- Enable AAA security services.
- Configure a network authorization method list.
- Apply the network authorization method list to a specific interface line (skip this step if you configure the default method).

4. Procedure

Enable AAA security services.

```
Device> privilege
Device# config-system terminal
Device(cfg)# aaa-config new-pattern
```

Configure the default network authorization method list.

```
Device(cfg)# aaa-config authorization net default server-group radius none
```

5. Verification

Run the **display aaa-info methodlists** command on the device to display configuration results.

```
Device# display aaa-config methodlists

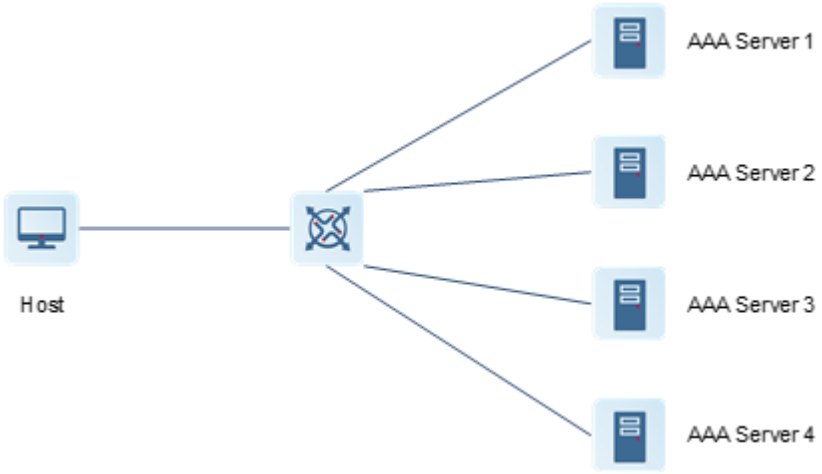
Authentication methodlists:

Accounting methodlists:

Authorization methodlists:
aaa-config aaa-authorization net efault server-group radius none
```

6. Configuration Files

```
!
aaa-config new-pattern
!
aaa-config aaa-authorization net default server-group radius none
!
```



1.14.5 Configuring an AAA Server Group

1. Requirements

A custom AAA server group needs to be created to provide AAA services.

2. Topology

Figure 1-6 Topology of an AAA Server Group

3. Notes

- Configure AAA servers.
- Create an AAA custom server group.
- Add server group members to the custom server group.

4. Procedure

(1) Add AAA servers (the following uses RADIUS servers as an example).

```
Device> privilege
Device# config-system terminal
Device(cfg)# rds-server host 10.1.1.1
Device(cfg)# rds-server host 10.1.1.2
Device(cfg)# rds-server host 10.1.1.3
Device(cfg)# rds-server host 10.1.1.4
```

(2) Configure a global RADIUS server communication key.

```
Device(cfg)# rds-server share-key radiuskey
```

(3) Create a server group named **group1** and add members to the group.

```
Device(cfg)# aaa-config group server rds group1
Device(cfg-gs-radius)# server 10.1.1.1
Device(cfg-gs-radius)# server 10.1.1.2
Device(cfg-gs-radius)# exit
```

(4) Create a server group named **group2** and add members to the group.

```
Device(cfg)#aaa-config group server rds group2
Device(cfg-gs-radius)# server 10.1.1.3
Device(cfg-gs-radius)# server 10.1.1.4
Device (cfg-gs-radius)# exit
```

5. Verification

Run the **display aaa-info group** command on the device to display the configuration results.

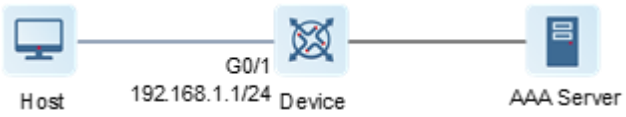
```
Device# display aaa-info group
Type            Reference    Name
---------- ---------- ----------
radius         1              radius
tacacs+        1               tacacs+
radius         1              group1
radius         1              group2
```

6. Configuration Files

```
!
rds-server host 10.1.1.1
rds-server host 10.1.1.2
rds-server host 10.1.1.3
rds-server host 10.1.1.4
rds-server share-key radiuskey
!
aaa-config group server rds group1
 server 10.1.1.1
 server 10.1.1.2
!
aaa-config group server rds group2
 server 10.1.1.3
 server 10.1.1.4
!
```

7. Common Errors

For RADIUS servers that use non-default authentication ports and non-default accounting ports, the authentication port or accounting port is not specified when the **server** command is run to add servers.



1.14.6 Configuring Domain-based AAA Services

1. Requirements

After a domain is created and a security method list is specified for the domain, users belonging to the domain use security methods of the domain for authentication, authorization, and accounting.

2. Topology

Figure 1-7 Topology of Domain-Based AAA Services

3. Notes

- Configure a RADIUS server in advance so that RADIUS server authentication and accounting can be performed.
- Enable AAA security services.
- Configure an AAA security method list.
- Enable domain-based AAA services.
- Create a domain.
- Associate the AAA security method list with the domain.
- Configure domain attributes.

4. Procedure

(1) Enable AAA security services.

```
Device> privilege
Device# config-system terminal
Device(cfg)# aaa-config new-pattern
```

(2) Configure an AAA server (the following uses the RADIUS server as an example).

```
Device(cfg)# rds-server host 192.168.1.2 share-key radiuskey
```

(3) Configure an AAA security method list.

```
Device(cfg)# aaa-config authentication line-login default server-group radius
Device(cfg)# aaa-config aaa-accounting net list3 start-and-stop server-group radius
```

(4) Enable domain-based AAA services.

```
Hostname(cfg)# aaa-config domain enable
```

(5) Create a domain and configure domain attributes.

```
Device(cfg)# aaa-config domain domain.com
Device(cfg-aaa-domain)# authentication line-login reset
Device(cfg-aaa-domain)# aaa-accounting net list3
Device(cfg-aaa-domain)# username-format without-domain
```

5. Verification

Run the **display aaa-config domain** command on the device to display domain configuration.

```
Device# display aaa-config domain domain.com

=============Domain domain.com=============
```

```
State: Active
Username format: With-domain
Access limit: No limit

Selected method list:
 authentication line-login reset
 aaa-accounting net list3
```

6. Configuration Files

```
!
aaa-config new-pattern
aaa-config domain enable
!
aaa-config domain domain.com
 authentication line-login default
 aaa-accounting net list3
 username-format without-domain
!
aaa-config accounting net list3 start-and-stop server-group radius
aaa-config authentication dot1x default server-group radius
!
radius-server host 192.168.1.2 key radiuskey
!
```

1.15 Common Errors

- When a local method is configured to provide AAA security services, no user information is configured in the local database.
- When a remote server group method is configured to provide AAA security services, no RADIUS/TACACS+ server is configured and no user information is configured on the server.

1 Configuring RADIUS

1.1 Introduction

1.1.1 Overview

The Remote Authentication Dial-In User Service (RADIUS) is a distributed authentication, authorization and accounting (AAA) protocol based on the client/server architecture. It works with AAA to provide AAA security services for users.

When providing AAA security services, a network device serves as a RADIUS client to provide user information to the RADIUS server to initiate security service requests. The remote RADIUS server stores user information and network service information, and provides security services for users by responding to requests from the RADIUS client.

RADIUS is usually applied in networks that have high security requirements and allow remote user access. As a completely open protocol, many systems (such as UNIX, Windows 2000, and Windows 2008) support the installation of RADIUS as a system component. Therefore, the RADIUS server becomes the most widely used security server.

1.1.2 Principles

1. Basic Concepts

- Client/server mode

  RADIUS uses the client/server mode and consists of RADIUS clients and the RADIUS server.

  - As the initiator of RADIUS requests, a RADIUS client usually runs on a network access server (NAS). It provides user information for the RADIUS server, and receives and processes responses from the RADIUS server, for example, accepting or rejecting user access, and requesting user-specific information.
  - The RADIUS server maintains the IP addresses and shared key of RADIUS clients as well as configured user information, and provides authentication, authorization, and accounting services by responding to requests from RADIUS clients. One RADIUS server usually corresponds to multiple RADIUS clients.

- Shared key

  A shared key is a string shared between a RADIUS client and the server. It is used to encrypt and decrypt user passwords during RADIUS packet transmission and generate packet verification fields, in an effort to ensure RADIUS communication security.

- RADIUS server group

  Security methods used in AAA security services are based on server groups. Likewise, RADIUS provides AAA security services based on RADIUS server groups. One security method corresponds to one RADIUS server group and one or more RADIUS severs can be configured in each RADIUS server group.

  If multiple RADIUS servers are configured in a RADIUS server group, when a device fails to communicate with the first RADIUS server or the first RADIUS server is unreachable, the device automatically attempts

to communicate with the second RADIUS server, and so on. The attempt lasts till the communication succeeds or the communication with all RADIUS servers fails.

2. RADIUS Packet

- Packet structure

Figure 1-1 Structure of a RADIUS Packet

Fields contained in the packet structure shown in Figure 1-1 are described in Table 1-1.

Table 1-1 Description of Fields Contained in a RADIUS Packet

Field	Length	Description	Remarks
Code	1 byte	Identifies the packet type.	Values corresponding to common packet types and their meanings are as follows: **1**: Access-Request **2**: Access-Accept **3**: Access-Reject **4**: Accounting-Request **5**: Accounting-Response **11**: Access-Challenge
Identifier	1 byte	Matches a request with a response packet.	Request packets and response packets of the same type have the same identifier value.
Length	2 bytes	Indicates the length of a RADIUS packet.	The value is the sum of the lengths of the **Code**, **Identifier**, **Length**, **Authenticator**, and **Attributes** fields. If the length of a received packet is greater than the value of **Length**, the content beyond the value of **Length** is ignored as filling information. If the length of a received packet is smaller than the value of **Length**, the packet is discarded.

Field	Length	Description	Remarks
Authenticator	16 bytes	Verifies packets and encrypts and decrypts user passwords.	N/A
Attributes	Variable length	Carries authentication, authorization, and accounting information.	This field usually contains multiple attributes and each attribute is represented in the type, length, value (TLV) format.

- RADIUS attributes

  RADIUS attributes carry authentication, authorization, and accounting information, and each attribute is represented in the TLV format, as described in Table 1-2.

Table 1-2 Description of RADIUS Attribute Fields

Field	Length	Description
Type	1 byte	Attribute type
Length	1 byte	Total length of an attribute (TLV)
Value	Variable length	Attribute description

Table 1-3 RADIUS Attribute List

Attribute No.	Attribute Name	Attribute No.	Attribute Name
1	User-Name	43	Acct-Output-Octets
2	User-Password	44	Acct-Session-Id
3	CHAP-Password	45	Acct-Authentic
4	NAS-IP-Address	46	Acct-Session-Time
5	NAS-Port	47	Acct-Input-Packets
6	Service-Type	48	Acct-Output-Packets
7	Framed-Protocol	49	Acct-Terminate-Cause
8	Framed-IP-Address	50	Acct-Multi-Session-Id
9	Framed-IP-Netmask	51	Acct-Link-Count
10	Framed-Routing	52	Acct-Input-Gigawords
11	Filter-ID	53	Acct-Output-Gigawords
12	Framed-MTU	55	Event-Timestamp
13	Framed-Compression	60	CHAP-Challenge

Attribute No.	Attribute Name	Attribute No.	Attribute Name
14	Login-IP-Host	61	NAS-Port-Type
15	Login-Service	62	Port-Limit
16	Login-TCP-Port	63	Login-LAT-Port
18	Reply-Message	64	Tunnel-Type
19	Callback-Number	65	Tunnel-Medium-Type
20	Callback-ID	66	Tunnel-Client-Endpoint
22	Framed-Route	67	Tunnel-Server-Endpoint
23	Framed-IPX-Network	68	Acct-Tunnel-Connection
24	State	69	Tunnel-Password
25	Class	70	ARAP-Password
26	Vendor-Specific	71	ARAP-Features
27	Session-Timeout	72	ARAP-Zone-Access
28	Idle-Timeout	73	ARAP-Security
29	Termination-Action	74	ARAP-Security-Data
30	Called-Station-Id	75	Password-Retry
31	Calling-Station-Id	76	Prompt
32	NAS-Identifier	77	Connect-Info
33	Proxy-State	78	Configuration-Token
34	Login-LAT-Service	79	EAP-Message
35	Login-LAT-Node	80	Message-Authenticator
36	Login-LAT-Group	81	Tunnel-Private-Group-id
37	Framed-AppleTalk-Link	82	Tunnel-Assignment-id
38	Framed-AppleTalk-Network	83	Tunnel-Preference
39	Framed-AppleTalk-Zone	84	ARAP-Challenge-Response
40	Acct-Status-Type	85	Acct-Interim-Interval
41	Acct-Delay-Time	86	Acct-Tunnel-Packets-Lost
42	Acct-Input-Octets	87	NAS-Port-Id

- Introduction to RADIUS attributes

  This section describes some of the important attributes.

  - Attribute 31

  When a RADIUS client sends a request packet to the RADIUS server, information is filled in attribute 31 (**Calling-Station-ID**) to identify the user to be authenticated. The MAC address of a user is often used as the attribute content. For example, in IEEE 802.1X authentication, the device uses the MAC address of the device where the IEEE 802.1X client resides as the attribute content.

Different RADIUS servers have different requirements for the format of the MAC address in attribute 31. Therefore, ensure that the MAC address format used by RADIUS clients is the same as that used by the server. Currently, the following three MAC address formats are supported.

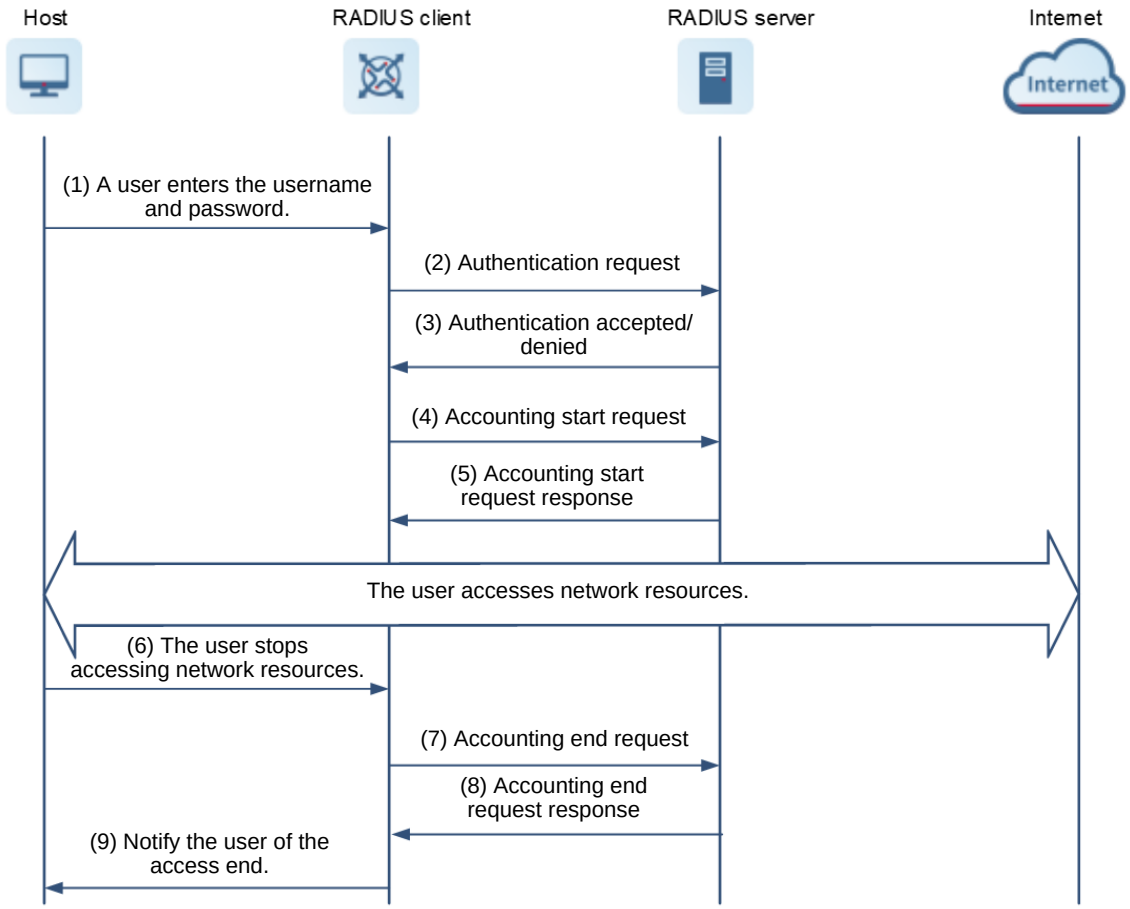
Table 1-4 Supported Formats of the MAC Address in Attribute 31

MAC Address Format	Description
ietf	Standard format specified in the Internet Engineering Task Force (IETF) standard (RFC3580). It uses hyphens (-) as the separator, for example, 00-D0-F8-33-22-AC.
normal	Dotted hexadecimal format using dots (.) as the separator, for example, 00d0.f833.22ac.
unformatted	Default format with no separator, for example, 00d0f83322ac.

- Attribute 26

Attribute 26 (**Vendor-Specific**) is also called a private attribute, which allows device vendors to define attributes. Device vendors can define multiple attributes in the TLV format in attribute 26. Table 1-5 lists private attributes supported by our company's products.

Table 1-5 List of Private Attributes



ID	Function	Type	Extended Type
1	max-down-rate	1	76
2	port-priority	2	77
3	user-ip	3	3
4	VLAN-id	4	4
5	last-supplicant-version	5	5
6	net-ip	6	6
7	user-name	7	7
8	password	8	8
9	file-directory	9	9
10	file-count	10	10
11	file-name-0	11	11
12	file-name-1	12	12
13	file-name-2	13	13
14	file-name-3	14	14
15	file-name-4	15	15
16	max-up-rate	16	16
17	current-supplicant-version	17	17
18	flux-max-high32	18	18
19	flux-max-low32	19	19
20	proxy-avoid	20	20

ID	Function	Type	Extended Type
21	dailup-avoid	21	21
22	ip-privilege	22	22
23	login-privilege	42	42
26	IPv6-multicast-address	79	79
27	IPv4-multicast-address	87	87
62	sdg-type	62	62
85	sdg-zone-name	85	85
103	sdg-group-name	103	103

3. RADIUS Authentication, Authorization, and Accounting

RADIUS provides authentication, authorization, and accounting for users. The interaction process is shown in Figure 1-2.

Figure 1-2 RADIUS Authentication, Authorization, and Accounting Process

- RADIUS authentication and authorization process

  a A user enters the username and password and sends them to a RADIUS client.

b After receiving the username and password, the RADIUS client sends an authentication request packet to the RADIUS server. The password in the authentication request packet is encrypted.

c After receiving the authentication request, the RADIUS server checks whether the username and password are legitimate. If yes, the RADIUS server accepts the authentication request and delivers authorization information of the user. If no, the RADIUS server rejects the authentication request.

- RADIUS accounting process

a If the RADIUS server returns an authentication success message in the user authentication process, the RADIUS client sends an accounting start request packet to the RADIUS server.

b The RADIUS server returns an accounting start response packet and starts accounting.

c When stopping accessing network resources, the user sends a disconnection request to the RADIUS client.

d The RADIUS client sends an accounting end request packet to the RADIUS server.

e The RADIUS server returns an accounting end response packet and stops accounting.

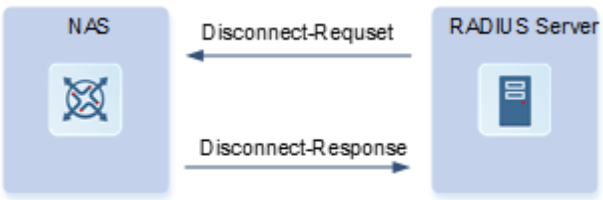
f The user is disconnected from the network and cannot access network resources.

4. RADIUS Packet Retransmission Upon Timeout

After sending a packet to the RADIUS server, a RADIUS client uses a timer to test whether the RADIUS server responds within the specified time. If the RADIUS server does not respond within the specified time, the RADIUS client retransmits the packet. The following timeout and retransmission parameters need to be configured:

- RADIUS server timeout duration

  The response time of a RADIUS server depends on its performance and the network environment. Configure a proper timeout duration based on the actual situation.



- Retransmission count
- Whether accounting update packets need to be retransmitted

5. RADIUS Forcible Logoff

Users can go offline actively. In addition, the RADIUS server can send messages to force authenticated users offline.

RADIUS forcible logoff is a user logoff management method defined in the protocol of Dynamic Authorization Extensions to RADIUS. The NAS and RADIUS server exchange Disconnect-Messages (DMs) to force authenticated users offline. The protocol of Dynamic Authorization Extensions to RADIUS enables NASs from different vendors to be compatible with RADIUS servers in user logoff processing.

Figure 1-3 DM Interaction of Dynamic Authorization Extensions to RADIUS

The DM interaction between a RADIUS server and the NAS is as follows:

(1) The RADIUS server actively sends a Disconnect-Request message to port UDP3799 of the NAS to initiate a user logoff request.

(2) The NAS searches for the user based on the user session information and username carried in the Disconnect-Request message and logs off the user.

(3) The NAS sends the logoff result to the RADIUS server through a Disconnect-Response message.

1.1.3 Protocols and Standards

- RFC 2865: Remote Authentication Dial In User Service (RADIUS)
- RFC 2866: RADIUS Accounting
- RFC 2867: RADIUS Accounting Modifications for Tunnel Protocol Support
- RFC 2868: RADIUS Attributes for Tunnel Protocol Support
- RFC 2869: RADIUS Extensions
- RFC 3576: Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)

1.2 Configuration Task Summary

RADIUS configuration includes the following tasks:

(1) Configuring RADIUS Basic Features

(2) Configuring a RADIUS Server Group

(3) (Optional) Configuring RADIUS Attributes Select at least one of the following tasks to configure.

- Configure the Attribute Format
- Configuring Private Attributes
- Configuring Compatibility with Devices of Other Vendors

(4) (Optional) Configuring RADIUS Reachability Detection

(5) (Optional) Configuring the DSCP Value for RADIUS Packets

(6) (Optional) Configuring the Units of Data Flows and Packets to Be Sent to a RADIUS Server

(7) (Optional) Configuring the Accounting-On Function

(8) (Optional) Configuring the Accounting Packet Copying Function

1.3 Configuring RADIUS Basic Features

1.3.1 Overview

This section describes how to configure parameters for the communication between a network device and a RADIUS server to ensure normal communication between them. After the parameters are configured, the device can correctly send AAA authentication, authorization, and accounting requests to the RADIUS server and give responses.

1.3.2 Restrictions and Guidelines

- Before configuring RADIUS, ensure that the network communication between the device and the RADIUS

server is in good condition.

- Before configuring RADIUS IPv6 authentication, ensure that the RADIUS server supports RADIUS IPv6 authentication.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a RADIUS remote server.

rds-server host [**oob** [**via Mgmt** *Mgmt_number*]] { *ipv4-address* | *ipv6-address* } [**authentication-port** *auth-port-number* | **accounting-port** *acct-port-number*] * [**detect user-name** *username* [**ignore-accounting-port**] [**ignore-authentication-port**] [**timeout** *idle-time*]] [**share-key** [**0** | **7**] *text-string*]

No RADIUS remote server is configured by default.

If a RADIUS server is not added to a RADIUS server group, the device uses the global routing table when communicating with the RADIUS server. Otherwise, the device uses the virtual routing and forwarding (VRF) routing table of the RADIUS server group.

(4) Configure a shared key for the communication between the device and the RADIUS server.

rds-server share-key [**0** | **7**] *key*

No shared key for the communication between the device and the RADIUS server is configured by default.

A shared key is the basis for correct communication between the device and the RADIUS server. The same shared key must be configured on them both to ensure normal communication between them.

(5) (Optional) Configure the source address for RADIUS packets.

ip radius-mode source-interface *interface-type interface-number*

The source IP address of RADIUS packets is set by the network layer by default.

After this command is configured, the device uses the first IP address of the interface specified in the command as the source address of RADIUS packets. Ensure that the communication between the configured address and the RADIUS server is normal. Specifying the source IP address for packets to be sent to the RADIUS server can reduce the NAS information maintenance workload on the RADIUS server.

(6) (Optional) Configure the source UDP port to be used by the device to send RADIUS packets.

rds-server source-port *source-port*

The source UDP port used by the device to send RADIUS packets is a random packet by default.

(7) (Optional) Configure the waiting time, after which the device retransmits a RADIUS request packet.

rds-server timeout *timeout*

The default waiting time before the retransmission of a RADIUS packet is **5** seconds.

(8) (Optional) Configure the accounting update packet retransmission function for Web-authenticated users.

rds-server account update retransmit

The accounting update packet retransmission function is enabled for Web-authenticated users by default.

The configuration does not affect users of other authentication types.

(9) (Optional) Enable the function of copying and sending RADIUS accounting packets to servers in a specified server group.

rds-server accounting-copy *group*

By default, the function of copying and sending RADIUS accounting packets is disabled.

When this command is run on an interface, the RADIUS accounting packets on the interface are copied and sent to servers in a specified server group.

(10) (Optional) Enable compatibility with username encapsulation format.

radius user-name compatible

Compatibility with username encapsulation format is disabled by default.

After this function is enabled, the username in the RADIUS packet can be encapsulated in its original format instead of UTF-8.

(11) (Optional) Configure the value of the **NAS-IP-Address** field in RADIUS packets.

rds-server nas-ip-address { *ipv4-address* | *ipv6-address* }

By default, the value of the **NAS-IP-Address** field is not configured.

1.4 Configuring a RADIUS Server Group

1.4.1 Overview

One or more RADIUS servers can be added to each RADIUS server group, which provides AAA services for users as a whole.

1.4.2 Restrictions and Guidelines

- RADIUS security services are a type of AAA services and need to be used in combination with AAA features. RADIUS provides security services for users as one method in an AAA method list.
- When configuring the authentication and accounting method lists, you can specify server groups separately for them.
- In a user-defined server group, you can only specify and apply servers in the default server group.
- RADIUS server groups support VRF instances. When a server group in a specified VRF instance is used, the source address used by the device to communicate with a remote server must be obtained from the VRF instance. If you run the **ip radius-mode source-interface** command to specify the source interface for request packets, the IP address obtained from this source interface takes priority over that found in the VRF instance.
- The name of a server group cannot be set to the predefined keyword **radius**.
- If a server group is configured with an NAS IP address, the NAS IP address is used for RADIUS packet encapsulation preferentially. If not, the IP address of the interface sending the packet is used.
- The NAS IP address configured on the server group

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a RADIUS server group.

aaa-config group server rds *group-name*

No RADIUS server group is configured by default.

You can group RADIUS servers so that authentication and accounting can be completed by different server groups.

(4) Add a server to the RADIUS server group.

server { *ipv4-address* | *ipv6-address* } [**authentication-port** *acct-port* | **accounting-port** *auth-port*] *

No server is added to a RADIUS server group by default.

(5) (Optional) Specify a VRF instance for the RADIUS server group.

ip vrf binding *vrf-name*

No VRF instance is specified for a RADIUS server group by default.

The VRF instance specified for a RADIUS server group must use a valid name configured using the **vrf definition** command in global configuration mode.

(6) (Optional) Configure an MGMT port to be used by the RADIUS server group.

ip oob [**via mgmt** *mgmt-number*]

No MGMT port to be used by a RADIUS server group is configured by default.

(7) (Optional) Configure the NAS IP address of the RADIUS server group.

nas-ip-address *ip-addr*

No NAS IP address of the RADIUS server group is configured by default.

1.5 Configuring RADIUS Attributes

1.5.1 Overview

RADIUS attributes are used to carry authentication, authorization, and accounting information to be used in packet interaction. You can configure the attribute format, private attribute processing method, and vendor compatibility.

1.5.2 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configure the Attribute Format
- Configuring Private Attributes
- Configuring Compatibility with Devices of Other Vendors

1.5.3 Configure the Attribute Format

1. Overview

This section describes how to configure the attribute format to be used in encapsulation and parsing.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure RADIUS attributes. Configure at least one of the tasks.

- Configure the format of the MAC address used in attribute 31 (**Calling-Station-ID**).

  ds-server attribute 31 mac-addr format { **3hyphen** | **standard** | **with-dot** | **none-format** | { { **colon-split | dot-split | hyphen-split** } **{ mode1 | mode2** } [**lowercase | uppercase**] } }

  The MAC address used in attribute 31 uses the unformatted pattern.

  Some RADIUS servers (mainly used for IEEE 802.1X authentication) can identify only MAC addresses in the IETF format. In this case, set the format of MAC addresses used in attribute 31 to the IETF format.

- Configure the encapsulation format for the **NAS-Port-ID** attribute.

  rds-server attribute nas-port-id format { **mode**1 | **with-dot** | **port-vid** | **qinq** }

  The default encapsulation format of the **NAS-Port-ID** attribute is the normal format.

  Use this command to configure the encapsulation format for the **NAS-Port-ID** attribute applicable to 802.1Q in 802.1Q (QinQ) scenarios or non-QinQ scenarios.

- Configure the parsing mode for the **Class** attribute.

  rds-server attribute class user-flow-control { **format-16bytes** | **format-32bytes** | **unit bit/s** | **unit byte/s** }

  The function of parsing the rate limit configuration from the **Class** attribute of RADIUS packets is disabled by default.

  Configure this command if a server needs to deliver the rate limit value by using the **Class** attribute.

- Configure whether RADIUS authentication request packets carry a specified attribute.

  rds-server authentication attribute *type* { **package** | **unpackage** }

  According to the RFC standard, attributes that must be carried in authentication requests are carried by default, attributes that do not need to be carried are not carried by default, and other attributes are in the unset state by default.

- Configure whether RADIUS accounting request packets carry a specified attribute.

  rds-server account attribute *type* { **package | unpackage** }

  According to the RFC standard, attributes that must be carried in accounting requests are carried by default, attributes that do not need to be carried are not carried by default, and other attributes are in the unset state by default.

1.5.4 Configuring Private Attributes

1. Overview

Vendors can define private attributes to implement multiple features that are not supported by the standard RADIUS protocol. You can configure the methods used by devices to process private attributes based on the actual environment. Private attributes configured in this section are all our company's private attributes.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure private attributes. Configure at least one of the tasks.

- Configure the device to set the private attribute **port-priority** delivered by the server to the class of service (CoS) value of an interface.

  rds set qos cos

  The device sets the private attribute **port-priority** delivered by the server to the differentiated services code point (DSCP) value by default.

- Configure the device to support the **CUI** attribute.

  rds support cui

  The function of supporting the **CUI** attribute by RADIUS is disabled by default.

1.5.5 Configuring Compatibility with Devices of Other Vendors

1. Overview

In actual deployment environments, the devices may interconnect to RADIUS servers of other vendors. Private attributes defined by different vendors are different. It is necessary to enable compatibility with the configuration of devices of other vendors.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure compatibility with devices of other vendors. Configure at least one of the tasks.

- Configure whether RADIUS authentication request packets carry the private attributes of a specified vendor.

  rds-**server authentication vendor** { **cisco | cmcc** | **microsoft** } **package**

  Authentication request packets do not carry private attributes of other vendors by default.

- Configure whether RADIUS accounting request packets carry the private attributes of a specified vendor.

  rds-**server account vendor** { **cisco | cmcc** | **microsoft** } **package**

  Accounting request packets do not carry private attributes of other vendors by default.

- Configure RADIUS to parse private attributes of Cisco, Huawei, and Microsoft devices carried in packets.

  rds vendor-**specific attribute support** { **cisco** | **huawei** | **ms** }

  RADIUS parses private attributes of Cisco, Huawei, and Microsoft devices carried in packets by default.

- Enable the function of not differentiating private vendor IDs during RADIUS packet parsing.

  rds vendor-specific extend

  RADIUS identifies only private vendor ID during packet parsing by default.

- Configure the mode of parsing private attributes.

  rds vendor-specific attribute support { **cisco** | **huawei** | **ms** }

  RADIUS parses private attributes of Cisco, Huawei, and Microsoft devices carried in packets by default.

  If the server is an application server, the RADIUS private attribute type needs to be configured to achieve compatibility.

1.6 Configuring RADIUS Reachability Detection

1.6.1 Overview

A RADIUS server can be only in the reachable or unreachable state. The device will not send authentication, authorization, or accounting requests of access users to an unreachable RADIUS server unless all servers in the RADIUS server group are unreachable.

The device maintains the reachability status of each RADIUS server. The device selects a reachable RADIUS server preferentially to improve the handling performance of RADIUS services.

The device actively detects whether a specified RADIUS server is reachable. After the active detection function is configured, the device periodically sends detection requests (authentication requests or accounting requests) to the RADIUS server. The active detection interval is **60** minutes when the RADIUS server is reachable and **1** minute when the RADIUS server is unreachable.

1.6.2 Restrictions and Guidelines

- To enable active detection for a specified RADIUS server, perform the following configuration when configuring the RADIUS server:
  - Configure a test username for the RADIUS server.
  - Configure at least one tested port (authentication port or accounting port) for the RADIUS server.
- It is judged that a RADIUS server is unreachable only when both conditions below are met:
  - The device fails to receive a correct response packet from the RADIUS server within the specified timeout duration.
  - The number of times that the device sends request packets to the same RADIUS server consecutively reaches the specified timeout count.
- If any of the following conditions is met for an unreachable RADIUS server, the RADIUS server is considered reachable.
  - The device receives correct responses from the RADIUS server.
  - The duration in which the RADIUS server is unreachable exceeds the time configured using the **rds-server deadtime** command, and active detection is disabled for the RADIUS server.
  - The authentication port or accounting port of the RADIUS server is updated on the device.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the criteria for the device to judge that a RADIUS server is unreachable.

rds-server dead-condition { **time** *timeout* | **time** *timeout* **attempts** *tries-number* | **attempts** *tries-number* }

The criteria for judging that a RADIUS server is unreachable are that the timeout duration is 60 seconds and the consecutive timeout count is 10 by default.

If a RADIUS server meets both the duration condition and the consecutive request timeout count condition, it is deemed that the RADIUS server is unreachable.

(4) Configure active detection and set the IP address, authentication port, or accounting port for the remote RADIUS server.

rds-server host { *ipv4-address* | *ipv6-address* } [**accounting-port** *acct-port-number* | **authentication-port** *auth-port-number*] *

No active detection is configured by default.

(5) (Optional) Configure the number of times that the device sends requests to a RADIUS server consecutively before confirming that the RADIUS server is unreachable.

rds-server retransmit *retransmit-times*

The device sends requests to a RADIUS server three times consecutively before confirming that the RADIUS server is unreachable by default.

(6) (Optional) Configure the duration for the device to stop sending request packets to an unreachable RADIUS server.

rds-server deadtime *deadtime*

Even if a RADIUS server is unreachable, the device still sends requests to the RADIUS server by default.

If active detection is enabled for a RADIUS server, the time parameter configured by the **rds-server deadtime** command does not take effect on the RADIUS server.

1.7 Configuring the DSCP Value for RADIUS Packets

1.7.1 Overview

DSCP is in the type of service (ToS) field of the IP header and is used to identify the packet transmission priority.

A larger DSCP value indicates a higher packet priority. The default DSCP value of RADIUS packets is **0**. You can configure the DSCP value for RADIUS packets to change the transmission priority of RADIUS packets.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the DSCP value for RADIUS packets.

radius dscp *dscp-value*

The default DSCP value of RADIUS packets is **0**.

1.8 Configuring the Units of Data Flows and Packets to Be Sent to a RADIUS Server

1.8.1 Overview

The default units of data flows and data packets to be sent to a RADIUS server are bytes and packets respectively. You can configure the units of data flows and data packets to be sent to a RADIUS server based on the actual network situation.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the units of data flows and data packets to be sent to a RADIUS server.

rds data-flow-format { { **data byte** | **data giga-byte** | **data kilo-byte** | **data mega-byte** } | { **packet giga-packet** | **packet kilo-packet** | **packet mega-packet** | **packet one-packet** } } *

The default units of data flows and data packets to be sent to a RADIUS server are bytes and packets respectively.

1.9 Configuring the Accounting-On Function

1.9.1 Overview

The accounting-on function is used to notify a RADIUS server of the device restart. After the device is restarted, online users are forced offline. However, the RADIUS server does not perceive the device restart and does not log off the users. As a result, the users encounter an exception when initiating re-authentication. Therefore, it is necessary to enable the accounting-on function.

1.9.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the function of sending accounting-on packets upon device restart.

rds-server accounting-on enable

The function of sending accounting-on packets upon device restart is enabled by default.

1.10 Configuring the Accounting Packet Copying Function

1.10.1 Overview

RADIUS accounting packets are sent to one server specified in the accounting method list by default. After this function is enabled, the device copies accounting packets and sends the packets to all servers in a server group.

1.10.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure the function of copying and sending accounting packets to servers in a specified group.

rds-sever accounting-copy *group*

The function of copying and sending RADIUS accounting packets is disabled by default.

1.11 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

Run the **debugging** commands to output debugging information.

⚠ Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-6 RADIUS Monitoring

Command	Purpose
display radius parameter	Displays global parameters of a RADIUS server.
display radius server	Displays the configuration of a RADIUS server.

Command	Purpose
display radius vendor-specific	Displays the configuration of the RADIUS private attribute type.
display radius auth statistics	Displays RADIUS authentication statistics.
display radius acct statistics	Displays RADIUS accounting statistics.
display radius group	Displays the configuration of a RADIUS server group.
display radius attribute	Displays RADIUS standard attributes.
debugging radius detail	Debugs RADIUS packets.
debugging radius extend event	Debugs the function of Dynamic Authorization Extensions to RADIUS.
debugging radius extend detail	Debugs packets of Dynamic Authorization Extensions to RADIUS.
debugging radius extend error	Prints information related to packets of Dynamic Authorization Extensions to RADIUS for debugging.

1.12 Configuration Examples

1.12.1 Configuring RADIUS Authentication, Authorization, and Accounting

1. Requirements

A RADIUS server needs to be used for authentication, authorization, and accounting of login users.

2. Topology

Figure 1-4 Topology of RADIUS Authentication, Authorization, and Accounting

3. Notes

- Configure device information and add login users on the RADIUS server.
- Enable AAA security services on the device.
- Configure RADIUS server information on the device.
- Configure the RADIUS authentication method list, authorization method list, and accounting method list.
- Apply the RADIUS authentication, authorization, and accounting methods to a specific line.

4. Procedure

(1) Configure device information and add login users on the RADIUS server. The configuration is omitted here. For details, see the RADIUS server configuration.

(2) Enable AAA security services.

```
Device> privilege
Device# config-system terminal
Device(cfg)# aaa-config new-pattern
```

(3) Configure a RADIUS server (the IP address of the RADIUS server is set to 192.168.1.3 and the shared key is set to **sharekey** here).

```
Device(cfg)# rds-server host 192.168.1.3 share-key sharekey
```

(4) Configure the authentication, authorization, and accounting method lists.

```
Device(cfg)# aaa-config authentication line-login radius-method server-group rds
Device(cfg)# aaa-config authorization execute radius-method server-group rds
Device(cfg)# aaa-config accounting execute radius-method start-stop server-group rds
```

(5) Apply the authentication, authorization, and accounting methods to a line.

```
Device(cfg)# line vty 0 4
Device(cfg-line)# line-login authentication radius-method
Device(cfg-line)# aaa-authorization execute radius-method
Device(cfg-line)# aaa-accounting execute radius-method
```

5. Verification

After entering the correct username and password, a user can log in to the device successfully.

```
User Access Verification

Username:hostname1
Password:password1

Device#
```

After login, the user has only the privilege level granted by the server and can run commands only under this privilege level.

After the user logs out, accounting information of the user can be queried on the RADIUS server. For details about how to query accounting information, see the RADIUS server configuration.

6. Configuration Files

```
!
aaa-config new-pattern
!
aaa-config accounting execute radius-method start-stop server-group radius
aaa-config authorization execute radius-method server-group radius
aaa-config authentication line-login radius-method server-group radius
!
rds-server host 192.168.1.3 share-key 7 $10$275$g8oXDDIPVeA=$
```

```
!
line console 0
line vty 0 4
 aaa-accounting execute radius-method
 aaa-authorization execute radius-method
 line-login authentication radius-method
!
```

7. Common Errors

The shared key configured on the device is inconsistent with that used by the RADIUS server.

1.12.2 Configuring RADIUS Reachability Detection

1. Requirements

RADIUS reachability detection needs to be configured to identify unreachable RADIUS servers.

2. Topology

Figure 1-5 Topology of RADIUS Reachability Detection

3. Notes

- Configure the global criteria for judging that a RADIUS server is unreachable.
- Configure an IP address for the RADIUS server and configure active detection parameters.

4. Procedure

Configure the global criteria for judging that a RADIUS server is unreachable as follows: The consecutive timeout count is **5** and the timeout duration is **120** seconds.

```
Device> privilege
Device# config-system terminal
Device(cfg)# rds-server dead-condition time 120 attempts 5
```

Set the IP address of the RADIUS server to 192.168.1.3, detection username to **detect**, and detection interval to **90** minutes, and disable the server authentication port detection.

```
Device(cfg)# rds-server host 192.168.1.3 detect user-name detect ignore-accounting-port timeout 90
```

5. Verification

Disconnect the network communication between the device and the server with the IP address 192.168.1.3. Initiate RADIUS authentication through the device. After 120 seconds, run the **display rds server** command to check that the server status is "Dead".

```
Device# display rds server
Server IP:       192.168.1.3
Accounting Port:    1813
```

```
Authen    Port:         1812
mom         flag:         1
Test Username:       detect
Test Idle Time:      1 Minutes
Test Ports:             Authen and Accounting
Server State:         Dead
      Current duration 1254s, previous duration 2918s
      Dead: total time 1257s, count 1
      Statistics:
            Authen: request 22, timeouts 81
            Author: request 22, timeouts 81
            Account: request 23, timeouts 83
```

6. Configuration Files

```
!
rds-server host 192.168.1.3 detect user-name detect ignore-accounting-port timeout 90 share-key 7
$10$275$g8oXDDIPVeA=$
rds-server dead-condition time 120 attempts 5
!
```

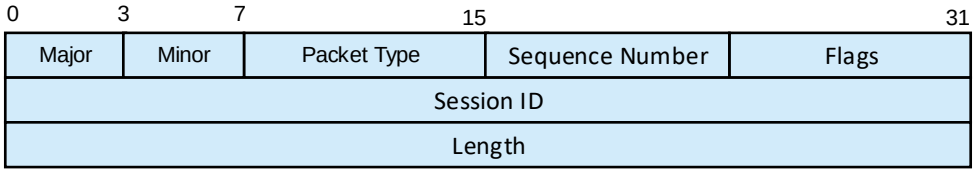
1 Configuring TACACS

1.1 Introduction

1.1.1 Overview

Terminal Access Controller Access Control System (TACACS) is a distributed authentication, authorization and accounting (AAA) protocol based on the client/server architecture. TACACS+ has enhanced functions on the basis of the TACACS protocol, to provide the authentication, authorization and accounting services for users. This following describes TACACS+.



Both TACACS+ and Remote Authentication Dial-In User Service (RADIUS) are capable of providing AAA security services. Compared with RADIUS, TACACS+ has the following advantages:

- It is implemented based on the Transmission Control Protocol (TCP) and provides more reliable network transmission.
- TACACS+ encrypts both packet bodies and passwords to boost security.
- Authentication is separated from authorization. The authentication server and authorization server can be deployed separately in remote deployment.
- TACACS+ supports authorization and accounting on configuration commands.

1.1.2 Principles

1. TACACS+ Packet

Figure 1-1 TACACS+ Packet Structure

Fields contained in the TACACS+ packet structure shown in Figure 1-1 are described in Table 1-1.

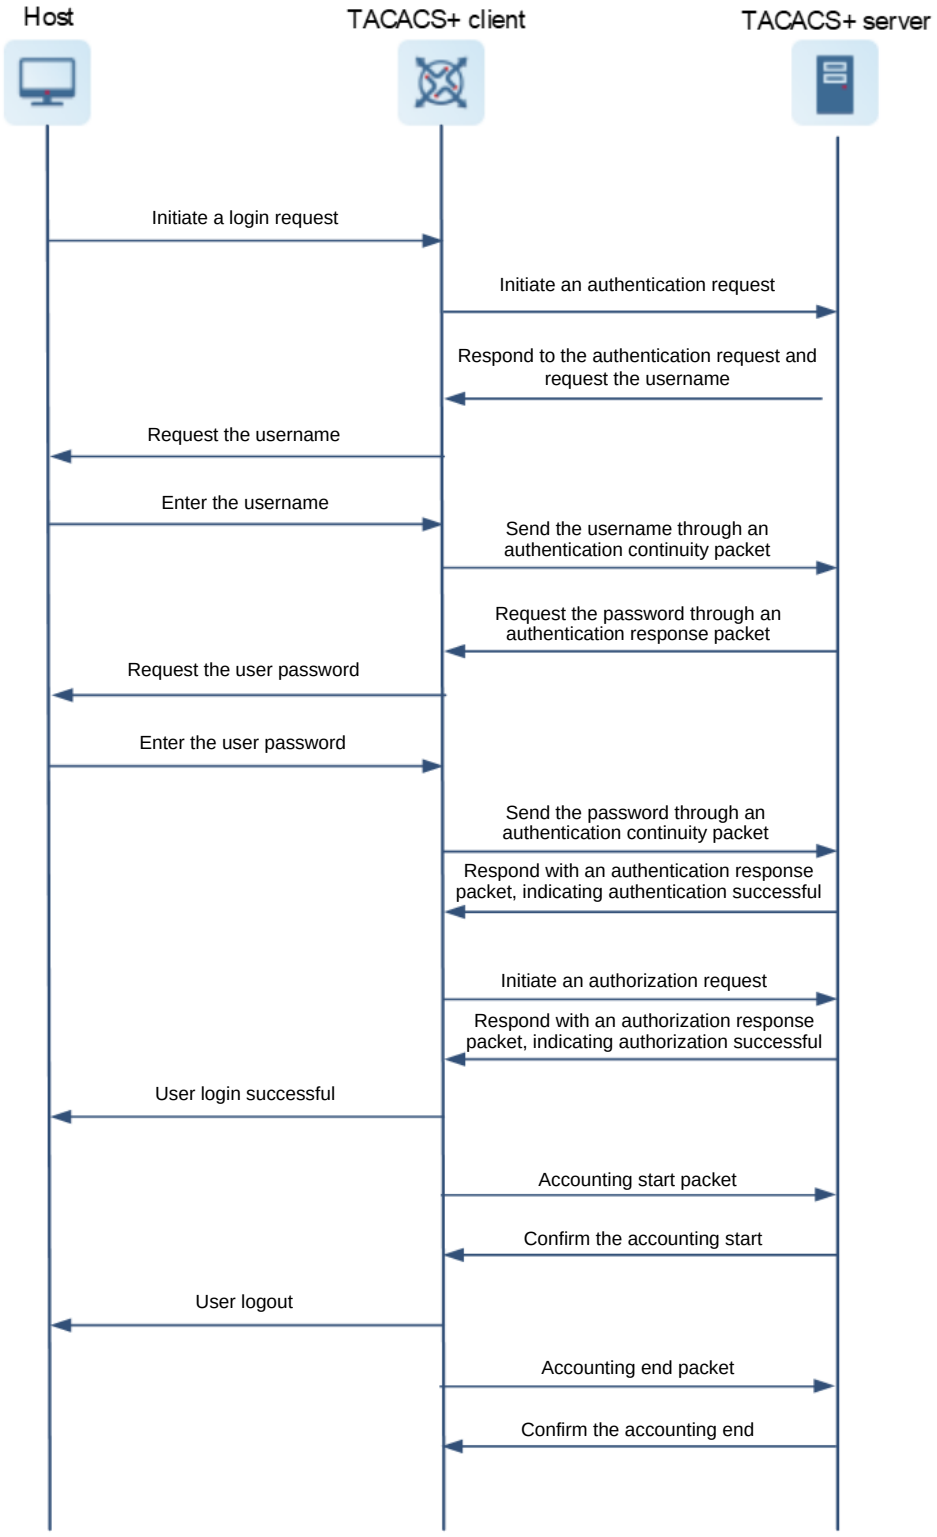


Table 1-1 Description of Fields Contained in a TACACS+ Packet

Field	Length	Description
Major Version	4 bits	Major TACACS+ version
Minor Version	4 bits	Minor TACACS+ version
Packet Type	1 byte	Packet type. The options are as follows: **0x01**: Indicates an authentication packet. **0x02**: Indicates an authorization packet. **0x03**: Indicates an accounting packet.

Field	Length	Description
Sequence Number	1 byte	Sequence number of a data packet in the current session (The sequence number of the first TACACS+ data packet in a session must be 1 and the sequence number of each subsequent data packet increases by one. The client sends data packets only with an odd sequence number and TACACS+ Daemon sends data packets only with an even sequence number.)
Flags	1 byte	Whether the data packet is encrypted
Session ID	4 bytes	TACACS+ session ID
Length	4 bytes	Body length of a TACACS+ data packet (excluding the header)

2. Packet Exchange Process

Figure 1-2 TACACS+ Packet Exchange Flowchart

As shown in Figure 1-2, the TACACS+ protocol basically involves the authentication, authorization, and accounting processes. The network access server (NAS) requests security services from the TACACS+ server as a TACACS+ client.

(1) Authentication process

a A user initiates a login request to the NAS.

b After receiving the user request, the NAS sends an authentication start packet to the TACACS+ server to initiate an authentication request.

c The TACACS+ server responds to the authentication request and asks the NAS to provide the username.

d The NAS asks the user terminal to provide the username.

e The user enters the username and sends it to the NAS.

f The NAS sends the username to the TACACS+ server through an authentication continuity packet.

g After receiving the username, the TACACS+ server continues to ask the NAS for the user password.

h The NAS requests the user terminal to provide the password.

i The user enters the password and sends it to the NAS.

j The NAS sends the password to the TACACS+ server through an authentication continuity packet.

k After receiving the password, the TACACS+ server verifies the password and then returns an authentication success message to the NAS.

(2) Authorization process

a The NAS initiates an authorization request to the TACACS+ server.

b The TACACS+ server responds to the authorization request by returning an authorization success message to the NAS.

c After receiving the authorization success message, the NAS allows the user to log in to the NAS and perform operations within the authorized scope.

(3) Accounting process

a The NAS sends an accounting start request to the TACACS+ server.

b After receiving the accounting start request, the TACACS+ server starts accounting and returns an accounting request acceptance message to the NAS.

c If the user logs out, the NAS sends an accounting end request to the TACACS+ server after receiving a user logout message.

d After receiving the accounting end request, the TACACS+ stops accounting and returns an accounting end message.

1.1.3 Protocols and Standards

- RFC 1492: Terminal Access Controller Access Control System

1.2 Configuration Task Summary

TACACS+ configuration includes the following tasks:

- Configuring TACACS+ Basic Features
- (Optional) Configuring TACACS+ Reachability Detection
- (Optional) Configuring a TACACS+ Server Group

1.3 Configuring TACACS+ Basic Features

1.3.1 Overview

This section describes how to configure parameters for the communication between the device and a TACACS+ server to ensure normal communication between them. After the parameters are configured, the device can correctly send AAA authentication, authorization, and accounting requests to the TACACS+ server and give responses.

1.3.2 Restrictions and Guidelines

Configuring TACACS+ basic features only ensures proper communication between the device and a TACACS+ server. To provide AAA security services for users, you still need to reference the TACACS+ server in an AAA method list.

When the single-connection mode is disabled, the multi-connection mode is used by default. That is, a TCP connection is established for each session and released after the session ends. When the single-connection mode is enabled, a TCP connection is established during the first interaction with the server. Subsequent sessions with the server use the TCP connection. A TCP connection does not need to be established for each session.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable AAA.

aaa-config new-pattern

(4) Configure a TACACS+ server.

tacplus-server host [**oob** [**via Mgmt** *Mgmt-number*]] { *ipv4-address* | *ipv6-address* } [**protocol-port** *port-number*] [**detect user-name** *username*] [**verify-time** *idle-time*] [**timeout** *timeout*] [**single-connection**] [**share-key** [**0** | **7**] *key*]

No TACACS+ server is configured by default.

You can specify a shared key for a TACACS+ server when configuring the server. If it is not specified, the global shared key will be used.

(5) (Optional) Configure the global shared key for the communication between the device and TACACS+ server.

tacplus-server share-key [**0** | **7**] *key*

No global shared key is configured for the device and TACACS+ server by default.

(6) (Optional) Configure the source address for TACACS+ packets.

ip tacacs-mode source-interface *interface-type interface-number*

No source address is configured for TACACS+ packets and the address is set by the network layer by default.

You can run this command to specify an outbound interface for packets. After this command is configured, the first IP address of the interface is used as the source address of TACACS+ packets.

(7) (Optional) Configure the timeout duration for the TACACS+ server.

tacplus-server timeout *timeout*

The default timeout duration of a TACACS+ server is **5** seconds in the communication between the device and the TACACS+ server.

(8) (Optional) Configure the single connection timeout duration for a TACACS+ server.

tacacs-server single-connect-timeout *timeout*

The default single connection timeout duration is 30 minutes, and the range is from 0 to 480. After the timeout duration times out, a connection is reestablished when the single-connection mode is used again.

1.4 Configuring TACACS+ Reachability Detection

1.4.1 Overview

A TACACS+ server can be only in the reachable or unreachable state. The device will not send authentication, authorization, or accounting requests of access users to an unreachable TACACS+ server unless all servers in the TACACS+ server group are unreachable.

The device maintains the reachability status of each TACACS+ server. The device selects a reachable TACACS+ server preferentially to improve the handling performance of TACACS+ services.

The device actively detects whether a specified TACACS+ server is reachable. After the active detection function is configured for a TACACS+ server, the device periodically sends detection requests (authentication requests or accounting requests) to the TACACS+ server. The active detection interval is **60** minutes when the TACACS+ server is reachable and **1** minute when the TACACS+ server is unreachable.

1.4.2 Restrictions and Guidelines

- To enable active detection for a specified TACACS+ server, perform the following configuration when configuring the TACACS+ server:
  - Configure a test username for the TACACS+ server.
  - Configure at least one tested port (authentication port or accounting port) for the TACACS+ server.
- It is judged that a TACACS+ server is unreachable only when both conditions below are met:
  - The device fails to receive a correct response packet from the TACACS+ server within the specified timeout period.
  - The consecutive transmission count of a request packet sent by the device to the same TACACS+ server reaches the specified timeout count.
- If any of the following conditions is met for an unreachable TACACS+ server, the TACACS+ server is considered reachable:
  - The device receives a correct response from the TACACS+ server.
  - The duration in which the TACACS+ server is unreachable exceeds the time configured using the **tacplus-server deadtime** command and active detection is disabled for the TACACS+ server.
  - The authentication port or accounting port of the TACACS+ server is updated on the device.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the criteria for the device to judge that a TACACS+ server is unreachable.

tacplus-server dead-condition { **time** *timeout* | **time** *timeout* **attempts** *tries-number* | **attempts** *tries-number* }

The criteria for the device to judge that a TACACS+ server is unreachable are that the server timeout duration is **60** seconds and the consecutive timeout count is **10** by default.

(4) (Optional) Configure the duration for the device to stop sending request packets to an unreachable TACACS+ server.

tacplus-server deadtime *deadtime*

Even if a TACACS+ server is unreachable, the device still sends requests to the TACACS+ server by default.

If active detection is enabled for a TACACS+ server, the time parameter configured by the **tacplus-server deadtime** command does not take effect on the TACACS+ server.

1.5 Configuring a TACACS+ Server Group

1.5.1 Overview

One or more TACACS+ servers can be added to each TACACS+ server group, which provides AAA services for users as a whole.

When the single-connection mode is disabled, the multi-connection mode is used by default. That is, a TCP connection is established for each session and released after the session ends. When the single-connection mode is enabled, a TCP connection is established during the first interaction with the server. Subsequent sessions with the server use the TCP connection. A TCP connection does not need to be established for each session.

1.5.2 Restrictions and Guidelines

- TACACS+ security services are a type of AAA services and need to be used in combination with the AAA features. TACACS+ provides security services for users as one method in an AAA method list.
- When configuring the authentication, authorization, and accounting method lists, you can specify server groups separately for them.
- In a user-defined server group, you can only specify and apply servers in the default server group.
- TACACS+ server groups support virtual routing and forwarding (VRF) instances. When a server group in a specified VRF instance is used, the source address used by the device to communicate with a remote server must be obtained from the VRF instance. If you run the **ip tacplus-mode source-interface** command to specify the source interface for request packets, the IP address obtained from this source interface takes priority over that found in the VRF instance.

- The name of a server group cannot be set to the predefined keyword **tacacs+**.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a TACACS+ server group.

aaa-config group server tacplus *group-name*

No TACACS+ server group is configured by default.

You can group TACACS+ servers so that authentication, authorization, and accounting can be completed by different server groups.

(4) Add a server to the TACACS+ server group.

server { *ipv4-address* | *ipv6-address* } [**single-connection**]

No server is added to a TACACS+ server group by default.

(5) (Optional) Specify a VRF instance for the TACACS+ server group.

ip vrf binding *vrf-name*

No VRF instance is specified for a TACACS+ server group by default.

The VRF instance configured for a TACACS+ server group must use a valid name configured using the **vrf definition** command in global configuration mode.

(6) Configure an MGMT port to be used by the TACACS+ server group.

ip oob [**via mgmt** *mgmt-number*]

No MGMT port to be used by a TACACS+ server group is configured by default.

(7) (Optional) Configure the function of carrying the **nas-ip** attribute in packets.

nas-ip { *ipv4-address* | *ipv6-address* }

Packets do not carry the **nas-ip** attribute by default.

1.6 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** commands to output debugging information.

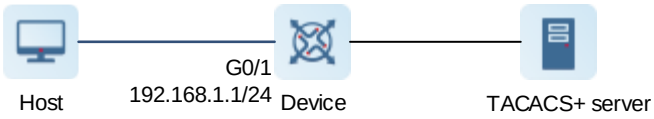
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-2 TACACS+ Monitoring

Command	Purpose
display tacacs	Displays the interaction between the device and each TACACS+ server.
debugging tacacs+	Debugs TACACS+.

1.7 Configuration Examples



1.7.1 Configuring TACACS+ for Login Authentication

1. Requirements

A TACACS+ server needs to be used for authentication of login users.

2. Topology

Figure 1-3 Topology of Login Authentication Using TACACS+

3. Notes

- Configure device information and add login users on the TACACS+ server.
- Enable AAA security services on the device.
- Configure TACACS+ server information on the device.
- Configure a TACACS+ authentication method list.
- Apply the TACACS+ authentication methods to a specific line.

4. Procedure

(1) Configure device information and add login users on the TACACS+ server. The configuration is omitted here. For details, see the TACACS+ server configuration.

(2) Enable AAA security services.

```
Device> privilege
Device# config-system terminal
Device(cfg)# aaa-config new-pattern
```

(3) Configure a TACACS+ server (the IP address of the TACACS+ server is set to 192.168.1.3 and the shared key is set to **sharekey** here).

```
Device(cfg)# tacplus-server host 192.168.1.3 share-key sharekey
```

(4) Configures an authentication method list.

```
Device(cfg)# aaa-config authentication line-login tacacs-method server-group tacacs+
```

(5) Apply the authentication methods to a line.

```
Device(cfg)# line vty 0 4
Device(cfg-line)# line-login authentication tacacs-method
```

5. Verification

After entering the correct username and password, a user can log in to the device successfully.

```
User Access Verification

Username:hostname1
Password:password1

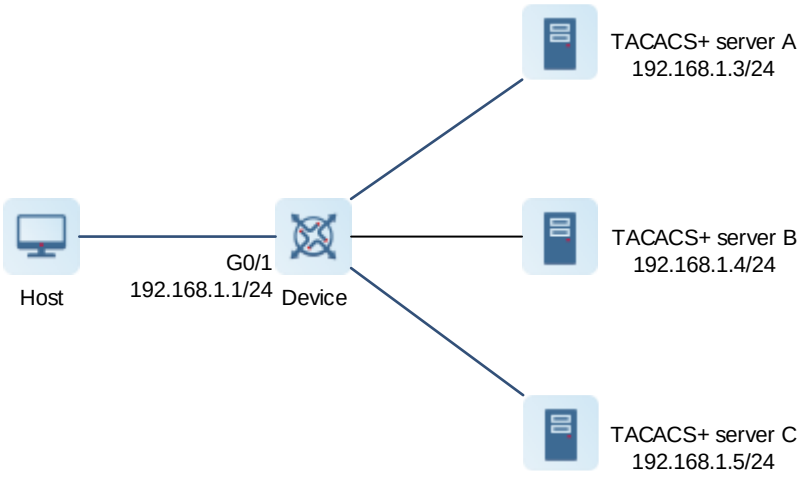
Device#
```

6. Configuration Files

```
!
aaa-config new-pattern
!
aaa-config authentication line-login tacacs-method server-group tacplus
!
tacplus-server host 192.168.1.3 share-key 7 $10$275$g8oXDDIPVeA=$
!
line console 0
line vty 0 4
 line-login authentication tacacs-method
!
```

7. Common Errors

The shared key configured on the device is inconsistent with that used by the TACACS+ server.



1.7.2 Configuring Separated Authentication, Authorization and Accounting by Using TACACS+

1. Requirements

The user authentication, authorization, and accounting services need to be separately completed by different TACACS+ server groups.

2. Topology

Figure 1-4 Topology of Separated Authentication, Authorization, and Accounting of TACACS+

3. Notes

- Configure device information and add login users on the TACACS+ server.
- Enable AAA security services on the device.
- Configure TACACS+ servers on the device and add them to different TACACS+ server groups.
- Configure TACACS+ authentication, authorization, and accounting method lists.
- Apply the TACACS+ authentication, authorization, and accounting methods to a specific line.

4. Procedure

(1) Configure device information and add login users on the TACACS+ server. The configuration is omitted here. For details, see the TACACS+ server configuration.

(2) Enable AAA security services.

```
Device> privilege
Device# config-system terminal
Device(cfg)# aaa-config new-pattern
```

(3) Configure TACACS+ server A and add it to TACACS+ server group **tacacs1**. (The IP address of TACACS+ server A is set to 192.168.1.3 and the shared key is set to **sharekey** here.)

```
Device(cfg)# tacplus-server host 192.168.1.3 share-key sharekey
Device(cfg)# aaa-config group server tacplus tacacs1
Device(cfg-gs-tacacs+)# server 192.168.1.3
Device(cfg-gs-tacacs+)# exit
```

(4) Configure server groups **tacacs2** and **tacacs3** by referring to the steps of configuring server group **tacacs1**.

```
Device(cfg)# tacplus-server host 192.168.1.4 share-key sharekey
Device(cfg)# aaa-config group server tacplus tacacs2
Device(cfg-gs-tacacs+)# server 192.168.1.4
Device(cfg-gs-tacacs+)# exit
Device(cfg)# tacplus-server host 192.168.1.5 share-key sharekey
Device(cfg)# aaa-config group server tacplus tacacs3
```

```
Device(cfg-gs-tacacs+)# server 192.168.1.5
Device(cfg-gs-tacacs+)# exit
```

(5) Configure an authentication method list to use server group **tacacs1**, an authorization method list to use server group **tacacs2**, and an accounting method list to use server group **tacacs3**.

```
Device(cfg)# aaa-config authentication line-login tacacs-method group tacacs1
Device(cfg)# aaa-config authorization execute radius-method server-group tacacs2
Device(cfg)# aaa-config accounting execute radius-method start-and-stop server-group tacacs3
```

(6) Apply the authentication methods, authorization methods, and accounting methods to a line.

```
Device(cfg)# line vty 0 4
Device(cfg-line)# line-login authentication tacacs1
Device(cfg-line)# aaa-authorization execute tacacs2
Device(cfg-line)# aaa-accounting execute tacacs3
```

5. Verification

After entering the correct username and password configured on TACACS+ server A, a user can log in to the device successfully.

```
User Access Verification

Username:hostname1
Password:password1

Device#
```

After login, the user has only the privilege level granted by TACACS+ server B and can only run commands under this privilege level.

After the user logs out, accounting information of the user can be queried on TACACS+ server C. For details about how to query accounting information, see the TACACS+ server configuration.

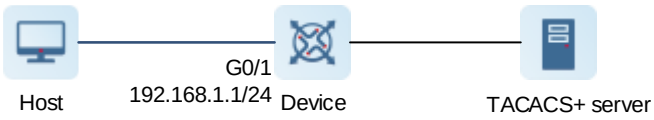
6. Configuration Files

```
!
aaa-config new-pattern
!
aaa-config accounting execute radius-method start-and-stop server-group tacacs3
aaa-config authorization exec radius-method server-group tacacs2
aaa-config authentication line-login radius-method server-group tacacs1
!
tacplus-server host 192.168.1.3 share-key 7 $10$275$g8oXDDIPVeA=$
tacplus-server host 192.168.1.4 share-key 7 $10$275$g8oXDDIPVeA=$
tacplus-server host 192.168.1.5 share-key 7 $10$275$g8oXDDIPVeA=$
!
!
aaa-config group server tacplus tacacs1
 server 192.168.1.3
!
```

```
aaa-config group server tacplus tacacs2
 server 192.168.1.4
!
aaa-config group server tacplus tacacs3
 server 192.168.1.5
!
line console 0
line vty 0 4
 aaa-accounting execute tacacs3
 aa-authorization execute tacacs2
 line-login authentication tacacs1
!
```

7. Common Errors

- The shared key configured on the device is inconsistent with that used by the TACACS+ server.
- Undefined servers are added to a server group.



1.7.3 Configuring Reachability Detection

1. Requirements

TACACS+ reachability detection needs to be configured to identify unreachable TACACS+ servers.

2. Topology

Figure 1-5 Topology of TACACS+ Reachability Detection

3. Notes

- Configure the global criteria for judging that a TACACS+ server is unreachable.
- Configure an IP address for the TACACS+ server and configure active detection parameters.

4. Procedure

Configure the global criteria for judging that a TACACS+ server is unreachable as follows: The consecutive timeout count is **5** and the timeout duration is **120** seconds.

```
Device> privilege
Device# config-system terminal
Device(cfg)# racplus-server dead-condition time 120 attempts 5
```

Set the IP address of the TACACS+ server to 192.168.1.3, detection username to **detect**, detection interval to **90** minutes.

```
Device(cfg)# tacplus-server host 192.168.1.3 detect user-name detect verify-time 90
```

5. Verification

Disconnect the network communication between the device and the server with the IP address 192.168.1.3. Initiate TACACS+ authentication through the device. After 120 seconds, run the **display tacacs-mode** command to check that the server status is "Dead".

```
Device# display tacacs-mode server
Tacacs+ Server : 192.168.1.3/49
state: Dead
Socket Opens: 0
Socket Closes: 0
Total Packets Sent: 0

1 Configuring SCC

1.1 Overview

The Security Control Center (SCC) provides common configuration methods and policy integration for various access control and network security services, so that these services can coexist on one device to meet diversified access and security control requirements in various scenarios.

Typical access control services include 802.1x, web authentication, Address Resolution Protocol (ARP) check, and IP source guard, and typical network security services include access control list (ACL), NFPP, and gateway-targeted ARP spoofing prevention. When two or more access control or network security services are enabled on the same device, the SCC coordinates coexistence based on related policies.

1.2 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the IPv4 User Capacity

1.3 Configuring the IPv4 User Capacity

1.3.1 Overview

The IPv4 user capacity is used to limit the maximum number of IPv4 access users on a port of the device. When the total number of IPv4 access users on a port reaches the limit, new users cannot access the network over this port. You need to select a proper user capacity based on the actual environment to guard against brutal force impacts from unauthorized users and improve the operational stability of the device.

1.3.2 Restrictions and Guidelines

IPv4 users include those generated through 802.1x authentication, web authentication, and other binding functions. IPv4 users on a port may be generated over the port or globally. For example, when a global IPv4 user is bound to a port by running the corresponding command, the user is also calculated as a user on the port.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

interface aggregateport *interface-number*

(4) Configure the IPv4 user capacity on a port.

nac-author-user maximum *max-user-number*

The IPv4 user capacity on a port is not limited by default.

1.4 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** commands to output debugging information.

⚠ Caution

The output debugging information occupies system resources. Therefore, disable the debugging switch immediately after use.

Table 1-1 Monitoring

Command	Purpose
display nac-author-user [**interface** *interface-type interface-number*]	Displays IPv4 user entries on a port.
display access-control packet statistics [**interface** *interface-type interface-number* | **vlan** *vlan-id*]	Displays statistics about packets filtered due to access control.
debugging scc event	Debugs the SCC running process.
debugging scc user	Debugs SCC user entries.
debugging scc acl-display summary	Debugs ACL summary stored in the SCC delivered by various services.
debugging scc acl-display all	Debugs all ACLs stored in the SCC.

1 Configuring Password Policies

1.1 Introduction

1.1.1 Overview

A password policy provides the password detection function for applications that need to configure accounts and passwords (for example, creating local users) on a device to ensure that users use passwords that meet security specifications and prevent password crackdown due to low password complexity.

1.2 Restrictions and Guidelines

The password lifecycle, repeated password use prevention, and forcible weak password change functions take effect only to global passwords (**privilege cipher** and **privilege safe-cipher**) and local user passwords (**user-account** *username* **password** *password*) and are invalid to passwords in line configuration mode.

1.3 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

(1) Configuring the Minimum Password Length

(2) Enabling Strong Password Detection

(3) Enabling Forcible Weak Password Change

(4) Configuring a Password Lifecycle

(5) Configuring Repeated Password Use Prevention

(6) Configuring Encrypted Password Storage

(7) Enabling Special Character Detection

1.4 Configuring the Minimum Password Length

1.4.1 Overview

The minimum password length is used to limit the length of user passwords.

If the password entered by a user is shorter than the minimum password length, the system displays an error prompt, asking the user to specify another password of an appropriate length.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the minimum password length.

password policy min-size *min-size*

No minimum length is configured for passwords by default.

1.5 Enabling Strong Password Detection

1.5.1 Overview

Strong password detection is used to detect the complexity of a password and prevent password crackdown due to low complexity.

The strong password detection function will send an alarm and disallow the user to configure the password in the following scenarios:

- The password is the same as or similar to the account.
- The password contains only one or two types of digits, uppercase letters, lowercase letters, and special characters.
- The password length is shorter than the specified length (no less than eight characters by default).

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the strong password detection function.

password policy strong

The strong password detection function is enabled by default.

1.6 Enabling Forcible Weak Password Change

1.6.1 Overview

The forcible weak password change function is used together with another password policy (such as the minimum password length or strong password detection).

After the forcible weak password change function is enabled, a warning prompt will be displayed if a user uses a weak password (containing less than eight bytes, or containing only one or two types of digits, uppercase letters, and lowercase letters) during login or configuration.

If both the forcible weak password change function and another password policy are enabled, the password will continue to be checked according to the other password policy during user login. If the password does not meet requirements of the other password policy, a prompt for changing the password will be displayed. The user is allowed to log in only after the new password meets requirements of the password policy.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable forcible weak password change.

password policy forced-password-modify

Forcible weak password change is disabled by default.

1.7 Configuring a Password Lifecycle

1.7.1 Overview

The password lifecycle defines the validity time of a password.

If a user enters a password that has already expired during login, the system gives a prompt, indicating that the password has expired, and asks the user to reset the password.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the password lifecycle.

password policy life-cycle *life-cycle*

No password lifecycle is configured by default.

1.8 Configuring Repeated Password Use Prevention

1.8.1 Overview

The repeated password use prevention function prevents users from using historically configured passwords as new passwords.

The system records passwords used by a user to a historical password list. If a newly configured password is within the list, the system gives a prompt and asks the user to specify another password. The maximum number of records in the password list can be manually configured. When the number of records in the password list reaches the limit, a new password record will overwrite the earliest password record.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-terminal terminal

(3) Prevent repeated use of passwords configured in the latest specified number of times.

password policy no-repeat-times *no-repeat-times*

Repeated password use is allowed by default.

1.9 Configuring Encrypted Password Storage

1.9.1 Overview

Encrypted password storage is used to store passwords after encryption.

When administrators run the **display current-config** command to display configurations or run the **save terminal** command to save configuration files, passwords configured by users are displayed in ciphertext format if encrypted password storage is enabled and displayed in plaintext format if encrypted password storage is disabled.

1.9.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable encrypted password storage.

service password-encryption-storage

Encrypted password storage is disabled by default.

1.10 Enabling Special Character Detection

1.10.1 Overview

After strong password detection and special character detection are configured, passwords that contain only special characters are invalid and cannot be configured successfully. Special characters include space, tilde (~), backtick (`), exclamation mark (!), at sign (@), number sign (#), dollar sign ($), percent sign (%), caret (^), ampersand (&), asterisk (*), brackets (()), underscore (_), plus sign (+), minus sign (–), equal sign (=), braces ({}), vertical bar (|), square brackets ([]), backslash (\), colon (:), quotation mark ("), semicolon (;), apostrophe ('), angle brackets (<>), comma (,), period (.), and slash (/).

1.10.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable special character detection.

password policy printable-character-check

Special character detection is disabled by default.

1.11 Monitoring

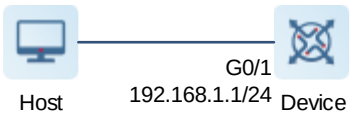
Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
display password policy	Displays configured password security policies.

1.12 Configuration Examples

1.12.1 Requirements



To ensure password complexity, you can configure password policies on a device to limit users' passwords.

Password security requirements are as follows:

- A password must be a string of at least eight characters.
- A password cannot be the same as the account.
- A password contains only one or two types of digits, uppercase letters, and lowercase letters.
- A password is valid for 90 days.
- Passwords must be stored in encrypted mode.
- A password cannot be the same as historical passwords configured in the latest three times.

1.12.2 Topology

Figure 1-1 Configuring Password Policies

1.12.3 Notes

- Set the minimum password length to 8.
- Enable strong password detection.
- Set the password lifecycle to 90 days.
- Enable encrypted password storage.
- Configure repeated password use prevention to disable the use of historical passwords configured in the latest three times.

1.12.4 Procedure

Enter the global configuration mode.

```
Device> privilege
Device# config-system terminal
```

Set the minimum password length to 8.

```
Device(cfg)# password policy min-size 8
```

Enable strong password detection.

```
Device(cfg)# password policy strong
```

Set the password lifecycle to 90 days.

```
Device(cfg)# password policy life-cycle 90
```

Enable encrypted password storage.

```
Device(cfg)# service password-encryption-storage
```

Configure repeated password use prevention to disable the use of historical passwords configured in the latest three times.

```
Device(cfg)# password policy no-repeat-times 3
```

1.12.5 Verification

Run the **display password policy** command to display configured password policies.

```
Device# display password policy
Global password policy configurations:
  Password encryption:                  Enabled
  Password strong-check:                Enabled
  Password forced-password-modify:      Disabled
  Password min-size:                    Enabled (8 characters)
  Password life-cycle:                  Enabled (90 days)
  Password no-repeat-times:             Enabled (max history record: 3)
  Password printable-character-check:   Disabled
```

1.12.6 Configuration Files

```
!
password policy life-cycle 90
password policy no-repeat-times 3
password policy min-size 8
password policy strong
service password-encryption-storage
```

1 Configuring SSH

1.1 Introduction

1.1.1 Overview

Secure Shell (SSH) is a network security protocol that requires encryption and authentication and is used for remote access and file transfer.

SSH is based on the server/client structure. The device supports both the SSH server and client functions. As an SSH server, the device can connect to multiple SSH clients. As an SSH client, the device allows users to establish SSH connections with devices that support the SSH server function.

The SSH function is similar to the Telnet service. However, the encryption and authentication features of SSH can ensure stronger security guarantee for users. When users log in to the device through an insecure network environment, SSH can effectively protect the device against attacks, such as IP address spoofing and plaintext password interception.

1.1.2 Principles

1. SSH Version

SSHv1 and SSHv2 are available, and the two are mutually exclusive. Compared with SSHv1, SSHv2 provides higher performance and security.

The device supports both versions and supports SSH interaction using the IPv4 and IPv6 addresses. Unless otherwise specified, SSH in this document refers to SSHv2.

2. SSH Exchange Process

Interaction between an SSH client and an SSH server is classified into seven phases: connection establishment, version negotiation, key exchange and algorithm negotiation, user authentication, session request, session interaction, and session closure.

- Connection establishment
  a The server listens on Transmission Control Protocol (TCP) port 22 and waits for a connection request from the client.
  b The client initiates a TCP connection request to port 22 of the server to establish a TCP connection with the server.
- Version negotiation
  a The server sends a version negotiation packet to the client.
  b The client receives and processes the packet and replies the version to be used to the server.
  c The server processes the reply from the client and determines whether version negotiation is successful.
- Key exchange and algorithm negotiation

  If the version negotiation succeeds, key exchange and algorithm negotiation are performed.

a The server and the client exchange the algorithm negotiation packet with each other and determine the final algorithm based on their capacity.

b The server and the client work together to generate a session key and session ID according to the key exchange algorithm and host key, which will be applied to subsequent user authentication, data encryption, and data decryption.

- User authentication

  After the encrypted channel is set up, user authentication is performed.

  a The client sends an authentication request to the server.

  b The server repeatedly conducts authentication for the client until the authentication succeeds or the server shuts down the connection because the maximum number of authentication attempts is reached.

- Session request

  a After the authentication is successful, the client sends a session request to the server.

  b The server waits and processes the client's session request. After the session request is successfully processed, the SSH client and server enter the session interaction phase.

- Session interaction

  In this phase, bidirectional transmission and processing of encrypted data are allowed.

  a The client sends commands that need to be executed to the server.

  b The server decrypts, parses, and processes these commands.

  c The server encrypts and sends the processing result to the client.

  d The client decrypts and processes the message from the server.

- Session closure

  The server and client disconnect the connection, and close the session.

3. User Authentication Mechanism

SSH supports password authentication, public key authentication, and other client authentication mechanisms.

- Password authentication

  Password authentication authenticates a client by verifying the username and password.

  a The client sends encrypted username and password to the server to request password authentication.

  b After receiving the request, the server decrypts the information, authenticates the client's identity through the Authentication, Authorization and Accounting (AAA) service (including local authentication and remote authentication), and sends an authentication success or failure message to the client.

- Public key authentication

  Public key authentication uses digital signature algorithms, such as Rivest-Shamir-Adleman (RSA) and Digital Signature Algorithm (DSA) to authenticate a client.

  a The client sends a public key authentication request to the server. This request contains information, including the username, public key, and public key algorithm.

  b After receiving the request, the server checks whether the public key is valid.

c If not, the server directly returns an authentication failure message. If yes, the server performs digital signature authentication on the client and returns a message indicating successful or failed authentication.

Note

Public key authentication applies only to SSHv2 clients.

4. Public Key Algorithm

A public key algorithm is an asymmetric encryption algorithm used to encrypt communication data between an SSH client and server to ensure data transfer security.

The device supports three public key algorithms: RSA, DSA, Elliptic Curves Cryptography (ECC), and ED25519.

- RSA

  RSA is based on most factorization algorithms and can be used for key and signature exchange. Due to low encryption and decryption efficiency, it does not apply to encryption and decryption of a large number of data.

- DSA

  Compared with RSA, DSA can be used only for signature and cannot be used for data encryption and decryption or key exchange. However, its efficiency is much higher than that of RSA.

- ECC

  ECC is based on the discrete logarithm algorithm and is difficult to be cracked down. In same security conditions, ECC has higher processing efficiency and lower storage and bandwidth requirements than RSA and DSA.

- ED25519

  ED25519 is the EdDSA signature scheme using SHAKE256 and Curve448 defined in RFC 8032. Compared with RSA, it is equally secure and has a shorter key, with a high signature and verification performance.

Protocols and Standards

- RFC 4251: The Secure Shell (SSH) Protocol Architecture
- RFC 4252: The Secure Shell (SSH) Authentication Protocol
- RFC 4253: The Secure Shell (SSH) Transport Layer Protocol
- RFC 4254: The Secure Shell (SSH) Connection Protocol
- RFC 4419: Diffie-Hellman Group Exchange for the Secure Shell (SSH) Transport Layer Protocol
- RFC 4716: The Secure Shell (SSH) Public Key File Format
- RFC 4819: Secure Shell Public Key Subsystem
- RFC 3526: More Modular Exponential (MODP) Diffie-Hellman groups for Internet Key Exchange (IKE)
- RFC 2409: The Internet Key Exchange (IKE)
- RFC 1950: ZLIB Compressed Data Format Specification version 3.3
- RFC 8030: EdDSA Instances

1.2 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

(1) Configuring SSH Server

- Enabling SSH Server
- (Optional) Configuring the SSH Server Version
- (Optional) Configuring the Listening Port
- (Optional) Configuring the Key and Key Exchange Algorithm of the SSH Server
- (Optional) Configuring the Encryption Algorithm
- (Optional) Configuring Authentication Parameters
- (Optional) Configuring an ACL
- (Optional) Configuring IP Address Blocking
- (Optional) Disconnecting an SSH Client Connection

(2) Configuring SCP Server

(3) Configuring SSH Client

- Establishing a Connection with the SSH Server
- (Optional) Restoring an Established SSH Client Session
- (Optional) Disconnecting a Suspended SSH Client Session

(4) Configuring SCP Client

(5) Configuring SSH Server

(6) Configuring SFTP Client

1.3 Configuring SSH Server

1.3.1 Overview

After the SSH server function is configured on a device, SSH clients can remotely log in to the device.

1.3.2 Configuration Tasks

SSH server configuration includes the following tasks:

- Enabling SSH Server
- (Optional) Configuring the SSH Server Version
- (Optional) Configuring the Listening Port
- (Optional) Configuring the Key and Key Exchange Algorithm of the SSH Server
- (Optional) Configuring the Encryption Algorithm
- (Optional) Configuring Authentication Parameters
- (Optional) Configuring an ACL
- (Optional) Configuring IP Address Blocking
- (Optional) Disconnecting an SSH Client Connection

1.3.3 Enabling SSH Server

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the SSH server function.

enable-server service ssh-server

The SSH server function is disabled by default.

(4) (Optional) Enable the SSHv1 function.

ip ssh-server compatible-ssh1x enable

The SSHv1 function is disabled by default.

To use the SSHv1 version, enable the SSHv1 function first.

1.3.4 Configuring the SSH Server Version

1. Overview

The SSH server supports the SSHv1 and SSHv2 versions. Compared with SSHv1, SSHv2 has higher performance and security. During actual configuration, select a proper SSH server version based on the client version and security requirements.

2. Restrictions and Guidelines

The SSH server is compatible with SSHv1 and SSHv2 clients by default, that is, clients of both versions can connect to the SSH server. After an SSH server version is configured, only clients of the corresponding version can connect to the server.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the SSH server version.

ip ssh-server version *version-type*

The SSH server is compatible with the SSHv1 and SSHv2 clients by default.

1.3.5 Configuring the Listening Port

1. Overview

An SSH server uses port 22 to listen to client connections by default. The listening port can be changed through configuration.

Port 22 is a protocol-defined standard port and vulnerable to attacks from malicious users. If an attacker accesses this port frequently in a short time, problems such as bandwidth waste and performance deterioration

may occur. As a result, other users cannot access the server (that is, the DoS attack). Changing the listening port can effectively prevent the problems.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the listening port of the SSH server.

ip ssh-server port *ssh-monitor-port*

The default listening port of the SSH server is port **22**.

1.3.6 Configuring the Key and Key Exchange Algorithm of the SSH Server

1. Overview

The key and key exchange algorithm of the SSH server are configured to establish a communication connection between the client and server.

2. Restrictions and Guidelines

SSHv1 uses an RSA key, and SSHv2 uses an RSA or a DSA key. If an RSA key is generated, both SSHv1 and SSHv2 can use the key. If a DSA key is generated, only SSHv2 can use the key.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Generate the public key of the SSH server.

ssh-crypto key generate { **dsa** | **ecc** | **rsa | ed25519** }

No public key is generated on the SSH server by default.

If no key is generated on the SSH server, this parameter must be configured. To delete the public key of the SSH server, run the **ssh-crypto key remove** { **dsa** | **ecc** | **rsa | ed25519** } command instead of the **unset** form of this command.

(4) Configure the DH key exchange algorithms supported by the SSH server.

ip ssh-server key-exchange { **curve25519_sha256** | **curve25519_sha256@libssh.org** | **dh_group_exchange_sha1** | **dh_group_exchange_sha256** | **dh_group14_sha1** | **dh_group14_sha256** | **dh_group16_sha512** | **dh_group18_sha512** | **dh_group1_sha1** | **ecdh_sha2_nistp256** | **ecdh_sha2_nistp384** | **ecdh_sha2_nistp521** }

The SSHv2 servers support curve25519_sha256, curve25519_sha256@libssh.org, dh_group_exchange_sha256, dh_group14_sha256, dh_group16_sha512, dh_group18_sha512 , ecdh_sha2_nistp256, ecdh_sha2_nistp384 and ecdh_sha2_nistp521 for key exchange, and SSHv1 servers support none by default.

(5) (Optional) Configure the minimum length of the key generated by the key exchange algorithm of the SSH server.

ip ssh-server dh-exchange min-len { **1024** | **2048** }

The default minimum length is **2048** bytes.

1.3.7 Configuring the Encryption Algorithm

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the encryption modes supported by the SSH server.

ip ssh-server cipher-mode { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-cbc** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **blowfish-cbc** | **cbc** | **ctr** | **des-cbc** | **gcm** | **chacha-only** | **others** } *

The encryption modes supported by the SSH server are **ctr**, **gcm** and **chacha-only** by default.

It is approved that **cbc** and **others** encryption algorithms can be decrypted in a limited period of time. Therefore, organizations or companies that have high security requirements can set the encryption modes supported by the SSH server to **ctr**, **gcm** and **chacha-only** to enhance the security level of the SSH server.

(4) Configure the message authentication algorithms supported by the SSH server.

ip ssh-server hmac-algorithm { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sha2-256-etm** | **sha2-512-etm** }

SSHv1 servers do not support any message authentication algorithms, and SSHv2 servers support the sha2-256, sha2-512, sha2-256-etm and sha2-512-etm message authentication algorithms by default.

1.3.8 Configuring Authentication Parameters

1. Overview

Parameters related to user authentication include the authentication timeout time, number of authentication attempts, and public key authentication.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the user authentication timeout time on the SSH server.

ip ssh-server time-out *timeout-time*

The default user authentication timeout time on the SSH server is **120** seconds.

If authentication still does not succeed when the user authentication timeout time expires, user authentication fails.

(4) Configure the number of authentication attempts allowed on the SSH server.

ip ssh-server authentication-retries *retry-times*

The default maximum number of authentication attempts allowed on the SSH server is **3**.

If the number of authentication attempts of a user by using the account and password exceeds the configured number of authentication attempts, user authentication fails.

(5) Associate with the public key file and username of a client.

ip ssh-server peer *username* **public-key** { **dsa** | **ecc** | **rsa** | **ed25519** } *filename-path*

If a client needs to use public key authentication, the client's public key and username need to be associated with the device. Only SSHv2 supports public key authentication.

1.3.9 Configuring an ACL

1. Overview

An ACL can filter out users who meet specific rules. This prevents unauthorized users from accessing the device through SSH and causing security risks.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an ACL on the SSH server.

(IPv4 address)

ip ssh-server access-apply { *acl-name* | *acl-number* }

No IPv4 ACL is configured on the SSH server by default.

(IPv6 address)

ipv6 ssh-server access-apply *acl-name*

No IPv6 ACL is configured on the SSH server by default.

1.3.10 Configuring IP Address Blocking

1. Overview

When the number of authentication failures for login through SSH reaches the configured limit in an authentication failure count period, the source IP address is blocked. That is, the SSH client that uses this source IP address is not allowed to log in to the device to prevent the device being attacked. The SSH client can log in to the device only after the IP address is awakened. This function is enabled by default and can be manually disabled.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable IP address blocking on the SSH server.

ip ssh-server ip-block disable

The IP address blocking function of the SSH server is enabled by default.

Run the **unset** form of this command to disable this feature.

(4) (Optional) Configure the number of authentication failures for blocking an IP address and the time period for counting authentication failures on the SSH server.

ip ssh-server ip-block failed-times *failed-times* **period** *period-time*

The allowed maximum number of authentication failures is **6**, and the time period for counting authentication failures is **5** minutes by default.

(5) (Optional) Configure the time period for awakening blocked IP addresses on the SSH server.

ip ssh-server ip-block reactive *reactive-interval*

Blocked IP addresses are awakened every **10** minutes by default.

After the time period for awakening blocked IP addresses is reached, SSH clients using these IP addresses can log in to the SSH server again.

(6) (Optional) Clear user information with blocked IP addresses and authentication failures.

cleanup ssh ip-block { *ipv4-address* | *ipv6-address* | **all** }

After the user information is cleared, corresponding clients can log in to the SSH server again.

1.3.11 Disconnecting an SSH Client Connection

(1) Enter the privileged EXEC mode.

privilege

(2) Disconnect an established SSH client connection.

remove ssh { *session-id* | **vty** *session-id* }

Serving as an SSH server, the device may connect to multiple SSH clients. You can run this command to forcibly disconnect a client from the device. The client disconnection methods are as follows:

- Specify an SSH session ID. To display the SSH session ID of a client, run the **display ssh** command.
- Specify a Virtual Teletype (VTY) session ID. To display the VTY session ID of a client, run the **display users** command. This command can be used to disconnect SSH connections only.

1.4 Configuring SCP Server

1.4.1 Overview

Secure copy protocol (SCP) is a protocol that supports network file transfer. SCP is implemented based on RCP. RCP is responsible for file transfer, and SSH provides the authentication and encryption functions for RCP.

After the SCP server function is configured on the device, users can run the **scp** command to upload files to or download files from the device. Data exchanged during the process is encrypted for security.

1.4.2 Restrictions and Guidelines

The SSH server function must be enabled before the SCP server function is configured.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the SCP server function.

ip scp-server set enable

The SCP server function is disabled by default.

(4) (Optional) Configure the transmission path for uploading files to or downloading files from the SCP server.

ip scp-server set topdir { **flash:/***path* | **tmp:/***path* | **usb0:/***path* }

The default transmission path for file upload and download is **flash:/**.

1.5 Configuring SSH Client

1.5.1 Overview

When the local device is configured as an SSH client, the device can establish an SSH connection to another device that provides the SSH server service to remotely log in to the device for management operations.

1.5.2 Configuration Tasks

SSH client configuration includes the following tasks:

(1) Establishing a Connection with the SSH Server

(2) (Optional) Restoring an Established SSH Client Session

(3) (Optional) Disconnecting a Suspended SSH Client Session

1.5.3 Establishing a Connection with the SSH Server

(1) Enter the privileged EXEC mode.

privilege

(2) Establish a remote encrypted session with the SSH server as an SSH client.

ssh-server [**oob**] [**-v** { **1** | **2** } | **-c** { **3des** | **aes128-cbc** | **aes192-cbc** | **aes256-cbc** | **aes128-ctr** | **aes192-ctr** | **aes256-ctr** | **aes128-gcm** | **aes256-gcm** | **chacha-poly** } | **-l** *username* | **-m** { **hmac-md5-96** | **hmac-md5-128** | **hmac-sha1-96** | **hmac-sha1-160** | **hmac-sha2-256** | **hmac-sha2-512** | **hmac-sha2-256-etm** | **hmac-sha2-512-etm** } | **-p** *port-num*] * { *ipv4-address* | *hostname* } [**via** *mgmt-name*] [**/src-address** { **ip** *ipv4-address* | **ipv6** *ipv6-address* | **interface** *interface-type interface-number* }] [**/vrf** *vrf-name*]

SSHv1 supports only the DES (56-bit key) and 3DES (168-bit key) encryption algorithms. SSHv2 supports the following Advanced Encryption Standards (AES): ASE128-CBC, AES192-CBC, AES256-CBC, AES128-CTR, AES192-CTR, AES256-CTR, AES128-QCM, AES256-QCM and CHACHA-POLY. If you specify an unmatched encryption or authentication algorithm when selecting an SSH version, the unmatched algorithm will be ignored when a connection is established.

(3) Enter the global configuration mode.

config-system terminal

(4) (Optional) Configure the source interface of the SSH client.

ip ssh-client source-interface *interface-type interface-number*

No SSH client source interface is configured by default.

After the source interface is configured, the SSH client uses the IP address on this interface as the global source address during communication. If no source interface is configured, the source address of SSH packets will be obtained by querying the corresponding route based on the destination address. If no source interface or source IP address is independently specified for an SSH connection, the global configuration is used.

1.5.4 Restoring an Established SSH Client Session

1. Overview

After the device establishes an SSH session with the SSH server as a client, you can press Ctrl+Shift+6+X to exit the session temporarily. After exiting the session, you can run the corresponding command to restore the session.

2. Restrictions and Guidelines

To display information about the SSH connections established by the device as an SSH client, run the **display ssh-session** command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Restore an established SSH client session.

ssh-session *session-id*

1.5.5 Disconnecting a Suspended SSH Client Session

1. Overview

After the device connects to the SSH server as an SSH client, you can run the corresponding command to disconnect an SSH session with the specified session ID.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Disconnect a suspended SSH client session.

remove ssh-session *session-id*

You can run the **display ssh-session** command to display *session-id* of the device.

1.6 Configuring SCP Client

1.6.1 Overview

When the local device is configured as an SCP client, the device can run the **scp** command to upload files to or download files from a device that provides the SCP server service. Data exchanged during the process is encrypted for security.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Configure the source interface of the SCP client.

ip scp client source-interface *interface-type interface-number*

No SCP client source interface is configured by default.

After the source interface is configured, the SCP client uses the IP address on the interface as the global source address during communication. If no source interface is configured, the source address of SCP packets will be obtained by querying the corresponding route based on the destination address. If no source interface or source IP address is independently specified for an SCP connection, the global configuration is used.

(4) Upload files to or download files from the remote SCP server as an SCP client.

scp [**oob**] [**-v** { **1** | **2** } | **-c** { **3des** | **aes128-cbc** | **aes192-cbc** | **aes256-cbc** | **aes128-ctr** | **aes192-ctr** | **aes256-ctr** | **aes128-gcm** | **aes256-gcm** | **chacha-poly** } | **-m** { **hmac-md5-96** | **hmac-md5-128** | **hmac-sha1-96** | **hmac-sha1-160** | **hmac-sha2-256** | **hmac-sha2-512** | **hmac-sha2-256-etm** | **hmac-sha2-512-etm** } | **-p** *port-num*] * *source-file destination-file* [**via** *mgmt-name*] [**/src-address** { **ip** *ipv4-address* | **ipv6** *ipv6-address* | **interface** *interface-type interface-number* }] [**/vrf** *vrf-name*]

1.7 Configuring SFTP Server

1.7.1 Overview

After the SSH File Transfer Protocol (SFTP) server function is configured on the device, users can use commands of the SFTP client console to upload files to and download files from the device. All the data exchanged in this process is transmitted in encrypted mode to provide high security.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the SFTP server function.

ip sftp server enable

The SFTP server function is disabled by default.

> ⚠ Caution
>
> To prevent high CPU usage, run the **ip sftp server max-sessions-num** command to limit the maximum number of sessions.

(4) (Optional) Configure the root path for uploading files to or downloading files from the SFTP server.

ip sftp server topdir { **flash:/***path* | **flash2:/***path* | **sd0:/***path* | **sata0:/***path* | **tmp:/***path* | **usb0:/***path* | **usb1:/***path* }

The default root path on the SFTP server is **flash:/**.

(5) (Optional) Configure the maximum number of SFTP session connections.

ip sftp server max-sessions-num *session-numbers*

The maximum number of SFTP session connections is 5 by default.

1.8 Configuring SFTP Client

1.8.1 Overview

After the local device is configured as the SFTP client, you can connect to the SFTP server by using an SFTP command to upload and download files locally or remotely in the client console. All the data exchanged in this process is transmitted in encrypted mode to provide high security.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Configure the source interface used by the SFTP client.

ip sftp client source-interface interface-type interface-number

No source interface is configured for the SFTP client by default.

After the source interface is configured, the SFTP client uses the IP address of this interface as the global source address. If no source interface is configured, the device obtains the source address of the SFTP packets by querying the destination address in the corresponding route. If no source interface or address is specified separately for an SFTP connection, the global configuration applies.

(4) (Optional) Configure an SSH version for global SFTP connections.

ip sftp client version { **1** | **2** }

SSHv2 is used for global SFTP connections by default.

(5) (Optional) Configure the global SSH encryption algorithms supported by the SFTP client.

ip sftp client cipher-mode { **3des | aes128-cbc | aes128-ctr | aes128-gcm | aes192-cbc | aes192-ctr | aes256-cbc | aes256-ctr | aes256-gcm** | **chacha-poly** }

The SFTP client supports the following encryption algorithms by default: 3DES-CBC, AES-128-CBC, AES128-CTR, AES128-GCM, AES-192-CBC, AES192-CTR, AES-256-CBC, AES256-CTR, AES256-GCM and CHACHA20-POLY1305.

(6) (Optional) Configure the global SSH message authentication algorithms supported by the SFTP client.

ip sftp client hmac-algorithm { **hmac-md5-128** | **hmac-md5-96** | **hmac-sha1-160** | **hmac-sha1-96** | **hmac -sha2-256** | **hmac -sha2-512** | **hmac -sha2-256-etm** | **hmac -sha2-512-etm** }

SSHv1 does not support any message authentication algorithms, and SSHv2 supports the following message authentication algorithms by default: MD5-128, SHA1-160, SHA1-96, MD5-96, SHA2-256, SHA2-512, SHA2-256-ETM, and SHA2-512-ETM.

(7) (Optional) configure the global Diffie–Hellman (DH) key exchange algorithms used by the SFTP client.

ip sftp client key-exchange { **curve25519_sha256** | **curve25519_sha256@libssh.org** | **dh_group_exchange_sha**1 | **dh_group_exchange_sha256** | **dh_group14_sha**1 | **dh_group14_sha256** | **dh_group16_sha512** | **dh_group18_sha512** | **dh_group**1**_sha**1 | **ecdh_sha**2**_nistp**256 | **ecdh_sha**2**_nistp**384 | **ecdh_sha**2**_nistp**521 }

SSHv1 does not support any key exchange algorithms, and SSHv2 supports the following key exchange algorithms by default: dh_group1_sha1, dh_group14_sha1, dh_group14_sha256, dh_group16_sha512, dh_group18_sha512, dh_group_exchange_sha1, dh_group_exchange_sha256, curve25519_sha256@libssh.org, curve25519_sha256, ecdh_sha2_nistp256, ecdh_sha2_nistp384, and ecdh_sha2_nistp521.

(8) (Optional) Configure the top directory on the SFTP client.

ip sftp client topdir { **flash:**/*path* | **flash2:**/*path* | **sd0:**/*path* | **sata0:**/*path* | **tmp:**/*path* | **usb0:**/*path* | **usb1:**/*path* }

The default top directory on the SFTP client is **flash:/**.

(9) (Optional) Configure a rate limit for file transfer using SFTP.

ip sftp client speed-limit *speed-limit-rate*

The default rate limit for file transfer using SFTP is 8192 kbit/s.

(10) Configure the device as the SFTP client, connect it to the SFTP server, and enter the SFTP client console to manage files.

sftp [**oob**] [**-v** { 1 | 2 } | **-c** { 3**des** | **aes**128-**cbc** | **aes**192-**cbc** | **aes**256-**cbc** | **aes**128-**ctr** | **aes**192-**ctr** | **aes**256-**ctr** | **aes**128-**gcm** | **aes256-gcm** | **chacha-poly** } | **-k** { curve25519_sha256 | curve25519_sha256@libssh.org | **dh_group_exchange_sha1** | **dh_group_exchange_sha256** | **dh_group14_sha1** | **dh_group14_sha256** | **dh_group16_sha512** | **dh_group18_sha512** | **dh_group1_sha1** | **ecdh_sha2_nistp256** | **ecdh_sha2_nistp384** | **ecdh_sha2_nistp521** } | **-m** { **hmac**-**md**5-96 | **hmac**-**md**5-128 | **hmac**-**sha**1-96 | **hmac**-**sha**1-160 | **hmac**-**sha**2-256 | **hmac**-**sha**2-512 | **hmac**-**sha**2-256-etm | **hmac**-**sha**2-512-etm } | **-p** *port-num*] * { *user@hostname* | *user@ip-address* } [**via mgmt** *mgmt-number*] [/**source** { **ip** *ipv4-address* | **ipv**6 *ipv6-address* | interface *interface-type interface-number* }] [/**vrf** *vrf-name*]

1.9 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** commands to output debugging information.

Caution

System resources are occupied when debugging information is output. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
display ip ssh-config	Displays effective configurations of the SSH server.
display ssh	Displays information about established SSH connections.
display ssh ip-block { **all** | **list** }	Displays information about blocked IP addresses and authentication failures.
display ss crypto-key pubkey { **dsa** | **ecc** | **rsa** | **ed25519** }	Displays partial public key information of the SSH server.
display ssh-session	Displays information about established SSH client sessions.
debugging ssh	Debugs sessions of the SSH server.
debugging ssh client	Debugs sessions of the SSH client.

1.10 Configuration Examples

1.10.1 Configuring Line Password Authentication for SSH Users

1. Requirements

After the SSH server function is enabled on a device, users can use the password configured in line configuration mode to log in to the device.

2. Topology

Figure 1-1 Configuring Line Password Authentication for SSH Clients

3. Notes

- Enable the SSH server function.
- Configure the line password.
- Enable password authentication in the line.

4. Procedure

(1) Enable the SSH server function.

```
Device> privilege
Device# config-system terminal
Device(cfg)# enable-server service ssh-server
```

(2) Set the line password to **password1**.

```
Device(cfg)# line vty 0 4
Device(cfg-line)# password password1
```

(3) Enable password authentication in the line.

```
Device(cfg-line)# line-login
```

5. Verification

- Use the client software to log in to the device through SSH. The password is **password1**, and the username can be any value. Verify that the login is successful. Use the PuTTY software as an example. The login page is as follows:

```
login as: anyname
anyname@192.168.1.1's password:

Last login: Apr  2 2021 10:00:00 from 192.168.1.2 through ssh.
Device#
```

- Run the **display ip ssh-server** command to verify that the SSH server takes effect.

```
Device# display ip ssh-config
SSH Enable - version 2.0
SSH Port:                       22
SSH Cipher Mode:                ctr,gcm
SSH HMAC Algorithm:             sha2-256,sha2-512
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server:                 disabled
SSH dh-exchange min-len: 2048
SSH SFTP Server:                disable
SSH ip-block:                   enabled
```

- Run the **display ssh** command to display the SSH connection information. Verify that a connection with username **anyname** (used during login) exists.

```
Device# display ssh
Connection Version Encryption          Hmac              Compress     State                Username
         1       2.0 aes256-ctr        hmac-sha2-256 none         Session started anyname
```

- Run the **display users** command to display information about connected clients.

```
Device#display users
Line                User            Host(s)                 Idle          Location
---------------- ------------ -------------------- ---------- -------------------
   0 con 0          ---              idle                      00:00:16     ---
```

```
*  1 vty 0          ---          idle                 00:00:00     192.168.1.2
```

6. Configuration Files

```
!
enable-server service ssh-server
!
line console 0
line vty 0 4
 line-login
 password 7 $10$396$mnO2p3SVaxm7$
!
```

1.10.2 Configuring Local User Authentication for SSH Clients

1. Requirements

After the SSH server function is enabled on a device, users can use the local account created on the device to log in to the device through SSH.

2. Topology

Figure 1-2 Configuring Local User Authentication for SSH Clients

3. Notes

- Enable the SSH server function.
- Add a local user account.
- Enable local user authentication in the line.

4. Procedure

(1) Enable the SSH server function.

```
Device> privilege
Device# config-system terminal
Device(cfg)# set service ssh-server
```

(2) Add a local user whose username is **hostname1** and password is **password1**.

```
Device(cfg)# username hostname1 password password1
```

(3) Enable local user authentication in the line.

```
Device(cfg)# line vty 0 4
Device(cfg-line)# login local
```

5. Verification

- Use the client software to log in to the device through SSH. The username is **hostname1**, and the password is **password1**. Verify that the login is successful. Use the PuTTY software as an example. The login page is

as follows:

```
login as: hostname1
hostname1@192.168.1.1's password:

Last login: Apr    2 2021 10:00:00 from 192.168.1.2 through ssh.
Device>
```

- Run the **display ip ssh-server** command to verify that the SSH server takes effect.

```
Device# display ip ssh-server
SSH Enable - version 2.0
SSH Port:                       22
SSH Cipher Mode:                ctr,gcm
SSH HMAC Algorithm:             sha2-256,sha2-512
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server:                 disabled
SSH dh-exchange min-len: 2048
SSH ip-block:                   enabled
```

- Run the **display ssh-server** command to display the SSH connection information. Verify that a connection with username **hostname1** exists.

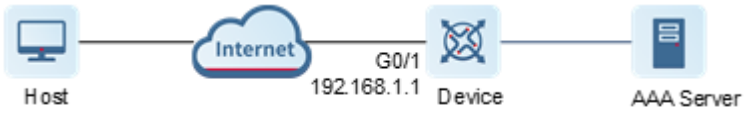
```
Device# display ssh-server
Connection Version Encryption          Hmac              Compress     State                Username
         1       2.0 aes256-ctr        hmac-sha2-256 none          Session started hostname1
```

- Run the **display users** command to display information about connected clients. Verify that a client whose username is **hostname1** exists.

```
Device#display users
Line                 User           Host(s)                Idle          Location
---------------- ------------ -------------------- ---------- -------------------
    0 con 0          ---            idle                    00:00:16     ---
*   1 vty 0          hostname1      idle                     00:00:00     192.168.1.2
```

6. Configuration Files

```
!
username hostname1 password 7 $10$2fe$Rd/C4ijEl+UN$
!
set service ssh-server
!
line console 0
line vty 0 4
 login local
!
```



1.10.3 Configuring AAA Authentication for SSH Clients

1. Requirements

SSH clients can be authenticated using the AAA mode.

2. Topology

Figure 1-3 Configuring AAA Authentication for SSH Clients

3. Notes

- Configure the AAA server and add an AAA user on the AAA server.
- Enable the SSH server function.
- Enable the AAA service on the device and set the SSH authentication method to AAA server.
- Enable AAA authentication in the line.

4. Procedure

(1) Configure the AAA server and add an AAA user whose username is **hostname1** and password is **password1** on the AAA server. (For details about AAA server configuration, see *Configuring AAA*.)

(2) Enable the SSH server function.

```
Device> privilege
Device# config-system terminal
Device(cfg)# enable-server service ssh-server
```

(3) Enable AAA services.

```
Device(cfg)# aaa-config new-pattern
```

(4) Configure the address and shared key of the AAA server (a RADIUS server is used as an example here, the IP address is set to **192.168.1.3**, and the shared key is set to **radiuskey**).

```
Device(cfg)# rds-server host 192.168.1.3 share-key radiuskey
```

(5) Configure the login authentication method list **login-method** and select **radius** as the authentication method. The backup method **local** is configured. This ensures that a backup solution is available when the AAA server is faulty.

```
Device(cfg)# aaa-config authentication line-login login-method server-group radius native
```

(6) Enable AAA authentication in the line.

```
Device(cfg)# line vty 0 4
Device(cfg-line)# line-login authentication login-method
```

5. Verification

- Use the client software to log in to the device through SSH. The username is **hostname1**, and the password is **password1**. Verify that the login is successful. Use the PuTTY software as an example. The login page is

as follows:

```
login as: hostname1
hostname1@192.168.1.1's password:

Last login: Apr  2 2021 10:00:00 from 192.168.1.2 through ssh.
Device>
```

- Run the **display ip ssh-config** command to verify that the SSH server takes effect.

```
Device# display ip ssh-config
SSH Enable - version 2.0
SSH Port:                       22
SSH Cipher Mode:                ctr,gcm
SSH HMAC Algorithm:             sha2-256,sha2-512
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server:                 disabled
SSH dh-exchange min-len: 2048
SSH SFTP Server:                disable
SSH ip-block:                   enabled
```

- Run the **display ssh** command to display the SSH connection information. Verify that a connection with username **hostname1** exists.

```
Device# display ssh
Connection Version Encryption          Hmac              Compress     State                Username
         1       2.0 aes256-ctr        hmac-sha2-256 none           Session started hostname1
```

- Run the **display users** command to display information about connected clients. Verify that a client whose username is **hostname1** exists.

```
Device#display users
Line                 User           Host(s)                Idle          Location
---------------- ------------ -------------------- ---------- -------------------
    0 con 0          ---            idle                    00:00:16     ---
*   1 vty 0          hostname1      idle                     00:00:00     192.168.1.2
```

6. Configuration Files

1.10.4 Configuring Public Key Authentication for SSH Clients

1. Requirements

When the device serves as the SSH server, users can use public key authentication to log in to the device without needing a password.

2. Topology

Figure 1-4 Configuring Public Key Authentication for SSH Clients

3. Notes

- Use the client software to generate a pair of keys (public key and private key).
- Copy the public key file to the flash memory of the device and associate the key with the user.

4. Procedure

(1) Configure a local user and enable local user authentication in a line. For details, see 1.10.2 Configuring Local User Authentication for SSH Clients.

(2) Use the client software to generate a pair of keys. The Ubuntu environment is used as an example. The generated private key is **id_rsa** and public key is **id_rsa.pub**.

```
root@ubuntu:~# ssh-keygen
Generating public/private rsa key pair.
Enter file in which to save the key (/root/.ssh/id_rsa):
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /root/.ssh/id_rsa.
Your public key has been saved in /root/.ssh/id_rsa.pub.
The key fingerprint is:
SHA256:6a/sWJjpx97QQEs9Aoiph5Ry452ybIyNyZUsT48Irrw root@ubuntu
The key's randomart image is:
+---[RSA 2048]----+
|   .o ..         |
|.o= .   . .      |
|o=.o..   + o     |
|+.+=o   o + .    |
|+O*oo    S       |
|++*o . = o       |
|o.      +.+ .    |
|..     . +o+     |
| E.    o+=.o     |
+----[SHA256]-----+
```

(3) Copy the public key file to the flash memory of the device (omitted).

(4) Associate the public key with **hostname1**.

```
Device> privilege
Device# config-system terminal
Device(cfg)# ip ssh-server peer hostname1 public-key rsa flash:test_key.pub
```

5. Verification

Verify that users can log in to the device through public key authentication. (The Ubuntu environment is used as an example.)

```
root@ubuntu:~/.ssh# ls
id_rsa    id_rsa.pub
root@ubuntu:~/.ssh# ssh-server -i id_rsa hostname1@192.168.1.1

Last login: Apr 2 2021 10:00:00 through console.
Device>
```

6. Configuration Files

```
!
user-account hostname1 password 7 $10$2fe$Rd/C4ijEl+UN$
!
ip ssh-server peer hostname1 public-key rsa flash:id_rsa.pub
!
enable-server service ssh-server
!
line console 0
line vty 0 4
 line-login local
!
```

1.10.5 Configuring SCP Server

1. Requirements

When the device serves as the SCP server, users can run the **scp** command to upload files to and download files from the device.

2. Topology

Figure 1-5 Configuring SCP Server

3. Notes

- Enable the SSH server function.
- Enable the SCP server function.

4. Procedure

(1) Configure a local user and enable local user authentication in a line. For details, see 1.10.2 Configuring Local User Authentication for SSH Clients.

(2) Enable the SSH server function.

```
Device> privilege
Device# config-system terminal
Device(cfg)# enable-server service ssh-server
```

(3) Enable the SCP server function.

```
Device(cfg)# ip scp-server set enable
```

5. Verification

- Verify that the client can run the **scp** command to upload files to the device. The Ubuntu environment is used as an example here.

(1) In the Ubuntu shell environment, run the **scp** command to upload **file.txt** to the device.

```
root@ubuntu:~# scp file.txt hostname1@192.168.1.1:/
hostname1@192.168.1.1's password:
file.txt                                      100%    14        0.0KB/s     00:00
```

(2) Check whether **file.txt** exists in the flash directory of the device.

```
Device> privilege
Device# dir flash:file.txt
Number   Properties       Size                  Time                        Name
------   ----------   ----------   ------------------------   --------------------
  1          -rwx          14B          Fri Apr 2 10:00:00 2021    file.txt
```

- Verify that the client can run the **scp** command to download files from the device. The Ubuntu environment is used as an example here.

(1) The **file.txt** file exists in the flash directory of the device.

```
Device> privilege
Device# dir flash:file.txt
Number   Properties       Size                  Time                        Name
------   ----------   ----------   ------------------------   --------------------
  1          -rwx          14B          Fri Apr 2 10:00:00 2021    file.txt
```

(3) In the Ubuntu shell environment, run the **scp** command to download **file.txt** from the device and rename it as **file1.txt**.

```
root@ubuntu:~# scp hostname1@192.168.1.1:/file.txt file1.txt
hostname1@192.168.1.1's password:
file.txt                                      100%    14        0.0KB/s     00:00
```

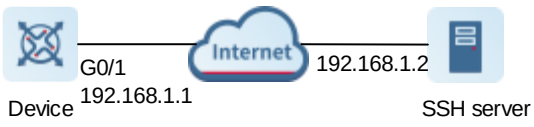
(4) In the Ubuntu shell environment, verify that the **file1.txt** file has been downloaded.

```
root@ubuntu:~# ls -l file1.txt
-rwxr--r-- 1 root root 14 Apr 2 10:00 file1.txt
```

6. Configuration Files

```
!
```

```
user-account hostname1 password 7 $10$2fe$Rd/C4ijEl+UN$
!
enable-server service ssh-server
!
ip scp-server set enable
!
line console 0
line vty 0 4
 line-login local
!
```



1.10.6 Configuring SSH Client

1. Requirements

When the device serves as an SSH client, the device can log in to the SSH server through SSH.

2. Topology

Figure 1-6 Configuring SSH Client

3. Notes

- Configure a valid user on the SSH server.
- Run the **ssh-server** command to log in to the SSH server.

4. Procedure

(1) Configure a valid user on the SSH server. (For details, see the SSH server configuration.)

(2) Run the **ssh-server** command to log in to the SSH server.

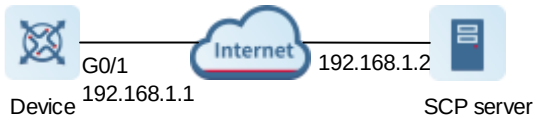
```
Device> privilege
Device# ssh -l admin 192.168.1.2
```

5. Verification

- Verify that the device logs in to the SSH server successfully.

```
Device# ssh -l hostname1 192.168.1.2
%Trying 192.168.1.2, 22,...open
hostname1@192.168.1.2's password:

Last login: Apr 2 2021 10:00:00 from 192.168.1.1 through ssh.
```



1.10.7 Configuring SCP Client

1. Requirements

When the device serves as an SCP client, the device can run the **scp** command to upload files to and download files from the SCP server.

2. Topology

Figure 1-7 Configuring SCP Client

3. Notes

- Configure a valid user on the SCP server.
- Run the **scp** command to upload files to or download files from the SCP server.

4. Procedure

(1) Configure a valid user on the SCP server. For details, see the SCP server configuration.

(2) Run the **scp** command to copy **file.txt** from the SCP server to the flash memory of the device.

```
Device> privilege
Device# scp hostname1@192.168.1.2:/file.txt flash:/file.txt
```

(3) Run the **scp** command to copy local file **file.txt** from the device to the SCP server.

```
Device> privilege
Device# scp hostname1@192.168.1.2:/file.txt flash:/file.txt
```

5. Verification

- Verify that the file on the SCP server is successfully copied to a local directory.

```
Device# scp oob flash:/file.txt hostname1@192.168.1.2:/file.txt

%Trying 192.168.1.2, 22,...open
hostname1@192.168.1.2's password:
Press Ctrl+C to quit
!
Transmission success.
```

- Verify that the local file is successfully copied to the SCP server.

```
Device# scp hostname1@192.168.1.2:/file.txt flash:/file.txt

%Trying 192.168.1.2,...open
hostname1@192.168.1.2's password:
Press Ctrl+C to quit
!
Transmission success.
```

1.10.8 Configuring SFTP Server

1. Requirements

The device functions as the SFTP server to receive file upload and download commands from the SFTP client.

2. Topology

Figure 1-8 Topology for Configuring the SFTP Server

3. Notes

- Enable the SSH service and configure the username and password.
- Enable the SFTP server function.

4. Procedure

(1) Enable the SSH service.

```
Device> privilege
Device# config-system terminal
Device(cfg)# enable-server service ssh-server
Device(cfg)# username aaa password Ruijie.123
```

(2) Enable the SFTP server function.

```
Device(cfg)# ip sftp server enable
```

(3) Connect the PC to the SFTP server using the SFTP client or the **sftp** command.

```
PC> sftp aaa@192.168.1.1
Connected to 192.168.1.1.
sftp>
```

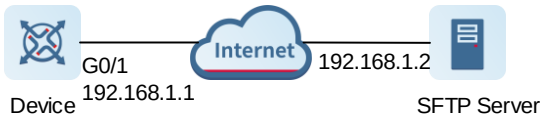
5. Verification

- Run the **ls** command to check the files in the device directory.

```
sftp> ls -l
drwxrwxrwx       2 root         root                160 Dec 17    2020 addr
drwxr-xr-x       3 root         root                224 Dec 17    2020 cmpnt
-rw-rw-rw-       1 root         root              10162 Aug    8 15:30 config.text
-rw-r--r--       1 root         root               9002 Oct 22    2021 config.text.bak
-rwxrwxrwx       1 root         root                171 Aug    8 15:30 config_vsu.dat
......
sftp>
```

- Check that files are downloaded to the device directory.

```
sftp> get config.text
Fetching /data/config.text to config.text
/data/config.text                                  100% 2295KB     6.4MB/s     00:00
sftp>
```



1.10.9 Configuring SFTP Client

1. Requirements

The device functions as the SFTP client. The **sftp** command can be used to establish a connection for accessing the console to upload files to and download files from the SFTP server.

2. Topology

Figure 1-9 Topology for Configuring the SFTP Client

3. Notes

- Configure users on the SFTP server.
- Run the **sftp** command to connect the device to the SFTP server and access the console.
- Run the **put** and **get** commands to upload and download files.

4. Procedure

(1) Configure available users on the SFTP server. (The configuration is omitted. For details, see the *SFTP Server User Manual*.)

(2) Run the **sftp** command on the device to access the client console.

```
Device> privilege
Device# sftp admin@192.168.1.2
%Trying 192.168.1.2, 22,...open
admin@192.168.1.2's password:
Connected to 192.168.1.2:22.
sftp>
```

(3) Run the **get** command to copy the **file.txt** file from the SFTP server to the flash drive of the device.

```
sftp> get file.txt
```

(4) Run the **put** command to copy the local file **file.txt** to the SFTP server.

```
sftp> put file.txt
```

5. Verification

- Check that the file on the SFTP server is copied to the local device.

```
sftp> get file.txt
Fetching /home/admin/file.txt to file.txt
```

```
/home/admin/file.txt                          100% 2295KB     1.7MB/s   00:00
sftp>
```

- Check that the local file is copied to the SFTP server.

```
sftp> put file.txt
Uploading file.txt to /home/admin/file.txt
file.txt                                      100% 2295KB     1.5MB/s   00:00
sftp>
```

1.8.1 Configuring Basic Functions of CPP 11

1 Configuring CPP

1.1 Introduction

1.1.1 Overview

Many malicious attacks exist in the network environment. CPU attack packets significantly increase the CPU usage of a device, which affects the CPU to process and respond to the CPU to normal services and thus causes device function exceptions. CPU protect policy (CPP) protects the CPU of a device. By controlling the traffic of different types of packets sent to the CPU of the device and scheduling their priorities, users can defend against malicious attacks in the network and ensure that the CPU processes normal protocol packets.

1.1.2 Basic Concepts

1. QoS

As a network security mechanism, Quality of Service (QoS) is a technology that is used to solve network delay and congestion.

Differentiated Service (DiffServ) is a typical model of QoS that provides different services to packets by classifying service streams.

2. Bandwidth

Bandwidth specifies the maximum data transmission rate and the rate threshold for packet transmission in this document. When the data transmission rate exceeds the bandwidth, packets beyond the bandwidth are discarded. Therefore, the transmission rates of different types of packets must be equal to or smaller than the bandwidth. Both the bandwidth and data transmission rate use the unit of packets per second (pps).

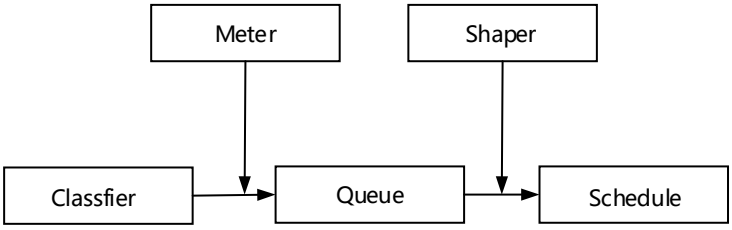
3. L2/L3/L4

L2/L3/L4 means a hierarchical structure of packets based on the TCP/IP model. L2 means layer-2 headers, namely, the Ethernet encapsulation part; L3 means layer-3 headers, namely, the IP encapsulation part; L4 means layer-4 headers, usually, the TCP/UDP encapsulation part.

4. Priority Queue

The strict priority (SP) queue scheduling algorithm is a QoS scheduling algorithm. This scheduling algorithm requires packets to be processed based on the queue priority from high to low. The CPU must process first the packets in a high-priority queue and then those in a low-priority queue.

Packets to be sent to the CPU are cached in the SP queue and scheduled according to the algorithms of the SP queue. Packet scheduling is the process of selecting and transmitting packets in a priority queue to the CPU.



5. CPU Interface

A device caches packets before it sends them to the CPU. Sending the packets to the CPU is similar to a packet output process from the port. The CPU port is a virtual port through which packets are sent to the CPU. The priority queue and SP queue scheduling algorithms apply to only data packets that are transmitted through this CPU port.

1.1.3 Processing Process

The CPP function protects the CPU by using the standard QoS DiffServ model.

Figure 1-1 CPP Implementation Model

1. Classifier

The classifier classifies all packets to be sent to the CPU by the L2, L3 and L4 information of the packets. Classifying packets is the basis for implementing QoS policies. In subsequent actions, CPP can, according to the classification, implement different policies and provide different services. Packets on a device are classified by the supported protocols and management functions, for example, Bridge Protocol Data Unit (BPDU) packets of Spanning Tree Protocol (STP) and packets of Internet Control Message Protocol (ICMP). Packet types cannot be customized.

Note

Packet classification varies with products due to hardware difference. For details, see *Specifications* for details.

2. Meter

The meter limits the rates of different types of packets based on the set rate thresholds. You can set different rate thresholds for various packet types. When the rate of a packet type exceeds the threshold, the packets beyond the threshold are discarded.

By using the meter, you can control the rate of a packet type sent to the to the CPU within a threshold to prevent specific attack packets from exerting great impacts on the CPU resources. This is the level-1 protection of CPP.

3. Queue

Queues are used to classify packets at level 2. You can select the same queue for different packet types; queues cache packets in a device and provide services for the scheduler and shaper.

CPP queues are SP queues. The SPs of the packets are determined based on the time when they are added to a queue. Packets with a larger queue number have a higher priority.

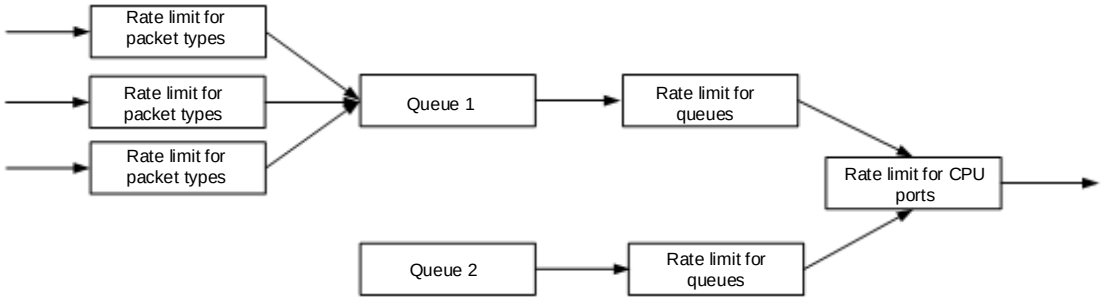
4. Scheduler

The scheduler schedules packets based on SPs of queues. Packets in a high-priority queue are first scheduled.

Before being scheduled, the packets to be sent to the CPU are cached in queues. When being scheduled, the packets are sent to the CPU for processing.

Note

Only the SP scheduling policy is supported and cannot be modified.



5. Shaper

The shaper shapes the packets to be sent to the CPU. When the actual rate of packets is greater than the shaping threshold, the packets must continue to cache in the queue and cannot be scheduled. When packet rates fluctuate, the shaper ensures that the rates of packets sent to the CPU are smooth (not more than the shaping threshold).

When the shaper is available, packets in a low-priority queue may be scheduled before those in a high-priority queue. If the rate of packets in a queue with a priority exceeds the shaping threshold, scheduling of the packets in this queue is stopped temporarily. Therefore, the shaper can prevent only the packets in high-priority queues from being scheduled.

Since the shaper limits the scheduling rates of packets, it provides the rate limit function. The shaper provides level-2 rate limit for priority queues and all packets sent to the CPU (CPU port). The shaper and meter functions provide 3-level rate limit and level-3 protection for the CPU.

Figure 1-2 3-Level Rate Limit of CPP

1.2 Configuration Task Summary

CPP configuration includes the following tasks:

- Notes
- Table 1-1 describes CPP functions supported by different products.

Table 1-1 CPP Functions Supported by Different Products

Function	Product Supporting the Function
Configuring Automatic Protection Function	S6980-64QC and S6580-24DC8QC
Configuring Automatic Protection Function for Ports	S6980-64QC and S6580-24DC8QC

- Configuring Basic Attributes of CPP
- Configuring Alarm Print Function of CPP
- Configuring Automatic Protection Function
- Configuring Automatic Protection Function for Ports

1.3 Notes

Table 1-1 describes CPP functions supported by different products.

Table 1-2 CPP Functions Supported by Different Products

Function	Product Supporting the Function
Configuring Automatic Protection Function	S6980-64QC and S6580-24DC8QC
Configuring Automatic Protection Function for Ports	S6980-64QC and S6580-24DC8QC

1.4 Configuring Basic Attributes of CPP

1.4.1 Overview

The implementation model of CPP includes five basic functional components: classifier, meter, queue, scheduler, and shaper. A device uses fixed classification policies for the classifier and SP scheduling algorithms for the scheduler.

In different network scenarios, users can configure personalized CPPs based on the meter, queue, and shaper to prevent packet attacks and network flapping from affecting normal operation of the CPU of a device.

- Configure a bandwidth for a specific packet type based on the meter to limit the packet transmission rate. Packets beyond the bandwidth are directly discarded.
- Configure a priority queue for a specific packet type based on the queue function. Packets in a high-priority queue are scheduled first.
- Configure a bandwidth for a CPU port and that for a specific priority queue to limit the packet transmission rate. Packets beyond the bandwidth are directly discarded.

1.4.2 Restrictions and Guidelines

- In one of the following situations, you must adjust the bandwidth for a specific packet type:
  - If a type of packets are discarded though they do not initiate attacks, you must increase the bandwidth for this packet type.
  - If a type of packets initiate attacks and cause CPU running exception, you must decrease the bandwidth for this packet type.
- In one of the following situations, you must adjust the priority queue for a specific packet type:
  - If a type of packets initiate attacks and cause exception in other packets in the same queue, you may put this type of packets into an unused queue.
  - A type of packets may not be discarded, and they are in the same queue with other types of packets in use. To prevent the bandwidth for other types of packets in the same queue from discarding packets, you can put this type of packets into a high-priority queue.
- In one of the following situations, you must adjust the bandwidth for a priority queue:
  - If the bandwidth for a type of packets increases, causing the available bandwidth for other packets in the same priority queue to decrease, you must appropriately increase the bandwidth for this priority queue.

- If attack packets are put into a priority queue and no other packets in use stay in the same queue, you should decrease the bandwidth for this priority queue.

- When you configure a bandwidth for a specific packet type, note that decreasing the bandwidth may affect the normal service traffic of this packet type. To apply CPP based on users, use the NFPP function. For more information about NFPP configuration, see *Configuring NFPP*.
- The bandwidth configuration for a packet type must match the bandwidth configuration for a priority queue. For the three levels of CPU protection, applying only one level of protection may cause negative effects. For example, if you increase the bandwidth for a packet type, you must also adjust the bandwidth for its priority queue. Otherwise, the other packets in the same priority queue may be affected.
- You are not advised to modify the bandwidth of the CPU port.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the basic attributes of CPP, and configure at least one task.

- Configure a bandwidth for a packet type.

  cpu-protect type *packet-type* **bandwidth** *bandwidth-value*

  Each packet type has a rate threshold (bandwidth) by default, and this rate threshold may be modified, but may not be removed.

- Configure a priority queue for a packet type.

  cpu-protect type *packet-type* **traffic-class** *traffic-class-number*

  Each packet type has a priority queue by default.

  The default priority queues for packet types depend on the actual product version.

- Configure a bandwidth for a priority queue.

  cpu-protect traffic-class *traffic-class-number* **bandwidth** *bandwidth-value*

  A shaping threshold (bandwidth) is determined for each priority queue by default, and this shaping threshold may be modified, but may not be removed.

- Configure a bandwidth for the CPU interface.

  cpu-protect cpu bandwidth *bandwidth-value*

  No bandwidth is configured for a CPU port by default.

1.5 Configuring Alarm Print Function of CPP

1.5.1 Overview

After the alarm print function of CPP is enabled, you can view the alarm logs of lost packets and detect packet attacks to the CPU of the device timely. For the normal service packets that are discarded falsely, you can adjust the CPP configuration to avoid subsequent packet loss.

The configuration effect of the alarm print function is as follows:

- After the alarm print function is enabled for a packet type, the corresponding alarm log is printed if packets of this type are lost.
- After the alarm print function is enabled for a priority queue, the alarm log is printed if packets in this queue are lost.
- After an alarm period is configured, a device periodically detects the lost packets sent to the CPU, and the alarm is printed only once for the packet loss in this specified period.

1.5.2 Restrictions and Guidelines

- You can configure the alarm print function with two methods. Select either of them to validate this function. Commands configured between the configuration methods produce the same function effect. If they are configured, the later configured command takes effect. To facilitate management, you are advised to adopt one configuration method.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an alarm period of CPP. Please configure only one task.

- **cpu-protect alarm period** *period-value*
- **cpp-warn warn-period** *interval*

The default alarm period of CPP is **10** minutes.

(4) Enable the alarm print function for a packet type. Please configure only one task.

- **cpu-protect alarm type** *packet-type* **enable**
- **cpp-warn type** *packet-type* **warn**

The alarm print function for packets is not enabled by default.

(5) Enable the alarm print function for a queue. Please configure only one task.

- **cpu-protect alarm traffic-class** *traffic-class-number* **enable**
- **cpp-warn traffic-class** *traffic-class-number* **warn**

The alarm print function for priority queues is not enabled by default.

1.6 Configuring Automatic Protection Function

Note

Only S6980-64QC and S6580-24DC8QC support configuration of automatic protection.

1.6.1 Overview

The automatic protection function allows a device to protect the application layer data based on sessions. The function ensures the normal operation of attacked services.

- After the automatic protection function is enabled based on packet types, the dynamic link protocol packets of the service module can get sufficient signaling to reduce protocol flapping when the packets are attacked.
- After it configures a domain for the customized security packet type, the function allows the matched security packets to get sufficient signaling to reduce protocol flapping when the packets are attacked.
- After it configures bandwidth for user trust packets, the function allows the trust packets to get sufficient signaling for forwarding, and limits the excessive bandwidth occupied by the packets.

1.6.2 Restrictions and Guidelines

- When the hardware capacity is insufficient, the whitelist entries configured by the Command Line Interface (CLI) or automatically delivered by services fail to be installed. A syslog is printed through the FP component on the device to indicate an entry capacity problem. Finally, the packet whitelist becomes invalid.
- You can enable the automatic protection function of protocol packets either in global configuration mode or for a packet type. If you do not configure the automatic protection function for a packet type, the global configuration of the automatic protection function prevails. If you configure the automatic protection function for a packet type, the configuration for this packet type prevails and the global configuration is not used.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the automatic protection function for protocol packets.

cpu-protect auto-defend [**type** *packet-type*] **enable**

When protocol flapping occurs frequently for a packet type, you can attempt to enable the automatic protection function for this packet type to prevent these packets from being affected by other protocol packets.

The automatic protection function for the dynamic routing protocol packets is disabled by default.

(4) Configure a trust packet type.

cpu-protect auto-defend trusted-host type *packet-type* { **src-ip** *ipv4-addres* | **src-ip6** *ipv6-address* | **src-mac** *mac-address* }

Each service is configured with a default trust packet type by default.

(5) Configure a bandwidth for packets under automatic protection.

cpu-protect auto-defend type *packet-type* **bandwidth** *value*

The bandwidth for trust packets under automatic protection is **80%** of the global bandwidth by default.

1.7 Configuring Automatic Protection Function for Ports

Note

Only S6980-64QC and S6580-24DC8QC support configuration of automatic protection for ports.

1.7.1 Overview

If a packet attack occurs on a port, the attack packets sent to the CPU through this port occupy bandwidth. As a result, other protocol packets cannot be sent to the CPU for processing and thus services are interrupted.

The automatic protection function can defend against packet attacks to CPU ports. The implementation effect is as follows:

- After the automatic protection function for a port is enabled, a device can detect packet attacks on this port.
- After it configures an automatic protection attack threshold for a port that transmits protocol packets, this function allows the packets to have sufficient signaling for forwarding and limits the excessive bandwidth occupied by the packets.
- After it configures a blacklist to impose a rate limiting threshold for the ports in the blacklist, this function allows service packets to get sufficient bandwidth on other ports.
- After it configures a monitoring period for a port, this function limits the rates of attack packets on this port within the period. After the period, this function limits the rates of attack packets if the protocol packets received on this port remain in excess of the attack threshold. Otherwise, the limit is removed.
- After the attack alarming function is enabled on a port, syslogs are generated and Simple Network Management Protocol (SNMP) Trap messages are sent when attacks occur or are cleared. The alarm message is triggered when they occur or are cleared. The alarm is not given repeatedly during a monitoring period.

1.7.2 Restrictions and Guidelines

- When the default hardware capacity is insufficient, the blacklist entries fail to be installed. A syslog is printed through the FP component on the device to indicate an entry capacity problem. Finally, the rate limit by the hardware may become ineffective and must be reconfigured by software.
- To detect a specific network environment, you can enable the packet statistics function on a port and check attacks based on the packet statistics. If any, enable the automatic protection function on the port and configure an attack threshold and a rate limiting threshold based on the environmental configuration.
- The blacklist can take effect on a port only when the automatic protection function is enabled on this port.
- You can enable the automatic protection function in global configuration mode or for a port. If you do not configure the automatic protection function for a port, the global configuration of the automatic protection function prevails. If you configure the automatic protection function for a port, the configuration for this port prevails and the global configuration is not used.
- You can configure the packet penalty threshold for an attacked port in global configuration mode or for a specific packet type. If you do not configure the penalty threshold for a specific packet type, you impose a penalty threshold on packets in the global configuration mode when an attack is detected on a port. If you configure a penalty threshold for a specific packet type, the configuration for this packet type prevails.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the automatic protection function for a port.

cpu-protect auto-port-defend [**interface** *interface-type interface-number* | **interface range** *interface-type start-number end-number*] **enable**

The automatic protection function for a port is disabled by default.

(4) Configure an attack threshold for a packet type under automatic protection on a port.

cpu-protect auto-port-defend type *packet-type* **attack-threshold** *threshold-value*

No attack threshold is configured for a packet type under automatic protection on a port by default.

(5) Configure a rate limiting threshold for all packets on an attacked port.

cpu-protect auto-port-defend limit threshold *threshold-value*

In the monitoring period, a rate limiting threshold will be applied to a port if an attack is detected on the port.

The rate limiting threshold for all packets on an attacked port is **5%** of the bandwidth for this interface by default.

(6) Configure a rate limiting threshold for specific packets on an attacked port.

cpu-protect auto-port-defend limit type *packet-type* **threshold** *threshold-value*

In the monitoring period, a rate limiting threshold is applied to the specific packets on a port if an attack is detected on the port.

The rate limiting threshold for specific packets on an attacked port is **5%** of the bandwidth for the port packets by default.

(7) Configure a blacklist for a port.

cpu-protect auto-port-defend blacklist interface *interface-type interface-number*

If a port that normally sends and receives packets is not identified as an attack interface, but affects traffic of services, you can add this port to a blacklist to reduce the traffic of this port.

A port is a trust port and is not in the blacklist by default.

(8) Configure a monitoring period for a port.

cpu-protect auto-port-defend monitor-period *value*

The default attack monitoring period of a port is **300** seconds.

(9) Enable the attack alarm function for a port.

cpu-protect auto-port-defend alarm enable

The attack alarm function for a port is disabled by default. After an attack occurs or is cleared, syslogs are not output and SNMP Trap messages are not sent to prompt users.

1.8 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

⚠ Caution

- Running the **cleanup** command may lose vital information and thus interrupt services.
- The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
cleanup cpu-protect counters [**device** *device-number*] [**slot** *slot-number*]	Clears CPP statistics.
cleanup cpu-protect counters mboard	Clears the CPP statistics on the master device.
cleanup cpu-protect statistics [**interface** *interface-type interface-number*]	Clears the CPP statistics on an interface.
display cpu-protect type *packet-type* [**device** *device-number*] [**slot** *slot-number*]	Displays the configuration and statistics of a packet type.
display cpu-protect traffic-class *traffic-class-number* [**device** *device-number*] [**slot** *slot-number*]	Displays the configuration and statistics of a priority queue.
display cpu-protect cpu	Displays the configuration on the CPU port.
display cpu-protect { **mboard** | **summary** }	Displays all the configuration and statistics on the master device.
display cpu-protect [**device** *device-number*] [**slot** *slot-number*]	Displays all the configuration and statistics of CPP.
display cpu-protect statistics [**interface** *interface-type interface-number*]	Displays the statistics on a CPP port.
display cpu-protect statistics type *packet-type*	Displays the statistics of a packet type on a CPP port.
display cpu-protect auto-defend	Displays automatic protection configuration and whitelist packet statistics.
display cpu-protect auto-defend summary	Displays the automatic protection configuration.
display cpu-protect auto-defend config	Displays the trust packet configuration.
display cpu-protect auto-port-defend	Displays the blacklist configuration on a port.
display cpu-protect auto-port-defend statistics	Displays the blacklist statistics on a port.
display cpu-protect auto-port-defend summary	Displays the automatic protection configuration on a port.
display cpu-protect auto-port-defend attacked summary	Displays the packet attack information on a port.
display cpu-protect linkage summary	Displays the protocol correlation state.

Note

The above monitoring command is compatible with chassis devices and cassette devices, as well as the standalone mode and VSU mode.

If the **device** and **slot** keywords are not entered, the **cleanup** command is used to clear the statistics of all nodes and interfaces in the system and the **display** command is used to display the configuration on the master device.

In the stand-alone mode, the **device** keyword is invisible. For chassis devices, the **slot** keyword is used to specify a line card; for cassette devices, the **slot** keyword is invisible.

In the VSU mode, the **device** keyword specifies a chassis or cassette device. If the **device** keyword is not entered, it specifies the master chassis or the master device. For chassis devices, if the **device** keyword is entered, the **slot** keyword must also be entered to mark a line card in a chassis; for cassette devices, the **slot** keyword is invisible.

Note

Only S6980-64QC and S6580-24DC8QC can display automatic protection-related configurations, allowlist packet statistics, automatic protection configuration, trusted packet configuration of automatic protection, blocklist configuration and statistics of automatic protection for ports, automatic protection configuration for ports, and protocol attack information of automatic protection for ports.

1.9 Configuration Examples

1.9.1 Configuring Basic Functions of CPP

1. Requirements

Address Resolution Protocol (ARP), IP, Open Shortest Path First (OSPF), dot1x, Virtual Router Redundancy Protocol (VRRP), Telnet and ICMP streams are available in the system. In the current configuration, ARP and dot1x streams are in priority queue 2; IP, ICMP and Telnet streams are in priority queue 4; OSPF streams are in priority queue 3; and VRRP streams are in priority queue 6. The bandwidth for each packet type is 10,000 pps; the bandwidth for each priority queue is 20,000 pps; and the bandwidth for the CPU port is 100,000 pps. If the device suffers ARP packet attacks, you must enable the CPP function to prevent the packet attacks and network flapping and ensure the normal running of other services on the device.

2. Notes

- Classify ARP attack packets into priority queue 1 and limit the bandwidth for ARP packets or the priority queue.
- Classify OSPF packets into priority queue 5.
- Classify IP attack packets (without the ARP entries) into priority queue 3 and limit the bandwidth for IP packets or the priority queue.

3. Procedure

Configure the basic attributes of CPP.

```
DeviceA> privilege
```

```
DeviceA# config-system terminal
DeviceA(cfg)# cpu-protect type arp traffic-class 1
DeviceA(cfg)# cpu-protect type arp bandwidth 5000
DeviceA(cfg)# cpu-protect type ospf traffic-class 5
DeviceA(cfg)# cpu-protect type v4uc-route traffic-class 3
DeviceA(cfg)# cpu-protect traffic-class 3 bandwidth 5000
DeviceA(cfg)# end
```

4. Verification

Run the **display cpu-protect** command to view the configuration and statistics.

```
DeviceA# display cpu-protect
%cpu port bandwidth: 100000(pps)
Traffic-class     Bandwidth(pps)    Rate(pps)    Drop(pps)
-------------     --------------    ---------    ---------
 0                20000             0            0
 1                20000             0            0
 2                20000             0            0
 3                5000              0            0
 4                20000             0            0
 5                20000             0            0
 6                20000             0            0
 7                20000             0            0
Packet Type            Traffic-class    Bandwidth(pps)    Rate(pps)    Drop(pps)    Total          Total Drop

1 Configuring NFPP

1.1 Introduction

1.1.1 Overview

Many malicious attacks exist in the network environment. If no protection policies are available, attack packets occupy the CPU resources of a device. As a result, the CPU cannot process normal protocol packets and control packets and the device does not normally run. The network foundation protection policy (NFPP) protects devices from attacks and keeps a low CPU load for the devices under attack to ensure normal operation of services and stable operation of the entire network.

1.1.2 Basic Concepts

1. ARP Guard

In a LAN, the Address Resolution Protocol (ARP) can parse an IP address into a MAC address to ensure smooth communication. The Denial of Service (DoS) is a process of sending many invalid ARP packets to a gateway in a network to cause the gateway not to provide services for normal hosts. To avoid this type of attacks, configure a rate limiting threshold for the ARP packets and isolate the source of the attack.

2. IP Guard

Hacking attack and network virus intrusion start at a host that scans network activities. Many scanned packets occupy network bandwidth and thus affect normal communication of the network. To avoid this type of attacks, we configure the IP guard function for a device. This function also reduces the CPU usage of the device. IP attacks include the following two types:

- Scan changes in the destination IP address. This type of attacks consume network bandwidth and increase device load. This indicates most of upcoming hacking attacks.
- Send IP packets to an unconfigured destination IP address. This attack is designed for the CPU of a device. On an L3 device, if a destination IP address is configured, packets are forwarded by the chip without consuming CPU resources. Otherwise, the packets are sent to the CPU and the latter sends ARP requests to request the MAC address of the destination IP address. If too many packets sent to the CPU, this consumes many CPU resources. To avoid this type of attacks, we configure a rate limiting threshold for the IP packets and isolate the source of the attack.

3. ARP Source Suppression

When IP packets are sent to an unconfigured destination IP address at a high rate, they are forwarded to the CPU, triggering the device to send ARP requests to request the MAC address of the destination IP address. If too many packets sent to the CPU, this consumes many CPU resources. To avoid this type of attacks, isolate the source of the attack and enable the function of ARP source suppression. If IP packets that trigger ARP requests exceed the threshold in the specified period, the IP packets out of the threshold are discarded.

4. TCP SYN Guard

TCP-SYN-Flood attack is also called half-open connection attack. An attacker sends SYN packets to the target device without responding to the SYN+ACK packets returned by the target device. If it does not receive the SYN+ACK responses, the target device waits and thus a half-open connection is formed. The attacker allows the target device to generate many half-open connections with this method, forcing the target device to waste resources on the half-open connections.

The available TCP connections of a server are limited. If a malicious attacker sends this type of connection requests consecutively in an attack, the available TCP connections of this server become congested. Thus, the available system resources and available bandwidth drop dramatically, affecting normal network services. Consequently, a DoS occurs.

To avoid the TCP-SYN-Flood attack, configure the TCP SYN guard function on the device to limit the sending rates of TCP SYN packets.

5. ICMP Guard

The Internet Control Message Protocol (ICMP) is a common means of network fault diagnosis. According to the principle of ICMP, when a host sends an ICMP Echo Request packet, the receiver returns an ICMP Echo Reply upon receipt of the packet. This process requires CPU coordination. If an attacker sends many ICMP requests to the target device, many CPU resources are consumed, which may interrupt normal device operation in extreme conditions. This is called an ICMP flood attack. To avoid it, configure a rate limiting threshold for the ICMP packets and isolate the source of the attack.

6. DHCP Guard

The Dynamic Host Configuration Protocol (DHCP) is widely used in a LAN to dynamically assign IP addresses. A DHCP starvation attack is the most popular DHCP attack that broadcasts DHCP requests by using a false MAC address. When a network attacker sends enough DHCP requests, it can exhaust the address space of the DHCP server within a period. In this case, the legal host fails to request IP addresses from the DHCP server and thus cannot access a network. To avoid this type of attacks, configure a rate limiting threshold for the DHCP packets and isolate the detected source of the attack.

7. DHCPv6 Guard

DHCPv6 is widely used in a LAN to dynamically assign IPv6 addresses. Like DHCPv4, DHCPv6 has security problems. Therefore, the attack methods of DHCPv4 are applicable to DHCPv6. When a network attacker sends enough DHCPv6 requests, it can exhaust the address space of the DHCPv6 server within a period. In this case, the legal host fails to request IPv6 addresses from the DHCP server and thus cannot access a network. To avoid this type of attacks, configure a rate limiting threshold for DHCPv6 packets and isolate the detected source of the attack.

8. ND Guard

Neighbor discovery (ND) parses addresses, discovers routes and prefixes, and redirects routes in an IPv6 network. A ND process involves five types of packets: Neighbor Solicitation (NS), Neighbor Advertisement (NA), Router Solicitation (RS), Router Advertisement (RA), and Redirect packets. The five types of packets are called ND packets collectively.

ND Snooping listens to ND packets in a network, filters out invalid ND packets, and monitors IPv6 users and binds these users to ports to avoid theft of IPv6 addresses. ND Snooping requires ND packets to be sent to the

CPU. If they are sent at a high rate, this initiates an attack on the CPU. Therefore, we must configure ND guard to limit the rates of ND packets.

9. Customized Guard

There are many types of network protocols, including routing protocols such as OSPF, BGP, and RIP. To exchange packets between devices running different protocols, the packets must be sent to the CPU and processed by the protocol. Each protocol running on a device gives attackers a chance to initiate attacks. If an attacker sends many protocol packets to a network device, this consumes many CPU resources of the device, even affecting device operation.

Network protocols are diverse and grow constantly. Different protocols are demanded in different user environments. Therefore, protocol-specific guard functions have some limitations. To avoid this type of attacks, configure the customized guard function for the device to allow users to flexibly define and configure guard types to meet guard requirements in different user environments.

1.1.3 Rate Limiting Threshold and Attack Identification for Hosts

By configuring a rate limiting threshold for attack packets of hosts, a device can identify different attack scenarios such as host attacks, ARP scanning, and IP scanning. Host attacks can be identified in the following ways:

- Identify hosts according to the source IP address, VLAN ID, and port.
- Identify hosts according to the source MAC address, VLAN ID, and port on the link layer.

Each host is configured with a rate limiting threshold and an attack or attack threshold. The rate limiting threshold must be smaller than the attack threshold.

- If a single host sends attack packets at a rate higher than the rate limiting threshold, packets out of the threshold are discarded.
- If a single host sends attack packets at a rate higher than the attack threshold, the host behavior is identified as an attack and recorded into the log. Meanwhile, a Trap message is sent.
- If the received ARP packets exceed the scanning threshold in the configured period, the source MAC address in the packets is unchanged and the source IP address is changing on the link layer, or the source MAC address and source IP address on the link layer are unchanged but the destination IP address is changing, an ARP scanning attack is suspected.
- If the received IP packets exceed the scanning threshold in the configured period and the source IP address in the packets is unchanged and the destination IP address is changing, an IP scanning attack is suspected.

Note

- When NFPP detects attacks of a specific packet type, NFPP can send an alarm message to users. To avoid frequent alarm messages, NFPP does not resend an alarm within 60 seconds running after the message is generated.
- To prevent frequent log printing from consuming CPU resources, NFPP writes attacks related log content into the buffer and prints the log content from the buffer at the specified rate. NFPP does not limit the rates of Trap messages.
- Only ARP guard and IP scanning guard support the scanning prevention function.

1.1.4 Rate Limiting and Attack Identification for Ports

Each port is configured with a rate limiting threshold and an attack threshold. The rate limiting threshold must be smaller than the attack threshold.

- If a single port sends packets at a rate higher than the rate limiting threshold, packets out of the threshold are discarded.
- If a single port sends packets at a rate higher than the attack threshold, the port behavior is recorded into the log. Meanwhile, a Trap message is sent.

1.1.5 Hardware Isolation

Hardware is isolated by the guard policy after an attack is detected. Isolation requires a filter of hardware. Attack packets from an isolated device are not sent to the CPU for processing to ensure normal operation of the device.

Hardware isolation falls into host based isolation and port-based isolation. The port-based isolation configures a rate limit for physical ports. Only ARP guard and ND guard support hardware isolation based on physical ports.

To isolate attackers, you must configure policies for hardware entries. Because hardware resources are limited, a log is printed to remind users when such resources are exhausted.

Note

Only ARP guard can be configured with the global isolation and forwarding function and the rate limit function for port-based isolation and forwarding.

1.1.6 Monitoring Time

Monitoring hosts can detect attacks in the system. If the isolation time is 0 (indicating no isolation), the guard module automatically monitors attackers through software based on the configured monitoring time. If the isolation time is not 0, the guard module isolates attackers through hardware.

During software monitoring, when the isolation time is configured as a non-zero value, the guard module automatically isolates the attackers under software monitoring through hardware and configures the timeout time of the software monitoring as the isolation time. The monitoring time takes effect only when the isolation time is 0.

1.1.7 Trust Host

To stop monitoring a host is to trust the host. You can configure the host as a trusted host to allow it to send packets to the CPU.

1.2 Configuration Task Summary

NFPP configuration includes the following tasks:

(1) Configuring ARP Guard

(2) Configuring IP Guard

(3) Configuring TCP-SYN Guard

(4) Configuring ICMP Guard

(5) Configuring DHCP Guard

(6) Configuring DHCPv6 Guard

(7) Configuring ND Guard

(8) Customizing Guard

(9) Disabling Guard

(10) Configuring NFPP Logs

1.3 Configuring ARP Guard

1.3.1 Overview

ARP guard is used to detect, process, and prevent ARP based packet attacks. It includes the following functions:

- Identify ARP attacks based on hosts or physical ports. This function can determine an attack host based on the source IP address/MAC address (link layer), VLAN ID, and physical port. A rate limiting threshold and an attack threshold can be configured for each attack identification method. When the ARP packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the ARP packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent to remind users of ARP attacks.
- Identify ARP scanning attacks. For the ARP packets received within 10 seconds, if the source MAC address is unchanged and the source IP address is changing on the link layer, or the former and source IP address on the link layer are unchanged but the destination IP address is changing more than the specified scanning threshold of times, an ARP scanning attack is suspected and an alarm is printed to remind users.
- Suppress the ARP source. In this type of attacks, ARP requests are triggered through IP packets to consume CPU resources. If the number of IP packets with inexistent destination IP address exceeds the threshold in the specified period, the IP packets out of the threshold are discarded.
- Isolate the source of ARP attacks based on hosts or ports.
  - This function configures hardware entries to isolate the identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
  - After isolation takes effect, you can enable the isolation forwarding function to limit the isolation range so that only the management plane of the target CPU is isolated and packets on the data plane are still forwarded.
  - If the port-based isolation entries take effect, the default action is to discard all attack packets. After you enable the function of port-based rate limit forwarding, you can allow some of packets to pass through by changing the isolation action.
- Monitor host attacks through software. After this function guard identifies any attacks, it can monitor the attack host through software in the configured monitoring time.

1.3.2 Restrictions and Guidelines

- ARP guard is to solve the ARP DoS attacks on a device. This function can reduce the impact of this type of attacks on the device, but does not cope with ARP spoofing attacks or ARP attacks in a network.
- If this function is configured in global configuration mode and interface configuration mode, the interface

configuration prevails. For example, if the ARP guard function is enabled on an interface and then disabled in global configuration mode, the function remains effective on this interface.

- After the ARP guard function is disabled, the system automatically clears the entries related to the monitored hosts, scanning hosts, and isolated ports.
- The rate limiting threshold configured based on a MAC address has a higher priority than that configured based on an IP address, and the rate limiting threshold configured based on an IP address has a higher priority than that configured based on a port. To optimize the ARP guard effect, users are advised to configure rate limiting thresholds and attack thresholds for hosts based on the following rules:
  Attack threshold based on source MAC address > Rate limiting threshold based on source MAC address > Attack threshold based on IP address > Rate limiting threshold based on IP address
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- An ARP scanning table can store only 256 latest records. When the ARP scanning table is full, new records overwrite old ones. ARP scanning attacks may be misjudged. Therefore, when ARP guard does not isolate a detected host that is suspected to initiate an ARP scanning attack, this function only provides some information for the reference of users.
- ARP source suppression conflicts with the isolation function of IP guard scan. If the latter is enabled, you cannot enable the function of ARP source suppression.
- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:
  - If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
  - If you change the isolation time to 0 from a non-zero value, entries of the isolated attacker are directly deleted without monitoring the attacker through software.
- After you enable the isolation function, the recorded attack host occupies the security module entry.

  You are advised to configure an isolation interval of at least 180 seconds. When both port-based rate limiting and isolation are enabled, isolation will be triggered only when port-based rate limiting and isolation intervals expire.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.
  - When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.

1.3.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the function of global ARP guard.

arp-guard enable

The function of global ARP guard is enabled by default.

(5) (Optional) Configure the global isolation time of ARP guard.

arp-guard isolate-period [*interval* | **permanent**]

The default global isolation time of ARP guard is **0**, and the isolation function is disabled by default.

(6) (Optional) Enable the function of global isolation forwarding of ARP guard.

arp-guard isolate-forwarding enable

The function of global isolation forwarding of ARP guard is enabled by default.

Note

This command is not supported by S6580-24DC8QC.

(7) (Optional) Enable the function of port-based rate limit forwarding of ARP guard.

arp-guard speedlimit-forwarding enable

The function of port-based rate limit forwarding of ARP guard is disabled by default.

Note

This command is not supported by S6580-24DC8QC.

(8) Configure the monitoring time of ARP guard.

arp-guard monitor-period *interval*

The default monitoring time of ARP guard is **600** seconds.

(9) Configure the maximum number of monitored hosts of ARP guard in global configuration mode.

arp-guard monitored-host-limit *limit-number*

The maximum number of monitored hosts of ARP guard in global configuration mode is **20000** by default.

(10) Configure a global rate limiting threshold of ARP guard.

arp-guard speed-limit { **per-port** *speed-limit* | **per-src-ip** *speed-limit* | **per-src-mac** *speed-limit* }

The default global rate limiting thresholds of ARP guard for each interface, each source IP address, and each source MAC address are 1,000 pps, 30 pps, and 30 pps respectively on S6920-4C, S6510-48VS8CQ, S6250-48XS8CQ, and S6980-64QC.

(11) Configure a global attack threshold of ARP guard.

arp-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* | **per-src-mac** *attack-threshold* }

The default global attack thresholds of ARP guard for each interface, each source IP address, and each source MAC address are 2,500 pps, 1,500 pps, and 1,500 pps respectively on S6920-4C, S6510-48VS8CQ, S6250-48XS8CQ, and S6980-64QC.

(12) Configure a global scanning threshold of ARP guard.

arp-guard scan-threshold *scan-threshold*

The default global scanning threshold of ARP guard is 100 packets per 10 seconds.

(13) Enable the function of ARP source suppression.

arp-guard suppress-mode enable

The function of ARP source suppression is disabled by default.

(14) Configure a threshold of ARP source suppression.

arp-guard suppress-threshold *suppress-threshold*

The default threshold of ARP source suppression is **5** pps.

(15) Configure the period of ARP source suppression.

arp-guard suppress-period *interval*

No period of ARP source suppression is configured by default.

1.3.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the ARP guard function on an interface.

nfpp arp-guard enable

The ARP guard function is disabled on an interface by default.

(5) Configure the isolation time of ARP guard on an interface.

nfpp arp-guard isolate-period [*interval* | **permanent**]

No isolation time of ARP guard is configured on an interface by default. The global isolation time of ARP guard is used.

(6) Configure a rate limiting threshold and an attack threshold of ARP guard on an interface.

nfpp arp-guard policy { **per-port** *speed-limit attack-threshold* | **per-src-ip** *speed-limit attack-threshold* | **per-src-mac** *speed-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of ARP guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of ARP guard are used.

(7) Configure a local scanning threshold of ARP guard on an interface.

nfpp arp-guard scan-threshold *scan-threshold*

No local scanning threshold of ARP guard is configured on an interface by default. The global scanning threshold of ARP guard is used.

1.4 Configuring IP Guard

1.4.1 Overview

After the IP guard function is enabled, a device can detect several common types of IP attacks timely, and ensure its stable operation by rate limit and host isolation. IP guard includes the following functions:

- Identify IP attacks based on hosts or physical ports. This function can determine an attack host based on the source IP address, VLAN ID, and physical port. A rate limiting threshold and an attack threshold can be configured for each attack identification method. When the IP packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the IP packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent to remind users of IP attacks.
- Identify IP scanning attacks. For the IP packets received within 10 seconds, if the source IP address is unchanged and the destination IP address (not the local address) is changing more than the specified scanning threshold of times, an IP scanning attack is suspected and an alarm is printed to remind users.
- Isolate IP attackers based on hosts. This function configures hardware entries to isolate identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
- Monitor attack hosts through software.
  - After this function identifies any attacks, it can monitor the attack host through software in the configured monitoring time.
  - This function can configure a specified host as a trusted host based on its IP address so that the host is free from software monitoring and allowed to send packets to the CPU.

1.4.2 Restrictions and Guidelines

- IP guard is to solve IP attacks whose destination IP address is not a local IP address. If the destination IP address is a local IP address, the rates of IP packets are limited by the function of CPU protect policy (CPP).
- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails. For example, if the IP guard function is enabled on an interface and then disabled in global configuration mode, the function is still enabled on this interface.
- After the IP guard function is disabled, the system automatically clears the entries related to the monitored hosts.
- The rate limiting threshold configured based on a source IP address has a higher priority than that configured based on a port.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- The isolation function of IP guard conflicts with the function of ARP source suppression. Therefore, you cannot configure the two functions at the same time.

- If you enable them at the same time, you cannot configure the isolation time of IP guard.
- If you enable the function of ARP source suppression and configure the global or local isolation time for IP guard, you cannot enable the IP guard function.

To configure the isolation function of IP guard, make sure to disable the function of ARP source suppression.

- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:
  - If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
  - If you change the isolation time to 0 from a non-zero value, entries related to the isolated attacker are directly deleted without monitoring the attacker through software.
- After you enable the isolation function, the recorded attack host occupies the security module entry.

  You are advised to configure an isolation interval of at least 180 seconds. When both port-based rate limiting and isolation are enabled, isolation will be triggered only when port-based rate limiting and isolation intervals expire.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.
  - When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.
- IP guard can be configured with trusted hosts. When entries in the table of monitored hosts match the trusted hosts (their IP addresses are the same), the system automatically deletes the entries of the IP addresses. IP guard can be configured with a maximum of 500 trusted hosts.

1.4.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the global IP guard function.

ip-guard enable

The global IP guard function is enabled by default.

(5) (Optional) Configure the global isolation time of IP guard.

ip-guard isolate-period [*interval* | **permanent**]

The default global isolation time of IP guard is **0**, and the isolation function is disabled by default.

If the isolation function is enabled, attack host information occupies a hardware entry of the security module.

(6) Configure the monitoring time of IP guard.

ip-guard monitor-period *interval*

The default monitoring time of IP guard is **600** seconds.

(7) Configure the maximum number of monitored hosts of IP guard.

ip-guard monitored-host-limit *number*

The maximum number of monitored hosts of IP guard is **20000** by default.

(8) (Optional) Configure a global rate limiting threshold of IP guard.

ip-guard speed-limit { **per-port** *speed-limit* | **per-src-ip** *speed-limit* }

The default global rate limiting thresholds of IP guard for each interface and each source IP address are 100 pps and 20 pps respectively on S6920-4C, S6510-48VS8CQ, S6250-48XS8CQ, and S6980-64QC.

(9) Configure a global attack threshold of IP guard.

ip-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* }

The default global attack thresholds of IP guard for each interface and each source IP address are 400 pps and 200 pps respectively on S6920-4C, S6510-48VS8CQ, S6250-48XS8CQ, and S6980-64QC.

(10) Configure a global scanning threshold of IP guard.

ip-guard scan-threshold *scan-threshold*

The default global scanning threshold of IP guard is 100 packets per 10 seconds.

(11) (Optional) Configure the trusted hosts of IP guard.

ip-guard trusted-host *ipv4-address mask*

No host is configured as a trusted host of IP guard by default.

1.4.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the IP guard function on an interface.

nfpp ip-guard enable

The IP guard function is disabled on an interface by default.

(5) Configure the local isolation time of IP guard on an interface.

nfpp ip-guard isolate-period [*interval* | **permanent**]

No isolation time of IP guard is configured by default.

(6) Configure a local rate limiting threshold and a local attack threshold of IP guard on an interface.

nfpp ip-guard policy { **per-port** *speed-limit attack-threshold* | **per-src-ip** *speed-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of IP guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of IP guard are used.

(7) Configure a scanning threshold of IP guard on an interface.

nfpp ip-guard scan-threshold *scan-threshold*

No local scanning threshold of IP guard is configured on an interface by default. The global scanning threshold of IP guard is used.

1.5 Configuring TCP-SYN Guard

Note

This command is not supported by the S6920-4C, S6510-48VS8CQ, S6250-48XS8CQ, or S6510-32CQ.

1.5.1 Overview

An attacker can launch an attack against the device connected through TCP connections. To detect and prevent the TCP-SYN flooding attacks, you can enable the TCP-SYN guard function on the devices. TCP-SYN guard includes the following functions:

- Identify TCP-SYN attacks based on hosts or physical ports. This function can determine an attack host based on the source IP address, VLAN ID, and physical port. A rate limiting threshold and an attack threshold can be configured for each attack identification method. When the TCP-SYN packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the TCP-SYN packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent.
- Isolate TCP-SYN attackers based on hosts. This function configures hardware entries to isolate identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
- Monitor attack hosts through software.
  - After this function identifies any attacks, it can monitor the attack host through software in the configured monitoring time.
  - This function can configure a specified host as a trusted host of TCP-SYN guard based on its IP address so that it is free from software monitoring and allowed to send packets to the CPU.

1.5.2 Restrictions and Guidelines

- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- The rate limiting threshold configured based on a source IP address has a higher priority than that configured based on a port.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.

- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:
  - If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
  - If you change the isolation time to 0 from a non-zero value, entries related to the isolated attacker are directly deleted without monitoring the attacker through software.
- After you enable the isolation function, the recorded attack host occupies the security module entry.

  You are advised to configure an isolation interval of at least 180 seconds. When both port-based rate limiting and isolation are enabled, isolation will be triggered only when port-based rate limiting and isolation intervals expire.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.
  - When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.
- TCP-SYN guard can be configured with trusted hosts. When entries in the table of monitored hosts match the trusted hosts (their IP addresses are the same), the system automatically deletes the entries of the IP addresses. TCP-SYN guard can be configured with a maximum of 500 trusted hosts.

1.5.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the global TCP-SYN guard function.

tcp-syn-guard enable

Global TCP-SYN guard is enabled by default.

(5) (Optional) Configure the global isolation time of TCP-SYN guard.

tcp-syn-guard isolate-period [*interval* | **permanent**]

The default global isolation time of TCP-SYN guard is **0**, and the isolation function is disabled by default.

(6) Configure the monitoring time of TCP-SYN guard.

tcp-syn-guard monitor-period *interval*

The default monitoring time of TCP-SYN guard is **600** seconds.

(7) Configure the maximum number of monitored hosts of TCP-SYN guard.

tcp-syn-guard monitored-host-limit *number*

The maximum number of monitored hosts of TCP-SYN guard is **20000** by default.

(8) Configure a global rate limiting threshold of TCP-SYN guard.

tcp-syn-guard speed-limit { **per-port** *speed-limit* | **per-src-ip** *speed-limit* }

The default global rate limiting thresholds of TCP-SYN guard for each interface and each source IP address are 100 pps and 20 pps respectively on S6980-64QC, and not configured on S6920-4C, S6510-48VS8CQ, or S6250-48XS8CQ.

(9) Configure a global attack threshold of TCP-SYN guard.

tcp-syn-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* }

The default global attack thresholds of TCP-SYN guard for each interface and each source IP address are 400 pps and 200 pps respectively on S6980-64QC, and not configured on S6920-4C, S6510-48VS8CQ, or S6250-48XS8CQ.

(10) (Optional) Configure the trusted hosts of TCP-SYN guard.

tcp-syn-guard trusted-host *ipv4-address mask*

No host is configured as a trusted host of TCP-SYN guard by default.

1.5.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the TCP-SYN guard function on an interface.

nfpp tcp-syn-guard enable

The TCP-SYN guard function is not configured on an interface by default. The global TCP-SYN guard function is used.

(5) Configure the isolation time of TCP-SYN guard on an interface.

nfpp tcp-syn-guard isolate-period { *interval* | **permanent** }

No local isolation time of TCP-SYN guard is configured by default. The global isolation time of TCP-SYN guard is used.

(6) Configure the local rate limiting threshold and local attack threshold of TCP-SYN guard on an interface.

nfpp tcp-syn-guard policy { **per-port** *speed-limit attack-threshold* | **per-src-ip** *speed-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of TCP-SYN guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of TCP-SYN guard are used.

1.6 Configuring ICMP Guard

1.6.1 Overview

The ICMP guard function configured for a device is used to prevent an attacker from consuming system resources by sending many ICMP requests. ICMP guard includes the following functions:

- Identify ICMP attacks based on hosts or physical ports. This function can determine an attack host based on the source IP address, VLAN ID, and port. A rate limiting threshold and an attack threshold can be configured for each attack identification method. When the ICMP packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the ICMP packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent.
- Isolate ICMP attackers based on hosts. This function configures hardware entries to isolate identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
- Monitor attack hosts through software.
  - After this function identifies any attacks, it can monitor the attack host through software in the configured monitoring time.
  - This function can configure a specified host as a trusted host of ICMP guard based on its IP address so that it is free from software monitoring and allowed to send packets to the CPU.

1.6.2 Restrictions and Guidelines

- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- After the ICMP guard function is disabled, the system automatically clears the entries related to the monitored hosts.
- The rate limiting threshold configured based on a source IP address has a higher priority than that configured based on a port.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:
  - If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
  - If you change the isolation time to 0 from a non-zero value, entries related to the isolated attacker are directly deleted without monitoring the attacker through software.
- After you enable the isolation function, the recorded attack host occupies the security module entry.

  You are advised to configure an isolation interval of at least 180 seconds. When both port-based rate limiting and isolation are enabled, isolation will be triggered only when port-based rate limiting and isolation intervals expire.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the

existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.

- When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.

- ICMP guard can be configured with trusted hosts. When entries in the table of monitored hosts match the trusted hosts (their IP addresses are the same), the system automatically deletes the entries of the IP addresses. ICMP guard can be configured with a maximum of 500 trusted hosts.

1.6.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the function of global ICMP guard.

icmp-guard enable

The function of global ICMP guard is enabled by default.

(5) (Optional) Configure the global isolation time of ICMP guard.

icmp-guard isolate-period [*interval* | **permanent**]

The default global isolation time of ICMP guard is **0**, and the isolation function is disabled by default.

(6) Configure the monitoring time of ICMP guard.

icmp-guard monitor-period *interval*

The default monitoring time of ICMP guard is **600** seconds.

(7) Configure the maximum number of monitored hosts.

icmp-guard monitored-host-limit *number*

The maximum number of monitored hosts is **20000** by default.

(8) Configure the global rate limiting threshold of ICMP guard.

icmp-guard speed-limit { **per-port** *speed-limit* | **per-src-ip** *speed-limit* }

The default global rate limiting thresholds of ICMP guard for each interface and each source IP address are 1,000 pps and 800 pps respectively on S6920-4C, S6510-48VS8CQ, S6250-48XS8CQ, and S6980-64QC.

(9) Configure the global attack threshold of ICMP guard.

icmp-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* }

The default global attack thresholds of ICMP guard for each interface and each source IP address are 1,500 pps and 1,200 pps respectively on S6920-4C, S6510-48VS8CQ, S6250-48XS8CQ, and S6980-64QC.

(10) (Optional) Configure the trusted hosts of ICMP guard.

icmp-guard trusted-host *ipv4-address mask*

No host is configured as a trusted host by default.

1.6.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the ICMP guard function on an interface.

nfpp icmp-guard enable

The ICMP guard function is not configured on an interface by default. The global ICMP guard function is used.

(5) Configure the local isolation time of ICMP guard on an interface.

nfpp icmp-guard isolate-period { *interval* | **permanent** }

No local isolation time of ICMP guard is configured on an interface by default. The global isolation time of ICMP guard is used.

(6) Configure the local rate limiting threshold and local attack threshold of ICMP guard on an interface.

nfpp icmp-guard policy { **per-port** *speed-limit attack-threshold* | **per-src-ip** *speed-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of ICMP guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of ICMP guard are used.

1.7 Configuring DHCP Guard

1.7.1 Overview

In a DHCP starvation attack, all IP addresses of a DHCP server are exhausted. As a result, the DHCP server fails to provide the address assignment service, thus affecting the network access of legal users. To address this type of attacks, you must deploy the DHCP guard function on a device.

DHCP guard includes the following functions:

- Identify DHCP attacks based on hosts or physical ports. This function can determine an attack host based on the source MAC address, VLAN ID, and port on the link layer. A rate limiting threshold and an attack threshold can be configured for each attack identification method. When the DHCP packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the DHCP packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent.
- Isolate DHCP attackers based on hosts. This function configures hardware entries to isolate identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
- Monitor attack hosts through software. After an attack is identified, this function monitors the attack host

through software in the configured monitoring time.

1.7.2 Restrictions and Guidelines

- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- After the DHCP guard function is disabled, the system automatically clears the entries related to the monitored hosts.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:
  - If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
  - If you change the isolation time to 0 from a non-zero value, entries related to the isolated attacker are directly deleted without monitoring the attacker through software.
- After you enable the isolation function, the recorded attack host occupies the security module entry.

  You are advised to configure an isolation interval of at least 180 seconds. When both port-based rate limiting and isolation are enabled, isolation will be triggered only when port-based rate limiting and isolation intervals expire.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.
  - When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.
- If a port is configured as trusted by the DHCP Snooping function, the DHCP guard function becomes invalid to avoid misjudging DHCP traffic on the trusted port. For trusted port configuration in DHCP Snooping, see *Configuring DHCP Snooping*.

1.7.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the function of global DHCP guard.

dhcp-guard enable

The function of global DHCP guard is enabled by default.

(5) (Optional) Configure the global isolation time of DHCP guard.

dhcp-guard isolate-period { *interval* | **permanent** }

The default global isolation time of DHCP guard is **0**, and the isolation function is disabled by default.

(6) Configure the monitoring time of DHCP guard.

dhcp-guard monitor-period *interval*

The default monitoring time of DHCP guard is **600** seconds.

(7) Configure the maximum number of monitored hosts.

dhcp-guard monitored-host-limit *number*

The maximum number of monitored hosts of DHCP guard is **20000** by default.

(8) Configure the global rate limiting threshold of DHCP guard.

dhcp-guard speed-limit { **per-port** *speed-limit* | **per-src-mac** *speed-limit* }

The default global rate limiting thresholds of DHCP guard for each interface and each source MAC address are 1,000 pps and 5 pps respectively on S6920-4C, S6510-48VS8CQ, S6250-48XS8CQ, and S6980-64QC.

(9) Configure the global attack threshold of DHCP guard.

dhcp-guard attack-threshold { **per-port** *attack-threshold* | **per-src-mac** *attack-threshold* }

The default global attack thresholds of DHCP guard for each interface and each source MAC address are 1,200 pps and 10 pps respectively on S6920-4C, S6510-48VS8CQ, S6250-48XS8CQ, and S6980-64QC.

1.7.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the DHCP guard function on an interface.

nfpp dhcp-guard enable

The DHCP guard function is disabled on an interface by default. The global DHCP guard function is enabled.

(5) Configure isolation time of DHCP guard on an interface.

nfpp dhcp-guard isolate-period [*interval* | **permanent**]

No local isolation time of DHCP guard is configured on an interface by default. The global isolation time of DHCP guard is used.

(6) Configure the local rate limiting threshold and local attack threshold of DHCP guard on an interface.

nfpp dhcp-guard policy { **per-port** *speed-limit attack-threshold* | **per-src-mac** *speed-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of DHCP guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of DHCP guard are used.

1.8 Configuring DHCPv6 Guard

1.8.1 Overview

Like DHCPv4, DHCPv6 has security problems. Therefore, the attack methods of DHCPv4 are applicable to DHCPv6. To prevent this type of attacks, we must also deploy the DHCPv6 guard policy. DHCPv6 guard includes the following functions:

- Identify DHCPv6 attacks based on hosts or physical ports. This function can determine an attack host based on the source MAC address, VLAN ID, and port on the link layer. A rate limiting threshold and an attack threshold can be configured for each attack identification method.
- Isolate DHCPv6 attackers based on hosts. This function configures hardware entries to isolate identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
- Monitor attack hosts through software. After an attack is identified, this function monitors the attack host through software in the configured monitoring time.

1.8.2 Restrictions and Guidelines

- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- After the DHCPv6 guard function is disabled, the system automatically clears the entries related to the monitored hosts.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:
  - If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
  - If you change the isolation time to 0 from a non-zero value, entries related to the isolated attacker are directly deleted without monitoring the attacker through software.
- After you enable the isolation function, the recorded attack host occupies the security module entry.

  You are advised to configure an isolation interval of at least 180 seconds. When both port-based rate limiting and isolation are enabled, isolation will be triggered only when port-based rate limiting and isolation intervals expire.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the

existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.

- When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.

- If a port is configured as trusted by the DHCPv6 Snooping function, the DHCPv6 guard function becomes invalid to avoid misjudging DHCPv6 traffic on the trusted port. For trusted port configuration in DHCPv6 Snooping, see *Configuring DHCPv6 Snooping*.

1.8.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the function of global DHCPv6 guard.

dhcpv6-guard enable

The function of global DHCPv6 guard is enabled by default.

(5) Configure the monitoring time of DHCPv6 guard.

dhcpv6-guard monitor-period *interval*

The default monitoring time of DHCPv6 guard is **600** seconds.

(6) Configure the maximum number of monitored hosts.

dhcpv6-guard monitored-host-limit *number*

The maximum number of monitored hosts of DHCPv6 guard is **20000** by default.

(7) Configure the global rate limiting threshold of DHCPv6 guard.

dhcpv6-guard speed-limit { **per-port** *speed-limit* | **per-src-mac** *speed-limit* }

The default global rate limiting thresholds of DHCPv6 guard for each interface and each source MAC address are 1,000 pps and 5 pps respectively on S6920-4C, S6510-48VS8CQ, S6250-48XS8CQ, and S6980-64QC.

(8) Configure the global attack threshold of DHCPv6 guard.

dhcpv6-guard attack-threshold { **per-port** *attack-threshold* | **per-src-mac** *attack-threshold* }

The default global attack thresholds of DHCPv6 guard for each interface and each source MAC address are 1,200 pps and 10 pps respectively on S6920-4C, S6510-48VS8CQ, S6250-48XS8CQ, and S6980-64QC.

1.8.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the DHCPv6 guard function on an interface.

nfpp dhcpv6-guard enable

The DHCPv6 guard function is disabled on an interface by default. The global DHCPv6 guard function is used.

(5) Configure the local rate limiting threshold and local attack threshold of DHCPv6 guard on an interface.

nfpp dhcpv6-guard policy { **per-port** *speed-limit attack-threshold* | **per-src-mac** *speed-limit attack-threshold* }

No local rate limiting threshold is local attack threshold of DHCPv6 guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of DHCPv6 guard are used.

1.9 Configuring ND Guard

1.9.1 Overview

ND packets of ND guard fall into three types by use:

- Type 1: Neighbor requests and neighbor advertisements, which are used to parse addresses.
- Type 2: Route requests, which are used to discover gateways for hosts.
- Type 3: Route advertisements, which are used to advertise gateways and prefixes; and redirection packets, which are used to advertise better next hops.

ND guard identifies ND packets based on physical ports. This function prevents attacks by configuring rate limiting thresholds for attack ports and isolating the ports.

1.9.2 Restrictions and Guidelines

- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- After you enable the ND Snooping function by running the **ipv6 nd snooping enable** command, all ND packets are NDSNP packets. In this case, you must configure rate limiting thresholds and attack thresholds for the NDSNP packets to validate the guard.
- After you enable the isolation function, the recorded attack host occupies the security module entry. If the port-based isolation entries take effect, the default action is to discard all attack packets. After you enable the function of port-based rate limit forwarding, you can allow some of packets to pass through by changing the isolation action.

You are advised to configure an isolation interval of at least 180 seconds. When both port-based rate limiting and isolation are enabled, isolation will be triggered only when port-based rate limiting and isolation intervals expire.

- Rate limit by hardware is ineffective to NDSNP packets.

1.9.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the global ND guard function.

nd-guard enable

The function of global ND guard is enabled by default.

(5) Enable the function of port-based rate limit forwarding of ND guard.

nd-guard speedlimit-forwarding enable

The function of port-based rate limit forwarding of ND guard is enabled by default.

Note

This command is not supported by S6580-24DC8QC.

(6) Configure the global rate limiting threshold of ND guard.

nd-guard speed-limit per-port { **ndsnp** *speed-limit* | **ns-na** *speed-limit* | **ra-redirect** *speed-limit* | **rs** *speed-limit* }

The default global rate limiting thresholds of ND guard for NDSNP packets, neighbor requests and advertisements, route advertisements and redirection packets, and route requests are not configured, 1,000 pps, 500 pps, and 500 pps respectively on S6920-4C, S6510-48VS8CQ, and S6250-48XS8CQ, 3,000 pps, 1,000 pps, 500 pps, and 500 pps respectively on S6980-64QC.

(7) Configure the global attack threshold of ND guard.

nd-guard attack-threshold per-port { **ndsnp** *attack-threshold* | **ns-na** *attack-threshold* | **ra-redirect** *attack-threshold* | **rs** *attack-threshold* }

The default global attack thresholds of ND guard for NDSNP packets, neighbor requests and advertisements, route advertisements and redirection packets, and route requests are not configured, 2500 pps, 800 pps, and 800 pps respectively on S6920-4C, S6510-48VS8CQ, and S6250-48XS8CQ, 6,000 pps, 2,500 pps, 800 pps, and 800 pps respectively on S6980-64QC.

1.9.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the ND guard function on an interface.

nfpp nd-guard enable

The ND guard function is disabled on an interface by default. The global ND guard function is enabled.

(5) Configure the local rate limiting threshold and local attack threshold of ND guard on an interface.

nfpp nd-guard policy per-port { **ndsnp** *speed-limit attack-threshold* | **ns-na** *speed-limit attack-threshold* | **ra-redirect** *speed-limit attack-threshold* | **rs** *speed-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of ND guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of ND guard are used.

1.10 Customizing Guard

1.10.1 Overview

Users can customize guard types and guard policies to solve network attacks in special application scenarios.

Customized guard includes the following functions:

- Allow users to combine packet type fields and use them as packet types of customized guard to meet requirements of guard scenarios.
- Configure guard policies based on hosts and ports. Host guard policies include those based on the source IP address, VLAN ID and port, or those based on the source MAC address, VLAN ID and port on the link layer. A rate limiting threshold and an attack threshold can be configured for each guard policy. When the packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent.
- Monitor attack hosts through software.
  - After this function identifies any attacks, it can monitor the attack host through software in the configured monitoring time.
  - This function can configure a specified host as a trusted host based on its IPv4, IPv6, or MAC address so that it is free from software monitoring and allowed to send packets to the CPU without rate limit and processing.

1.10.2 Restrictions and Guidelines

- Customized guard allows users to combine packet type fields to include most existing protocol types and expand new protocol types. Improper configuration of the packet type fields may cause a network exception. Therefore, users must well understand network protocols before they configure this function.

- Customized guard has a higher packet detection priority than basic guard types. When packets match the customized guard policy and the policy of a basic guard type, they preferentially undergo rate limit and attack identification according to the customized guard policy. To ensure the configuration effect of basic guard types, try to refer to the configuration guide when you configure the packet type fields of customized guard.
- Customized guard policies must be configured with different type names and packet types. Matched packet types must differ from the packet types of existing guard types, including those of basic guard types such as ARP guard, IP guard, ICMP guard, TCP-SYN guard, DHCP guard, DHCPv6 guard, and ND guard.
- You can configure packet types of customized guard by combining the following fields. These fields include Ethernet link layer type (etype), source MAC address (src-mac), destination MAC address (dst-mac), IPv4 or IPv6 protocol number (protocol), source IPv4 or IPv6 address (src-ip/src-ipv6), destination IPv4 or IPv6 address (dst-ip/dst-ipv6), source port on the transport layer (src-port), and destination port on the transport layer (dst-port).

  To configure the matched fields of packet fields, conform with the following limit rules. Otherwise, the configuration fails:

  - The IPv4 or IPv6 protocol number (protocol) is configurable only when the Ethernet link layer type (etype) is IPv4 or IPv6.
  - The source IPv4 address (src-ip) and destination IPv4 address (dst-ip) are configurable only when the Ethernet link layer type (etype) is IPv4.
  - The source IPv6 address (src-ipv6) and destination IPv6 address (dst-ipv6) are configurable only when the Ethernet link layer type (etype) is IPv6.
  - The source port on the transport layer (src-port) and destination port on the transport layer (dst-port) are configurable only when the IPv4 or IPv6 protocol number (protocol) is TCP or UDP.
- For the three types of customized guard policies that are based on the source IP address, source MAC address, and port, you must configure at least one type. That is, you must configure the global rate limiting threshold and global attack threshold of customized guard. Otherwise, the customized guard function does not take effect. You can configure a host policy based on the source IP address, VLAN ID, and port only when the specified Ethernet link layer type (etype) is IPv4 or IPv6.
- The rate limiting threshold based on a source MAC address has a higher priority than that based on a source IP address. The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- Only after you configure packet types and guard policies can you enable the customized guard function. If you do not complete any configuration, you are reminded that the current customized guard is not completely configured and the configuration fails.
- The host policy of customized guard on an interface must be consistent with the global host policy configuration. For example, if no global rate limiting threshold and global attack threshold are configured based on the source IP address, you cannot configure the local rate limiting threshold and local attack threshold on an interface.
- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- After the customized guard function is disabled, the system automatically clears the entries related to the monitored hosts.

- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.
  - When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.
- When you configure trusted hosts, note that:
  - You must configure matched packet types before you configure trusted hosts.
  - The trusted hosts of customized guard must be consistent with the matched packet types. For example, only when the Ethernet link layer type (etype) is IPv4, can you add IPv4 addresses as trusted IP addresses. Similarly, when the matched packet type is IPv4, IPv6 addresses cannot be added as trusted IP addresses.
  - You can configure all hosts in a network segment as trusted hosts by configuring masks.
  - When entries in the table of monitored hosts match the trusted hosts, the system automatically deletes the entries of the IP addresses.
  - ICMP guard can be configured with a maximum of 500 trusted hosts.

1.10.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Customize a guard type, and enter the configuration mode of the NFPP customized guard type.

define *define-name*

(5) Configure the matched packet types of the customized guard type.

match-rule { **dst-ip** *destination-ipv4-address* [**dst-ip-mask** *mask*] | **dst-ipv6** *destination-ipv6-address* [**dst-ipv6-masklen** *prefix-length*] | **dst-mac** *destination-mac* [**dst-mac-mask** *destination-mac-mask*] | **dst-port** *port-number* | **etype** *type* | **protocol** *protocol* | **src-ip** *source-ipv4-address* [**src-ip-mask** *mask*] | **src-ipv6** *source-ipv6-address* [**src-ipv6-masklen** *prefix-length*] | **src-mac** *source-mac-address* | **src-port** *port-number* } *

(6) Configure the global rate limiting threshold and global attack threshold of the customized guard type.

global-policy { **per-port** *speed-limit attack-threshold* | **per-src-ip** *speed-limit attack-threshold* | **per-src-mac** *speed-limit attack-threshold* }

No global rate limiting threshold or global attack threshold of the customized guard type is configured by default.

They must be configured. Otherwise, you cannot enable the customized guard function.

(7) Configure the monitoring time of the customized guard type.

monitor-**period** *interval*

The default monitoring time of a customized guard type is **600** seconds.

(8) Configure the maximum number of monitored hosts of the customized guard type.

monitored-**host**-**limit** *number*

The maximum number of monitored hosts is **20000** by default.

(9) Configure the trusted hosts of the customized guard type.

trusted-host { *ipv4-address mask* | *ipv6-address*/*prefix-length* | *mac-address mask* }

No host is configured as a trusted host of the customized guard type by default.

(10) Enable the function of global customized guard.

define *define-name* **enable**

The function of global customized guard is disabled by default.

1.10.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the customized guard function on an interface.

nfpp define *define-name* **enable**

The customized guard function is disabled on an interface by default. The global customized guard function is used.

(5) Configure the local rate limiting threshold and local attack threshold of the customized guard type on an interface.

nfpp define *define-name* **policy** { **per-port** *speed-limit attack-threshold* | **per-src-ip** *speed-limit attack-threshold* | **per-src-mac** *speed-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of the customized guard type is configured on an interface by default. The global rate limiting threshold and global attack threshold of the customized guard type are used.

1.11 Disabling Guard

1.11.1 Overview

Users can disable or enable all basic types of global guard function by running one command. Basic guard types supported by this function include ARP guard, IP guard, ICMP guard, TCP-SYN guard, DHCP guard, DHCPv6 guard, and ND guard.

1.11.2 Restrictions and Guidelines

- This function applies to only basic guard types and does not affect the customized guard types.
- This function applies to the guard functions in global configuration mode and does not affect the guard functions in interface configuration mode.
- After you run the one-click enabling/disabling command, the configuration of this command cannot be displayed by running the **display current-config** command.
- The one-click enabling/disabling command is to actually enable or disable basic guard types in global configuration mode. After you run this command to disable basic guard types, the **display current-config** command allows you to display the global disabling command of each basic guard function. After you run this command to enable basic guard types, the **display current-config** command allows you to display the default configuration.
- This command cannot be saved, but its running result can be saved and take effect after device restart.

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable all the basic types of global guard of NFPP.

all-guard enable

1.12 Configuring NFPP Logs

1.12.1 Overview

When many attacks are launched to a device, the generated prompts may affect user experience. You can configure the size of a log buffer, system message rate, and filtering conditions to restrictively record and display logs.

- NFPP retrieves logs from a special buffer at a rate, uses them to generate system messages, and clears the logs from the buffer. Therefore, you can configure the rate of generating system messages from logs of the log buffer through NFPP to control the message report frequency and avoid log spamming.
- You can also configure filtering conditions to obtain required log information accurately and filter out logs that do not comply with the filtering rules.
- To monitor whether an attack occurs, you can print logs on a screen in real time.

1.12.2 Restrictions and Guidelines

- After active/standby switchover of a device, the device will clear logs in a buffer and record new logs again.
- Even if a device does not suffer an attack, logs are continuously retrieved from the buffer to generate system messages.
- When the log buffer overflows, new logs overwrite the stale logs, and the log buffer displays an entry with attributes being "-". In this case, you must increase the log buffer size or improve the generation rate of system messages.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Configure the size of a log buffer.

log_buf entries *number*

The default size of the NFPP log buffer is **256** entries.

(5) Configure the rate of generating system messages from logs of the log buffer through NFPP.

log_buf log_num *message-number* **interval_time** *interval*

No rate of generating system messages from logs of the log buffer is configured through NFPP and NFPP logs are not written into the buffer by default.

If the values of the *message-number* and *interval* parameters are **0**, logs are used by NFPP to immediately generate system messages without being written into the buffer.

(6) Configure NFPP to record the logs of a specified VLAN and a specified interface.

logging { **interface** *interface-type interface-number* | **vlan** *vlan-range }*

NFPP records the logs of all VLANs and interfaces by default.

(7) Enable the function of screen log output.

log_buf enable

The function of screen log output is disabled by default and logs are saved in the buffer.

1.13 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

⚠ Caution

Running the **cleanup** command may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
cleanup nfpp arp-guard scan	Clears the scanning table of ARP guard.
cleanup nfpp arp-guard hosts	Clears the monitored hosts of ARP guard.
cleanup nfpp ip-guard hosts	Clears the monitored hosts of IP guard.
cleanup nfpp tcp-syn-guard hosts	Clears the monitored hosts of TCP-SYN guard.
cleanup nfpp nd-guard hosts	Clears the monitored hosts of ND guard.
cleanup nfpp icmp-guard hosts	Clears the monitored hosts of ICMP guard.
cleanup nfpp dhcp-guard hosts	Clears the monitored hosts of DHCP guard.
cleanup nfpp dhcpv6-guard hosts	Clears the monitored hosts of DHCPv6 guard.
cleanup nfpp define *define-name* **hosts**	Clears the monitored hosts of customized guard.
cleanup nfpp log	Clears NFPP log buffer.
display nfpp arp-guard summary	Displays ARP guard configuration.
display nfpp arp-guard hosts	Displays the monitored hosts of ARP guard.
display nfpp arp-guard scan	Displays the scanning table of ARP guard.
display nfpp ip-guard summary	Displays the IP guard configuration.
display nfpp ip-guard hosts	Displays the monitored hosts of IP guard.
display nfpp ip-guard trusted-host	Displays the trusted hosts of IP guard.
display nfpp tcp-syn-guard summary	Displays the configuration parameters of TCP-SYN guard.
display nfpp tcp-syn-guard hosts	Displays the monitored hosts of TCP-SYN guard.
display nfpp tcp-syn-guard trusted-host	Displays the scanning table of TCP-SYN guard.
display nfpp icmp-guard summary	Displays the configuration parameters of ICMP guard.
display nfpp icmp-guard hosts	Displays the monitored hosts of ICMP guard.
display nfpp icmp-guard trusted-host	Displays the trusted hosts of ICMP guard.
display nfpp dhcp-guard summary	Displays the configuration parameters of DHCP guard.
display nfpp dhcp-guard hosts	Displays the monitored hosts of DHCP guard.
display nfpp dhcpv6-guard summary	Displays the DHCPv6 guard configuration.
display nfpp dhcpv6-guard hosts	Displays the monitored hosts of DHCPv6 guard.
display nfpp nd-guard summary	Displays the ND guard configuration.

Command	Purpose
display nfpp nd-guard hosts	Displays the trusted hosts of ND guard.
display nfpp define summary [*name*]	Displays the customized guard configuration.
display nfpp define hosts *name*	Displays the monitored hosts of the customized guard.
display nfpp define trusted-host *name*	Displays the trusted hosts of the customized guard.
display nfpp log summary	Displays the statistics of the NFPP log buffer.
display nfpp log buffer [**statistics**]	Displays the log buffer of NFPP.

1.14 Configuration Examples

1.14.1 Configuring CPU Guard

1. Requirements

In a network system, protocols such as ARP, IP, TCP-SYN, ICMP, DHCP, DHCPv6, and ND are popular targets of attacks. This may cause packet forwarding failure and high CPU usage. You can enable guard policies to ensure the stable running of devices.

2. Notes

- Configure the rate limiting threshold, attack threshold and isolation time of ARP guard.
- Configure the rate limiting threshold, attack threshold and isolation time of IP guard.
- Configure the rate limiting threshold, attack threshold and isolation time of TCP-SYN guard.
- Configure the rate limiting threshold, attack threshold and isolation time of ICMP guard.
- Configure the rate limiting threshold, attack threshold and isolation time of DHCP guard.
- Configure the rate limiting threshold and attack threshold of DHCPv6 guard.
- Configure the rate limiting threshold and attack threshold of ND guard.

3. Procedure

Configure ARP guard on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# nfpp
DeviceA(cfg-nfpp)# arp-guard speed-limit per-src-mac 5
DeviceA(cfg-nfpp)# arp-guard attack-threshold per-src-mac 10
DeviceA(cfg-nfpp)# arp-guard isolate-period 180
```

Configure IP guard on Device A.

```
DeviceA(cfg-nfpp)# ip-guard speed-limit per-src-ip 20
DeviceA(cfg-nfpp)# ip-guard attack-threshold per-src-ip 30
DeviceA(cfg-nfpp)# ip-guard isolate-period 180
```

```
DeviceA(cfg-nfpp)# ip-guard trusted-host 192.168.201.46 255.255.255.255
```

Configure TCP-SYN guard on Device A.

```
DeviceA(cfg-nfpp)# tcp-syn-guard speed-limit per-src-ip 20
DeviceA(cfg-nfpp)# tcp-syn-guard attack-threshold per-src-ip 30
DeviceA(cfg-nfpp)# tcp-syn-guard isolate-period 180
DeviceA(cfg-nfpp)# tcp-syn-guard trusted-host 192.168.201.46 255.255.255.255
```

Configure ICMP guard on Device A.

```
DeviceA(cfg-nfpp)# icmp-guard speed-limit per-src-ip 20
DeviceA(cfg-nfpp)# icmp-guard attack-threshold per-src-ip 30
DeviceA(cfg-nfpp)# icmp-guard isolate-period 180
```

Configure DHCP guard on Device A.

```
DeviceA(cfg-nfpp)# dhcp-guard speed-limit per-src-ip 20
DeviceA(cfg-nfpp)# dhcp-guard attack-threshold per-src-ip 30
DeviceA(cfg-nfpp)# dhcp-guard isolate-period 180
DeviceA(cfg-nfpp)# dhcp-guard trusted-host 192.168.201.46 255.255.255.255
```

Configure DHCPv6 guard on Device A.

```
DeviceA(cfg-nfpp)# dhcpv6-guard speed-limit per-src-ip 20
DeviceA(cfg-nfpp)# dhcpv6-guard attack-threshold per-src-ip 30
DeviceA(cfg-nfpp)# dhcpv6-guard trusted-host 192.168.201.46 255.255.255.255
```

Configure ND guard on Device A.

```
DeviceA (cfg-nfpp)# nd-guard speed-limit per-port ns-na 30
DeviceA (cfg-nfpp)# nd-guard attack-threshold per-port ns-na 50
```

4. Verification

Run the **display nfpp arp-guard summary** command to display the configuration.

```
DeviceA# display nfpp arp-guard summary
(Format of column Speed-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)
Interface Status    Isolate-period Speed-limit          Attack-threshold Scan-threshold
Global       Disable 180                  4/5/100             8/10/200             15

Maximum count of monitored hosts: 1000
Monitor period: 600s
```

Run the **display nfpp arp-guard hosts** command to display the monitored hosts.

```
DeviceA# display nfpp arp-guard hosts
If col_filter 1 displays '*', it means "hardware do not isolate host".
 VLAN       interface     IP address             MAC address         remain-time(s)
 ----       ---------     ----------             -----------         --------------
 1            Gi0/43          5.5.5.16               -                    175
Total: 1 host
```

Run the **display nfpp arp-guard scan** command to display the scanned hosts.

```
DeviceA# display nfpp arp-guard scan
VLAN    interface           IP address             MAC address         timestamp
```

```
----  ---------  ----------  -----------  ---------
1     Gi0/5      -           001a.a9c2.4609  2013-4-30 23:50:32
1     Gi0/5      192.168.206.2  001a.a9c2.4609  2013-4-30 23:50:33
1     Gi0/5      -           001a.a9c2.4609  2013-4-30 23:51:33
1     Gi0/5      192.168.206.2  001a.a9c2.4609  2013-4-30 23:51:34
Total: 4 record(s)
```

Note

If attack traffic carries the VLAN ID 0, NFPP may consider the corresponding host as an attack host and configure a rate limiting threshold for the attack traffic. Run the **display nfpp arp-guard host** command to display the attack hosts. The VLAN ID field may be displayed as a port PVID or hidden.

Run the **display nfpp ip-guard summary** command to display the configuration.

```
DeviceA# display nfpp ip-guard summary
(Format of column Speed-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)
Interface Status   Isolate-period Speed-limit      Attack-threshold Scan-threshold
Global    Disable 180            20/-/100        30/-/200         100

Maximum count of monitored hosts: 1000
Monitor period: 600s
```

Run the **display nfpp ip-guard hosts** command to display the monitored hosts.

```
DeviceA# display nfpp ip-guard hosts
If col_filter 1 displays '*', it means "hardware do not isolate host".
 VLAN    interface   IP address          Reason    remain-time(s)
 ----    ---------   ----------          ------    --------------
  1      Gi0/5       192.168.201.47      ATTACK    160
Total: 1 host
```

Run the **display nfpp ip-guard trusted-host** command to display the trusted hosts.

```
DeviceA# display nfpp ip-guard trusted-host
IP address              mask
----------              ----
192.168.201.46          255.255.255.255
Total: 1 record(s)
```

Note

If attack traffic carries the VLAN ID 0, NFPP may consider the corresponding host as an attack host and configure a rate limiting threshold for the attack traffic. Run the **display nfpp ip-guard host** command to display the attack hosts. The VLAN ID field may be displayed as a port PVID or hidden.

Run the **display nfpp tcp-syn-guard summary** command to display the configuration.

```
DeviceA# display nfpp tcp-syn-guard summary
(Format of column Speed-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)
Interface Status   Isolate-period Speed-limit      Attack-threshold Scan-threshold
Global    Disable 180            20/-/100        30/-/200         100
```

```
Maximum count of monitored hosts: 1000
Monitor period: 600s
```

Run the **display nfpp tcp-syn-guard hosts** command to display the monitored hosts.

```
DeviceA# display nfpp tcp-syn-guard hosts
If col_filter 1 displays '*', it means "hardware do not isolate host".
 VLAN      interface     IP address            Reason      remain-time(s)
 ----      ---------     ----------            ------      --------------
  1          Gi0/5          192.168.201.47      ATTACK      160
Total: 1 host
```

Run the **display nfpp tcp-syn-guard trusted-host** command to display the trusted hosts.

```
DeviceA# display nfpp tcp-syn-guard trusted-host
IP address                mask
----------                ----
192.168.201.46          255.255.255.255
Total: 1 record(s)
```

Note

If attack traffic carries the VLAN ID 0, NFPP may consider the corresponding host as an attack host and configure a rate limiting threshold for the attack traffic. Run the **display nfpp tcp-syn-guard host** command to display the attack hosts. The VLAN ID field may be displayed as a port PVID or hidden.

Run the **display nfpp icmp-guard summary** command to display the configuration.

```
DeviceA# display nfpp icmp-guard summary
(Format of column Speed-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)
Interface Status   Isolate-period Speed-limit          Attack-threshold Scan-threshold
Global      Disable 180                 20/-/100            30/-/200             100

Maximum count of monitored hosts: 1000
Monitor period: 600s
```

Run the **display nfpp icmp-guard hosts** command to display the monitored hosts.

```
DeviceA# display nfpp icmp-guard hosts
If col_filter 1 displays '*', it means "hardware do not isolate host".
 VLAN      interface     IP address            Reason      remain-time(s)
 ----      ---------     ----------            ------      --------------
  1          Gi0/5          192.168.201.47      ATTACK      160
Total: 1 host
```

Run the **display nfpp icmp-guard trusted-host** command to display the trusted hosts.

```
DeviceA# display nfpp icmp-guard trusted-host
IP address                mask
----------                ----
192.168.201.46          255.255.255.255
Total: 1 record(s)
```

Note

If attack traffic carries the VLAN ID 0, NFPP may consider the corresponding host as an attack host and configure a rate limiting threshold for the attack traffic. Run the **display nfpp icmp-guard host** command to display the attack hosts. The VLAN ID field may be displayed as a port PVID or hidden.

Run the **display nfpp dhcp-guard summary** command to display the configuration.

```
DeviceA# display nfpp dhcp-guard summary
(Format of column Speed-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)
Interface Status    Isolate-period Speed-limit          Attack-threshold Scan-threshold
Global    Disable 180                20/-/100           30/-/200         100

Maximum count of monitored hosts: 1000
Monitor period: 600s
```

Run the **display nfpp dhcp-guard hosts** command to display the monitored hosts.

```
DeviceA# display nfpp dhcp-guard hosts
If col_filter 1 displays '*', it means "hardware do not isolate host".
 VLAN      interface     IP address            Reason      remain-time(s)
 ----      ---------     ----------            ------      --------------
  1          Gi0/5          192.168.201.47      ATTACK      160
Total: 1 host
```

Run the **display nfpp dhcp-guard trusted-host** command to display the trusted hosts.

```
DeviceA# display nfpp dhcp-guard trusted-host
IP address               mask
----------               ----
192.168.201.46           255.255.255.255
Total: 1 record(s)
```

Note

If attack traffic carries the VLAN ID 0, NFPP may consider the corresponding host as an attack host and configure a rate limiting threshold for the attack traffic. Run the **display nfpp dhcp-guard host** command to display the attack hosts. The VLAN ID field may be displayed as a port PVID or hidden.

Run the **display nfpp dhcpv6-guard summary** command to display the configuration.

```
DeviceA# display nfpp dhcpv6-guard summary
(Format of column Speed-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)
Interface Status    Isolate-period Speed-limit          Attack-threshold Scan-threshold
Global    Disable 180                20/-/100           30/-/200         100

Maximum count of monitored hosts: 1000
Monitor period: 600s
```

Run the **display nfpp dhcpv6-guard hosts** command to display the monitored hosts.

```
DeviceA# display nfpp dhcpv6-guard hosts
```

```
If col_filter 1 displays '*', it means "hardware do not isolate host".
 VLAN      interface     IP address              Reason       remain-time(s)

1 Configuring Storm Control

1.1 Introduction

1.1.1 Overview

When a local area network (LAN) has excess broadcast, multicast, or unknown unicast data flows, the network speed will slow down and packet transmission will have an increased timeout probability. This situation is called a LAN storm. A storm may occur when topology protocol execution or network configuration is incorrect.

Storm control can be implemented to limit broadcast, multicast, or unknown unicast data flows. When the rate of broadcast, multicast, or unknown unicast data flows received over a device port exceeds the specified range, the device transmits only packets in the specified range and discards packets beyond the range until the packet rate falls within the range. This prevents flooded data from entering the LAN and causing a storm.

1.1.2 Principles

1. Storm Control Based on the Percentage-based Bandwidth Threshold

If the rate of data flows received over a device port exceeds the specified bandwidth, excess data flows are discarded until the rate falls within the threshold.

Note

When the storm suppression threshold is set to the percentage-based bandwidth, products may convert the configured value to a multiple of the step supported by the product. Therefore, the actual effective suppression threshold on a port may be smaller than the configured suppression threshold.

2. Storm Control Based on the Packets-per-Second Threshold

If the rate of data flows received over a device port exceeds the configured packets-per-second threshold, excessive data flows are discarded until the rate falls within the threshold.

3. Storm Control Based on the Kilobits-per-Second Threshold

If the rate of data flows received over a device port exceeds the configured kilobits-per-second threshold, excessive data flows are discarded until the rate falls within the threshold.

Note

When the storm suppression threshold is set to kilobits-per-second, products may convert the configured value to a multiple of the step supported by the product. Therefore, the actual effective suppression threshold on a port may be smaller than the configured suppression threshold.

4. Storm Control Action

Within the storm control detection interval (10s by default), when the average rate of received packets exceeds the specified allowed packet rate, you can configure the storm control action to handle the interface. The action will be triggered if any one among the configured broadcast, multicast, or unknown unicast thresholds is violated.

1.2 Configuring Storm Control

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Enable packet storm control.

storm-control-enable { **broadcast** | **multicast** | **unicast** } [**level** *percent* | **pps** *packets* | *rate*]

Packet storm control is disabled by default.

(5) (Optional) Configure the storm control action.

storm-control-enable action { **shutdown** | **trap** }

No storm control action is configured by default.

The storm control action can be configured only after storm control is enabled.

(6) (Optional) Configure storm control logging.

storm-control-enable enable log

Storm control logging is disabled by default.

(7) (Optional) Configure the interval for storm control detection.

storm-control-enable interval

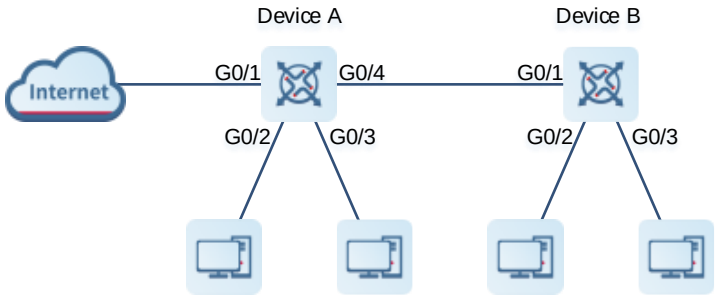
The default interval for storm control detection is 10s.

1.3 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
display storm-control-enable [*interface-type interface-number*]	Displays storm control information.



1.4 Configuration Examples

1. Requirements

Enable storm control to prevent excessive broadcast, multicast, or unknown unicast data flows in a LAN, which will cause the network speed to slow down.

2. Topology

Figure 1-1 Topology of Configuring Storm Control

3. Notes

Enable storm control on access devices A and B.

4. Procedure

(1) Enable storm control on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface list gigabitethernet 0/2,0/3,0/4
DeviceA(cfg-if-range)# storm-control-enable broadcast
DeviceA(cfg-if-range)# storm-control-enable multicast
DeviceA(cfg-if-range)# storm-control-enable unicast-pkt
```

(2) Enable storm control on Device B.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceB(cfg)# interface list gigabitethernet 0/1,0/2,0/3
DeviceB(cfg-if-range)# storm-control-enable broadcast
DeviceB(cfg-if-range)# storm-control-enable multicast
DeviceB(cfg-if-range)# storm-control-enable unicast-pkt
```

5. Verification

(1) Check whether storm control is enabled on Device A.

```
DeviceA# display storm-control-enable
Interface                    Broadcast Control Multicast Control Unicast Control Action
------------------------- ----------------- ----------------- ---------------- --------
```

```
        GigabitEthernet 0/1          Disabled          Disabled          Disabled       none
        GigabitEthernet 0/2           default           default           default       none
        GigabitEthernet 0/3           default           default           default       none
        GigabitEthernet 0/4          default           default           default       none
```

(2) Check whether storm control is enabled on Device B.

```
DeviceA# display storm-control-enable
Interface                    Broadcast Control Multicast Control Unicast Control Action
------------------------- ----------------- ----------------- ---------------- --------
        GigabitEthernet 0/1           default           default           default       none
        GigabitEthernet 0/2           default           default           default       none
        GigabitEthernet 0/3           default           default           default       none
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/2
 storm-control-enable broadcast
 storm-control-enable multicast
 storm-control-enable unicast-pkt
!
interface GigabitEthernet 0/3
 storm-control-enable broadcast
 storm-control-enable multicast
 storm-control-enable unicast-pkt
!
interface GigabitEthernet 0/4
 storm-control-enable broadcast
 storm-control-enable multicast
 storm-control-enable unicast-pkt
!
End
```

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 storm-control-enable broadcast
 storm-control-enable multicast
 storm-control-enable unicast-pkt
!
interface GigabitEthernet 0/2
 storm-control-enable broadcast
 storm-control-enable multicast
 storm-control-enable unicast-pkt
!
```

```
interface GigabitEthernet 0/3
 storm-control-enable broadcast
 storm-control-enable multicast
 storm-control-enable unicast-pkt
!
end
```

1 Configuring uRPF

Note

S6980-64QC and S6920-4C do not support the uRPF function.

1.1 Introduction

1.1.1 Overview

Unicast Reverse Path Forwarding (uRPF) is a function that protects the network against source address spoofing.

uRPF obtains the source address and inbound interface of a received packet and searches for a forwarding entry in the forwarding table based on the source address. If no entry is configured, the packet is discarded. In uRPF strict mode, if the outbound interface of the forwarding entry does not match the inbound interface of the packet, the packet is also discarded.

1.1.2 Principles

1. Basic Concepts

- uRPF strict mode

  uRPF obtains the source address and inbound interface of a received packet and searches for a forwarding entry in the forwarding table based on the source address. If the entry does not exist, the packet is discarded. If the outbound interface of the forwarding entry does not match the inbound interface of the packet, the packet is also discarded. The strict mode requires that the inbound interface of a received packet must be the outbound interface of the route entry to the source address of the packet.

  The uRPF strict mode is often deployed on a point-to-point (P2P) interface, and inbound and outbound data streams must go through the network of the P2P interface. uRPF blocks the packets with spoofed source addresses at the access layer or aggregation layer to prevent sending such packets from PCs to the core network.

- uRPF loose mode

  uRPF reversely searches for a route based on the source IP address of a received packet. The outbound interface of the next hop on the route does not need to be the inbound interface of the received packet. However, the route cannot be a route of a host on the local network.

  The loose mode is applicable to asymmetric routes or multi-homed networks with asymmetric traffic. On a multi-homed network, the user network is connected to multiple Internet service providers (ISPs), and the inbound and outbound traffic is not symmetric. To prevent invalid packets from attacking the user network, deploy the uRPF loose mode on the outbound interface connected to ISPs.

- uRPF packet loss rate

  The uRPF packet loss rate is the number of packets discarded due to the uRPF check per second. The unit is packets/second, that is, pps.

- Interval for calculating the uRPF packet loss rate

It refers to the interval from the previous time the packet loss rate is calculated to the current time the packet loss rate is calculated.

- Sampling interval of the uRPF packet loss rate

  It refers to the interval at which the number of lost packets is collected for calculating the packet loss rate. This interval must be greater than or equal to the interval for calculating the packet loss rate.

- Threshold of the uRPF packet loss rate

  It refers to the maximum packet loss rate that is acceptable. When the packet loss rate exceeds the threshold, alarms can be sent to users through syslogs or trap messages. You can adjust the threshold of the packet loss rate based on the actual network conditions.

- Alarm interval of the uRPF packet loss rate

  It refers to the interval at which alarms are sent to users. You can adjust the alarm interval based on the actual network conditions to prevent frequent output of logs or trap messages.

2. Enabling uRPF

Enable uRPF to perform a uRPF check on IP packets, thus protecting the device against source address spoofing.

uRPF can be configured in interface configuration mode.

- Interface configuration mode

  uRPF is performed for packets received on the configured interface.

3. Notifying the uRPF Packet Loss Rate

To conveniently monitor lost packets after uRPF is enabled, the device uses syslogs or trap messages to proactively notify users of the packet loss information detected in the uRPF check.

In the period from the time when uRPF is enabled to the time when the sampling interval arrives, the packet loss rate is the number of lost packets measured within the sampling interval divided by the uRPF enabling time. After that, the packet loss rate is calculated as follows:
Current packet loss rate = (Current number of lost packets measured at the calculation interval – Number of lost packets measured before the sampling interval)/Sampling interval

1.1.3 Protocols and Standards

- RFC 2827: Network Ingress Filtering: DDOS Attacks which employ IP Source Address Spoofing
- RFC 3704: Ingress Filtering for Multi-homed Networks

1.2 Restrictions and Guidelines

- uRPF is implemented with the help of existing unicast routes in the network. Therefore, unicast routes must be configured in the network.
- uRPF checks only source addresses of packets whose destination addresses are unicast addresses and does not check packets whose destination addresses are multicast or IPv4 broadcast addresses.
- uRPF cannot be enabled on a range of interfaces.
- uRPF does not check DHCP/BOOTP packets whose source IP address is 0.0.0.0 and destination IP address is 255.255.255.255.

- uRPF does not check loopback packets sent by the local device to itself.

1.3 Configuration Task Summary

uRPF configuration includes the following tasks:

(1) Enabling uRPF.

- Enabling uRPF on an Interface

(2) (Optional) Configuring uRPF Packet Loss Rate Advertisement. Configure at least one of the tasks.

- Configuring Global Packet Loss Rate Parameters
- Configuring Packet Loss Rate Parameters on an Interface

1.4 Enabling uRPF on an Interface

1.4.1 Overview

uRPF is performed for packets received on the configured interface to prevent source address spoofing.

1.4.2 Restrictions and Guidelines

- Both the uRPF strict mode and loose mode can be configured on an interface.
- uRPF cannot be configured in global configuration mode and interface configuration mode simultaneously.
- The default route is not used for a uRPF check by default. You can configure **allow-def-route** to use the default route for a uRPF check if necessary.
- After the uRPF IPv4 command is configured, a switch will perform a uRPF check on both IPv4 packets. Currently.
- The uRPF strict mode supports matching of equal-cost routes. If a packet received on an interface matches an equal-cost route during the uRPF check, the packet will be processed according to the uRPF loose mode.
- After uRPF is enabled, the route forwarding capacity of a device will be reduced by half.
- After uRPF is enabled on interfaces, a uRPF check is performed for all packets received on physical ports corresponding to these interfaces, which increases the scope of packets checked by uRPF. If a packet received on a tunnel port is also received on the preceding physical ports, the packet is also checked by uRPF. In such a scenario, be cautious in enabling uRPF.

Specification

A switch supports configuration of uRPF on a Layer 3 Ethernet interface or link aggregation, also support configuration of uRPF on a switch virtual interface (SVI). For details about the switch products, contact technical support engineers.

- uRPF does not support association with the ACL option.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Enable uRPF for an interface. Configure at least one of the tasks.

- Enable IPv4 uRPF for an interface.

  ip check unicast-pkt src-address reachable-via { **any** | **rx** } [**allow-def-route**] [*acl-number*]

  IPv4 uRPF is disabled for an interface by default.

  Switches support configuration of IPv4 uRPF on a Layer 3 Ethernet interface or link aggregation.

1.5 Configuring uRPF Packet Loss Rate Advertisement

1.5.1 Overview

After uRPF packet loss information monitoring is enabled, a device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the uRPF check so that the users can monitor the network status conveniently.

1.5.2 Restrictions and Guidelines

uRPF must be enabled.

1.5.3 Configuration Tasks

Configure at least one of the tasks.

- Configuring Global Packet Loss Rate Parameters
- Configuring Packet Loss Rate Parameters on an Interface

1.5.4 Configuring Global Packet Loss Rate Parameters

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure global packet loss rate parameters. Configure at least one of the tasks.

- Configure the interval of calculating the uRPF IPv4 packet loss rate.

  ip check urpf drop-pkt-rate compute interval *interval*

  The default interval for calculating the uRPF IPv4 packet loss rate is **30** seconds.

- Configure the alarm interval for the uRPF IPv4 packet loss rate.

  ip check urpf drop-pkt-rate notify hold-down *hold-down-time*

The default alarm interval for the uRPF IPv4 packet loss rate is **300** seconds.

1.5.5 Configuring Packet Loss Rate Parameters on an Interface

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure packet loss rate parameters on an interface. Configure at least one of the tasks.

- Enable uRPF packet loss information monitoring.

  ip check urpf drop-pkt-rate notify

  uRPF packet loss information monitoring is disabled by default.

- Configure the threshold of the uRPF packet loss rate.

  ip check urpf notification threshold *rate-value*

  The default threshold of the uRPF packet loss rate is **1000** packets per second.

  If the threshold is **0**, a notification is sent for every packet that is discarded because it fails in the uRPF check.

1.6 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** commands to output debugging information.

⚠ Caution

- The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **cleanup** commands to clear information.

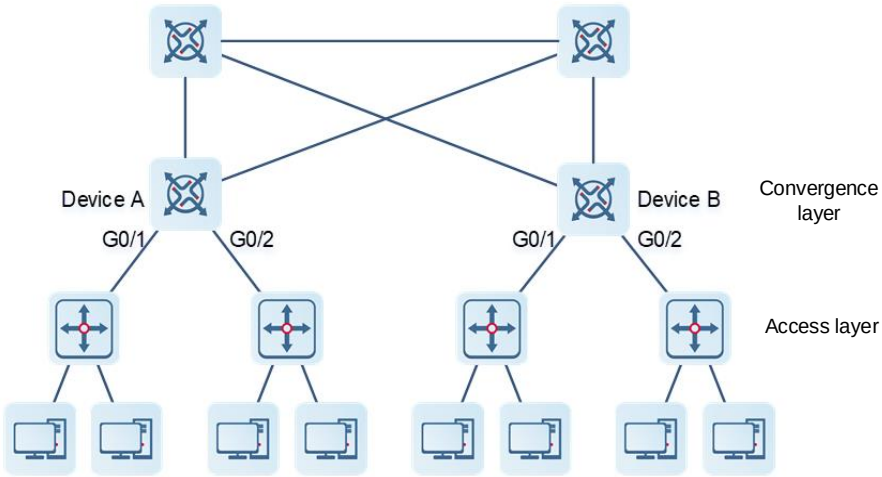
⚠ Caution

- Running the **cleanup** command during operation of the device may lose vital information and interrupt services.

Table 1-1 Monitoring

Command	Purpose
display ip urpf [**interface** *interface-type interface-number*]	Displays the IPv4 uRPF configurations and statistics.
cleanup ip urpf [**interface** *interface-type interface-number*]	Clears IPv4 uRPF packet loss statistics.
debugging urpf event	Debugs uRPF events.
debugging urpf timer	Debugs uRPF timers.

1.7 Configuration Examples



1.7.1 Configuring the uRPF Strict Mode

1. Requirements

In uRPF strict mode, packets with spoofed source addresses are blocked at the access layer or aggregation layer to prevent sending such packets from PCs to the core network.

2. Topology

Figure 1-1 Configuring the uRPF Strict Mode

3. Notes

Enable the uRPF strict mode on the aggregation devices, including Devices A and B.

4. Procedure

(1) Configure Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
```

```
DeviceA(cfg)# interface gigabitethernet0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# ip address 195.52.1.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/1)# ip check unicast-pkt src-address reachable-via rx
DeviceA(cfg-if-GigabitEthernet 0/1)# ip check urpf drop-pkt-rate notify
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
DeviceA(cfg)# interface gigabitethernet0/2
DeviceA(cfg-if-GigabitEthernet 0/2)# ip address 195.52.2.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/2)# ip check unicast-pkt src-address reachable-via rx
DeviceA(cfg-if-GigabitEthernet 0/2)# ip check urpf drop-pkt-rate notify
DeviceA(cfg-if-GigabitEthernet 0/2)# exit
```

(2) Configure Device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface gigabitethernet0/1
DeviceB(cfg-if-GigabitEthernet 0/1)# ip address 195.52.3.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/1)# ip check unicast-pkt src-address reachable-via rx
DeviceB(cfg-if-GigabitEthernet 0/1)# ip check urpf drop-pkt-rate notify
DeviceB(cfg-if-GigabitEthernet 0/1)# exit
DeviceB(cfg)# interface gigabitethernet0/2
DeviceB(cfg-if-GigabitEthernet 0/2)# ip address 195.52.4.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/2)# ip check unicast-pkt src-address reachable-via rx
DeviceB(cfg-if-GigabitEthernet 0/2)# ip check urpf drop-pkt-rate notify
DeviceB(cfg-if-GigabitEthernet 0/2)# exit
```

5. Verification

If source address spoofing exists on the network, run the **display ip urpf** command to display the number of spoofing packets discarded by uRPF.

Display the number of spoofing packets discarded by uRPF on GigabitEthernet 0/1 of Device A.

```
DeviceA# display ip urpf interface gigabitethernet 0/1
IP check src-address reachable-via RX
IP check URPF drop-pkt-rate notify is enabled
IP check URPF notification threshold is 1000pps
Number of drop packets in this interface is 124
Number of drop-pkt-rate notification counts in this interface is 0
```

Display the number of spoofing packets discarded by uRPF on GigabitEthernet 0/2 of Device A.

```
DeviceA# display ip urpf interface gigabitethernet 0/2
IP check src-address reachable-via RX
IP check URPF drop-pkt-rate notify is enabled
IP check URPF notification threshold is 1000pps
Number of drop packets in this interface is 133
Number of drop-pkt-rate notification counts in this interface is 0
```

Display the number of spoofing packets discarded by uRPF on GigabitEthernet 0/1 of Device B.

```
DeviceB# display ip urpf interface gigabitethernet 0/1
IP check src-address reachable-via RX
```

```
IP check URPF drop-pkt-rate notify is enabled
IP check URPF notification threshold is 1000pps
Number of drop packets in this interface is 124
Number of drop-pkt-rate notification counts in this interface is 0
```

Display the number of spoofing packets discarded by uRPF on GigabitEthernet 0/2 of Device B.

```
DeviceB# display ip urpf interface gigabitethernet 0/2
IP check src-address reachable-via RX
IP check URPF drop-pkt-rate notify is enabled
IP check URPF notification threshold is 1000pps
Number of drop packets in this interface is 250
Number of drop-pkt-rate notification counts in this interface is 0
```

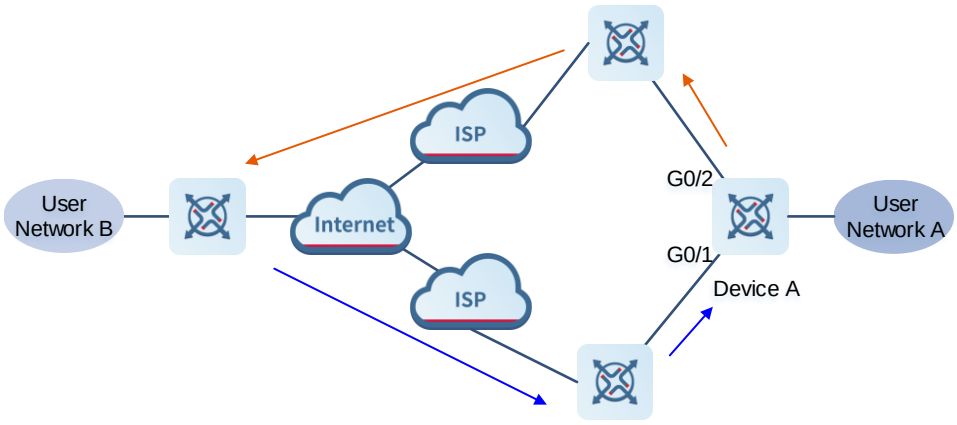
6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 ip address 195.52.1.1 255.255.255.0
 ip check unicast-pkt src-address reachable-via rx
 ip check urpf drop-pkt-rate notify
!
interface GigabitEthernet 0/2
 ip address 195.52.2.1 255.255.255.0
 ip check unicast-pkt src-address reachable-via rx
 ip check urpf drop-pkt-rate notify
!
end
```

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 ip address 195.52.3.1 255.255.255.0
 ip check unicast-pkt src-address reachable-via rx
 ip check urpf drop-pkt-rate notify
!
interface GigabitEthernet 0/2
 ip address 195.52.4.1 255.255.255.0
 ip check unicast-pkt src-address reachable-via rx
 ip check urpf drop-pkt-rate notify
!
end
```



1.7.2 Configuring the uRPF Loose Mode

1. Requirements

To prevent invalid packets from attacking the user network, deploy the uRPF loose mode.

2. Topology

Figure 1-2 Configuring the uRPF Loose Mode

3. Notes

Configure the uRPF loose mode on the outbound interfaces connected to ISPs.

4. Procedure

Enable the uRPF loose mode on GigabitEthernet 0/1 and GigabitEthernet 0/2.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet0/1)# ip address 195.52.1.2 255.255.255.252
DeviceA(cfg-if-GigabitEthernet0/1)# ip check unicast-pkt src-address reachable-via any
DeviceA(cfg-if-GigabitEthernet0/1)# ip check urpf drop-pkt-rate notify
DeviceA(cfg-if-GigabitEthernet0/1)# exit
DeviceA(cfg)# interface gigabitethernet 0/2
DeviceA(cfg-if-GigabitEthernet0/2)# ip address 152.95.1.2 255.255.255.252
DeviceA(cfg-if-GigabitEthernet0/2)# ip check unicast-pkt src-address reachable-via any
DeviceA(cfg-if-GigabitEthernet0/2)# ip check urpf drop-pkt-rate notify
DeviceA(cfg-if-GigabitEthernet0/2)# end
```

5. Verification

If source address spoofing exists on the network, run the **display ip urpf** command to display the number of spoofing packets discarded by uRPF.

```
DeviceA# display ip urpf
IP check URPF drop-pkt-rate compute interval is 300s
IP check URPF drop-pkt-rate notify hold-down is 300s
Interface gigabitEthernet0/1
IP check src-address reachable-via ANY
IP check URPF drop-pkt-rate notify is enabled
IP check URPF notification threshold is 1000pps
Number of drop packets in this interface is 4121
```

```
Number of drop-pkt-rate notification counts in this interface is 2
Interface gigabitEthernet0/2
IP check src-address reachable-via ANY
IP check URPF drop-pkt-rate notify is enabled
IP check URPF notification threshold is 1000pps
Number of drop packets in this interface is 352
Number of drop-pkt-rate notification counts in this interface is 0
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
  ip address 195.52.1.2 255.255.255.252
  ip check unicast-pkt src-address reachable-via any
  ip check urpf drop-pkt-rate notify
!
interface GigabitEthernet 0/2
  ip address 152.95.1.2 255.255.255.252
  ip check unicast-pkt src-address reachable-via any
  ip check urpf drop-pkt-rate notify
!
end
```

1 Configuring Security Log Auditing

1.1 Introduction

1.1.1 Overview

Security log auditing is used to record key operations on a device and audit and backtrack these operations afterwards to improve the device security and meet the national security standards.

Note

The following sections describe content related to security log auditing only.

1.1.2 Principles

1. Basic Concepts

- Key operation

  After enabling the security log auditing function, the device records logs for key operations, including account management, login events, system events, configuration file changes, and security log events. Key operations include:

  - Adding/deleting accounts
  - Editing authentication information
  - Modifying configurations (such as the DNS address and IP address)
  - User login/logout
  - Restarting/Stopping the device
  - Uploading/downloading files (when supported)
  - Editing user permissions (when supported)
  - Enabling/disabling log auditing and deleting logs

2. Enabling Security Log Auditing

After the security log auditing function is enabled, the device can record logs for key operations and locally store the logs.

When a user performs a key operation, such as account management, login/logout, system restart, configuration file change, or log auditing function enabling/disabling, the corresponding service module will collect information (such as time, username, IP address, operation log content, and operation result), generate a log, and write the log to the local database through the log auditing framework.

At 03:00:00 a.m. each day, the system checks whether any logs for key operations exceed the storage time. If yes, the logs will be deleted.

A maximum of 10,000 logs can be stored by default. After the number of stored logs exceeds the storage limit, new logs will overwrite the earliest ones.

3. Enabling the Function of Sending Security Logs to the Syslog Server

After a device is configured with the functions of syslog, and the security log auditing and sending functions are enabled, the log auditing framework will send generated logs to the syslog server to store.

1.2 Restrictions and Guidelines

- To protect the flash storage chip, newly generated logs will be cached in the memory and written to a file every 1 hour. When a restart command, such as **reboot**, is executed, logs will be written to a file. If many logs are generated in this hour and some logs are not written to the file in 1 hour, the logs will be lost.
- When logs are exported to a file, download the file in time. The file will be automatically deleted after 1 hour.

1.3 Configuration Task Summary

Configuration of security log auditing includes the following tasks:

(1) Enabling Security Log Auditing

(2) (Optional) Configuring the Local Storage Time for Security Logs

(3) (Optional) Configuring the Handling Time of Aged Security Logs

(4) (Optional) Configuring the Local Storage Capacity for Security Logs

1.4 Configuring Security Log Auditing

1.4.1 Overview

The security log auditing function can record logs for key operations on a device and locally store the logs. Log query and export are supported.

1.4.2 Enabling Security Log Auditing

1. Overview

After the security log auditing function is enabled, the device will record logs for key operations, including account management, login events, system events, configuration file changes and security log events, and store the logs to the local database.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable security log auditing.

security-log audit-enable

Security log auditing is enabled by default.

1.4.3 Configuring the Local Storage Time for Security Logs

1. Overview

After the local storage time is configured for security logs, the logs that have exceeded the storage time will be deleted.

2. Restrictions and Guidelines

Security logs that have exceeded the storage time will be deleted.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the local storage time for security logs.

security-log data-store-days *data-store-time*

The default local storage time for security logs is **65535** days.

1.4.4 Configuring the Handling Time of Aged Security Logs

1. Overview

After the handling time of aged security logs is configured, the system checks whether any logs have exceeded the storage time at the configured handling time (deviation: 5 minutes) and deletes expired logs.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the handling time of aged security logs.

security-log auto-vacuum-time *hh*:*mm*:*ss*

The default handling time of aged security logs is **03:00:00** every day.

1.4.5 Configuring the Local Storage Capacity for Security Logs

1. Overview

After the local storage capacity for security logs is configured, new logs will overwrite earliest ones when the capacity of locally stored logs exceeds the storage limit.

2. Restrictions and Guidelines

If flash space is limited, you can run this command to decrease the storage capacity for security logs.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the local storage capacity for security logs.

security-log data-store-items *log-number*

The default local storage capacity for security logs is **10000**.

1.5 Monitoring

Run the **delete** commands to clear information.

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** commands to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
debugging security-log errors	Debugs log auditing.
debugging security-log recv-info	Debugs received logs.
debugging security-log sql-info	Debugs the log database.
display security-log	Displays all logs.
display security-log config	Displays configurations.
display security-log detail { **all** | { **from** *YY//MM/DD hh*:*mm*:*ss* **to** *YY//MM/DD hh*:*mm*:*ss* } } [**hostname** *hostname*] [**log-type** { **acc_mnt** | **config** | **login** | **other** | **sec_log** | **sys** }] [**peerinfo** *peerinfo*] [**user** *username*] { [**order-by** { **log-type** | **time** } { **asc** | **desc** } [**start-item** *start-item* **end-item** *end-item*]] }	Displays the detailed log information, which can be filtered by time, log type, username, host name, and terminal information.
display security-log detail export { **all** | { **from** *YY//MM/DD hh*:*mm*:*ss* **to** *YY//MM/DD hh*:*mm*:*ss* } } [**hostname** *hostname*] [**log-type** { **acc_mnt** | **config** | **login** | **other** | **sec_log** | **sys** }] [**peerinfo** *peerinfo*] [**user** *username*] { [**order-by** { **log-type** | **time** } { **asc** | **desc** } [**start-item** *start-item* **end-item** *end-item*]] }	Exports the detailed log information, which can be filtered by time, log type, username, host name, and terminal information.

Command	Purpose
display security-log detail stat { **all** | { **from** *YY//MM/DD hh:mm:ss* **to** *YY//MM/DD hh:mm:ss* } } [**hostname** *hostname*] [**log-type** { **acc_mnt** | **config** | **login** | **other** | **sec_log** | **sys** }] [**peerinfo** *peerinfo*] [**user** *username*]	Displays the log statistics, which can be filtered by time, log type, username, host name, and terminal information.
display security-log info	Displays the statistics during log processing.
display security-log statistics	Displays the statistics.
security-log delete all	Deletes all logs.

1.6 Configuration Examples

1.6.1 Configuring Security Log Auditing

1. Requirements

To improve device security and audit and backtrack exceptions (such as key configurations being tampered) afterwards, key operations on a device need to be recorded. After the security log auditing function is enabled, the device records key operations, including account management, login events, system events, configuration file changes, and security log events. After logging in to the device, the administrator can monitor recent user behaviors through the records.

2. Topology

Figure 1-1 Configuring Security Log Auditing

3. Notes

- Enable security log auditing.
- Configure parameters related to security log auditing.

4. Procedure

Enable security log auditing.

```
Device> privilege
Device# config-system terminal
Device(cfg)# security-log audit-enable
```

Set the local storage time of security logs to **300** days.

```
Device(cfg)# security-log data-store-days 300
```

Set the handling time of aged security logs to **05:05:00** every day.

```
Device(cfg)# security-log auto-vacuum-time 05:05:00
```

Set the local storage capacity for security logs to **1000**.

```
Device(cfg)# security-log data-store-items 1000
```

5. Verification

Log in to the device, perform key operations, and run **display security-log detail all** 30s later to check the log auditing records.

```
Device# display security-log detail all
time, username, peerinfo, hostname, log-type: content
2019-10-22 10:00:02, admin, vty0(192.168.111.111), Device, SEC_LOG: SECURITY_LOG deleted all security log successfully
2019-10-22 10:00:02, admin, vty0(192.168.111.111), Device, SEC_LOG: SECURITY_LOG disabled security log audit configuration unsuccessfully
2019-10-22 10:00:03, ---, console, Device, SEC_LOG: SECURITY_LOG enabled security log audit configuration successfully
```

Run the **display security-log config** command to verify that the local storage time of security logs is 300 days, the handling time of aged security logs is 05:05:00 every day, and the local storage capacity for security logs is 1000.

```
Device# display security-log config
Security-log audit: enable
Limit number: 10000
Store days: 300
Auto vacuum time: 05:05:00
```

6. Configuration Files

```
hostname Device
!
security-log data-store-days 300
security-log data-store-items 1000
security-log auto-vacuum-time 05:05:00
!
end
```

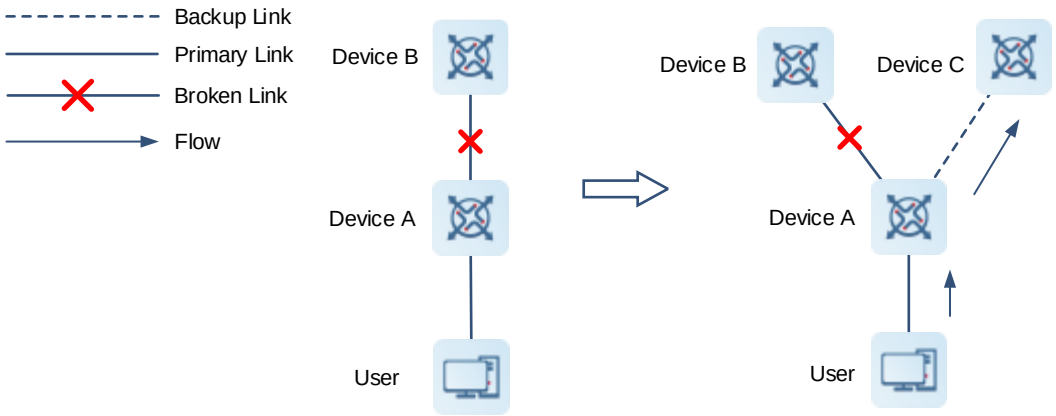
1 Configuring REUP

Rapid Ethernet Uplink Protection (REUP) provides a rapid uplink protection function. In the dual uplink networking, REUP is used to ensure normal communication between links, block redundant links, avoid link loops, and implement fast backup.



1.1 Introduction

1.1.1 Topology

The left topology in Figure 1-1 shows single uplink networking, where there is only one link between the user and the distribution device to implement communication. When the link between access device A and distribution device B fails, the link between the user and device B is disconnected, which interrupts all external services of the user.

The topology can be transformed into REUP dual uplink deployment topology, as shown in the right topology in Figure 1-1. In this topology, one link functions as the active link for normal communication, and the other link functions as a backup link and is not used for communication. When the active link fails, traffic is switched to the backup link. This helps reduce the impact of a single link failure on the network and improve reliability.

Figure 1-1 REUP Topology

REUP and the Spanning Tree Protocol (STP) are mutually exclusive on ports. Generally, a device runs STP in the downlink direction and runs REUP in the uplink direction to implement uplink backup and data protection in the case of faults. REUP can still provide basic link redundancy when STP is disabled. It also provides millisecond-level fault recovery faster than STP. Its main features are as follows.

- The uplink ports of REUP are configured in pairs, namely, an uplink port pair includes a forward port and a standby port. The standby port does not forward data packets. When the forward port fails, the standby port immediately becomes the forward port to forward data.
- REUP sends an address update packet to the upstream device so that the upstream device can update the MAC address information immediately. This function ensures that L2 data streams are restored rapidly after a link gets faulty.

1.1.2 Basic Concepts

1. REUP Pair

You can specify a port as the backup port of another port to configure an REUP pair, in which one port is the active port and the other is the backup port. When both ports are normal, one port is configured as the forward port and the other as the standby port.

2. MAC Address Update Message

According to the MAC address learning principle, before L2 link switching a user's MAC address entry exists on the forwarding link, and no packet is forwarded by the blocked link, so there is no user's MAC address entry on the blocked link. After switching, packets cannot be forwarded because they are still forwarded according to the existing MAC address entry of the user. MAC address update messages refer to FLUSH packets sent to an uplink device through private multicast packets. When an uplink device, on which the function of receiving MAC address update messages is enabled, receives a MAC address update message, the device updates the MAC entry on the relevant interface.

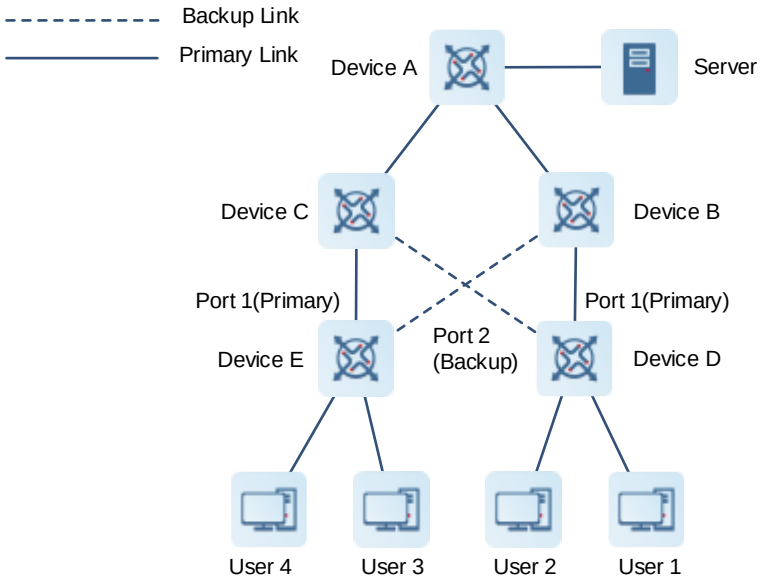
3. MAC Address Update Group

Multiple ports can be added to a group. If one port in the group receives a MAC address update message, the MAC address entries on other ports in the group are updated at the same time. In this case, the group is called a MAC address update group.

4. MAC Address Update Packet

MAC address update packets are sent to uplink devices of other manufacturers to ask them to update their MAC address entries, so as to implement compatibility with them.

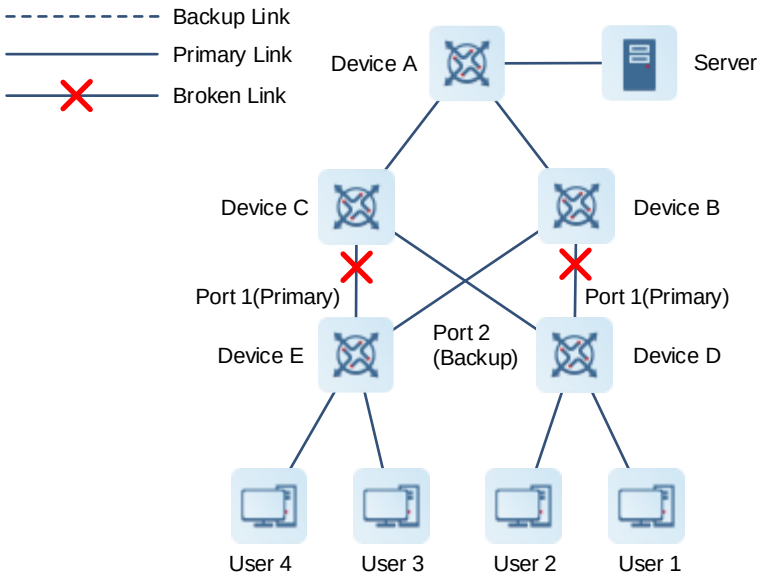
5. Link State Tracking Group



The uplink and downlink ports of a device can be added to a group at the same time, which is called a link state tracking group. If all uplink ports in the group are down, all downlink ports in this group are forced down.

1.1.3 Dual-Link Backup

When an active link is faulty, the link in the backup state will rapidly device to the forward state and start to forward data, to minimize the service interruption caused by the link failure. REUP adopts the real-time backup and batch backup mechanisms to ensure that the configuration and operating status of the standby device are completely consistent with those of the active device. When the master/slave switching occurs in a virtual device unit (VSU) scenario, the data flow is not cut off, the operating status of REUP is consistent with that before the switching, and link switching is not performed again.



- You can specify a port as the backup port of another port to configure an REUP pair. When the two ports are normal, one link is in the forwarding state (forwarding data packets) and the other link is in the backup state (not forwarding data packets).
- When the active link is faulty, the link in the backup state rapidly switches to the forwarding state and starts to forward data.
- When the faulty link recovers, it enters the backup state and does not forward data packets.
- The preemption mode can be configured to specify whether the link recovering from a fault preempts to become the link in the forwarding state.

Figure 1-2 Configuring Two Active Links

As shown in Figure 1-2, ports 1 and 2 of device D (device E) are connected to uplink switches B and C (switches C and B) respectively, and REUP is configured on ports 1 and 2. When the links are normal, port 1 is in the forwarding state and forwards data packets and port 2 is in the backup state and does not forward data packets.

Figure 1-3 Topology with Device D and Device E1Faulty

As shown in Figure 1-3, once port 1 fails, port 2 immediately starts to forward data packets and restores uplink transmission of the device. In the non-preemption mode, when the link of port 1 recovers, port 1 is in the backup state and does not forward data packets, and port 2 continues forwarding data packets. You must enable the REUP dual-link backup function on a port so that the port undertakes the REUP link switching when the port is faulty.

Note

- REUP, Ethernet Ring Protection Switching (ERPS), and Rapid Ethernet Ring Protection (RERP) do not share ports.
- On devices enabled with REUP, the storm control function must be disabled on all L2 ports.

1.1.4 MAC Address Update

During link switching, the MAC address entries on a port are updated to speed up packet convergence. As shown in Figure 1-2, the MAC address update process is analyzed as follows:

- Ports 1 and 2 of device D (device E) have the REUP dual-link backup enabled. Port 1 works as the active port. During normal communication, device A learns the MAC addresses of users 1 and 2 (users 3 and 4) from the port connecting to device B (device C).
- When port 1 of device D (device E) fails, port 2 quickly changes to the forwarding state and starts to forward data packets. In this case, device A has not learned the MAC addresses of users 1 and 2 (users 3 and 4) from the port connecting to device B (device C). The data packets sent by the server to users 1 and 2 (users 3 and 4) are forwarded to device C (B) by device A, causing loss of the packets from the server to users 1 and 2 (users 3 and MAC 4).

The following measures can be taken to avoid the above problem:

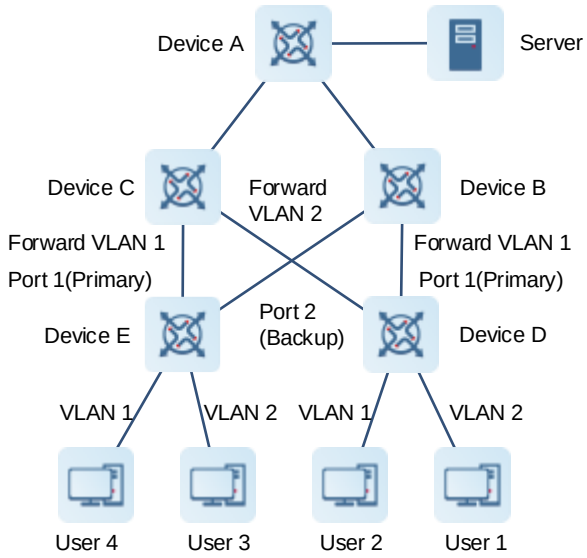
- Enable the MAC address update function on device D (device E). When port 2 starts to forward packets, device D (device E) sends a MAC address update message to port 2.
- After receiving the MAC address update message from port 2, device A updates the MAC address entries on the port of device A. In this way, device A forwards the packets sent by the server to the users, to the port connecting to device C (device B) to speed up packet transmission convergence.
- In addition, a MAC address update group can be configured, that is, multiple ports can be classified into the same group. When a port in this group receives a MAC address update message, the MAC address entries on other ports in the group are updated, to reduce the side effect of flooding caused by MAC address update.
- To be compatible with upstream devices not supporting MAC address update messages, device D (device E) sends MAC address update packets for users 1 and user 2 (users 3 and 4) upstream when port 2 switches to the forwarding state. In this way, device A updates the MAC addresses of users 1 and 2 (users 3 and 4) to the corresponding port and the downstream data transmission of device A is restored.

Based on the above process analysis, the relevant configuration to be involved includes the following items:

Table 1-1 Description of MAC Address Update Configuration Items

Configuration Item	Description
Sending MAC address updates	If the function of sending MAC address update messages is not enabled, no MAC address update message is sent when REUP dual-link backup switching is performed.

Configuration Item	Description
Receiving MAC address updates	If the function of receiving MAC address update messages is not enabled, a device cannot receive MAC address update messages from downlink devices during REUP dual-link backup switching and will not update the MAC addresses.
Specifying a VLAN for sending MAC address updates	If the VLAN in which an interface sends MAC address update messages is configured, the messages are sent in the configured VLAN; otherwise, the messages are sent in the default VLAN to which the interface belongs.
Specifying a VLAN for receiving MAC address updates	If no VLAN in which an interface receives MAC address update messages is configured, MAC address update messages are received in all the configured VLANs; otherwise, MAC address update messages are received in the specified VLAN.
MAC address update group	If no MAC address update group is configured, MAC address update is not performed when MAC address update packets are received.
Maximum number of MAC address update messages sent per second	A greater number of messages configured indicates more CPU time used for sending messages and fewer downstream packets to be lost.



1.1.5 VLAN Load Balancing

The VLAN load balancing function allows the two ports of a REUP pair to forward data packets of mutually exclusive VLANs so as to make full use of the link bandwidth.

As shown in Figure 1-4, the MAC address update process is analyzed as follows:

- Configure REUP dual-link backup and enable the VLAN load balancing of REUP on ports 1 and 2 of device D, and map VLAN 1 to instance 1 and VLAN 2 to instance 2. Data of VLAN 1 (instance 1) is transmitted through port 1 and data of VLAN 2 (instance 2) is transmitted through port 2. Perform the same configuration on device E.
- When a port is faulty, the other port takes over the transmission of all VLAN data.
- When the faulty port recovers and works properly within the preemption delay, the transmission of VLAN data in the charge of the faulty port is switched back to the recovered port.

Figure 1-4 Configuring VLAN Load Balancing

Therefore, the VLAN load balancing function needs to be enabled on the ports to make full use of the link bandwidth for packet forwarding when both links are normal.

Caution

- The instance mapping of REUP VLAN load balancing is controlled by the Multiple Spanning Tree Protocol (MSTP) module in a unified manner. For details about how to configure the instances, see *Configuring MSTP*.
- The VLAN load balancing function can be configured only on trunk, uplink, or hybrid ports.

1.1.6 Link State Tracking

Link state tracking means that, when an upstream link is faulty, the downstream link switches services to the backup upstream link so that the backup port can continue to forward packets. Link state tracking provides the function of notifying a downlink device to perform link switching when all the upstream links are faulty. You can configure the upstream and downstream ports of a link state tracking group and bind the link states of multiple downstream ports to multiple uplink ports to implement link state synchronization. In default configuration, when all uplinks in a tracking group are faulty, the downlink ports are shut down forcibly to ensure that the downlink transmission is switched from the active link to the backup link.

As shown in Figure 1-5, when the uplink of device B is faulty, link state tracking rapidly shuts down the downstream port of device B so that the upstream transmission of device D is switched to device C.

Figure 1-5 Topology with the Active Uplink Faulty

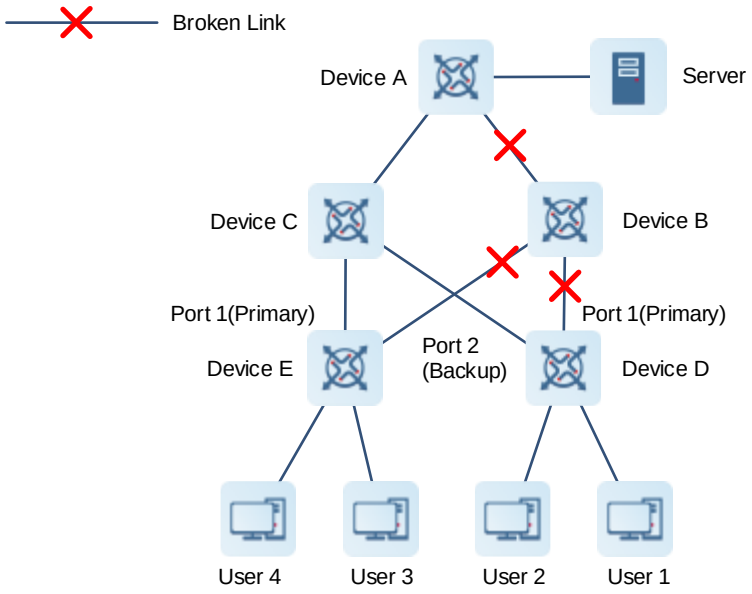


Table 1-2 Description of Link State Tracking Configuration Items

Configuration Item	Description
Link state tracking function	If the link state tracking function is not enabled, the state of a corresponding uplink port cannot be detected and packet forwarding switching cannot be implemented in time.
Downlink up delay function for a link state tracking group	By enabling the downlink up delay function, you can avoid frequent downlink switching caused by uplink flapping in a link state tracking group. That is, when the uplink becomes up, the downlink becomes up after a delay.
Adding a port to a link state tracking group	If a port is not added to a link state tracking group, the state of a corresponding uplink port cannot be detected and packet forwarding switching cannot be implemented in time.

1.2 Configuration Task Summary

REUP configuration includes the following tasks:

(1) Configuring Basic Features of REUP

(2) (Optional) Configuring the Preemption Function of REUP

(3) Configuring the MAC Address Update Function

(4) (Optional) Configuring VLAN Load Balancing

(5) Configuring Link State Tracking

1.3 Configuring Basic Features of REUP

1.3.1 Overview

When a link is faulty, another normal link switches to the forward state immediately to forward packets.

1.3.2 Restrictions and Guidelines

- One port belongs to only one REUP pair. Each active link has only one backup link. A backup link can be used as the backup link of only one active link. The active and backup links must use different ports.
- REUP supports Layer 2 physical ports and link aggregations, but does not support member ports of a link aggregation .
- The active and backup ports may be of different types and have different rates. For example, an AP can be used as the active port and a physical port can be configured as the backup port.
- Ports configured with REUP are not involved in STP calculation.
- Each device can be configured with a maximum of 16 REUP pairs.
- Ports successfully configured with REUP cannot be configured as Layer 3 interfaces or added to a link aggregation.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 2 Ethernet interface configuration mode.

interface *interface-type interface-number*

(4) Configure a REUP dual-link backup port.

flexlink pairs interface *interface-type interface-number*

No REUP dual-link backup port is configured by default.

1.4 Configuring the Preemption Function of REUP

1.4.1 Overview

- If the active link needs to always forward packets or the link for forwarding packets needs to be determined based on the link bandwidth, the preemption mode and delay time must be configured.
- You can determine the link to be used by configuring the preemption mode. If the preemption mode is set to bandwidth mode, a link with a greater bandwidth is used. The value of the bandwidth attribute of a link aggregation is the actual bandwidth of the link aggregation, equal to the number of link up member ports of the link aggregation multiplied by the speed attribute value of a member port. You can also set the preemption mode to forced mode to select a stable and reliable link forcibly.
- To avoid frequent active/backup link switching caused by faults, REUP provides a preemption delay function. After the two links recover, link switching is delayed (**35** seconds by default) for the faulty link to become

stable. A smaller delay means more frequent preemption switching after the faulty link recovers. When STP is enabled on an uplink, the preemption delay time of REUP should be greater than 35 seconds.

- The preemption mode can be set to three modes: forced, bandwidth, and off. In the bandwidth mode, a port with a greater bandwidth is selected to transmit data; in the forced mode, the active port is selected to transmit data; in the off mode, no preemption is performed.

1.4.2 Restrictions and Guidelines

REUP dual-link backup must be configured.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 2 Ethernet interface configuration mode.

interface *interface-type interface-number*

(4) Configure the preemption mode of REUP.

flexlink pairs interface *interface-type interface-number* **preemption mode** { **bandwidth** | **forced** | **off** }

The default link preemption mode of REUP is off mode.

(5) Configure the preemption delay time of REUP.

flexlink pairs interface *interface-type interface-number* **preemption delay** *interval*

The default preemption delay time of REUP is **35** seconds.

1.5 Configuring the MAC Address Update Function

1.5.1 Overview

- The MAC address update function can rapidly delete and update MAC address information on interfaces during link switching to make packet convergence faster.
- To reduce data loss in downstream data stream during link switching, you need to enable the function of sending MAC address update messages on a device that performs switching.
- During link switching, REUP sends a certain number of MAC address update packets to an uplink device per second to recover the downstream data transmission of the uplink device.
- When dual-link backup switching occurs, downstream data streams may be lost because the MAC address table of the uplink device is not updated in time. In order to reduce loss of L2 data streams, you need to update the MAC address table of the uplink device. In this case, you need to enable the function of receiving MAC address update messages on the uplink device.
- To reduce massive flooding caused by MAC address update, which may affect normal data transmission of the device, you can configure a MAC address update group. Only after all ports in a switching path are added to the same MAC address update group, can transmission of downstream data be rapidly recovered.
- For a VLAN in which the function of processing MAC address update messages is disabled, MAC address update packets can be used to recover the downlink transmission of uplink devices; however, the

convergence performance will be decreased in the case of link faults.

- After the function of sending MAC address update messages is enabled, MAC address update messages are sent to uplink devices during link switching.

1.5.2 Restrictions and Guidelines

- REUP dual-link backup must be configured.
- A maximum of eight address update groups can be configured on each device. Each address update group can contain a maximum of eight member ports and a port can belong to multiple address update groups.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the function of sending MAC address update private multicast messages.

mac-addr-table move update transit

No MAC address update private multicast message is sent by default.

(4) (Optional) Configure the maximum rate for sending MAC address update broadcast packets.

mac-addr-table move update max-update-rate *packet-per-second*

The default maximum rate for sending MAC address update broadcast packets is **150** packets/second.

(5) On an uplink device, enable the function of receiving MAC address update private multicast messages.

mac-addr-table move update receive

No MAC address update private multicast message is received by default.

(6) (Optional) On an uplink device, configure the VLAN ID range, in which MAC address update private multicast messages are received.

mac-addr-table move update receive vlan *vlan-range*

The MAC address update private multicast messages in all the VLAN ID ranges are received by default.

(7) Enter the interface configuration mode.

interface *interface-type interface-number*

(8) Configure the MAC address update group ID for the interface.

mac-addr-table update group [*group-id*]

No MAC address update group is configured by default.

(9) (Optional) Configure the ID of a VLAN, in which a port sends MAC address update private multicast messages.

mac-addr-table move update transit vlan *vlan-id*

By default, the ID of the VLAN, in which a port sends MAC address update private multicast messages is the local default VLAN of the port.

1.6 Configuring VLAN Load Balancing

1.6.1 Overview

- This function is used to maximize the utilization of link bandwidth.
- You can modify the mapping between instances and VLANs by using the instance mapping function of MSTP.
- The VLAN load balancing function allows the two ports of a REUP pair to forward data packets of mutually exclusive VLANs so as to make full use of the link bandwidth. That is, it allows some VLAN data packets to be forwarded through the backup link, but the active link does not forward these VLAN data packets. In this way, the active link and backup link forward different VLAN data packets and achieve load sharing.
- The VLAN load balancing of REUP relies on the mappings between VLANs and MSTP instances, and the instance mappings are controlled by the MSTP module in a unified manner. For details about how to configure the instances, see the description in "Configuring MSTP."

1.6.2 Restrictions and Guidelines

- REUP dual-link backup must be configured.
- VLAN load balancing cannot be configured on an access port but can share a port with STP.
- For ports successfully configured with VLAN load balancing, you cannot modify the port attributes but can modify the VLAN attributes of the ports.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a group of VLANs.

vlan { *vlan-id* | **range** *vlan-range* }

Only VLAN 1 exists by default.

(4) Return to the global configuration mode.

exit

(5) Enter the MST configuration mode.

spanning-tree mst configuration

(6) Configure the mappings between instances and VLANs, and add the VLAN group to one MST instance.

instance *instance-id* **vlan** *vlan-range*

Only instance **0** exists and all VLANs belong to instance **0** by default.

(7) Enter the Layer 2 Ethernet interface configuration mode.

interface *interface-type interface-number*

(8) Configure the VLAN load balancing function.

flexlink pairs interface *interface-type interface-number* **prefer instance** *instance-range*

The VLAN load balancing function is not configured by default.

1.7 Configuring Link State Tracking

1.7.1 Overview

- After detecting that the uplink is disconnected, REUP forcibly disconnects the downlink so that link switching can be performed.
- You must create a link state tracking group first and then add a port to the tracking group.
- You must enable the delay function so that the downlink can be up after the delay.
- You must create a link tracking group first and then add a port to the tracking group.
- When the number of uplink ports whose link status is restored in a link state tracking group is lower than the uplink port quantity threshold, the link state tracking group is in the Down state, and the link status of all downlink ports in the link state tracking group is forcibly changed to Down. When the number of uplink ports whose link status is restored is greater than or equal to the uplink port quantity threshold, the link state tracking group is restored to the normal state and the link status of all downlink ports in the link state tracking group is restored. The default uplink port quantity threshold is **1**.

1.7.2 Restrictions and Guidelines

- REUP dual-link backup must be configured.
- For the link state tracking function, each port belongs to only one link state tracking group and each device can be configured with up to two link state tracking groups. Each link state tracking group can have 8 upstream ports and 256 downstream ports.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable a link state tracking group.

link state enable-track-group [*track-number*]

All the link state tracking groups are disabled by default.

(4) Configure the downlink recovery delay time for the link state tracking group.

link state enable-track-group *track-number* **up-delay** *interval*

The downlink of a link state tracking group recovers without delay by default.

(5) Configure the uplink port quantity threshold for triggering status switching of a link state tracking group.

link state enable-track-group *track-number* **uplink-port-threshold** port-*number*

The default uplink port quantity threshold for triggering status switching of a link state tracking group is **1**.

(6) Enter the Layer 2 Ethernet interface configuration mode.

interface *interface-type interface-number*

(7) Add a port to the link state tracking group, and specify it as the uplink port of the group.

link state trace-group *track-number* **upstream**

No port is added to a link state tracking group by default.

(8) Add a port to the link state tracking group and specify it as the downlink port of the group.

link state trace-group *track-number* **downstream**

No port is added to a link state tracking group by default.

1.8 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

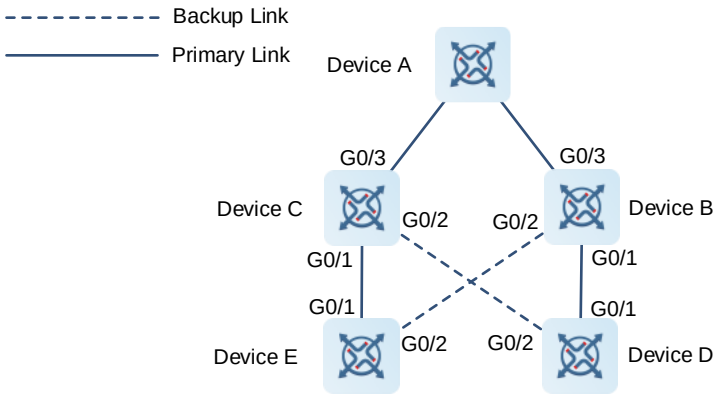
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-3 REUP Monitoring

Command	Purpose
display interfaces [*interface-type interface-number*] **flexlink pairs** [**detail**]	Displays the REUP dual-link backup information.
display mac-addr-table update group [**detail**]	Displays the configurations of a MAC address update group.
display mac-addr-table move update	Displays the statistics on MAC address update messages sent by an REUP pair.
display link state trace-group	Displays the information about a link state tracking group.
debugging reup all	Debugs all functions of REUP.
debugging reup process	Debugs the normal running process of REUP.
debugging reup packet	Debugs MAC address update messages of REUP.
debugging reup macupdt	Debugs MAC address update packets of REUP.
debugging reup ha	Debugs hot backup.
debugging reup error	Debugs errors occurring in REUP running.
debugging reup event	Debugs received events.
debugging reup status	Debugs statistics displayed when a show command is executed.

1.9 Configuration Examples



1.9.1 Configuring Basic Features of REUP

1. Requirements

An L3 device networking topology need to be built to simulate the scenario, in which there are two interconnection links between the access devices and the core devices.

2. Topology

Figure 1-6 Configuring Basic Features of REUP

3. Notes

- Configure REUP dual-link backup (GigabitEthernet 0/1 is the active port and GigabitEthernet 0/2 is the backup port) on access device D (device E).

4. Procedure

Perform the following configuration on device D.

```
DeviceD > privilege
DeviceD # config-system terminal
DeviceD (cfg)# interface gigabitethernet 0/1
DeviceD (cfg-if-GigabitEthernet 0/1)# switch-port mode trunk
DeviceD (cfg-if-GigabitEthernet 0/1)# flexlink pairs interface gigabitethernet 0/2
DeviceD (cfg-if-GigabitEthernet 0/1)# exit
```

Perform the following configuration on device E.

```
DeviceE > privilege
DeviceE # config-system terminal
DeviceE (cfg)# interface gigabitethernet 0/1
DeviceE (cfg-if-GigabitEthernet 0/1)# switch-port mode trunk
DeviceE (cfg-if-GigabitEthernet 0/1)# flexlink pairs interface gigabitethernet 0/2
DeviceD (cfg-if-GigabitEthernet 0/1)# exit
```

5. Verification

Run the **display interfaces flexlink pairs detail** command to verify that the configuration is correct.

```
DeviceD #display interfaces flexlink pairs detail
Device Backup Interface Pairs:
Active Interface            Backup Interface            State
--------------------------------------------------------------------------------
Gi0/1                       Gi0/2                       Active Up/Backup Standby

Interface Pair : Gi0/1, Gi0/2
Preemption Mode : off
Preemption Delay : 35 seconds
Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)
```

Run the **display interfaces flexlink pairs detail** command to check whether the configuration on device E is correct.

```
DeviceE #display interfaces flexlink pairs detail
Device Backup Interface Pairs:
Active Interface            Backup Interface            State
--------------------------------------------------------------------------------
Gi0/1                       Gi0/2                       Active Up/Backup Standby

Interface Pair : Gi0/1, Gi0/2
Preemption Mode : off
Preemption Delay : 35 seconds
Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)
```

6. Configuration Files

- Device D configuration file

```
hostname DeviceD
!
interface GigabitEthernet 0/1
 switch-port mode trunk
 flexlink pairs interface GigabitEthernet 0/2
!

end
```

- Device E configuration file

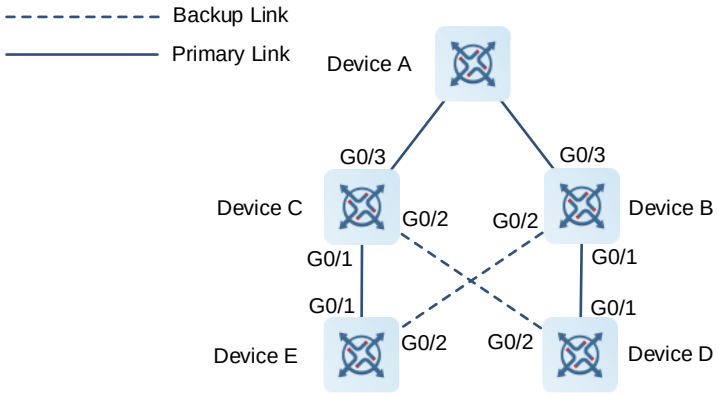
```
hostname DeviceE
!
interface GigabitEthernet 0/1
 switch-port mode trunk
 flexlink pairs interface GigabitEthernet 0/2
!

end
```

7. Common Errors

- When a port is added to an REUP pair, the port has been configured to belong to another REUP pair.

- A configured port is not a Layer 2 physical port or aggregate interface.



1.9.2 Configuring the MAC Address Update Function

1. Requirements

An L3 device networking topology need to be built to simulate the scenario, in which there are two interconnection links between the access devices and the core devices.

2. Topology

Figure 1-7 Configuring MAC Address Update

3. Notes

- Enable the function of sending MAC address update messages on access device D (device E).
- Enable the function of receiving MAC address update packets on device B (device C).
- Add all ports in the REUP switching path to the same MAC address update group.
- Gi0/1 and Gi0/3 of device B are the ports in the uplink switching path of device D, and Gi0/3 and Gi0/2 are the ports in the uplink switching path of device E. You can add ports Gi0/1, Gi0/2, and Gi0/3 to the same address update group. Similarly, you can perform the configuration on device C.
- Enable the function of receiving MAC address update packets on device A.
- Add all ports in the REUP switching path of device A to the same MAC address update group.

4. Procedure

Perform the following configuration on device D.

```
DeviceD > privilege
DeviceD # config-system terminal
DeviceD (cfg)# mac-addr-table move update transit
```

Perform the following configuration on device E.

```
DeviceE > privilege
DeviceE # config-system terminal
DeviceE ((cfg)# mac-addr-table move update transit
```

Perform the following configuration on device B.

```
DeviceB > privilege
```

```
DeviceB # config-system terminal
DeviceB (cfg)# mac-addr-table move update receive
DeviceB (cfg)# interface range gigabitethernet 0/1-3
DeviceB (cfg-if-list)# switch-port mode trunk
DeviceB (cfg-if-list)# mac-addr-table update trace-group 1
```

Perform the following configuration on device C.

```
DeviceC > privilege
DeviceC # config-system terminal
DeviceC (cfg)# mac-addr-table move update receive
DeviceC (cfg)# interface range gigabitethernet 0/1-3
DeviceC (cfg-if-list)# switch-port mode trunk
DeviceC (cfg-if-list)# mac-addr-table update trace-group 1
```

Perform the following configuration on device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# mac-addr-table move update receive
DeviceA(cfg)# interface range gigabitethernet 0/1-2
DeviceA(cfg-if-list)# switch-port mode trunk
DeviceA(cfg-if-list)# mac-addr-table update trace-group 1
```

5. Verification

Check the information about the MAC address update groups on device B.

```
DeviceD # display current-config | incl mac-ad
mac-addr-table move update transit
```

```
DeviceE # display current-config | incl mac-ad
mac-addr-table move update transit
```

```
DeviceB # display mac-addr-table update trace-group detail
display mac-addr-table update trace-group detailMac-address-table Update Group:1
Received mac-addr-table update message count:0
Group member            Receive Count      Last Receive Switch-ID          Receive Time
--------------------------------------------------------------------------------
Gi0/1                   0                  0000.0000.0000
Gi0/2                   0                  0000.0000.0000
Gi0/3                   0                  0000.0000.0000
```

Check the information about the MAC address update groups on device C.

```
DeviceC # display mac-addr-table update trace-group detail
Mac-address-table Update Group:1
Received mac-addr-table update message count:0
Group member            Receive Count      Last Receive Switch-ID          Receive Time
--------------------------------------------------------------------------------
Gi0/1                   0                  0000.0000.0000
```

```
Gi0/2                0                0000.0000.0000
Gi0/3                0                0000.0000.0000
```

Check the information about the MAC address update groups on device A.

```
DeviceA# display mac-addr-table update trace-group detail
Mac-address-table Update Group:1
Received mac-addr-table update message count:0
Group member          Receive Count      Last Receive Switch-ID          Receive Time
------------------------------------------------------------------------------
Gi0/1                0                0000.0000.0000
Gi0/2                0                0000.0000.0000
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 switch-port mode trunk
 mac-addr-table update trace-group 1
!
interface GigabitEthernet 0/2
 switch-port mode trunk
 mac-addr-table update trace-group 1
!
mac-addr-table move update receive

end
```

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 switch-port mode trunk
 mac-addr-table update trace-group 1
!
interface GigabitEthernet 0/2
 flexlink mode trunk
 mac-addr-table update trace-group 1
!
interface GigabitEthernet 0/3
 switch-port mode trunk
 mac-addr-table update trace-group 1
!
mac-addr-table move update receive

end
```

- Device C configuration file

```
hostname DeviceC
!
interface GigabitEthernet 0/1
 switch-port mode trunk
 mac-addr-table update trace-group 1
!
interface GigabitEthernet 0/2
 switch-port mode trunk
 mac-addr-table update trace-group 1
!
interface GigabitEthernet 0/3
 switch-port mode trunk
 mac-addr-table update trace-group 1
!
mac-addr-table move update receive

end
```

- Device D configuration file

```
hostname DeviceD
!
mac-addr-table move update transit

end
```

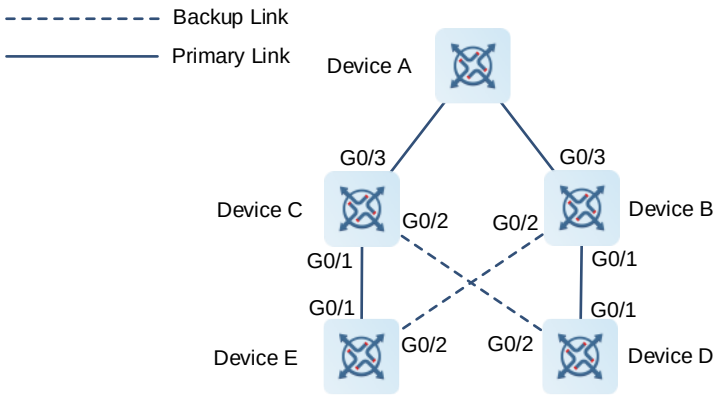
- Device E configuration file

```
hostname DeviceE
!
mac-addr-table move update transit

end
```

7. Common Errors

- A configured port is not a Layer 2 physical port or aggregate interface.



1.9.3 Configuring VLAN Load Balancing

1. Requirements

An L3 device networking topology need to be built to simulate the scenario, in which there are two interconnection links between the access devices and the core devices.

2. Topology

Figure 1-8 Configuring VLAN Loading Balancing

3. Notes

- Configure instance mappings on device D (device E) to map VLAN 1 to instance 1, VLAN 2 to instance 2, VLAN 3 to instance 3, and VLAN 4 to instance 4. For details about how to configure the mappings, see "Configuring MSTP" in *Ethernet Switching Configuration Guide*.
- Configure the VLAN load balancing function on device D (device E).

4. Procedure

Perform the following configuration on device D.

```
DeviceD > privilege
DeviceD # config-system terminal
DeviceD (cfg)# interface gigabitethernet 0/1
DeviceD (cfg-if-GigabitEthernet 0/1)# switch-port mode trunk
DeviceD (cfg-if-GigabitEthernet 0/1)# flexlink pairs interface gigabitethernet 0/2 prefer instance 2
DeviceD (cfg-if-GigabitEthernet 0/1)# exit
```

Perform the following configuration on device E.

```
DeviceE > privilege
DeviceE # config-system terminal
DeviceE (cfg)# interface gigabitethernet 0/1
DeviceE (cfg-if-GigabitEthernet 0/1)# switch-port mode trunk
DeviceD (cfg-if-GigabitEthernet 0/1)# flexlink pairs interface gigabitethernet 0/2 prefer instance 4
DeviceD (cfg-if-GigabitEthernet 0/1)# exit
```

5. Verification

Run the **display interfaces flexlink pairs detail** command to check the dual-link backup information configured on device D (device E).

```
DeviceD # display interfaces flexlink pairs detail
Device Backup Interface Pairs:
Active Interface            Backup Interface            State
--------------------------------------------------------------------------------
```

```
Gi0/1                    Gi0/2                    Active Up/Backup Up

Instances Preferred on Active Interface: Instance 0-1,3-64
        Mapping VLAN 1,3-4094

Instances Preferred on Backup Interface: Instance 2
        Mapping VLAN 2

Interface Pair : Gi0/1, Gi0/2
Preemption Mode : balance
Preemption Delay : 35 seconds
Bandwidth : Gi0/1(800 kbits), Gi0/2(100000 kbits)
```

Run the **display interfaces flexlink pairs detail** command to check the dual-link backup information configured on device E.

```
DeviceE # display interfaces flexlink pairs detail
Device Backup Interface Pairs:
Active Interface        Backup Interface        State
--------------------------------------------------------------------------------
Gi0/1                    Gi0/2                    Active Up/Backup Up

Instances Preferred on Active Interface: Instance 0-3,5-64
        Mapping VLAN 1-3,5-4094

Instances Preferred on Backup Interface: Instance 4
        Mapping VLAN 4

Interface Pair : Gi0/1, Gi0/2
Preemption Mode : balance
Preemption Delay : 35 seconds
Bandwidth : Gi0/1(800 kbits), Gi0/2(100000 kbits)
```

6. Configuration Files

- Device D configuration file

```
hostname DeviceD
!
interface GigabitEthernet 0/1
 switch-port mode trunk
 flexlink pairs interface gigabitethernet 0/2 prefer instance 2
!

end
```

- Device E configuration file

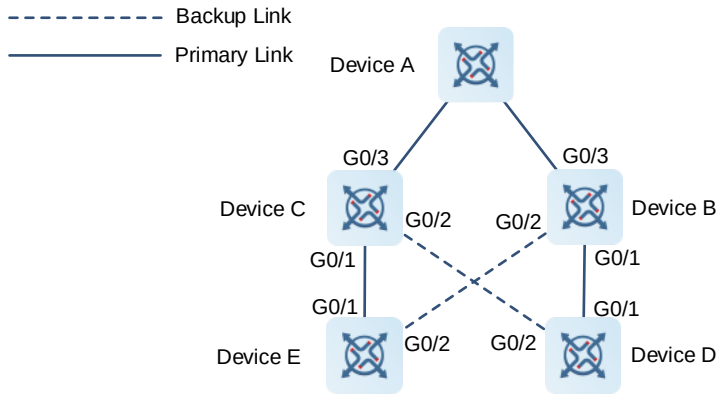
```
hostname DeviceE
!
interface GigabitEthernet 0/1
```

```
 switch-port mode trunk
 flexlink pairs interface gigabitethernet 0/2 prefer instance 2
!

end
```

7. Common Errors

- The mappings between VLAN IDs and instances are not configured.



1.9.4 Configuring Link State Tracking

1. Requirements

An L3 device networking topology need to be built to simulate the scenario, in which there are two interconnection links between the access devices and the core devices.

2. Topology

Figure 1-9 Configuring Link State Tracking

3. Notes

- Create link state tracking group 1 on device B (device C).
- On device B (device C), add the ports GigabitEthernet 0/1 and GigabitEthernet 0/2 as downlink ports of the link state tracking group and add the port GigabitEthernet 0/3 as an uplink port of the link state tracking group.

4. Procedure

Perform the following configuration on device B.

```
DeviceB > privilege
DeviceB # config-system terminal
DeviceB (cfg)# link state enable-track-group 1
DeviceB (cfg)# interface GigabitEthernet 0/1
DeviceB (cfg-if-GigabitEthernet 0/1)# link state trace-group 1 downstream
DeviceB (cfg-if-GigabitEthernet 0/1)# exit
DeviceB (cfg)# interface GigabitEthernet 0/2
DeviceB (cfg-if-GigabitEthernet 0/2)# link state trace-group 1 downstream
```

```
DeviceB (cfg-if-GigabitEthernet 0/2)# exit
DeviceB (cfg)# interface GigabitEthernet 0/3
DeviceB (cfg-if-GigabitEthernet 0/3)# link state trace-group 1 upstream
```

Perform the following configuration on device C.

```
DeviceC > privilege
DeviceC # config-system terminal
DeviceC (cfg)# link state enable-track-group 1
DeviceC (cfg)# interface GigabitEthernet 0/1
DeviceC (cfg-if-GigabitEthernet 0/1)# link state trace-group 1 downstream
DeviceC (cfg-if-GigabitEthernet 0/1)# exit
DeviceC (cfg)# interface GigabitEthernet 0/2
DeviceC (cfg-if-GigabitEthernet 0/2)# link state trace-group 1 downstream
DeviceC (cfg-if-GigabitEthernet 0/2)# exit
DeviceC (cfg)# interface GigabitEthernet 0/3
DeviceC (cfg-if-GigabitEthernet 0/3)# link state trace-group 1 upstream
```

5. Verification

Run the **display link state trace-group** command to check whether the configuration on device B is correct.

```
DeviceB # display link state trace-group
Link State Group:1    Status: enabled, Down
Upstream Interfaces :Gi0/3(Down)
Downstream Interfaces : Gi0/2(Down)

Link State Group:2    Status: Disabled, Down
Upstream Interfaces :
Downstream Interfaces :

(Up):Interface up     (Down):Interface Down     (Dis):Interface disabled
```

Run the **display link state trace-group** command to check whether the configuration on device C is correct.

```
DeviceC # display link state trace-group
Link State Group:1    Status: enabled, Down
Upstream Interfaces :Gi0/3(Down)
Downstream Interfaces : Gi0/2(Down)

Link State Group:2    Status: Disabled, Down
Upstream Interfaces :
Downstream Interfaces :

(Up):Interface up     (Down):Interface Down     (Dis):Interface disabled
```

6. Configuration Files

- Device B configuration file

```
hostname DeviceB
!
link state enable-track-group 1
```

```
interface GigabitEthernet 0/1
 link state trace-group 1 downstream
!
interface GigabitEthernet 0/2
 link state trace-group 1 downstream
!
interface GigabitEthernet 0/3
 link state trace-group 1 upstream
!

end
```

- Device C configuration file

```
hostname DeviceC
!
link state enable-track-group 1
interface GigabitEthernet 0/1
 link state trace-group 1 downstream
!
interface GigabitEthernet 0/2
 link state trace-group 1 downstream
!
interface GigabitEthernet 0/3
 link state trace-group 1 upstream
!

end
```

7. Common Errors

- Ports are added to a link state tracking group before the link state tracking group is enabled.

1 Configuring RLDP

1.1 Introduction

The Rapid Link Detection Protocol (RLDP) is an Ethernet link failure detection protocol, which is used to rapidly detect unidirectional link failures, bidirectional link failures, and downlink loop failures. When a failure is found, RLDP automatically shuts down relevant ports or asks users to manually shut down the ports according to the configured failure handling methods, to avoid wrong forwarding of traffic or Ethernet L2 loops.

1.1.1 Basic Concepts

1. Unidirectional Link Failure

A unidirectional link failure occurs when one end of the receiving or transmission link in an optical fiber is disconnected or not connected, one line in a twisted-pair cable is disconnected, or unidirectional disconnection occurs on an intermediate device between two devices. A unidirectional link failure can lead to wrong forwarding of traffic or the failure of a loop protection protocol such as Spanning Tree Protocol (STP).

2. Bidirectional Link Failure

A bidirectional link failure occurs when two optical fibers are disconnected, two lines in a twisted-pair cable are disconnected, or bidirectional disconnection occurs on an intermediate device between two devices. A bidirectional link failure can lead to the wrong forwarding of traffic.

3. Loop Failure

A loop failure occurs when a downlink port of a device is wrongly connected to another device and a loop forms. A loop failure can result in a broadcast storm.

4. Protocol Packets

RLDP defines the following three types of packets:

- Probe packets: L2 multicast packets used for neighbor negotiation, and unidirectional or bidirectional link detection. The default encapsulation format of the packets is of the Subnetwork Access Protocol (SNAP) type, which automatically changes to EthernetII if a neighbor sends EthernetII packets.
- Echo packets: L2 unicast packets in response to probe packets and used for unidirectional or bidirectional link detection. The default encapsulation format is of the SNAP type, which automatically changes to EthernetII if a neighbor sends EthernetII packets.
- Loop packets: L2 multicast packets for downlink loop detection. They can only be received by senders. The default encapsulation format of the packets is of the SNAP type.

5. Detection Interval

A detection interval and the maximum detection count can be configured for RLDP. A detection interval determines the period of sending probe packets and loop packets. When a device receives a probe packet, it replies with an echo packet immediately. A detection interval and the maximum detection count determine the maximum detection time (Detection interval × Maximum detection count + 1) for unidirectional or bidirectional link detection. If neither a probe nor an echo packet from a neighbor is correctly received within the maximum

detection time, the handling of unidirectional or bidirectional failures is triggered. The timers involved are described in Table 1-1.

Table 1-1 Description of RLDP Timers

Timer Name	Timer Description
Send timer	After the link detection function is enabled, the send timer is started and the probe packets or loop packets are sent regularly. The time interval of the send timer is the configured detection interval.
Timeout timer	● If a unidirectional or bidirectional link failure is detected, the timeout timer is started after the probe packet is sent, and the timeout time is the maximum detection time (Detection interval × Maximum detection count + 1). ● In unidirectional link detection, when the detection timeout time expires and a port can only receive the probe packet or response packet from the neighbor, it is considered that a unidirectional link failure occurs. ● In bidirectional link detection, when the detection timeout time expires and a port fails to receive the probe packet and response packet from the neighbor, it is considered that a bidirectional link failure occurs.

6. Neighbor Negotiation

When configured with unidirectional or bidirectional link detection, a port can learn a peer device as its neighbor. One port can learn only one neighbor, which is changeable. If the negotiation function is enabled, unidirectional or bidirectional link detection starts after a port finds a neighbor through negotiation. Negotiation is considered successful if the port receives a probe packet from the neighbor. However, if RLDP is enabled on a port after a failure already occurs, the port fails to learn a neighbor and detection fails to be started. In this case, you are advised to rectify the link failure first.

7. Associated Actions

The associated actions and recovery methods after a RLDP port failure are described in Table 1-2.

Table 1-2 Description of RLDP Port Failure Handling

Type	Associated Action/ Recovery Method	Description
Associated actions after a failure	warning	Only the relevant system log is printed to indicate the failed port and the failure type.
	Shutdown SVI	A system log is printed. If the failed port is a Layer 2 Ethernet interface or member port of a Layer 2 link aggregation, a switch virtual interface (SVI) is queried based on the access VLAN or native VLAN of the port, and then the SVI is shut down.
	Port errdisable	A system log is printed, the failed port is set in errdisable state, and the port enters the linkdown state physically.
	Block	A system log is printed, the forwarding state of the failed port is set to blocked, and the port does not forward received packets.

Type	Associated Action/ Recovery Method	Description
Recovery methods after a failure	Manual reset	Manually reset all the failed ports to the initialized state to restart link detection.
	Manual or automatic errdisable recovery	Recover all the failed ports to the initialized state manually or regularly (**30** seconds by default and configurable) and restart link detection.
	Automatic recovery	Under unidirectional or bidirectional link detection, if the handling method specified for failed ports does not enable the ports to enter the errdisable state, the ports can automatically recover to the initialized state based on probe packets exchanged with the neighbor, and link detection is restarted.
	Manual or automatic execution of the **rldp error-recover interval** command	All the failed ports recover to the initialized state regularly (configurable) and link detection is restarted.

8. RLDP Port State

RLDP ports can be in two states:

- Normal: Indicates the state of a port, on which link detection is enabled.
- Error: Indicates the state of a port, on which a unidirectional or bidirectional link failure or a loop failure is detected.

1.1.2 Detection Principles

A typical Ethernet link detection mechanism detects physical link connectivity through auto-negotiation at the physical layer. However, this detection mechanism has limitations. In some cases, devices are connected and work normally at the physical layer but L2 link communication fails or is abnormal. RLDP recognizes a neighbor device and detects whether a link failure exists by exchanging probe packets, echo packets, or loop packets with the neighbor device. Figure 1-1 shows the protocol states.

Figure 1-1 RLDP Protocol State Diagram

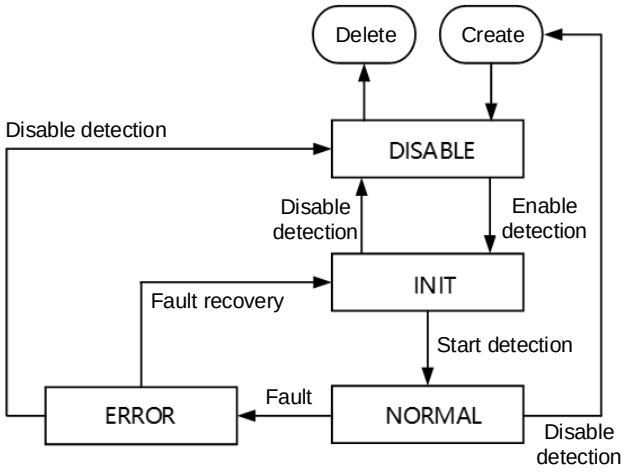

Figure 1-1 shows the detection logic of RLDP, which can be mainly in four states. The four states are described in Table 1-3.

Table 1-3 Description of RLDP States

State	Description
DISABLE	After the global RLDP function is enabled, all ports enter the disable state. Now, unidirectional link detection, bidirectional link detection, or downlink loop detection is not enabled on the ports. If the RLDP is disabled in any state, a port enters this state.
INIT	It refers to the initialized state after RLDP is just configured and enabled or a failure is rectified. Now, unidirectional link detection, bidirectional link detection, or downlink loop detection is enabled on ports, and the corresponding link failure handling methods are specified, or the links can recover from unidirectional failures, bidirectional failures, or loop failures automatically.
NORMAL	It refers to the state after detection is enabled for RLDP. For downlink loop detection, RLDP enters the state directly after enabled. For unidirectional or bidirectional link detection, RLDP enters the state directly or enters the state only after negotiation with a specified neighbor succeeds.
ERROR	It refers to the state after RLDP detects a failure. In this case, a unidirectional link failure or bidirectional link failure is detected on a port. The failure will be handled according to the specified failure handling method.

1.1.3 RLDP Detection

RLDP provides unidirectional link detection, bidirectional link detection, and downlink loop detection.

1. Unidirectional Link Detection

After unidirectional link detection is enabled, a port sends probe packets and receives echo packets from a neighbor regularly. It also receives probe packets from the neighbor and replies with echo packets to the

neighbor. If the port receives only probe packets but no echo packets, or none of them from the neighbor within the maximum detection time, handling of a unidirectional failure is triggered and the detection stops.

2. Bidirectional Link Detection

After bidirectional link detection is enabled, a port sends probe packets and receives echo packets from a neighbor regularly. It also receives probe packets from the neighbor and replies with echo packets to the neighbor. If the port receives neither probe packets nor echo packets from the neighbor within the maximum detection time, handling of a bidirectional failure is triggered and the detection stops.

3. Downlink Loop Detection

After downlink loop detection is enabled, a port sends loop packets regularly. After the same port or different ports on a device receive loop packets, a loop failure is triggered if any of the following cases occurs: The transmission and receiving ports of the packets are the same Layer 3 Ethernet interfaces or member ports of a Layer 3 link aggregation; the transmission and receiving ports of packets are Layer 2 interfaces or member ports of a Layer 2 link aggregation, the default VLANs of the ports are the same, and forwarding states of the ports are forward. The failure is handled according to the corresponding method and the detection stops.

1.2 Configuring Basic Features of RLDP

1.2.1 Overview

- You can enable RLDP unidirectional link detection, bidirectional link detection, or downlink loop detection to discover unidirectional, bidirectional, or loop failures.
- After global RLDP detection is enabled, the RLDP detection is started on each port normally.
- After the function is enabled in global configuration mode, RLDP detection on a port is started after successful neighbor negotiation.
- If loop detection latency interval is configured in global configuration mode, the downlink port loop cannot be detected in this period of time.
- In interface configuration mode, you can configure unidirectional RLDP detection, bidirectional RLDP detection, or downlink loop detection, and specify a failure handling method.
- You can restore all the failed ports and restart detection.

1.2.2 Restrictions and Guidelines

- Loop detection configured on an AP member port takes effect on all the member ports of the AP. Unidirectional link detection and bidirectional link detection take effect on an AP member port directly.
- The loop detection configuration of a physical port added to an AP must be the same as that of the other member ports of the AP. There are two cases. (1) If loop detection is not configured on the new member port but on the existing member ports, the new port adopts the configuration and detection results of the existing ports. (2) If the new member port and the existing member ports have different loop detection configurations, the new port adopts the configuration and detection results of the existing ports.
- When configuring the RLDP on an AP member port, you can configure only the "shutdown-port" and "warning" handling methods. If the failure handling method is not set to "shutdown-port" or "warning", it is modified to "shutdown-port" and takes effect.
- After the "shutdown-port" handling method is configured on a port, the port cannot resume RLDP detection

in the case of a failure. After confirming that the failure is rectified, you can run the **rldp reset** or **errdisable recovery** command to restore the port and restart detection. For the description and configuration of **errdisable recovery**, see *Configuring Ethernet Interface*.

1.2.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the global RLDP detection function.

rldp enable

The global RLDP detection function is disabled by default.

(4) (Optional) Configure global neighbor negotiation.

rldp neighbor-negotiation

The neighbor negotiation function is disabled by default.

(5) (Optional) Configure the global RLDP detection interval.

rldp detect-interval *interval*

The default interval for sending RLDP packets by a port is **3** seconds.

(6) (Optional) Configure a time interval for RLDP to recover failed ports.

rldp error-recover interval *interval*

No time interval for RLDP to recover failed ports regularly is configured by default.

(7) (Optional) Configure the maximum detection count of RLDP.

rldp detect-max *max-detect-num*ber

The default maximum detection count of RLDP is **2**.

(8) (Optional) Configure the global loop detection latency interval.

rldp detect-latency *interval*

The default latency interval for global RLDP loop detection is **0** seconds.

(9) Enter the Layer 2 Ethernet interface configuration mode.

interface *interface-type interface-number*

(10) Configure RLDP detection on the port.

rldp port { **bidirection-detect** | **loop-detect** | **unidirection-detect** } { **block** | **shutdown-port** | **shutdown-svi** | **warning** }

RLDP detection is not configured on a port by default.

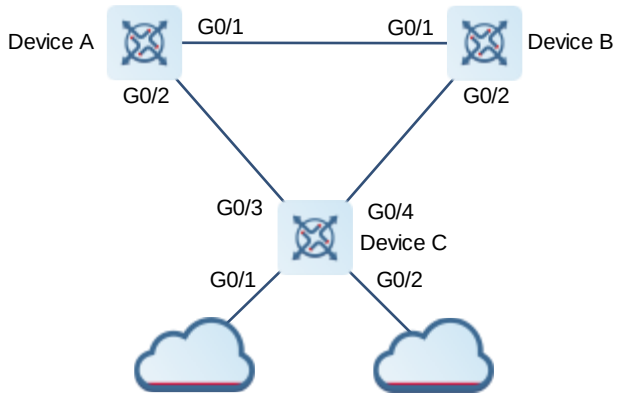
1.3 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Table 1-4 RLDP Monitoring

Command	Purpose
display rldp [**interface** *interface-type interface-number*]	Displays the RLDP running state.

1.4 Configuration Examples



1.4.1 Configuring Basic Features of RLDP

1. Requirements

The aggregation and access devices form a ring topology. STP is enabled on all devices to prevent loops and provide redundancy protection. To avoid a unidirectional or bidirectional link failure resulting in an STP failure, RLDP unidirectional link detection and bidirectional link detection are enabled between aggregation devices as well as between the aggregation devices and the access device. To avoid loops due to wrong connection in the downlink direction of the aggregation devices, RLDP downlink loop detection is enabled on the downlink ports of the aggregation devices and the access device. To avoid loops due to wrong connection in the downlink direction of the access device, RLDP downlink loop detection is enabled on all the downlink ports of the access device.

2. Topology

Figure 1-2 Configuring Basic Feature of RLDP

3. Notes

- Devices A and B are aggregation devices, and device C is an access device. User devices can be connected to downlink ports of device C. Devices A, B, and C are structured in a ring topology, and STP is enabled on each of them. For STP configuration, refer to the relevant configuration guide.
- Enable RLDP on device A, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port.
- Enable RLDP on device B, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port.
- Enable RLDP on device C, enable unidirectional and bidirectional link detection on the two uplink ports, and

enable loop detection on the two downlink ports.

4. Procedure

Perform the following configuration on device A.

```
Device A# config-system terminal
Device A(cfg)# rldp enable
Device A(cfg)# interface GigabitEthernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# rldp port unidirection-detect shutdown-port
Device A(cfg-if-GigabitEthernet 0/1)# rldp port bidirection-detect shutdown-port
Device A(cfg-if-GigabitEthernet 0/1)# exit
Device A(cfg)# interface GigabitEthernet 0/2
Device A(cfg-if-GigabitEthernet 0/1)# rldp port unidirection-detect shutdown-port
Device A(cfg-if-GigabitEthernet 0/1)# rldp port bidirection-detect shutdown-port
Device A(cfg-if-GigabitEthernet 0/1)# rldp port loop-detect shutdown-port
```

Perform the following configuration on device B.

```
Device B# config-system terminal
Device B(cfg)# rldp enable
Device B(cfg)# interface GigabitEthernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# rldp port unidirection-detect shutdown-port
Device B(cfg-if-GigabitEthernet 0/1)# rldp port bidirection-detect shutdown-port
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface GigabitEthernet 0/2
Device B(cfg-if-GigabitEthernet 0/1)# rldp port unidirection-detect shutdown-port
Device B(cfg-if-GigabitEthernet 0/1)# rldp port bidirection-detect shutdown-port
Device B(cfg-if-GigabitEthernet 0/1)# rldp port loop-detect shutdown-port
```

Perform the following configuration on device C.

```
Device C# config-system terminal
Device C(cfg)# rldp enable
Device C(cfg)# interface GigabitEthernet 0/3
Device C(cfg-if-GigabitEthernet 0/3)# rldp port unidirection-detect shutdown-port
Device C(cfg-if-GigabitEthernet 0/3)# rldp port bidirection-detect shutdown-port
Device C(cfg-if-GigabitEthernet 0/3)# exit
Device C(cfg)# interface GigabitEthernet 0/4
Device C(cfg-if-GigabitEthernet 0/4)# rldp port unidirection-detect shutdown-port
Device C(cfg-if-GigabitEthernet 0/4)# rldp port bidirection-detect shutdown-port
Device C(cfg-if-GigabitEthernet 0/4)# exit
Device C(cfg)# interface GigabitEthernet 0/1
Device C(cfg-if-GigabitEthernet 0/1)# rldp port loop-detect shutdown-port
Device C(cfg-if-GigabitEthernet 0/1)# exit
Device C(cfg)# interface GigabitEthernet 0/2
Device C(cfg-if-GigabitEthernet 0/2)# rldp port loop-detect shutdown-port
```

5. Verification

Check the RLDP state information on devices, A, B, and C. Device A is taken as an example. Run the **display rldp** command to check whether the configuration is correct.

```
Device A# display rldp
rldp state                    : enable
rldp hello interval: 3
rldp max hello           : 2
rldp local bridge    : 00d0.f822.33aa
-----------------------------------
Interface GigabitEthernet 0/1
port state             : normal
neighbor bridge : 00d0.f800.51b1
neighbor port       : GigabitEthernet 2/0/1
unidirection detect information:
        action: shutdown-port
        state : normal
bidirection detect information:
        action: shutdown-port
        state : normal

Interface GigabitEthernet 0/2
port state             : normal
neighbor bridge : 00d0.f800.41b0
neighbor port       : GigabitEthernet 0/3
unidirection detect information:
        action: shutdown-port
        state : normal
bidirection detect information:
        action: shutdown-port
        state : normal
loop detect information:
        action: shutdown-port
        state : normal
```

6. Common Errors

- RLDP is enabled together with private multicast address authentication or TPP.
- Neighbor negotiation is not enabled when unidirectional or bidirectional link detection is configured. RLDP must be enabled on a neighbor device in global or interface configuration mode; otherwise a unidirectional or bidirectional failure is detected.
- If neighbor negotiation prior to RLDP detection is specified when unidirectional or bidirectional link detection is configured, normal detection fails because no neighbor is learned in the case of an existing link failure. In this situation, you are advised to rectify the link failure first.
- You are not advised to specify Shutdown SVI as the failure handling method on a Layer 3 interface.
- You are not advised to specify Block as the failure handling method for a port, on which a loop protection protocol such as STP is enabled.

1.4.2 Configuring Unidirectional Link Detection

1. Requirements

As shown in Figure 1-3, device A is connected to device B through an optical fiber. The two lines are the Tx and Rx lines of the optical fiber. Unidirectional link detection is enabled on devices A and B. If a fault occurs on either the Tx end of device A or Rx end of device B or on either the Rx end of device A or Tx end of device B, RLDP can detect the unidirectional failure and handle it. If the failure is eliminated, the administrator can manually restore the RLDP state on devices A and B and restart detection.

2. Topology

Figure 1-3 Configuring Unidirectional Link Detection

3. Notes

- Enable global RLDP.
- Configure unidirectional link detection of RLDP on ports and define a method for handling unidirectional failures.

4. Procedure

Perform the following configuration on device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# rldp enable
DeviceA(cfg)# interface GigabitEthernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# rldp port unidirection-detect shutdown-port
```

Perform the following configuration on device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# rldp enable
DeviceB(cfg)# interface GigabitEthernet 0/1
DeviceB(cfg-if-GigabitEthernet 0/1)# rldp port unidirection-detect shutdown-port
```

5. Verification

Check the RLDP state information on device A.

```
DeviceA> privilege
DeviceA# display rldp
rldp state              : enable
rldp hello interval: 3
rldp max hello          : 2
rldp local bridge    : 00d0.f822.33aa
```

```
-----------------------------------
Interface GigabitEthernet 0/1
port state          : normal
neighbor bridge : 00d0.f800.51b1
neighbor port     : GigabitEthernet 0/1
unidirection detect information:
        action: shutdown-port
        state : normal
```

Check the RLDP state information on device B.

```
DeviceB> privilege
DeviceB# display rldp
rldp state               : enable
rldp hello interval: 3
rldp max hello         : 2
rldp local bridge    : 00d0.f800.51b1
-----------------------------------
Interface GigabitEthernet 0/1
port state          : normal
neighbor bridge : 00d0.f822.33aa
neighbor port     : GigabitEthernet 0/1
unidirection detect information:
        action: shutdown-port
        state : normal
```

6. Common Errors

- Global RLDP is not enabled at the local end or peer end.
- The RLDP detection method configured at the local end is inconsistent with that at the peer end.
- RLDP negotiation is not enabled, so a link failure is judged by mistake when unidirectional link detection of RLDP is configured at a single end.

1.4.3 Configuring Bidirectional Link Detection

1. Requirements

As shown in Figure 1-4, device A is connected to device B through an optical fiber. The two lines are the Tx and Rx lines of the optical fiber. Bidirectional link detection is enabled on devices A and B. If a fault occurs on the Tx end of device A and Rx end of device B or on the Rx end of device A and Tx end of device B, RLDP can detect a bidirectional failure and handle it. If the failure is eliminated, the administrator can manually restore the RLDP state on devices A and B and restart detection.

2. Topology

Figure 1-4 Configuring Bidirectional Link Detection

3. Notes

- Enable global RLDP.
- Configure bidirectional link detection of RLDP on ports and define a method for handling bidirectional failures.

4. Procedure

Perform the following configuration on device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# rldp enable
DeviceA(cfg)# interface GigabitEthernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# rldp port bidirection-detect shutdown-port
```

Perform the following configuration on device B.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# rldp enable
DeviceB(cfg)# interface GigabitEthernet 0/1
DeviceB(cfg-if-GigabitEthernet 0/1)# rldp port bidirection-detect shutdown-port
```

5. Verification

Check the RLDP state information on device A.

```
DeviceA> privilege
DeviceA# display rldp
rldp state               : enable
rldp hello interval: 3
rldp max hello         : 2
rldp local bridge    : 00d0.f822.33aa
-----------------------------------
Interface GigabitEthernet 0/1
port state           : normal
neighbor bridge : 00d0.f800.51b1
neighbor port      : GigabitEthernet 0/1
bidirection detect information:
        action: shutdown-port
        state : normal
```

Check the RLDP state information on device B.

```
DeviceB> privilege
DeviceB# display rldp
rldp state               : enable
rldp hello interval: 3
rldp max hello         : 2
rldp local bridge    : 00d0.f800.51b1
```

```
-----------------------------------
Interface GigabitEthernet 0/1
port state          : normal
neighbor bridge : 00d0.f822.33aa
neighbor port     : GigabitEthernet 0/1
bidirection detect information:
        action: shutdown-port
        state : normal
```

6. Common Errors

- Global RLDP is not enabled at the local end or peer end.
- The RLDP detection method configured at the local end is inconsistent with that at the peer end.
- If bidirectional link detection needs to be configured but RLDP negotiation is not enabled, a link failure will be detected at one end.

1 Configuring DLDP

The Data Link Detection Protocol (DLDP) achieves rapid detection of Ethernet link failures. A typical Ethernet link detection mechanism detects physical link connectivity through auto-negotiation at the physical layer. However, such a mechanism has limitations in L3 data connectivity detection, for example, the physical connection is normal but L3 data communication is abnormal. DLDP provides reliable L3 link detection information. After detecting a faulty link, DLDP disables the logical function of L3 ports to realize fast L3 protocol convergence.

1.1 Introduction

1.1.1 Basic Concepts

1. Detection Mode

Active mode and passive mode are two DLDP detection modes.

- Active mode (default): In this mode, Internet Control Message Protocol (ICMP) detection packets are sent actively.
- Passive mode: In this mode, ICMP detection packets are received passively. Namely, DLDP returns an ICMP reply packet upon receiving an ICMP echo packet, instead of actively sending ICMP echo packets to the peer end. It judges whether an ICMP echo packet is received within a specified period to determine whether the link to the peer port is faulty. This mode not only implements the function of detecting link connectivity for the both devices, but also saves the bandwidth resources and device CPU resources.

2. Inter-Network Segment Detection

If DLDP needs to detect reachability to an IP address in a non-directly connected network segment, you need to configure the next-hop IP address for the local port so that DLDP can obtain the next-hop MAC address through an Address Resolution Protocol (ARP) packet, encapsulate an ICMP packet correctly, and send it out. In this situation, however, you need to avoid receiving an ICMP reply packet from another link; otherwise, DLDP misjudges that the port does not receive an ICMP reply.

3. Detection Time

When a network device does not receive a reply packet from the peer end within the period of the detection interval multiplied by the number of retransmission times, the device determines that an L link failure occurs and actively shuts down the logical function of its L3 port (despite the physical link reachable). Once the L3 link connectivity recovers, the device restores the logical function of the L3 port.

- Detection interval: Indicates the interval at which DLDP detection packets (ICMP echo) are transmitted.
- Retransmission times: Indicates the maximum number of times that DLDP detection packets can be retransmitted after a DLDP detection failure occurs.

4. Recovery Times

A detected link may be unstable, for example, the link can be pinged through only intermittently. The results of single DLDP detection are that the link is up/ down multiple times, which further destabilizes the ring network.

The term recovery times indicates the number of times that DLDP needs to receive reply packets consecutively before a link switches from the down state to up state. The default number of recovery times is 3, that is, a link can be pinged successfully three times before it is set to up. The recovery times configuration reduces link detection sensitivity but increases stability. Related parameters can be adjusted according to the network condition.

1.1.2 DLDP Detection

When detecting that an L3 link is abnormal, DLDP actively shuts down the Layer 3 interfaces. After the DLDP function is enabled, DLDP sends an ARP packet to obtain the MAC address and outbound port of the detected device or the next-hop device reachable to the detected device. Then DLDP periodically sends IPv4 ICMP echo packets to the MAC address and outbound port to detect link connectivity. If DLDP does not receive an IPv4 ICMP reply packet from the detected device within a specified period, DLDP determines that the link is abnormal and sets the L3 port to down. You can configure the next-hop IP address, MAC address of the detected device, transmission interval, number of retransmission times, and number of recovery times based on the actual environment to enable the DLDP detection function.

1.1.3 MAC Address Binding

In a complex network environment, DLDP may obtain an invalid MAC address if abnormal ARP packets are transmitted (due to ARP spoofing) in the detected link. As a result, DLDP fails to conduct detection normally. To address this problem, you can bind the to-be-detected IP address (or the next-hop IP address) to the MAC address of the device to avoid a DLDP failure caused by ARP spoofing. After binding, DLDP sends ARP packets and ICMP packets with a fixed destination IP address and a fixed destination MAC address during detection. If the source IP address and MAC address in a received packet do not match the bound IP address and MAC address, DLDP does not process the packet.

1.2 Configuring DLDP Detection

1.2.1 Overview

DLDP detects L3 link connectivity. When an L3 link is abnormal, DLDP shuts down the related Layer 3 interfaces.

1.2.2 Restrictions and Guidelines

- To configure the DLDP function, configure the next-hop IP address, MAC address, transmission interval, retransmission times, and recovery times based on the actual environment. You are not advised to set the number of retransmission times and the number of recovery times to 1. You are advised to use the default value for the transmission interval. The number of DLDP sessions and the configured CPU protect policy (CPP) bandwidth must be considered when you adjust the value. Otherwise, the device performance consumption increases and misjudgment and flapping can be caused easily. In the case of more than 10 sessions, the recommended interval is not smaller than 100 ticks.
- DLDP can detect multiple IP addresses configured on an L3 port. DLDP sets the port to down when none of the IP addresses returns an ICMP reply. If one of the IP addresses resumes communication, DLDP sets the port to up.
- DLDP uses the first IP address of the L3 port as the source IP address of detection packets.

1.2.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 3 Ethernet interface configuration mode.

interface *interface-type interface-number*

(4) Enable DLDP detection.

dldp *ipv4-address* [*next-hop-ipv4-address*] [**mac-address** *mac-address*] [**interval** *tick-interval* | **resume** *resume-number* | **retry** *retry-number*]

By default, the number of retransmission times of DLDP detection is **4**, the number of recovery times is **3**, and the detection interval is **1** second.

(5) (Optional) Configure a DLDP detection mode.

dldp passive

The default DLDP detection mode is active mode.

(6) (Optional) Configure a global detection interval for DLDP detection.

dldp interval *tick-interval*

The default global detection interval of DLDP detection is **1** second.

The configuration of this command takes effect immediately for all DLDP detection operations.

(7) (Optional) Configure the number of global retransmission times for DLDP detection.

dldp retry *retry-number*

The default number of global retransmission times of DLDP detection is **4**.

The configuration of this command takes effect immediately for all DLDP detection operations.

(8) (Optional) Configure the number of link recovery times for all DLDP detection operations.

dldp resume *resume-number*

The default number of link recovery times of all DLDP detection operations is **3**.

The configuration of this command takes effect immediately for all DLDP detection operations.

1.3 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

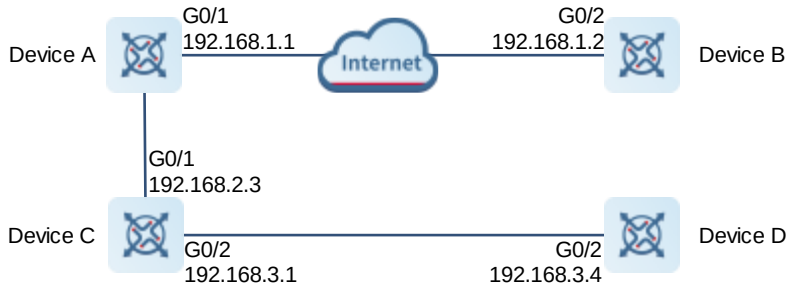
Caution

Running the **cleanup** command during operation of the device may lose vital information and interrupt services.

Table 1-1 DLDP Monitoring

Command	Purpose
cleanup dldp [**interface** *interface-type interface-number* [*ipv4-address*]]	Clears the statistics on link up/down counts of a DLDP monitoring point.
display dldp [**interface** *interface-type interface-number*]	Displays the configuration of a DLDP monitoring point.
display dldp [**interface** *interface-type interface-number*] [**statistic**]	Displays the statistics of a DLDP monitoring point.

1.4 Configuration Examples



1.4.1 Configuring DLDP Detection

1. Requirements

DLDP detection needs to be enabled on an L3 network to control the Layer 3 interfaces of devices A and B.

2. Topology

Figure 1-1 Configuring DLDP Detection

3. Notes

- Enable DLDP detection on the Layer 3 interfaces (GigabitEthernet 0/1 and GigabitEthernet 0/2) on device A to detect the L3 network connectivity from device A to device B and from device A to device D.
- To control the Layer 3 interfaces (GigabitEthernet 0/2) of device B, enable DLDP detection and configure passive mode on the port.

4. Procedure

Perform the following configuration on device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# dldp 192.168.1.2
Device A(cfg-if-GigabitEthernet 0/1)# exit
```

```
Device A(cfg)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# dldp 192.168.3.4 192.168.2.3
```

Perform the following configuration on device B.

```
Device B> privilege
Device B# config-system terminal
Device B(cfg)# interface gigabitethernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# dldp 192.168.1.1
Device B(cfg-if-GigabitEthernet 0/2)# dldp passive
```

5. Verification

Run the **display dldp** command to check the DLDP state information on devices A and B and check whether DLDP detection is enabled and works normally.

```
Device A# display dldp
Interface   Type            Ip           Next-hop      Interval   Retry   Resume   State
---------   -------   -----------   -----------   --------   -----   ------   ------
Gi0/1         Active    192.168.1.2                    100          4         3          Up
Gi0/1         Active    192.168.3.4   192.168.2.3   100          4         3          Up
```

```
Device B# display dldp
Interface   Type            Ip           Next-hop      Interval   Retry   Resume   State
---------   -------   -----------   -----------   --------   -----   ------   ------
Gi0/2         Passive   192.168.1.1                    100          4         3          Up
```

6. Common Errors

- An unreachable IPv4 unicast route is misjudged as a DLDP detection failure.
- DLDP detection fails because the peer device does not support ARP/ICMP replies.
- No next-hop IP address is configured for inter-network segment DLDP detection.

1 Configuring M-LAG

Note

M-LAG is not supported by the S6980-64QC, S6580-48CQ8QC, or S6580-24DC8QC.

1.1 Introduction

The multi-chassis link aggregation group (M-LAG) technology enables two devices supporting link aggregation to form a dual-active system, which is equivalent to one device. The equivalent device and the downlink device are interconnected through an aggregate port (AP). Deploying M-LAG improves the link reliability to the device level to meet the requirements of high availability scenarios.

1.1.1 Basic Concepts

Figure 1-1 M-LAG Topology

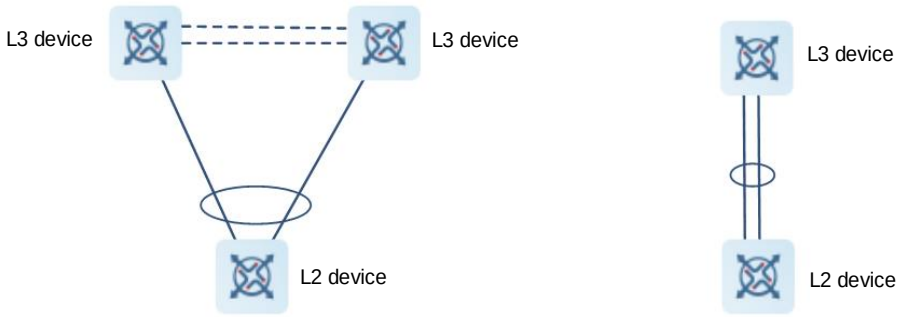

Figure 1-1 shows the M-LAG topology. Another similar technology is virtual switching unit (VSU), which also virtualizes multiple devices into one. M-LAG features the following advantages compared with the VSU topology.

- Stacking is discarded and only L2 virtualization is required. The two devices are still independent of each other. M-LAG reduces deployment difficulties and eliminates shortcomings brought by device stacking (for example, the software failure of the master device may make both devices unavailable).
- Devices can be upgraded independently without affecting the normal operation of the other device.

1. Domain ID

A domain ID is the unique identifier of an M-LAG system and distinguishes different M-LAG systems. Only two devices that share the same domain ID can compose an M-LAG system. At present, only one domain can be configured for one device, and only two devices can be configured in one domain.

2. VAP

On the two devices of M-LAG, a pair of link aggregations connected to the same access device form a virtual AP group (also known as VAP), which allows an access device to connect in dual-homing mode. Different access devices connect to different VAPs. Only Layer 2 link aggregations are supported in a VAP.

When the Link Aggregation Control Protocol (LACP) is enabled on the two link aggregations of a VAP, the same LACP system ID and system priority are used in LACP negotiation. For the uplink devices of an access device, the M-LAG dual devices are logically one device.

Note

Only Layer 2 link aggregations are supported in a VAP.

3. Peer Link

The link between two devices of M-LAG is called a peer link, which is used to synchronize data and transmit some traffic. The directly connected ports at both ends of a peer link are called peer link ports, which must be configured as Layer 2 link aggregations. To improve the reliability of the peer link, you are advised to deploy multiple physical links for the peer link. For chassis devices, deploy multiple physical ports on different cards to reduce the impact of a card failure.

To enhance the reliability of data transmission between M-LAG devices, use Transmission Control Protocol (TCP) for synchronous data transmission. You need to configure a switch virtual interface (SVI) on the peer link and configure L3 reachability between the master and slave devices of M-LAG to achieve data synchronization between the devices.

4. Device Role

During normal operation, the two M-LAG devices negotiate to decide the master and slave roles. Normally, both the master and slave devices participate in forwarding and there is no difference between them. When a fault occurs, the behaviors of the master and slave devices are different. For example, if the peer link gets faulty and the VAP of the two devices fails, service ports on the slave device need to be shut down and traffic needs to be forcibly switched to the master device, to prevent abnormal forwarding of the access device.

5. VAP Member Port

An AP joining a VAP is called a VAP member port, which is used to connect to an AP of an access device. You are advised to use LACP to enhance reliability.

6. Dual-Active Detection Link

A dual-active detection link is an L3 path, which is used to detect the dual-active state of M-LAG devices in case of a peer link failure. To ensure real-time detection, the dual-active detection link does not participate in any forwarding. You are advised to configure a separate L3 reachable link as a dual-active detection link (for example, configure the directly connected link between the management ports of two devices as a dual-active detection link).

7. Heartbeat Hold Time

When the peer link fails, both devices start the heartbeat hold timer, and waits for the packet of the keepalive mechanism on the dual-active detection link to be ready. After the timer expires, the devices start the dual-active detection to prevent error detection due to a packet delay.

8. Domain Negotiation Timeout Time

The VAPs on the two M-LAG devices use the same LACP system ID and system priority. When the devices are just started, VAP member ports start LACP negotiation only after M-LAG negotiation succeeds and the LACP

system ID and system priority are obtained. However, if the peer device is powered off, the negotiation fails all the time, causing the local VAP member port to fail. Therefore, you need to set negotiation timeout time. After the timeout time expires, the local device is deemed to work in the standalone state, and the LACP system ID and system priority of the local device are directly used to perform LACP negotiation.

9. Fast Convergence Mode

Fast convergence mode refers to unidirectional isolation without blocking unicast packets. When a VAP member port recovers from a failure, the MAC entry egress of the uplink port switches from the peer link port to the VAP member port. However, when there are many MAC entries, some traffic sent to the access device continues to use the peer link port during the switching. Due to the anti-loop mechanism of the M-LAG system, the peer device enables unidirectional isolation (the peer link port does not forward packets to the downlink port), resulting in traffic interruption. To implement fast convergence, you can configure not to block unicast packets during unidirectional isolation, but this may cause the downlink access device to receive duplicate packets. For example, device 1 and device 2 form an M-LAG system according to M-LAG configuration. The request packet of a downlink device is forwarded by device 1. At this moment, device 1 learns the MAC entry of the downlink device, but has not synchronized it to device 2. If the reply packet is forwarded by device 2, device 2 floods the packet in the VAP member port and peer link port. After receiving the packet from the peer link port, device 1 searches for the MAC address of the downlink device in the MAC address table, and also forwards the packet through the VAP member port. Now, the downlink device receives two duplicate reply packets.

Enabling the fast convergence mode accelerates the convergence for failure recovery, but there may be instantaneous duplicate packets. If you do not want duplicate packets in some scenarios, disable the fast convergence mode.

1.1.2 M-LAG System Negotiation

The basis of M-LAG application is that two devices pair with each other to form a system and provide the inter-device aggregation capability. The process is as follows:

1. System Pairing

After the domain ID, peer link, and peer-link-based L3 channel are configured for the two M-LAG devices, the devices synchronize the domain ID with each other through the L3 channel. After receiving a synchronization message, a device checks whether the domain ID is consistent with its local domain ID. If yes, the two devices pair with each other successfully.

2. Master/Slave Negotiation

After successful pairing, the two devices synchronize the system MAC address and M-LAG priority with each other, and compare their M-LAG priorities and system MAC addresses to elect the master and slave roles. The negotiation rules are as follows: The M-LAG priority is compared first, and a device with a higher M-LAG priority is elected as the master device. If the priorities are the same, the system MAC address is compared, and a device with a smaller MAC address is elected as the master device.

The LACP system ID and LACP system priority of the master device are selected as the LACP system ID and system priority of the M-LAG VAP. The LACP system ID and system priority are used when Layer 2 link aggregations in a VAP perform LACP negotiation.

Caution

When both the master and slave devices operate properly, packet forwarding is the same on them. However, packet forwarding is different on them in failure scenarios. For example, when the peer link is faulty, the VAP between the two devices fails. To avoid abnormal forwarding of traffic from the access device, the service ports on the slave device are shut down to switch traffic to the master device.

3. Forwarding Entry Synchronization

After successful M-LAG negotiation, the two devices synchronize forwarding entries mutually such as MAC entries and ARP entries, to ensure that the forwarding function of the dual-active system is consistent.

4. Dual-Active Detection

After M-LAG runs properly, heartbeat packets are sent periodically between the two devices to detect availability of the dual-active link. When a dual-active link failure is detected, if the peer link works properly, a prompt is displayed, reminding you to check the dual-active link.

When the peer link is faulty, the devices send dual-active detection packets to each other.

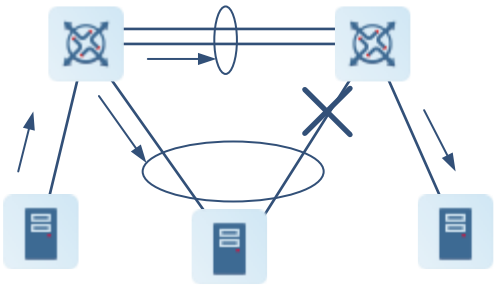
- If a device receives a detection response packet, dual master devices exist, and the service ports (the ports other than MGMT ports, peer link ports, and stacked ports) on the slave device are forced to enter the errdisable down state. To exempt a port from the errdisable down state, you can configure it as an excluded port, for example, the port used for dual-active detection.
- If no detection response packet is received, the peer device is faulty. If the local device is the slave device, it becomes the master device. If the local device is the master device, it does not take any actions.
- When the peer link recovers from the failure, the ports in the errdisable down state on the slave device recover immediately. However, because there may be a lot of protocols, it takes a certain period of time to complete convergence. During this period of time, the VAP member port is set to the up state in advance, which leads to a traffic forwarding failure and traffic interruption. Therefore, you can configure a delay for the port recovery so that the VAP member port recovers after the delay time expires.

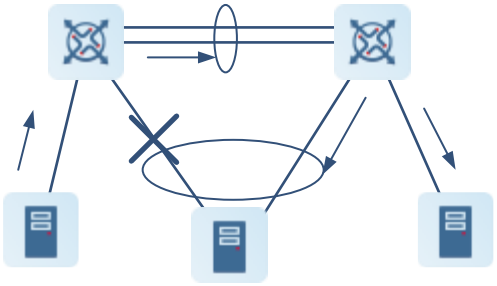
1.1.3 Anti-Loop Mechanism

When an access device connects to a network through M-LAG in dual-homing mode, the two APs of the VAP are distributed on two independent devices, and independent forwarding by the two APs may result in a loop or receiving of two copies of packets. M-LAG anti-loop rules are as follows:

- When the peer VAP member port works properly, traffic from the peer link is not forwarded to the local VAP member port, as shown in Figure 1-2.
- When the peer VAP member port fails, traffic from the peer link needs to be forwarded to the local VAP member port, as shown in Figure 1-3.

Figure 1-2 Peer Link Loop Prevention





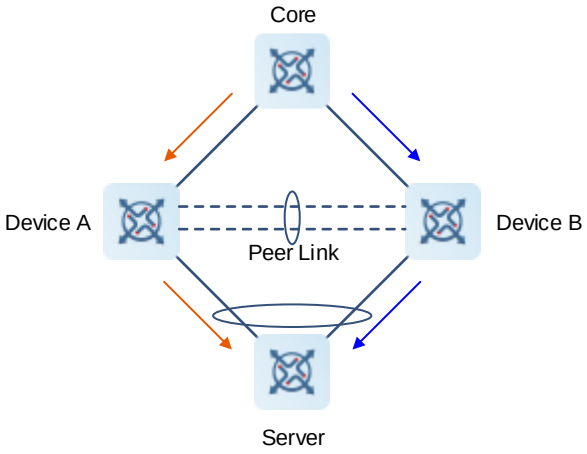


Figure 1-3 Peer Link Loop Removal

1.1.4 Local Port Preferential Forwarding

In a network, a peer link is regarded as a backup link. Service traffic is preferentially forwarded by local VAP member ports instead of peer links.

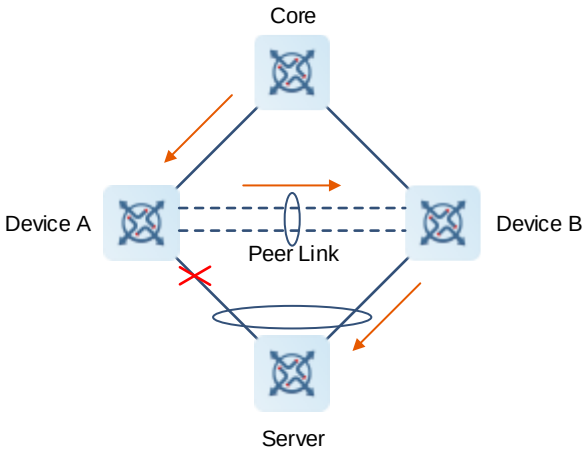

Figure 1-4 Forwarding Path of Service Traffic on a Normal Network

Through the following mechanism, M-LAG ensures that the device forwards service traffic by local VAP member ports preferentially on a normal network.

- The interfaces of a peer link keeps learning MAC addresses to ensure that the egress MAC addresses learned by the local ports are downlink ports.
- If a MAC table entry is synchronized from the M-LAG peer side, the device replaces the egress port of the MAC table entry with a local downlink port.
- Once the local VAP member ports of the device fail, service traffic will be forwarded through a peer link.

Figure 1-5 Forwarding Path of Service Traffic When the VAP Member Ports of Device A Fail

1.1.5 Configuration Consistency Check

In the M-LAG scenario, some service configurations need to be consistent on the two devices composing the M-LAG system, to ensure normal operation of the M-LAG system functions. Configuration information sharing of the M-LAG system realizes automatic configuration consistency check for the two devices in the M-LAG system. The configuration change at one end automatically triggers the configuration consistency check. When the configurations of the M-LAG master and slave devices are inconsistent, an alarm is prompted. If the key configurations on the master and slave devices of the M-LAG system are inconsistent, the service ports on the slave device are set to the errdisable down state; when the configuration consistency is restored, M-LAG recovers the ports in the errdisable down state on the slave device. According to the impact caused by configuration inconsistency, the configurations that need to be kept consistent are classified into two categories: key configuration (Type-1) and general configuration (Type-2).

- Key configuration: If the configurations are inconsistent between the devices at both ends of the M-LAG system, it causes the problems of a loop and a normal state with long-term packet loss.
- General configuration: If the configurations are inconsistent between the devices at both ends of the M-LAG system, the M-LAG system may operate abnormally. Compared with the key configuration, the problem of general configuration is easier to be found, and its impact on the networking environment is relatively minor.

Table 1-1 Configuration Consistency Check Table

Command Mode	Consistency Check Configuration Item	Type
Global configuration mode	Whether the Spanning Tree Protocol (STP) function is enabled	Type-1
	Configuration of the STP working mode	
	Whether the bridge protocol data unit (BPDU) protection function is enabled	
	Mappings between the Multiple Spanning Tree Protocol (MSTP) instances and virtual local area networks (VLANs)	
	SVI	Type-2

Command Mode	Consistency Check Configuration Item	Type
	VLAN and VXLAN network identifier (VNI) mapping configuration	
	OverlayRouter (OR) port configuration	
VAP member port	Whether the root protection function of an STP port is enabled	Type-1
	LACP mode configuration	
	STP priority	Type-2
	VLAN, to which a port is added	

Based on the handling method of inconsistency found in key configuration check, M-LAG consistency check can be performed in strict mode or loose mode.

- In strict mode, if the key configurations are inconsistent, the service ports on the M-LAG slave device are set to the errdisable state.
- When the general configurations are inconsistent, only an alarm is prompted regardless of the check mode.

1.2 Restrictions and Guidelines

- The peer link between the two devices must be an aggregate link. You are advised to use LACP aggregation and configure the peer link as a trunk port in L2 mode. Do not configure other services on the port.
- You are advised to configure multiple physical links for the peer link. For chassis devices, deploy physical links on different cards to avoid the impact of a card failure on the network.
- The dual-active detection link needs to be independent of the peer link to avoid a dual-active detection failure in case of a peer link failure.
- The M-LAG devices only synchronize the dynamic MAC/ARP entries, but not the static MAC/ARP configuration. The same static MAC/ARP entries need to be configured on the M-LAG devices.
- Only L2 APs can be configured as peer link ports or VAP member ports.

1.3 Configuration Task Summary

M-LAG configuration includes the following tasks:

(1) Configuring the M-LAG Function

1.4 Configuring the M-LAG Function

1.4.1 Overview

You can configure device link aggregation to enable an access device to connect to an M-LAG system in dual-homing mode. The traffic from an M-LAG device to the access device is first forwarded through the local VAP member port. When the local VAP member port fails, the traffic is forwarded to the M-LAG peer device. The dual-homing access meets requirements for balanced forwarding of traffic. When a single device or a single link fails, the device traffic is not affected and can be forwarded continuously.

1.4.2 Restrictions and Guidelines

- On M-LAG device, the two ports connected to the dual-homed access device need to join the same VAP.
- You are advised to use consistent configuration for the member ports of the same VAP on the two M-LAG devices to ensure normal traffic forwarding.
- The data synchronization channel needs to be established on the peer link.
- Due to the restriction of the M-LAG master and slave role election rules, the M-LAG master and slave roles are not changed under the following cases:
  - When the role of one device in the M-LAG system has been selected and the role of the other device is not selected, the priority change will not lead to role election.
  - When one device in the M-LAG system is in the dual-active errdisable state, the priority change will not lead to role election.
- Devices in an M-LAG system can be restarted only after you power down the system or run the **reboot** command. Using other methods to restart the device may cause the shutdown time of the keepalive port to be later than that of the peer link and the keepalive packet transmission interval out of the heartbeat hold time, and, consequently, the M-LAG slave device is wrongly set to the errdisable state by the dual-active detection mechanism. In this case, you are advised to configure a longer heartbeat hold time.

Table 1-2 Table of Special Constraints with Other Services

Feature	Description
Stacking	Devices can be used to build a stack first, and then the stack system can be used as an independent unit to build an M-LAG system.
CFM	The M-LAG and connectivity fault management (CFM) functions are mutually exclusive. They cannot be configured at the same time.
GVRP	The M-LAG and GARP VLAN Registration Protocol (GVRP) functions are mutually exclusive. They cannot be configured at the same time.
ERPS	The M-LAG and Ethernet Ring Protection Switching (ERPS) functions are mutually exclusive. They cannot be configured at the same time.
RLDP	The M-LAG and Rapid Link Detection Protocol (RLDP) functions are mutually exclusive. They cannot be configured at the same time.
Web authentication	The M-LAG and Web authentication functions are mutually exclusive. They cannot be configured at the same time.
dot1x	The M-LAG and dot1x functions are mutually exclusive. They cannot be configured at the same time.
Dynamic ARP detection	The M-LAG and dynamic ARP detection functions are mutually exclusive. They cannot be configured at the same time.

Feature	Description
DHCP	The two devices composing an M-LAG system do not support Dynamic Host Configuration Protocol (DHCP) snooping DHCP relay needs to be configured on both devices composing an M-LAG system. The DHCP server needs to be configured on both devices composing an M-LAG system and the addresses in the address pools of the two devices cannot be overlapped.
IP unicast routing	The M-LAG devices and connected devices cannot establish routing neighbor relationships through VAP member ports.
Multicast	M-LAG does not support IPv4 multicast or IPv6 multicast services.
IPSG	The two devices composing an M-LAG system do not support the IP source guard or IPv6 source guard.
VXLAN	● On the two devices composing an M-LAG system, L2 VNI mapping or outside center cannot be configured to implement the L2 data center interconnect (DCI). ● In scenarios where both M-LAG and VXLAN are configured, you are advised to configure one-to-one mappings between VNIs and VLANs on the peer link ports. The one-to-many mappings cause flooding of broadcast packets on the peer link ports. ● In scenarios where both M-LAG and VXLAN Layer 2 Ethernet subinterfaces are configured, peer link ports need to be added to all VNIs. ● In scenarios where both M-LAG and VXLAN Layer 2 Ethernet subinterfaces are configured, QinQ access is not supported on VXLAN L2 sub-ports.
Storm control	You are not advised to configure multicast packet storm control on physical member ports of a peer link. Otherwise, M-LAG synchronization packets are suppressed, resulting in data packet forwarding exceptions in the M-LAG system.
VLAN-mapping	The M-LAG and VLAN-mapping functions are mutually exclusive. They cannot be configured at the same time.

1.4.3 Configuration Tasks

M-LAG configuration includes the following tasks:

(1) Configuring Local and Peer IP Addresses

(2) Configuring Peer Link Ports

(3) Configuring M-LAG Attributes

(4) Configuring Member Ports of a Virtual Aggregate Interface

(5) Configuring Exceptional Interfaces

1.4.4 Configuring Local and Peer IP Addresses

1. Overview

To ensure normal negotiation between two devices that form an M-LAG system, you need to specify the local and peer IP addresses for entry synchronization and dual-active detection channels.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Configure the dual-active link unreachability logging.

logging vap keepalive-det

Note

This command is supported by only the S6510-32C.

(4) Configure a VAP domain.

vap domain *domain-id*

No VAP domain ID is configured by default.

The same VAP domain ID needs to be configured for the two devices used for dual-homing access.

(5) Configure the local and peer IP addresses for the Layer 3 channel used for entry synchronization.

data-sync { *local-ipv4-address* **peer** *peer-ipv4-address* | *local-ipv6-address* **peer** *peer-ipv6-address* }

No local and peer IP addresses are configured for a Layer 3 channel used for entry synchronization by default.

(6) Configure the local and peer IP addresses for the Layer 3 channel used for dual-active detection.

peer-keepalive local { *ipv4-address* | *ipv6-address* } **peer** { *ipv4-address* | *ipv6-address* } [*interface-type interface-number*] (Optional) Configure the domain negotiation timeout time.

1.4.5 Configuring Peer Link Ports

Note

This function is supported by only the S6980-64QC. S6920-4C, S6510-4C, S6520-64CQ, S6510-32CQ, and S6510-48VS8CQ.

2. Overview

The peer link is used to synchronize data and transmit some traffic. The directly connected ports at both ends of a peer link are called peer link ports, which must be configured as a Layer 2 aggregate interface. To improve the reliability of the peer link, you are advised to deploy multiple physical links for the peer link.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 2 aggregate interface configuration mode.

interface aggregateport *interface-number*

(4) Configure the Layer 2 aggregate interface as a peer link interface.

peer-link

When an interface is configured as a peer link port, other services cannot be configured on the interface, for example, it cannot be configured as a protected port. Moreover, MAC address learning is disabled on the interface, that is, M-LAG devices communicate with each other through flooding. You are advised to configure a peer link port with the trunk mode.

No peer link port is configured by default.

1.4.6 Configuring M-LAG Attributes

1. Overview

The values of the M-LAG attributes can be adjusted based on networking and service requirements.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a VAP domain.

vap domain *domain-id*

No VAP domain ID is configured by default.

(4) (Optional) Configure the domain negotiation timeout time.

domain-match delay *interval*

The default delay time is **120** seconds.

(5) (Optional) Configure the fast convergence mode.

fast-convergence

The fast convergence mode is enabled by default.

(6) (Optional) Configure a priority.

priority *priority*

The default priority is **4**.

(7) (Optional) Configure an interface recovery delay.

recover up-delay *interval* [**none-vap** *none-vap-interval*]

The default recovery delay is 120 seconds for VAP interfaces and 0 seconds for other interfaces.

(8) (Optional) Configure the heartbeat hold time.

peer-keepalive hold-time *interval*

The default heartbeat hold time for dual-active detection is **3** seconds.

(9) (Optional) Configure dual-active automatic recovery.

dual-active auto recovery

The dual-active automatic recovery function is disabled by default.

(10) (Optional) Configure consistency check.

vap consistency-check [**disable** | **loose** | **strict**]

Consistency check is not configured by default.

1.4.7 Configuring Member Ports of a Virtual Aggregate Interface

1. Overview

You can add aggregate interfaces into a virtual aggregate interface. You are advised to configure LACP to enhance reliability.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 2 aggregate interface configuration mode.

interface aggregateport *interface-number*

(4) Add an aggregate interface to a virtual aggregate interface group.

vap *vap-id*

1.4.8 Configuring Exceptional Interfaces

1. Overview

If M-LAG detects two active devices, it will configure the service interfaces (except for management interfaces, peer link ports, and stack interfaces) on the standby device as error down interfaces. To prevent an interface from being configured as an error down interface, you can configure this interface as an exceptional interface.

2. Procedure

(1) Enter the privileged EXEC mode.
privilege

(2) Enter the global configuration mode.
config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface *aggregateport interface-number*

- Enter the Layer 2 Ethernet sub-interface configuration mode.

interface *ethernet-type interface-number.subnumber*

- Enter the Layer 2 aggregate sub-interface configuration mode.

  interface *aggregateport interface-number.subnumber*

(4) (Optional) Configure an exceptional interface.
vap error-down except

No exceptional interface is configured by default.

1.5 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **cleanup** command to clear information.

Caution

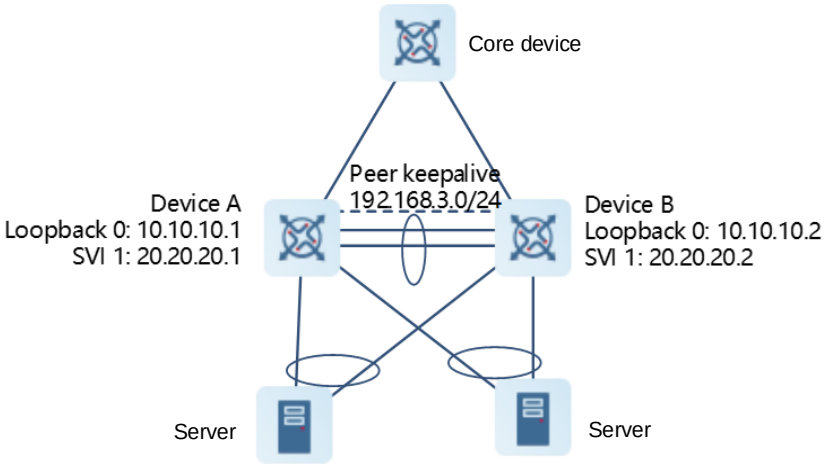
Running the **cleanup** commands may interrupt services due to loss of important information.

Table 1-3 M-LAG Monitoring

Command	Purpose
display vap	Displays the information about a VAP.
display vap data-sync	Displays the information about a data synchronization channel.
display vap keepalive	Displays the information about an M-LAG dual-active detection link.
display vap peer-link	Displays the information about the peer link.
display vap summary	Displays the brief information about M-LAG.
display vap peer-keepalive	Displays the information about a dual-active keepalive link.
display vap role	Displays the role information of M-LAG devices.
display vap error-down	Displays the errdisable state information of an M-LAG port.
display vap error-down except	Displays the configuration of the excluded port exempt from the errdisable state.
debugging mlag event	Debugs M-LAG events.

Command	Purpose
debugging mlag dad	Debugs M-LAG dual-active detection events.
debugging mlag dad-pkt	Debugs M-LAG keepalive packets.
debugging mlag mom	Debugs the M-LAG database.
debugging mlag cli	Debugs the M-LAG CLI configuration.
debugging mlag role	Debugs the M-LAG role negotiation.
debugging mlag role-pkt	Debugs M-LAG role negotiation packets.
debugging mlag error	Debugs M-LAG error events.
debugging mlag keypnt	Debugs M-LAG key events.
debugging mlag vap	Debugs the M-LAG group management.
debugging mlag log-file	Debugs the function of writing M-LAG logs into files.
debugging mlag [**cons-check** | **cons-mom**]	Debugs M-LAG configuration consistency check.
debugging mlag snmp	Debugs M-LAG trap.
cleanup vap error-down	Clear the ports from the errdisable state caused by M-LAG.
cleanup vap data-sync	Clear data records of the data synchronization channel.
cleanup vap keepalive	Clear data records of the heartbeat channel.

1.6 Configuration Examples



1.6.1 Connecting to an IP Network in Dual-Homing Mode

1. Requirements

A device needs to be configured to connect to an IP network in dual-homing mode.

2. Topology

Figure 1-6 Connecting to an IP Network in Dual-Homing Mode

3. Notes

- Configure interface IP addresses for all the devices.
- Configure a dynamic routing protocol (such as OSPF) on devices A and B and the core device.

4. Procedure

Configure a VAP domain on device A.

```
Device A> privilege
Device A# config-system terminal
Device A(cfg)# vap domain 1
Device A(cfg-vap-domain)# exit
```

Configure a data backup channel and a dual-active detection channel.

```
Device A(cfg)# interface loopback 0
Device A(cfg-if-Loopback 0)# ip address 10.10.10.1/32
Device A(cfg-if-Loopback 0)# exit
Device A(cfg)# vap domain 1
Device A(cfg-vap-domain)# data-sync local 20.20.20.1 peer 20.20.20.2
Device A(cfg-vap-domain)# peer-keepalive local 192.168.3.1 peer 192.168.3.2
Device A(cfg-vap-domain)# exit
Device A(cfg)# int vlan 1
Device A(cfg-if-VLAN 1)# ip address 20.20.20.1/24
Device A(cfg-if-VLAN 1)# exit
Device A(cfg)# ip route-config 10.10.10.2 255.255.255.255 20.20.20.2
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device A(cfg-if-GigabitEthernet 0/1)# ip address 192.168.3.1/24
```

Configure the peer link AP: aggregate interface 1. Add member port GigabitEthernet 0/4 and member port GigabitEthernet 0/5.

```
Device A(cfg)# interface aggregateport 1
```

```
Device A(cfg-if-AggregatePort 1)# switch-port mode trunk
Device A(cfg-if-AggregatePort 1)# peer-link
Device A(cfg-if-AggregatePort 1)# exit
Device A(cfg)# interface gigabitethernet 0/4
Device A(cfg-if-GigabitEthernet 0/4)# port-group 1 mode active
Device A(cfg-if-GigabitEthernet 0/4)# exit
Device A(cfg)# interface gigabitethernet 0/5
Device A(cfg-if-GigabitEthernet 0/5)# port-group 1 mode active
```

Configure VAP 2. Add the downlink port GigabitEthernet 0/2 to aggregate interface 2 and aggregate interface 2 to VAP 2.

```
Device A(cfg)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# port-group 2 mode active
Device A(cfg-if-GigabitEthernet 0/2)# exit
Device A(cfg)# interface aggregateport 2
Device A(cfg-if-AggregatePort 2)# switch-port access vlan 2
Device A(cfg-if-AggregatePort 2)# vap 2
```

Configure VAP 3. Add the downlink port GigabitEthernet 0/3 to aggregate interface 3 and aggregate interface 3 to VAP 3.

```
Device A(cfg)# interface gigabitethernet 0/3
Device A(cfg-if-GigabitEthernet 0/3)# port-group 3 mode active
Device A(cfg-if-GigabitEthernet 0/3)# exit
Device A(cfg)# interface aggregateport 3
Device A(cfg-if-AggregatePort 3)# switch-port access vlan 3
Device A(cfg-if-AggregatePort 3)# vap 3
```

Configure a VRRP dual-active gateway.

```
Device A(cfg)# vlan 2
Device A(cfg-vlan)# exit
Device A(cfg)# interface vlan 2
Device A(cfg-if-VLAN 2)# ip address 30.30.2.1/24
Device A(cfg-if-VLAN 2)# vrrp-config 1 ip 30.30.2.1
Device A(cfg-if-VLAN 2)# vrrp-config mode dual-active
Device A(cfg-if-VLAN 2)# exit
Device A(cfg)# vlan 3
Device A(cfg-vlan)# exit
Device A(cfg)# interface vlan 3
Device A(cfg-if-VLAN 2)# ip address 30.30.3.1/24
Device A(cfg-if-VLAN 2)# vrrp-config 1 ip 30.30.3.1
Device A(cfg-if-VLAN 2)# vrrp-config mode dual-active
```

Configure a monitor link, with the uplink port GigabitEthernet 0/1 and downlink ports GigabitEthernet 0/2 and GigabitEthernet 0/3.

```
Device A(cfg)# link state enable-track-group 1 up-delay 60
Device A(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# link state trace-group 1 upstream
Device A(cfg-if-GigabitEthernet 0/1)# exit
```

```
Device A(cfg)# interface gigabitethernet 0/2
Device A(cfg-if-GigabitEthernet 0/2)# link state trace-group 1 downstream
Device A(cfg-if-GigabitEthernet 0/2)# exit
Device A(cfg)# interface gigabitethernet 0/3
Device A(cfg-if-GigabitEthernet 0/3)# link state trace-group 1 downstream
```

Perform the following configuration on device B.

```
Device B> privilege
Device B# config-system terminal
```

Configure a VAP domain.

```
Device B(cfg)# vap domain 1
Device B(cfg-vap-domain)# exit
```

Configure a data backup channel and a dual-active detection channel.

```
Device B(cfg)# interface loopback 0
Device B(cfg-if-Loopback 0)# ip address 10.10.10.2/32
Device B(cfg-if-Loopback 0)# exit
Device B(cfg)# vap domain 1
Device B(cfg-vap-domain)# data-sync local 20.20.20.2 peer 20.20.20.1
Device B(cfg-vap-domain)# peer-keepalive local 192.168.3.2 peer 192.168.3.1
Device B(cfg-vap-domain)# exit
Device B(cfg)# int vlan 1
Device B(cfg-if-VLAN 1)# ip address 20.20.20.2/24
Device B(cfg-if-VLAN 1)# exit
Device B(cfg)# ip route-config 10.10.10.1 255.255.255.255 20.20.20.1
Device B(cfg)# interface gigabitethernet 0/1
Device A(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device B(cfg-if-GigabitEthernet 0/1)# ip address 192.168.3.2/24
```

Configure a peer link AP: aggregate interface1. Add member ports GigabitEthernet0/4 and GigabitEthernet 0/5.

```
Device B(cfg)# interface aggregateport 1
Device B(cfg-if-AggregatePort 1)# switch-port mode trunk
Device B(cfg-if-AggregatePort 1)# peer-link
Device B(cfg-if-AggregatePort 1)# exit
Device B(cfg)# interface gigabitethernet 0/4
Device B(cfg-if-GigabitEthernet 0/4)# port-group 1 mode active
Device B(cfg-if-GigabitEthernet 0/4)# exit
Device B(cfg)# interface gigabitethernet 0/5
Device B(cfg-if-GigabitEthernet 0/5)# port-group 1 mode active
```

Configure VAP 2. Add the downlink port GigabitEthernet 0/2 to aggregate interface 2 and aggregate interface 2 to VAP 2.

```
Device B(cfg)# interface gigabitethernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# port-group 2 mode active
Device B(cfg-if-GigabitEthernet 0/2)# exit
Device B(cfg)# interface aggregateport 2
Device B(cfg-if-AggregatePort 2)# switch-port access vlan 2
Device B(cfg-if-AggregatePort 2)# vap 2
```

Configure VAP 3. Add the downlink port GigabitEthernet 0/3 to aggregate interface 3 and aggregate interface 3 to VAP 3.

```
Device B(cfg)# interface gigabitethernet 0/3
Device B(cfg-if-GigabitEthernet 0/3)# port-group 3 mode active
Device B(cfg-if-GigabitEthernet 0/3)# exit
Device B(cfg)# interface aggregateport 3
Device B(cfg-if-AggregatePort 3)# switch-port access vlan 3
Device B(cfg-if-AggregatePort 3)# vap 3
```

Configure a VRRP dual-active gateway.

```
Device B(cfg)# vlan 2
Device B(cfg-vlan)# exit
Device B(cfg)# interface vlan 2
Device B(cfg-if-VLAN 2)# ip address 30.30.2.2/24
Device B(cfg-if-VLAN 2)# vrrp-config 1 ip 30.30.2.1
Device B(cfg-if-VLAN 2)# vrrp-config mode dual-active
Device B(cfg-if-VLAN 2)# exit
Device B(cfg)# vlan 3
Device B(cfg-vlan)# exit
Device B(cfg)# interface vlan 3
Device B(cfg-if-VLAN 2)# ip address 30.30.3.2/24
Device B(cfg-if-VLAN 2)# vrrp-config 1 ip 30.30.3.1
Device B(cfg-if-VLAN 2)# vrrp-config mode dual-active
```

Configure a monitor link, with the uplink port GigabitEthernet 0/1 and downlink ports GigabitEthernet 0/2 and GigabitEthernet 0/3.

```
Device B(cfg)# link state enable-track-group 1 up-delay 60
Device B(cfg)# interface gigabitethernet 0/1
Device B(cfg-if-GigabitEthernet 0/1)# link state trace-group 1 upstream
Device B(cfg-if-GigabitEthernet 0/1)# exit
Device B(cfg)# interface gigabitethernet 0/2
Device B(cfg-if-GigabitEthernet 0/2)# link state trace-group 1 downstream
Device B(cfg-if-GigabitEthernet 0/2)# exit

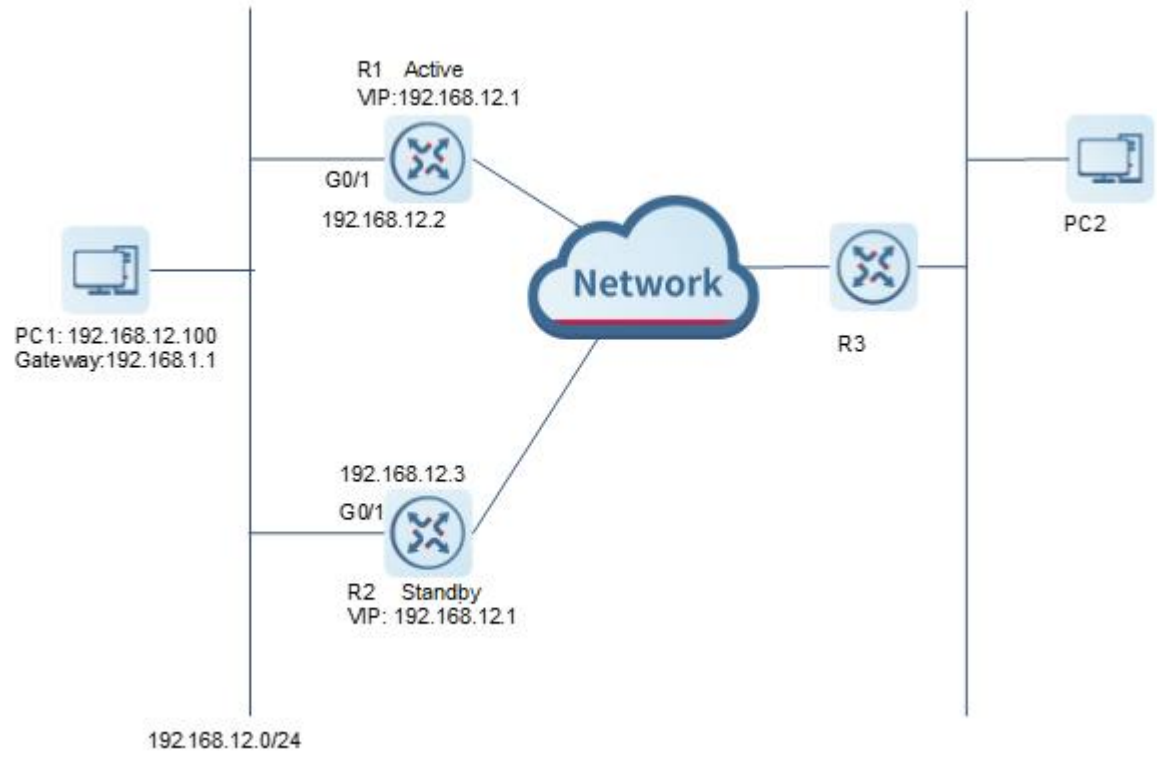
1 Configuring VRRP

1.1 Introduction

Virtual Router Redundancy Protocol (VRRP) is a fault-tolerant routing protocol. When a device used for routing and forwarding on a local area network (LAN) fails, VRRP enables another device to automatically take over services and data of the device, which helps achieve hot backup and fault tolerance of IP routing. In addition, VRRP ensures communication continuity and reliability for the hosts on the LAN. VRRP is applicable to LAN scenarios which require redundant backup of routing egresses.



Note

In this chapter, routers refer to the devices supporting routing, such as Layer 3 switches, routers and firewalls.

1.1.1 Basic Concepts

As shown in Figure 1-1, router 1 and router 2 form a VRRP backup group, and the gateway IP address configured for PC 1 is the virtual IP address of the VRRP backup group.

Figure 1-1 Diagram of Configuring VRRP

1. VRRP Router

A VRRP router refers to a router running VRRP. It is composed of one or more virtual routers.

2. Virtual Router

A virtual router, also called a VRRP standby group, is usually regarded as the default gateway of hosts on a shared LAN. A VRRP standby group contains a virtual router identifier (VRID) and a set of virtual IP addresses.

3. Active Router

In a VRRP standby group, only the active router responds to Address Resolution Protocol (ARP) requests and forwards IP packets. If a device is the IP address owner, it becomes the active router.

4. Standby Router

In a VRRP standby group, a standby router only monitors the state of the active router but does not respond to ARP requests or forward IP packets. When the active router fails, the standby router takes the chance to become the active router via election.

5. VRID

A virtual router identifier (VRID) is the unique identifier of a virtual router and distinguishes different VRRP back groups. Only a group of routers with the same VRID can form a VRRP standby group.

6. Priority

A VRRP standby group determines the position of each router in the virtual router based on its priority. The configurable priority range is from 1 to 254, and the priority of the VRRP router with the virtual router IP address must be 255. When the priority is 0, the current active node no longer joins the VRRP standby group, and the standby router is triggered to become the active node rapidly without waiting for the current active node to time out.

7. Virtual IP Address

A virtual IP address is the IP address of a virtual router. A virtual router can be configured with one or multiple virtual IP addresses.

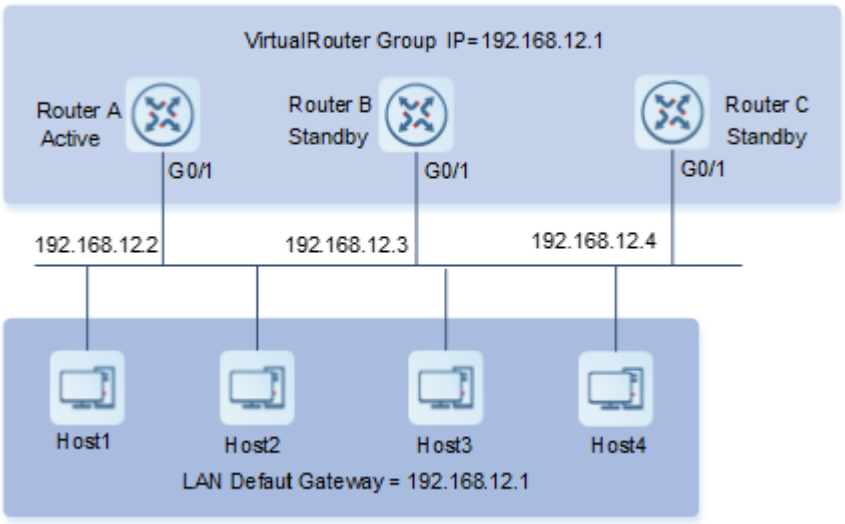
8. Virtual MAC Address

A virtual MAC address of VRRP complies with the Request for Comments (RFC) protocol standard. The virtual MAC address of an IPv4 VRRP standby group is "00-00-5E-00-01-{VRID}" (the virtual MAC address of an IPv6 VRRP standby group is “00-00-5E-00-02-{VRID}”), with the first five bytes fixed and the last byte of a VRRP standby group ID. A VRRP standby group responds to an ARP request by using its virtual MAC address instead of the real MAC address of an interface.

9. IP Address Owner

If the virtual IPv4/IPv6 address of a VRRP standby group is consistent with the IPv4/IPv6 address of the Ethernet port on which the VRRP standby group is configured, that is, the VRRP standby group has the real IP address of the Ethernet port, the VRRP standby group is collectively called an IP address owner. In such a case, the priority of the VRRP standby group is 255. If the Ethernet port is available, the VRRP standby group enters the active state automatically. The IP address owner receives and processes the packets whose destination IP address is the IP address of the virtual router.

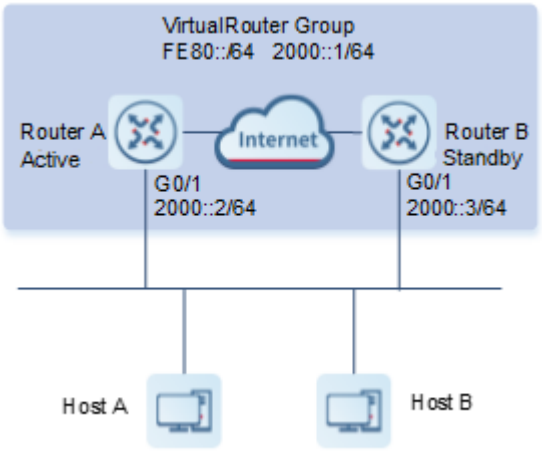
10. Preemption Mode



If a VRRP standby group runs in preemption mode, a standby router with a higher priority replaces the active router with a lower priority to become the active router of the VRRP standby group. If the VRRP standby group

runs in the non-preemption mode, as long as the active router runs properly, the standby router does not become the active router even if it is configured with a higher priority later. In some cases, even if the non-preemption mode is configured, a router that is just started in a VRRP standby group will preempt the position of the VRRP active router. The reason is that, when a device is started or the port just becomes active, the VRRP standby group on the port fails to receive the VRRP packet sent by the active device of the same standby group in time. In this case, the above problem can be avoided by delaying the start of the VRRP standby group.

1.1.2 VRRP Application

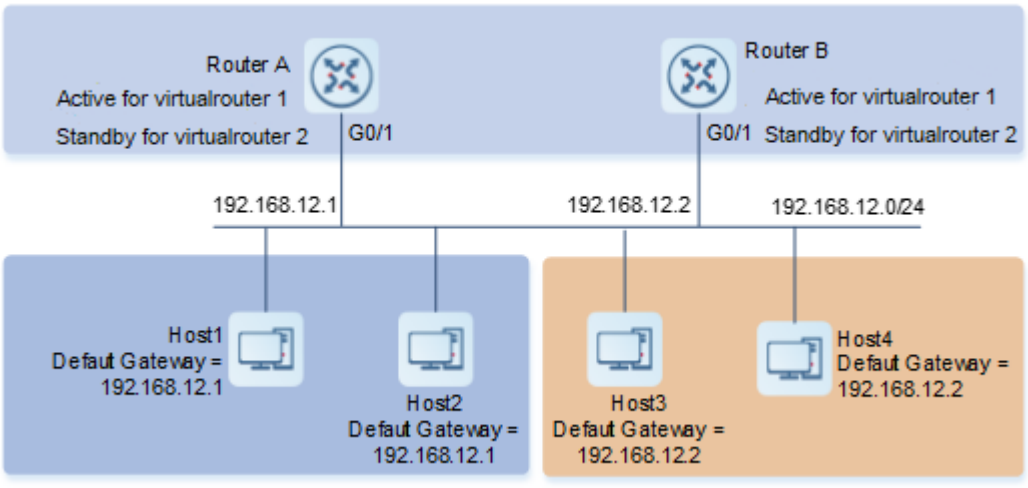


1. Active/Standby Redundancy

Figure 1-2 IPv4-based VRRP Active/Standby Redundancy

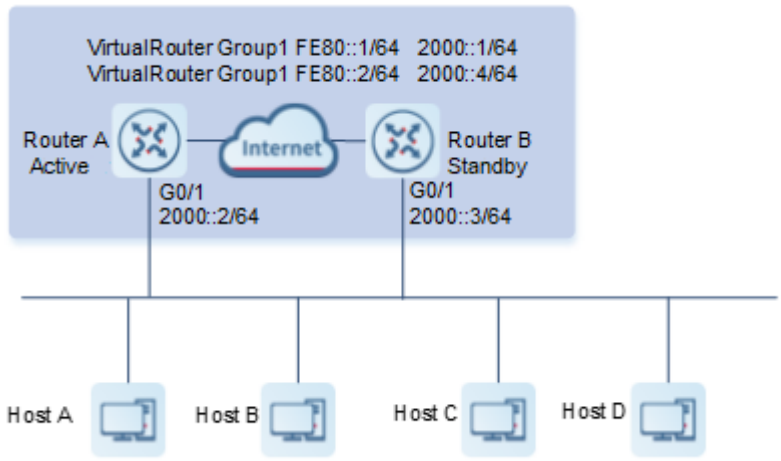
As shown in Figure 1-2, routers A, B, and C are all connected to the LAN through Ethernet ports, and VRRP is configured on the Ethernet ports connected to the LAN. The routers are in the same VRRP standby group, and the virtual IP address of the VRRP standby group is 192.168.12.1. Router A is elected as the active router of the VRRP standby group, and routers B and C are used as standby routers. Hosts 1, 2 and 3 use the IP address of the virtual router 192.168.12.1 as the gateway address. Packets from a host on the LAN to other networks are forwarded by the active router (router A). If router A fails, a active router is reelected between router B and router C to forward packets, to achieve simple routing redundancy.

Figure 1-3 IPv6-based VRRP Active/Standby Redundancy



As shown in Figure 1-3, both routers A and B are connected to the LAN through Ethernet ports, and IPv6 VRRP is configured on the Ethernet ports connected to the LAN. The routers are in the same IPv6 VRRP standby group, and the virtual IPv6 addresses of the IPv6 VRRP standby group are FE80::1/64 and 2000::1/64. Router A is elected as the active router of VRRP, and router B functions as a standby router. The hosts on the LAN take the IPv6 link local address FE80::1/64 of the virtual router as the gateway address. Packets from the hosts on the LAN to other networks are forwarded by the active router. If router A fails, router B forwards packets on behalf of router A, achieving simple routing redundancy.

- Before implementation: If the uplink or downlink port of router A fails, the data flow is interrupted, that is, a single point of failure occurs.
- After implementation: If router A fails, VRRP implements switching within seconds to ensure that services are not interrupted. This effectively avoids the problem of network interruption after a single link fails. In addition, you do not need to modify the configuration such as the dynamic routing protocol and routing discovery protocol. You do not need to modify the default gateway configuration for the host node of local link.



2. Load Balancing

Figure 1-4 IPv4-based VRRP Load Balancing

As shown in Figure 1-4, two virtual routers are configured. For virtual router 1, router A uses the IP address 192.168.12.1 of the Ethernet port GigabitEthernet 0/0 as the IP address of the virtual router, so router A becomes the active router and router B becomes the standby router. For virtual router 2, router B takes the IP address 192.168.12.2 of Ethernet port GigabitEthernet 0/0 as the IP address of the virtual router, so router B becomes the active router and router A becomes the standby router. In the LAN, hosts 1 and 2 take the IP address 192.168.12.1 of virtual router 1 as the default gateway address, while hosts 3 and 4 take the IP address 192.168.12.2 of virtual router 2 as the default gateway address. In this application of VRRP, routing redundancy is achieved between routers A and B, and the LAN traffic is shared between them to achieve load balancing.

Figure 1-5 IPv6-based VRRP Load Balancing

As shown in Figure 1-5, two virtual routers are configured. For virtual router 1, router A uses the IP address fe80::1/64 of the Ethernet port GigabitEthernet 0/1 as the IP address of the virtual router, so router A becomes the active router and router B becomes the standby router. For virtual router 2, router B takes the IP address fe80::2/64 of Ethernet port GigabitEthernet 0/1 as the IP address of the virtual router, so router B becomes the active router and router A becomes the standby router. On the LAN, hosts A and B use the IP address FE80::1 of virtual router 1 as the default gateway address (manually configured static IPv6 gateway), and hosts C and D use the IP address FE80::2 of virtual router 2 as the default gateway address (manually static configured IPv6 gateway). In this way, routing redundancy is achieved between routers A and B, and the LAN traffic is shared between them to achieve load balancing.

The devices involved are L3 devices or routers. L2 devices are not applicable.

- Before implementation: All traffic goes through the active router, causing a certain burden to the active router. Before the active router fails, the standby router has been always idle, leading to a resource waste.
- After implementation: Each device is not a single active router or standby router, but acts as different roles in different groups. Therefore, the connected devices can be assigned to different groups and forward traffic to different gateways to achieve traffic load balancing. Moreover, no device is kept idle all the time, and resources are fully utilized.

1.1.3 Packet Structure

VRRP has two versions available: VRRPv2 and VRRPv3. VRRPv2 is only applicable to IPv4 networks, and VRRPv3 is applicable to both IPv4 and IPv6 networks. A VRRP packet is used to send the priority and state of

the active device to all standby devices in the same standby group in multicast mode (with the destination address 224.0.0.18). The packet is encapsulated in an IP packet. The source address is the primary IP address (not the virtual IP address) of the packet sending port, the time to live (TTL) is 255, and the protocol ID is 112. Figure 1-6 and Figure 1-7 show the structures of VRRPv2 and VRRPv3 packets respectively.

Figure 1-6 Structure of VRRPv2 Packets

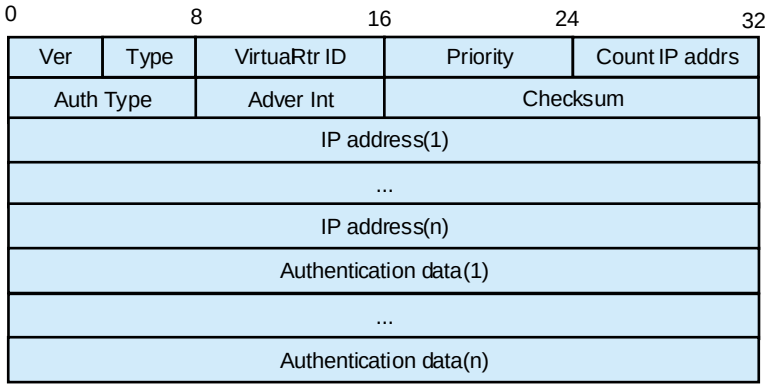


Figure 1-7 Structure of VRRPv3 Packets

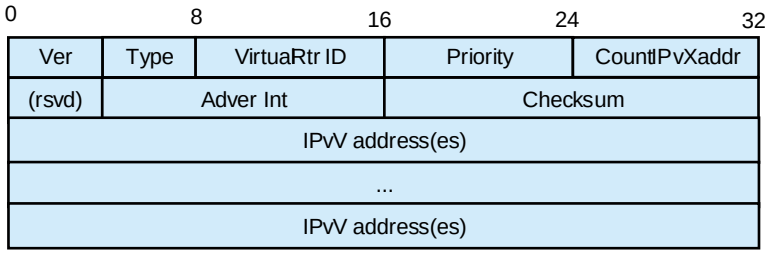

Table 1-1 Fields of VRRP Packets and Description

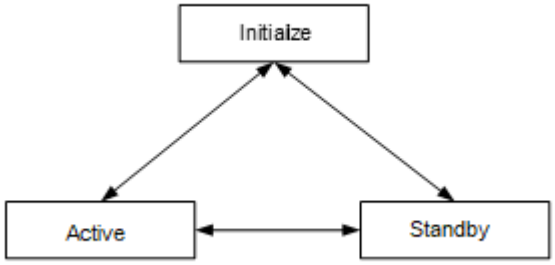
Packet Field	Description	
	VRRPv2	**VRRPv3**
Ver	Protocol version number. The value is 2.	Protocol version number. The value is 3.
Type	VRRP packet type. The value is 1, indicating that only the advertisement packets of VRRP are supported.	VRRP packet type. The value is 1, indicating that only the advertisement packets of VRRP are supported.
Virtual Rtr ID (VRID)	Virtual router ID (also the standby group ID). The value range is from 1 to 255.	Virtual router ID (also the standby group ID). The value range is from 1 to 255.



Packet Field	Description	
	VRRPv2	**VRRPv3**
Priority	Priority of the router in the standby group. The value range is from 0 to 255, and the default value is **100**. A larger value indicates a higher priority. When the priority is 0, the current active node no longer joins the VRRP standby group and the standby router is triggered to become the active node, instead of waiting for the current active node to time out. The priority 255 is reserved for the IP address owner, and the configurable range is from 1 to 254 for other routers.	Priority of the router in the standby group. The value range is from 0 to 255, and the default value is **100**. A larger value indicates a higher priority. When the priority is 0, the current active node no longer joins the VRRP standby group and the standby router is triggered to become the active node, instead of waiting for the current active node to time out. The priority 255 is reserved for the IP address owner, and the configurable range is from 1 to 254 for other routers.
Count IP Addrs/Count IPvX Addr	Number of virtual IPv4 addresses in the standby group.	Number of virtual IPv4 or virtual IPv6 addresses in the standby group.
Auth Type	Authentication type. Three authentication types are defined: ● **0**: Indicates no authentication. ● **1**: Indicates simple password (plaintext) authentication. ● **2**: Indicates MD5 authentication.	-
Advertise Interval	Interval of sending advertisement packets, in seconds. The default value is **1** second.	Interval of sending advertisement packets, in centiseconds. The default value is **100** centiseconds, namely, **1** second.
Checksum	16-bit checksum, used to check data corruption in the VRRP packet.	16-bit checksum, used to check data corruption in the VRRP packet.
IP Address/IPvX Address(es)	Virtual IPv4 addresses in the standby group. The number of addresses contained is defined in the **Count IP Addrs** field.	Virtual IPv4 addresses or virtual IPv6 addresses in the VRRP standby group. The number of addresses contained is defined in the **Count IPvX Addrs** field.
Authentication Data	Authentication key of the VRRP packet. At present, the authentication key is only used for simple password authentication. For the other authentication methods, **0** is filled in this field.	-

Packet Field	Description	
	VRRPv2	VRRPv3
rsvd	-	Reserved field for the VRRP packet. The field must be set to **0**.

1.1.4 VRRP State

There are three VRRP states: initialize, standby, and active. Figure 1-8 shows the state transition process.

Figure 1-8 VRRP State Transition Diagram

1. Initialize

Initialize is the initial state of VRRP. The system enters this state after startup. It only responds to startup, that is, it does not process VRRP packets.

- When the system is started, if the priority of the local VRRP standby group is 255 (namely, the IP address owner), then:
  - VRRP packets are sent immediately.
  - If the local VRRP standby group is an IPv4 virtual router, gratuitous ARP packets are sent to all the IPv4 addresses of the virtual router. If the local VRRP standby group is an IPv6 virtual router, gratuitous NA packets are sent to all the IPv6 addresses of the virtual router, the routing flag bit is 1, the request flag bit is 0, the coverage flag bit is 1, the target address is the IPv6 address of the virtual router (not destination address), and the link layer address in the target link layer option is the MAC address of the virtual router.
  - The advertisement information timer is configured to send VRRP advertisements regularly, that is, **Adver_Timer** is set to **Advertisement_Interval**.
  - The local VRRP standby group Device to the active state.
- When the system is started, if the priority of the local VRRP standby group is not 255, then:
  - **Active_Adver_Interval** is set to **Advertisement_Interval**.
  - **Active_Down_Timer** is set to **Active_Down_Interval**.
  - The local VRRP standby group Device to the standby state.

2. Standby

A standby virtual router is used to monitor the validity and state of the active virtual router.

- An IPv4 standby virtual router does not respond to the ARP request for the IP address of the virtual router, and an IPv6 standby virtual router does not respond to the neighbor solicitation (NS) packet for the IPv6 address of the virtual router.
- The standby virtual router discards packets whose destination MAC addresses are the MAC address of the VRRP standby group and packets whose destination IP addresses are the IP address of the VRRP standby group.
- The standby virtual router does not send protocol packets. It must receive the VRRP multicast packets sent by the active router to know the state of the active router.
- When a shutdown event is received, the standby virtual router deletes the host timeout timer and Device to the initialize state.
- If a timeout event of the host timeout timer is received, the standby virtual router sends VRRP advertisement information immediately. If the standby virtual router is an IPv4 virtual router, it broadcasts ARP packets to all the IPv4 addresses of the virtual router. If the standby virtual router is an IPv6 virtual router, it computes and joins the solicited-node multicast address for the IPv6 address associated with the virtual router, and sends non-request (gratuitous) NA packets to all the IPv6 addresses of the virtual router. The routing flag bit is 1, the request flag bit is 0, the coverage flag bit is 1, the target address is the IPv6 address of the virtual router (not destination address), and the link layer address in the target link layer option is the MAC address of the virtual router. **Adver_Timer** is set to **Advertisement_Interval**, and the virtual router Device to the active state.
- If a VRRP packet is received and the priority is 0, the host timeout timer **Active_Down_Timer** is reset to **Skew_Time**; if the priority of the received VRRP packet is greater than 0, and preemption is not allowed or the priority of the packet is greater than or equal to the priority of the local virtual router, **Adver Interval** is set to the **Active_Adver_Interval** field value in the packet and **Active_Down_Interval** is set to **Active_Down_Timer**, otherwise the packet is discarded.

3. Active

As the forwarding role in a VRRP standby group, the virtual router in the active state forwards virtual gateway packets.

- It sends VRRP multicast packets regularly, and forwards relevant packets passing through the virtual IP address and packets whose destination MAC address is the VRRP virtual MAC address.
- If the virtual router is an IPv4 virtual router, the VRRP virtual MAC address must be used to respond to the ARP requests whose destination IP addresses are the virtual IP address of the virtual router. If the virtual router is an IPv6 virtual router, it must respond to the NS packets whose destination IP addresses are the virtual IPv6 address of the virtual router and must be a member of the solicited-node multicast address for the IPv6 address associated with the virtual router.
- If **Accept_Mode** or **IPvX Owner** is configured, that is, the virtual router is the IPv4/IPv6 address owner, the packets whose destination IP addresses are the virtual IP address of the virtual router must be received, otherwise the packets are discarded.
- When the network port where the VRRP virtual router is located receives a shutdown event, the virtual router deletes the regular advertisement timer, removes the value of **Adver_Timer**, immediately sends a VRRP

advertisement packet with priority 0, and Device to the initialize state.

- If the timer for sending VRRP packets times out or a VRRP packet with priority 0 is received, the VRRP advertisement message is sent immediately, the timer for sending VRRP packets is reset, and **Adver_Timer** is assigned to **Advertisement_Interval**.
- If the priority of the received VRRP packet is greater than or equal to that of the corresponding VRRP virtual router at the local end and the source IP address of the received packet is greater than the primary IP address at the local end, the host timeout timer is reset, the regular advertisement timer is configured, and the virtual router Device to the standby state.
- If none of the above requirements is met, the packets are discarded.

1.1.5 VRRP Election

VRRP provides a simple mechanism for electing the active router, which provides the actual routing and forwarding service. The active router is elected in the following order:

(1) VRRP judges whether the VRRP device is an IP address owner. If so, VRRP Device to the active state.

(2) VRRP judges the VRRP priority in the same VRRP standby group. The device with a larger priority is in the active state.

(3) VRRP judges the primary IP address of the network port. The device with a larger primary IP address changes to the active state.

(4) The standby device determines whether to switch the state by monitoring the VRRP packet regularly sent by the active device. It Device the state in the following two cases:

- If the received advertisement state of the active device is normal, the priority of the active device's advertisement is lower than that of the standby device, and the preemption mode has been configured, the standby device Device to the active state.
- If no state advertisement is received from the active device within the timeout period and the preemption mode is configured, the standby device Device to the active state.

1.1.6 VRRP Timer

The main VRRP timers include the VRRP advertisement sending interval timer and the VRRP preemption delay timer.

- VRRP advertisement sending interval timer

You can adjust the time interval for the active router to send VRRP advertisement packets by configuring the VRRP advertisement sending interval timer. If the standby router still fails to receive a VRRP advertisement packet after waiting for at least three intervals, it regards itself as the active router, and sends a VRRP advertisement packet to reelect the active router.

- VRRP preemption delay timer

To avoid frequent active/standby switching between the members of the standby group and allow the standby router to have enough time to collect necessary information (such as the routing information), the standby router does not immediately preempt the position of the active router after receiving the advertisement packet with a priority lower than the local priority, but waits for a period of time (preemption delay) before sending a VRRP advertisement packet to take the place of the original active router.

1.1.7 VRRP Tracking

By correlating with the tracking function, VRRP monitors port state changes and the IP host accessibility and automatically adjusts the priority of the standby group to trigger role competition in the standby group, which causes state switching in the standby group and achieves fault monitoring and automatic switching. In this way, the network traffic is not interrupted. Two detection methods are available:

- Port state: VRRP detects the port state by receiving port state change messages. When a port is no longer in the up state, the priority of the current active router is automatically reduced to enable other standby routers to have the opportunity to become the active router. This avoids the failure of the entire virtual router due to the disconnection of a certain line.
- Host accessibility: Internet Control Message Protocol (ICMP) detection packets are sent regularly, and the time interval for sending detection packets, timeout time for waiting for responses, and continuous timeout count are configured to judge accessibility of the destination addresses.

⚠ Caution

- A monitored port must be a routable L3 logical port (for example, a routed port, an SVI, a loopback port, or a tunnel port). If a VRRP standby group is an IPv6 group, the IPv6 function needs to be enabled on the port first.
- The decrease in the priority value must be greater than the priority difference between the active and standby devices; otherwise the priority of the active device may be the same as that of the standby device after priority adjustment, and the active/standby state cannot be switched.

1.1.8 Protocols and Standards

- RFC 2338: Virtual Router Redundancy Protocol
- RFC 3768: Virtual Router Redundancy Protocol (VRRP)
- RFC 5798: Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6

1.2 Restrictions and Guidelines

- The IPv6 VRRP and IPv4 VRRP standby groups share the VRRP standby group ID. One VRRP standby group ID is applicable to an IPv4 VRRP standby group and an IPv6 VRRP standby group configured on the same port.
- When the IPv4 VRRP and IPv6 VRRP standby groups of the same port use the same VRRP standby group ID, two VRRP standby group IDs are used.

1.3 Configuration Task Summary

VRRP configuration includes the following tasks:

(1) Configuring IPv4 VRRP

(2) Configuring IPv6 VRRP

(3) Configuring IPv4 VRRP Tracking

(4) Configuring IPv6 VRRP Tracking

(5) (Optional) Configuring VRRP Attributes

All the following configuration tasks are optional and may be selected as needed.

- Configuring VRRP Basic Attributes
- Configuring a Method of Sending IPv4 VRRP Packets on a Super VLAN Port
- Configuring the Dual-Active Mode for an IPV4 VRRP Group
- Configuring the IPv4 VRRP Packet Version

1.4 Configuring IPv4 VRRP

1.4.1 Overview

IPv4 VRRP creates a standby group on a specified LAN segment after the standby group ID and virtual IPv4 address are configured, and then the VRRP single standby function is enabled on the corresponding port. You can configure multiple VRRP standby groups on the same Ethernet port to achieve load balancing and offer more stable and reliable network services through mutual standby.

1.4.2 Restrictions and Guidelines

- To achieve VRRP, the routers in a VRRP standby group must be configured with the same virtual IPv4 address.
- To achieve mutual standby between multiple IPv4 VRRP standby groups, configure multiple same IPv4 VRRP standby groups with different priorities on ports so that they act as the active and standby groups mutually.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the VXLAN router interface configuration mode.

  interface overlayrouter *interface-number*

(4) Enable IPv4 VRRP.

vrrp-config *group-id* **ip** *ipv4-address* [**secondary**]

IPv4 VRRP is disabled on a port by default.

(5) Configure a priority for the IPv4 VRRP standby group.

vrrp-config *group-id* **priority** *priority*

The default priority of an IPv4 VRRP standby group is **100**.

(6) (Optional) Configure a VRRP packet standard for the IPv4 VRRP standby group.

vrrp-config *group-id* **version** { **2** | **3** }

IPv4 VRRP adopts the VRRPv2 standard by default.

(7) (Optional) Configure an authentication string for the IPv4 VRRP standby group.

vrrp-config *group-id* **authentication** *authentication-string*

No authentication string of IPv4 VRRP is configured by default.

(8) (Optional) Configure a name for the IPv4 VRRP standby group.

vrrp-config *group-id* **description** *group-name*

No VRRP group name is configured by default.

(9) (Optional) Configure a VRRP advertisement interval for the IPv4 VRRP active router.

vrrp-config *group-id* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* }

The default VRRP advertisement interval of the VRRP active router is **1** second.

(10) (Optional) Enable the IPv4 VRRP timer learning function.

vrrp-config *group-id* **timers learn**

The advertisement interval timer learning function is disabled for an IPv4 VRRP standby group by default.

(11) (Optional) Configure the preemption mode for the IPv4 VRRP standby group.

vrrp-config *group-id* **preempt** [**delay** *delay-seconds*]

IPv4 VRRP runs in the preemption mode without preemption delay by default.

(12) (Optional) Configure a startup delay for the VRRP standby group on the port.

vrrp-config delay { **protocol-up** *min-seconds* | **reload** *reload-seconds* }

No VRRP group startup delay is configured by default.

1.5 Configuring IPv6 VRRP

1.5.1 Overview

IPv6 VRRP creates a standby group on a specified LAN segment after the standby group ID and virtual IPv6 address are configured, and then the VRRP single standby function is enabled on the corresponding port. You can configure multiple VRRP standby groups on the same Ethernet port to achieve load balancing and offer more stable and reliable network services through mutual standby.

1.5.2 Restrictions and Guidelines

- The first configured virtual address for IPv6 VRRP must be a link-local address, which can be deleted only

after other virtual addresses are deleted.

- The IPv6 function must be enabled on a port before IPv6 VRRP is configured.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the VXLAN router interface configuration mode.

  interface overlayrouter *interface-number*

(4) Enable the IPv6 function on the port.

ipv6 enable

(5) Enable IPv6 VRRP.

vrrp-config *group-id* **ipv6** *ipv6-address*

IPv6 VRRP is disabled on a port by default.

(6) Enable the function of receiving packets whose destination addresses are the IPv6 address of the virtual router.

vrrp-config ipv6 accept_mode

By default, an IPv6 VRRP group in the active state is not permitted to receive packets whose destination addresses are the IPv6 address of a virtual router, except the IPv6 VRRP group in owner state or the received NA/NS packets.

(7) Configure a priority for the IPv6 VRRP standby group.

vrrp-config ipv6 *group-id* **priority** *priority*

The default priority of an IPv6 VRRP standby group is **100**.

(8) (Optional) Configure a name for the IPv6 VRRP standby group.

vrrp-config ipv6 *group-id* **description** *group-name*

No VRRP group name is configured by default.

(9) (Optional) Configure a VRRP advertisement interval for the IPv6 VRRP active router.

vrrp-config ipv6 *group-id* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* } [**multiplier** *interval*]

The default VRRP advertisement interval of the VRRP active router is **1** second, and the timeout time is three times of the interval.

(10) (Optional) Enable the IPv6 VRRP timer learning function.

vrrp-config ipv6 *group-id* **timers learn**

The advertisement interval timer learning function is disabled for an IPv6 VRRP group by default.

(11) (Optional) Configure the preemption mode for the IPv6 VRRP standby group.

vrrp-config ipv6 *group-id* **preempt** [**delay** *delay-seconds*]

IPv6 VRRP runs in the preemption mode without preemption delay by default.

1.6 Configuring IPv4 VRRP Tracking

1.6.1 Overview

IPv4 VRRP tracking monitors the changes in port state and the IPv4 host accessibility. You can configure the optional packet detection parameter and bidirectional forwarding detection (BFD) correlation. The priority of a standby group can be adjusted dynamically to implement automatic switching and recovery of the standby group in case of a failure monitored.

1.6.2 Restrictions and Guidelines

- A monitored port must be a routable L3 logical port (for example, a routed port, an SVI, a loopback port, or a tunnel port).
- The support for BFD depends on the product version.
- If a VRRP group uses the actual IP address of an Ethernet port (in the owner state), the group priority is 255, and the monitored IP address or port can be configured, but the priority of the VRRP group is not changed.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the VXLAN router interface configuration mode.

  interface overlayrouter *interface-number*

(4) Configure a port to be monitored by an IPv4 VRRP standby group.

vrrp-config *group-id* **track** { *interface-type interface-number* | **bfd** *interface-type interface-number ipv4-address* } [*priority*]

No port to be monitored by an IPv4 VRRP standby group is configured by default. If a port to be monitored by an IPv4 VRRP standby group is configured and the priority parameter is not specified, the priority change value is 10.

(5) Configure an IP address to be monitored by the IPv4 VRRP standby group.

vrrp-config *group-id* **track** *ipv4-address* [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*]

No IP address to be monitored by an IPv4 VRRP standby group is configured by default. If an IP address to be monitored by an IPv6 VRRP group is configured, the time interval for sending detection packets is 3 seconds, and the timeout time for waiting for a response to a sent detection packet is 1 second, and the consecutive timeout count for judging that a tracked IP address is unreachable is 3.

(6) Configure BFD correlation with the IPv4 VRRP group.

vrrp-config *group-id* **bfd** *ipv4-address*

BFD correlation with an IPv4 VRRP group is not configured on a port by default.

(7) Return to the global configuration mode.

exit

(8) Configure global IPv4 VRRP BFD.

vrrp-config bfd *interface-type interface-number ipv4-address*

By default, no global BFD mode is configured for IPv4 VRRP to detect whether the active device is active.

1.7 Configuring IPv6 VRRP Tracking

1.7.1 Overview

IPv6 VRRP tracking monitors the changes in port state and the IPv6 host accessibility. You can configure the optional packet detection parameter to dynamically adjust the priority of a standby group and implement automatic switching and recovery of the standby group in case of a failure monitored.

1.7.2 Restrictions and Guidelines

- A monitored port must be a routable L3 logical port (for example, a routed port, an SVI, a loopback port, or a tunnel port).
- The IPv6 function needs to be first enabled on a port.
- If a tracked host IP address is a link-local address, specify a network port.
- If a VRRP group (in the owner state) uses the actual IP address of an Ethernet port, the group priority is 255,

and the monitored IP address or port can be configured, but the priority of the VRRP group is not changed.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the VXLAN router interface configuration mode.

  interface overlayrouter *interface-number*

(4) Enable the IPv6 function on the port.

ipv6 enable

(5) Configure a port to be monitored by an IPv6 VRRP group.

vrrp-config ipv6 *group-id* **track** { *interface-type interface-number* | **bfd** *interface-type interface-number peer-ipv6-address* } [*priority*]

No port to be monitored by an IPv6 VRRP group is configured by default. If a port to be monitored by an IPv6 VRRP group is configured and the priority parameter is not specified, the priority change value is 10.

(6) Configure an IPv6 address to be monitored by the IPv6 VRRP standby group.

vrrp-config ipv6 *group-id* **track** { *ipv6-global-address* | *ipv6-linklocal-address interface-type interface-number* } [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*Priority*]

No IP address to be monitored by an IPv6 VRRP group is configured by default. If an IP address to be monitored by an IPv6 VRRP group is configured, the time interval for sending detection packets is 3 seconds, the timeout time for waiting for a response to a sent detection packet is 1 second, and the consecutive timeout count for judging that a tracked IP address is unreachable is 3.

(7) Configure correlation between an IPv6 VRRP group and BFD.

vrrp-config ipv6 *group-id* **bfd** *ipv6-address*

Correlation between an IPv6 VRRP group and BFD is not configured on an interface by default.

(8) Return to the global configuration mode.

exit

(9) Configure global IPv6 VRRP BFD.

vrrp-config ipv6 bfd *interface-type interface-number ipv6-address*

No global BFD mode is configured for IPv6 VRRP to detect whether the active device is active by default.

1.8 Configuring VRRP Attributes

1.8.1 Overview

If a VRRP standby group has been set up, you can configure enhancement to increase the usability of the VRRP standby group.

1.8.2 Configuration Tasks

The VRRP attribute configuration includes the following tasks:

All the following configuration tasks are optional and may be selected as needed.

- Configuring VRRP Basic Attributes
- Configuring a Method of Sending IPv4 VRRP Packets on a Super VLAN Port
- Configuring the Dual-Active Mode for an IPV4 VRRP Group
- Configuring the IPv4 VRRP Packet Version

1.8.3 Notes

This section describes notes for configuring VRRP attribute functions.

Table 1-2 describes the VRRP attribute functions supported by different products.

Table 1-2 VRRP Attribute Functions Supported by Different Products

Function	Product Supporting the Function
Configuring a Method of Sending IPv4 VRRP Packets on a Super VLAN Port	S6920-4C, S6520-64CQ, S6510-32CQ, S6510-4C, S6510-48VS8CQ, S6250-48XS8CQ

1.8.4 Configuring VRRP Basic Attributes

1. Overview

If a VRRP standby group has been set up, you can configure basic attributes according to the actual situation.

2. Prerequisites

A VRRP standby group has been set up.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure VRRP basic attributes according to the actual situation.

- Configure a priority for the IPv4 VRRP standby group.

  vrrp-config *group-id* **priority** *priority*

  The default priority of an IPv4 VRRP standby group is **100**.

- Configure an authentication string of IPv4 VRRP.

  vrrp-config *group-id* **authentication** *authentication-string*

  No authentication string of IPv4 VRRP is configured by default.

- Configure a VRRP advertisement interval for the IPv4 VRRP active router.

  vrrp-config *group-id* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* } [**multiplier** *interval*]

  The default VRRP advertisement interval of the VRRP active router is **1** second, and the timeout time is three times of the interval.

- Configure the preemption mode for the IPv4 VRRP standby group.

  vrrp-config *group-id* **preempt** [**delay** *delay-seconds*]

  IPv4 VRRP runs in the preemption mode without preemption delay by default.

- Enable the IPv4 VRRP timer learning function.

  vrrp-config *group-id* **timers learn**

  The advertisement interval timer learning function is disabled for an IPv4 VRRP standby group by default.

- Configure a name for the IPv4 VRRP group.

  vrrp-config *group-id* **description** *group-name*

  No VRRP group name is configured by default.

- Configure a startup delay for the VRRP standby group on a port.

  vrrp-config delay { **protocol-up** *min-seconds* | **reload** *reload-seconds* }

  No VRRP group startup delay is configured by default.

1.8.5 Configuring a Method of Sending IPv4 VRRP Packets on a Super VLAN Port

Note

Only S6920-4C, S6520-64CQ, S6510-32CQ, S6510-4C, S6510-48VS8CQ, and S6250-48XS8CQ support configuring a method for sending IPv4 VRRP packets on a super VLAN interface.

1. Overview

The IPv4 VRRP protocol packets can be sent by the following three methods in a super VLAN. You can configure the method of sending advertisement packets.

- Sending IPv4 VRRP packets only to the first up sub VLAN in a super VLAN.
- Sending IPv4 VRRP packets to a specified sub VLAN in a super VLAN.
- Sending IPv4 VRRP packets to all the sub VLANs in a super VLAN.

2. Restrictions and Guidelines

- The configuration is effective only on super VLAN interfaces.
- If VRRP and VRRP plus are both enabled on a super VLAN interface, VRRP packets are sent to all the up sub-VLAN interfaces of the super VLAN interface.

3. Prerequisites

VRRP has been enabled on a super VLAN port.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the SVI configuration mode.

interface vlan *vlan-id*

(4) Configure a sub-VLAN range.

subvlan *vlan-range*

No sub-VLAN range is configured by default.

(5) Configure a method of sending IPv4 VRRP packets on a super VLAN port.

vrrp-config detection-vlan { **first-subvlan** | *subvlan-id* }

The IPv4 VRRP packets on a super VLAN port are sent to the first up sub VLAN only by default.

1.8.6 Configuring the Dual-Active Mode for an IPV4 VRRP Group

1. Overview

A VRRP group works in active/standby mode by default. To set both ends of a VRRP group in the active state and avoid sending keepalive packets, configure the dual-active mode for the VRRP group.

2. Restrictions and Guidelines

- The dual-active mode can be configured only on an SVI.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the SVI configuration mode.

interface vlan *vlan-id*

(4) Configure a VRRP group to work in dual-active state and configure the VRRP group not to send keepalive packets.

vrrp-config mode dual-active

A VRRP group works in active/standby mode by default.

1.8.7 Configuring the IPv4 VRRP Packet Version

1. Overview

The devices belonging to the same VRRP group should send packets according to the unified packet protocol: VRRPv2 or VRRPv3. By default, VRRPv2 is used for sending packets. VRRPv3 routers can recognize VRRPv2 packets, but VRRPv2 routers cannot recognize VRRPv3 packets. Configuring this function enables VRRPv3 routers to send VRRPv2 packets so as to communicate with VRRPv2 routers.

2. Restrictions and Guidelines

- The configuration is applicable to IPv4 VRRP only.
- If simple authentication has been configured for a VRRP group and the VRRP group is configured to send VRRPv2 packets, the authentication information is carried. If a VRRP group is configured to send VRRPv3 packets, the authentication information is not carried.
- The configuration only applies to the sending mode of VRRP packets and does not affect the receiving mode. For example, a VRRPv3 router can identify both VRRPv2 and VRRPv3 packets.

3. Prerequisites

IPv4 VRRP has been configured.

4. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the VRRP packet standard for an IPv4 VRRP standby group.

vrrp-config *group-id* **version** { **2** | **3** }

IPv4 VRRP adopts the VRRPv2 standard by default.

1.9 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

You can run the **debugging** command to output debugging information.

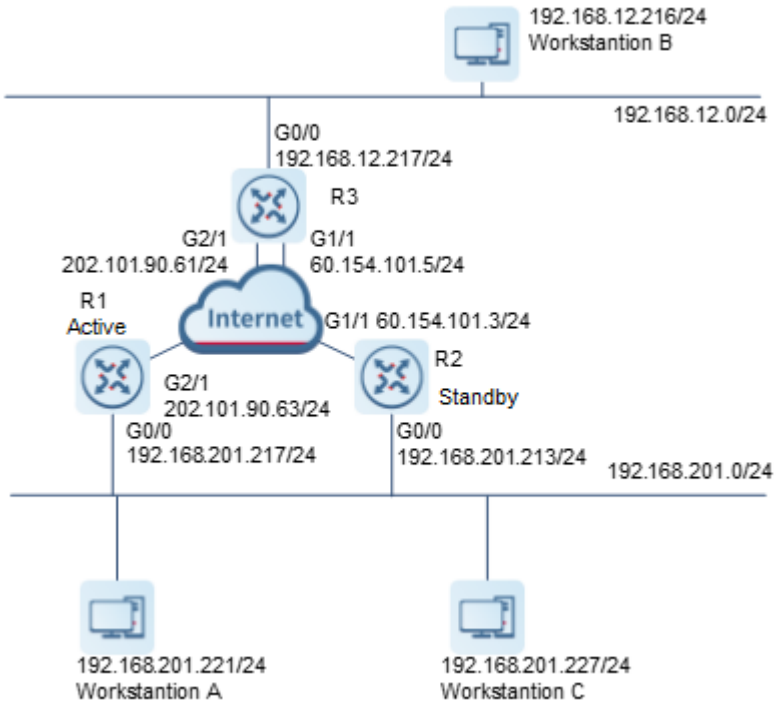
⚠ Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-3 VRRP Monitoring

Command	Purpose
display [**ipv6**] **vrrp-config** [**brief** | *group-id*]	Displays the brief or detailed information of IPv4/IPv6 VRRP.
display [**ipv6**] **vrrp-config interface** *interface-type interface-number* [**brief**]	Displays the information of an IPv4/IPv6 VRRP group on a specified port.
display vrrp-config [**brief** | *group-id*]	Displays the brief or detailed information of IPv4 VRRP.
display vrrp-config interface *interface-type interface-number* [**brief**]	Displays the information of an IPv4 VRRP group on a specified port.
display vrrp-config packet statistics [*interface-type interface-number* | **total**]	Displays the statistics of VRRP packets.
debugging [**ipv6**] **vrrp-config**	Debugs VRRP errors, events, packets, and state.
debugging [**ipv6**] **vrrp-config errors**	Debugs VRRP errors.
debugging [**ipv6**] **vrrp-config events**	Debugs VRRP events.
debugging vrrp-config packets [**acl** *acl-id* **|** [**icmp** | **protocol**] **interface** *interface-type interface-number* [*group-id*]] **debugging ipv6 vrrp-config packets** [**acl** *acl-name* | [**icmp** | **protocol**] **interface** *interface-type interface-number* [*group-id*]]	Debugs VRRP packets.
debugging [**ipv6**] **vrrp-config state**	Debugs VRRP state.
debugging vrrp-config	Debugs VRRP errors, events, packets, and state.
debugging vrrp-config errors	Debugs VRRP errors.
debugging vrrp-config events	Debugs VRRP events.
debugging vrrp-config packets [**acl** *acl-id* **|** [**icmp** | **protocol**] **interface** *interface-type interface-number* [*group-id*]]	Debugs VRRP packets.
debugging vrrp-config state	Debugs VRRP state.

1.10 Configuration Examples



1.10.1 Configuring IPv4 VRRP

1. Requirements

An IPv4 VRRP group and a to-be-monitored port need to be configured.

2. Topology

Figure 1-9 Configuring IPv4 VRRP

3. Notes

- Configure the work station cluster (192.168.201.0/24) to use the standby group composed of routers R1 and R2 and set the gateway address to the virtual router IP address configured for the standby group (192.168.201.1) so that the work station cluster accesses the remote work station cluster (192.168.12.0 /24) through the virtual router 192.168.201.1.
- On router R1, configure GigabitEthernet 2/1 as a VRRP monitored port.
- No VRRP but an ordinary routing function is configured on router 3.

4. Procedure

Perform the following configuration on router 3:

```
R3> privilege
R3# config-system terminal
R3(cfg)# interface GigabitEthernet 0/0
R3(cfg-if-GigabitEthernet 0/0)# unset switch-port
```

```
R3(cfg-if-GigabitEthernet 0/0)# ip address 192.168.12.217 255.255.255.0
R3(cfg-if-GigabitEthernet 0/0)# exit
R3(cfg)# interface GigabitEthernet 1/1
R3(cfg-if-GigabitEthernet 1/1)# unset switch-port
R3(cfg-if-GigabitEthernet 1/1)# ip address 60.154.101.5 255.255.255.0
R3(cfg-if-GigabitEthernet 1/1)# exit
R3(cfg)# interface GigabitEthernet 2/1
R3(cfg-if-GigabitEthernet 2/1)# unset switch-port
R3(cfg-if-GigabitEthernet 2/1)# ip address 202.101.90.61 255.255.255.0
R3(cfg-if-GigabitEthernet 2/1)# exit
R3(cfg)# router-protocol ospf
R3(cfg-router)# network-advertise 202.101.90.0 0.0.0.255 area 10
R3(cfg-router)# network-advertise 192.168.12.0 0.0.0.255 area 10
R3(cfg-router)# network-advertise 60.154.101.0 0.0.0.255 area 10
```

Perform the following configuration on router 1:

```
R1> privilege
R1# config-system terminal
R1(cfg)# interface GigabitEthernet 0/0
R1(cfg-if-GigabitEthernet 0/0)# ip address 192.168.201.217 255.255.255.0
R1(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 priority 120
R1(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 timers advertise 3
R1(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 ip 192.168.201.1
R1(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 track GigabitEthernet 2/1 30
R1(cfg-if-GigabitEthernet 0/0)# exit
R1(cfg)# interface GigabitEthernet 2/1
R1(cfg-if-GigabitEthernet 2/1)# ip address 202.101.90.63 255.255.255.0
R1(cfg-if-GigabitEthernet 2/1)# exit
R1(cfg)# router-protocol ospf
R1(cfg-router)# network-advertise 202.101.90.0 0.0.0.255 area 10
R1(cfg-router)# network-advertise 192.168.201.0 0.0.0.255 area 10
```

Perform the following configuration on router 2:

```
R2> privilege
R2# config-system terminal
R2(cfg)# interface GigabitEthernet 0/0
R2(cfg-if-GigabitEthernet 0/0)# ip address 192.168.201.213 255.255.255.0
R2(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 ip 192.168.201.1
R2(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 timers advertise 3
R2(cfg-if-GigabitEthernet 0/0)# exit
R2(cfg)# interface GigabitEthernet 1/1
R2(cfg-if-GigabitEthernet 1/1)# unset switch-port
R2(cfg-if-GigabitEthernet 1/1)# ip address 60.154.101.3 255.255.255.0
R2(cfg-if-GigabitEthernet 1/1)# exit
R2(cfg)# router-protocol ospf
R2(cfg-router)# network-advertise 60.154.101.0 0.0.0.255 area 10
R2(cfg-router)# network-advertise 192.168.201.0 0.0.0.255 area 10
```

5. Verification

Run the **display vrrp-config** command to verify the configuration.

Check whether router 1, which acts as the active router, reduces its VRRP standby group priority from 120 to 90 when GigabitEthernet2/1 connected to the wide area network (WAN) is unavailable. If yes, router 2 becomes the active router.

Check whether router 1 resumes its VRRP standby group priority from 30 to 120 when GigabitEthernet 2/1 connected to the WAN recovers. If yes, router 1 is reelected as the active router.

```
R1# display vrrp-config
GigabitEthernet 0/0 - Group 1
   State is Active
   Virtual IP address is 192.168.201.1 configured
   Virtual MAC address is 0000.5e00.0101
   Advertisement min_tx_interval is 3 sec
   Preemption is enabled
      min delay is 0 sec
   Priority is 120
   Active Router is 192.168.201.217 (local), priority is 120
   Active Down interval is 10.59 sec
   Tracking state of 1 interface, 1 up:
up     GigabitEthernet 2/1 priority reduce=30
```

Check the configuration on router 2.

```
R2# display vrrp-config
GigabitEthernet 0/0 - Group 1
   State is Standby
   Virtual IP address is 192.168.201.1 configured
   Virtual MAC address is 0000.5e00.0101
   Advertisement min_tx interval is 3 sec
   Preemption is enabled
      min delay is 0 sec
   Priority is 100
   Active Router is 192.168.201.217 , priority is 120
   Active Advertisement min_tx interval is 3 sec
   Active Down min_tx interval is 10.82 sec
```

6. Configuration Files

- Device R1 configuration file

```
hostname R1
!
interface GigabitEthernet 0/0
 unset switch-port
 ip address 192.168.201.217 255.255.255.0
 vrrp-config 1 priority 120
 vrrp-config 1 timers advertise 3
 vrrp-config 1 ip 192.168.201.1
```

```

```

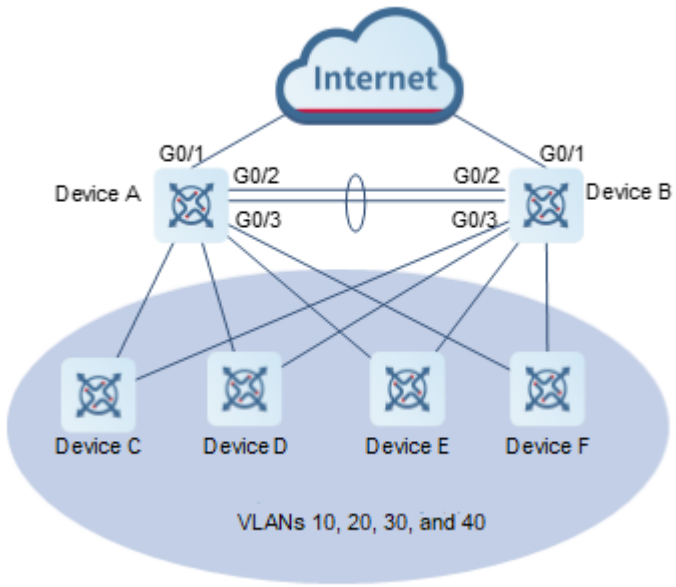
7. Common Errors

- Different virtual IP addresses of VRRP are configured on the routers in the same VRRP group, resulting in multiple active routers in the group.
- Different VRRP advertisement transmission intervals are configured on the routers in the same VRRP group and the timer learning function is not configured. As a result, multiple active routers arise in the group.
- Different VRRP packet versions are configured on the routers in the same VRRP group, resulting in multiple active routers in the group.
- For VRRPv2, the Ethernet ports of the routers in the same VRRP group all use the plaintext password authentication mode but use different authentication strings. As a result, multiple active routers arise in the group.



1.10.2 Configuring VRRP + MSTP

1. Requirements

As shown in Figure 1-10, VRRP and Multiple Spanning Tree Protocol (MSTP) can be configured to build a dual link standby network by using access devices and aggregation devices.

2. Topology

Figure 1-10 Configuring VRRP + MSTP

3. Notes

- Enable MSTP on devices (Device A, B, C, D, E, and F in this example). Configure VLAN-instance mappings (map VLANs 10 and 20 to instance 1, VLANs 30 and 40 to instance 2, and the rest VLANs to instance 0), and configure gateway devices (Device A and B in this example) as the root bridges of corresponding instances.
- Add the SVIs of all VLANs to corresponding VRRP standby groups, and set gateways to the active and standby routers of corresponding standby groups.Table 1-4 lists the configuration details in the example.

Table 1-4 Parameters for VRRP + MSTP Topology Configuration

Gateway	VLAN ID	SVI	Standby Group	Virtual IP Address	State
Device A	10	192.168.10.2	VRRP 10	192.168.10.1	Active
Device B		192.168.10.3			Standby
Device A	20	192.168.20.2	VRRP 20	192.168.20.1	Active
Device B		192.168.20.3			Standby
Device A	30	192.168.30.2	VRRP 30	192.168.30.1	Standby
Device B		192.168.30.3			Active
Device A	40	192.168.40.2	VRRP 40	192.168.40.1	Standby
Device B		192.168.40.3			Active

- Configure the uplink ports (port GigabitEthernet 0/1 of Device A and B in the example) of active routers in standby groups as the monitored ports of the active routers.
  - Create VLANs. Create VLANs 10, 20, 30, and 40 on Device A and B.
  - Configure MST regions. Map VLANs 10 and 20 to instance 1, VLANs 20 and 30 to instance 2, and the rest VLANs to instance 0 on Device A and B.
  - Configure Device A as the root bridge of MST 0 and MST 1, and Device B as the root bridge of MST 2.
  - Enable MSTP.
  - Configure SVIs for all the VLANs, add the SVIs to corresponding standby groups, and configure virtual IP addresses for the standby groups. Table 1-4 provides the corresponding configuration parameters.
  - Configure active routers and standby routers for all the groups.
  - Configure the uplink ports of active routers in VRRP standby groups as monitored ports of the VRRP groups.
  - Configure the interconnected ports of the core routers as a Layer 2 link aggregation.

4. Procedure

(1) Perform the following configuration on Device A:

Create VLANs 10, 20, 30, and 40.

```
DeviceA > privilege
DeviceA # config-system terminal
DeviceA (cfg)# vlan range 10,20,30,40
DeviceA (cfg)# exit
```

Map VLANs 10 and 20 to instance 1, VLANs 30 and 40 to instance 2, and the rest VLANs to instance 0.

```
DeviceA (cfg)# spanning-tree mst configuration
DeviceA (cfg-mst)# instance 1 vlan 10,20
DeviceA (cfg-mst)# instance 2 vlan 30,40
DeviceA (cfg-mst)# exit
```

On Device A, set the priority of MST 0 and MST 1 to **4096**, and the priority of MST 2 to **8192**.

```
DeviceA (cfg)# spanning-tree mst 0 priority 4096
DeviceA (cfg)# spanning-tree mst 1 priority 4096
DeviceA (cfg)# spanning-tree mst 2 priority 8192
```

Enable MSTP.

```
DeviceA (cfg)# spanning-tree
```

Configure SVIs for all the VLANs, add the SVIs to corresponding standby groups, and configure virtual IP addresses for the standby groups.

```
DeviceA (cfg)# interface vlan 10
DeviceA (cfg-if-VLAN 10)# ip address 192.168.10.2 255.255.255.0
DeviceA (cfg-if-VLAN 10)# vrrp-config 10 ip 192.168.10.1
DeviceA (cfg-if-VLAN 10)# exit
DeviceA (cfg)# interface vlan 20
DeviceA (cfg-if-VLAN 20)# ip address 192.168.20.2 255.255.255.0
DeviceA (cfg-if-VLAN 20)# vrrp-config 20 ip 192.168.20.1
DeviceA (cfg-if-VLAN 20)# exit
DeviceA (cfg)# interface vlan 30
DeviceA (cfg-if-VLAN 30)# ip address 192.168.30.2 255.255.255.0
DeviceA (cfg-if-VLAN 30)# vrrp-config 30 ip 192.168.30.1
DeviceA (cfg-if-VLAN 30)# exit
DeviceA (cfg)# interface vlan 40
DeviceA (cfg-if-VLAN 40)# ip address 192.168.40.2 255.255.255.0
DeviceA (cfg-if-VLAN 40)# vrrp-config 40 ip 192.168.40.1
DeviceA (cfg-if-VLAN 40)# exit
```

Increase the priority of standby groups 10 and 20 on Device A to **120**.

```
DeviceA (cfg)# interface vlan 10
DeviceA (cfg-if-VLAN 10)# vrrp-config 10 priority 120
DeviceA (cfg-if-VLAN 10)# exit
DeviceA (cfg)# interface vlan 20
DeviceA (cfg-if-VLAN 20)# vrrp-config 20 priority 120
DeviceA (cfg-if-VLAN 20)# exit
```

Configure the port GigabitEthernet 0/1 of Device A as a route port, and set the IP address to10.10.1.1/24.

```
DeviceA (cfg)# interface gigabitEthernet 0/1
DeviceA (cfg-if-GigabitEthernet 0/1)# unset switch-port
```

```
DeviceA (cfg-if-GigabitEthernet 0/1)# ip address 10.10.1.1 255.255.255.0
DeviceA (cfg-if-GigabitEthernet 0/1)# exit
```

Configure the port GigabitEthernet 0/1 of Device A as the monitored port of standby groups 10 and 20, and set *Priority decrement* to 30.

```
DeviceA (cfg)# interface vlan 10
DeviceA (cfg-if-VLAN 10)# vrrp-config 10 track gigabitEthernet 0/1 30
DeviceA (cfg-if-VLAN 10)# exit
DeviceA (cfg)# interface vlan 20
DeviceA (cfg-if-VLAN 20)# vrrp-config 20 track gigabitEthernet 0/1 30
DeviceA (cfg-if-VLAN 20)# exit
```

Configure the ports GigabitEthernet 0/2 and GigabitEthernet 0/3 to belong to a Layer 2 link aggregation, and configure the link aggregation as a trunk port.

```
DeviceA (cfg)# interface range gigabitEthernet 0/2-3
DeviceA (cfg-if-list)# port-group 1
DeviceA (cfg)# interface aggregateport 1
DeviceA (cfg-if-AggregatePort 1)# switch-port mode trunk
```

(2) Perform the following configuration on Device B:

Create VLANs 10, 20, 30, and 40.

```
DeviceB > privilege
DeviceB # config-system terminal
DeviceB (cfg)# vlan range 10,20,30,40
DeviceB (cfg-vlan-range)# exit
```

Map VLANs 10 and 20 to instance 1, VLANs 30 and 40 to instance 2, and the rest VLANs to instance 0.

```
DeviceB (cfg)# spanning-tree mst configuration
DeviceB (cfg-mst)# instance 1 vlan 10,20
DeviceB (cfg-mst)# instance 2 vlan 30,40
DeviceB (cfg-mst)# exit
```

On Device B, set the priority of MST 2 to **4096**, and the priority of MST 0 and MST 1 to **8192**.

```
DeviceB (cfg)# spanning-tree mst 2 priority 4096
DeviceB (cfg)# spanning-tree mst 0 priority 8192
DeviceB (cfg)# spanning-tree mst 1 priority 8192
```

Enable MSTP.

```
DeviceB (cfg)# spanning-tree
```

Configure SVIs for all the VLANs, add the SVIs to corresponding standby groups, and configure virtual IP addresses for the standby groups.

```
DeviceB (cfg)# interface vlan 10
DeviceB (cfg-if-VLAN 10)# ip address 192.168.10.3 255.255.255.0
DeviceB (cfg-if-VLAN 10)# vrrp-config 10 ip 192.168.10.1
DeviceB (cfg-if-VLAN 10)# exit
DeviceB (cfg)# interface vlan 20
DeviceB (cfg-if-VLAN 20)# ip address 192.168.20.3 255.255.255.0
DeviceB (cfg-if-VLAN 20)# vrrp-config 20 ip 192.168.20.1
```

```
DeviceB (cfg-if-VLAN 20)# exit
DeviceB (cfg)# interface vlan 30
DeviceB (cfg-if-VLAN 30)# ip address 192.168.30.3 255.255.255.0
DeviceB (cfg-if-VLAN 30)# vrrp-config 30 ip 192.168.30.1
DeviceB (cfg-if-VLAN 30)# exit
DeviceB (cfg)# interface vlan 40
DeviceB (cfg-if-VLAN 40)# ip address 192.168.40.3 255.255.255.0
DeviceB (cfg-if-VLAN 40)# vrrp-config 40 ip 192.168.40.1
DeviceB (cfg-if-VLAN 40)# exit
```

Increase the priority of VRRP 30 and VRRP 40 on Device B to **120**.

```
DeviceB (cfg)# interface vlan 30
DeviceB (cfg-if-VLAN 30)# vrrp-config 30 priority 120
DeviceB (cfg-if-VLAN 30)# exit
DeviceB (cfg)# interface vlan 40
DeviceB (cfg-if-VLAN 40)# vrrp-config 40 priority 120
DeviceB (cfg-if-VLAN 40)# exit
```

Configure the port GigabitEthernet 0/1 of Device B as a route port, and set the IP address to 10.10.2.1/24.

```
DeviceB (cfg)#interface gigabitEthernet 0/1
DeviceB (cfg-if-GigabitEthernet 0/1)# unset switch-port
DeviceB (cfg-if-GigabitEthernet 0/1)# ip address 10.10.2.1 255.255.255.0
DeviceB (cfg-if-GigabitEthernet 0/1)# exit
```

Configure the port GigabitEthernet 0/1 of Device B as the monitored port of standby groups 30 and 40, and set *Priority decrement* to 30.

```
DeviceB (cfg)# interface vlan 30
DeviceB (cfg-if-VLAN 30)# vrrp-config 30 track gigabitEthernet 0/1 30
DeviceB (cfg-if-VLAN 30)# exit
DeviceB (cfg)# interface vlan 40
DeviceB (cfg-if-VLAN 40)# vrrp-config 40 track gigabitEthernet 0/1 30
DeviceB (cfg-if-VLAN 40)# exit
```

Configure the ports GigabitEthernet 0/2 and GigabitEthernet 0/3 to belong to a Layer 2 link aggregation, and configure the link aggregation as a trunk port.

```
DeviceB  (cfg)# interface range gigabitEthernet 0/2-3
DeviceB  (cfg-if-list)# port-group 1
DeviceB  (cfg)# interface aggregateport 1
DeviceB  (cfg-if-AggregatePort 1)# switch-port mode trunk
```

5. Verification

Run the **display current-config** and **display vrrp-config brief** commands to check whether the configuration is correct.

```
DeviceA # display current-config
!
vlan 10
!
vlan 20
```

```
!
vlan 30
!
vlan 40
!
spanning-tree
spanning-tree mst configuration
 instance 0 vlan 1-9, 11-19, 21-29, 31-39, 41-4094
 instance 1 vlan 10, 20
 instance 2 vlan 30, 40
spanning-tree mst 0 priority 4096
spanning-tree mst 1 priority 4096
spanning-tree mst 2 priority 8192
interface GigabitEthernet 0/1
 unset switch-port

!
interface VLAN 30
 unset ip proxy-arp
 ip address 192.168.30.2 255.255.255.0
 vrrp-config 30 ip 192.168.30.1
!
```

```
interface VLAN 40
 unset ip proxy-arp
 ip address 192.168.40.2 255.255.255.0
 vrrp-config 40 ip 192.168.40.1
```

Check the VRRP state of device A.

```
DeviceA # display vrrp-config brief
Interface   Grp   Pri   timer   Own   Pre   State     Active addr     Group addr
VLAN 10      10    120   3        -     P     Active    192.168.10.2    192.168.10.1
VLAN 20      20    120   3        -     P     Active    192.168.20.2    192.168.20.1
VLAN 30      30    100   3        -     P     Standby   192.168.30.3    192.168.30.1
VLAN 40      40    100   3        -     P     Standby   192.168.40.3    192.168.40.1
```

Disconnect the uplink of Device A and check the VRRP state of the device.

```
DeviceA # display vrrp-config brief
Interface   Grp   Pri   timer   Own   Pre   State     Active addr     Group addr
VLAN 10      10    90    3        -     P     Standby   192.168.10.3    192.168.10.1

7. Common Errors

- Different VRRP authentication modes are configured on the Ethernet ports of routers in the same VRRP group, resulting in multiple active routers in the group.
- For VRRPv2, the Ethernet ports of the routers in the same VRRP group all use the plaintext password authentication mode but use different authentication strings. As a result, multiple active routers arise in the group.
- Different VRRP advertisement transmission intervals are configured on the routers in the same VRRP group and the timer learning function is not configured. As a result, multiple active routers arise in the group.
- Different virtual IP addresses of VRRP are configured on the routers in the same VRRP group, resulting in multiple active routers in the group.

1 Configuring VRRP Plus

1.1 Introduction

Virtual Router Redundancy Protocol Plus (VRRP Plus) is an extension of VRRP. It uses VRRP to implement gateway standby and load balancing in an IEEE 802.3 local area network (LAN). A standby router with VRRP enabled cannot forward packets. To use VRRP to implement load balancing, you need to manually configure multiple VRRP groups and set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This increases the workload of the network administrator. VRRP Plus is designed to address this issue. VRRP Plus automatically implements load balancing. It automatically distributes traffic of different hosts to members of a VRRP Plus group, and you do not need to configure multiple VRRP groups or set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This reduces the workload of the network administrator. You can enable a load balancing policy within a VRRP group without configuring multiple VRRP groups or different default gateways for hosts.

1.1.1 Basic Concepts

1. BVG

The balancing virtual gateway (BVG) allocates virtual MAC addresses to members of a VRRP Plus group. It responds to the gateway Address Resolution Protocol/Neighbor Discovery (ARP/ND) requests in the LAN, and forwards packets of hosts in the LAN.

2. BVF

The balancing virtual forwarder (BVF) forwards packets of hosts in the LAN. If a virtual MAC address is allocated to a BVF, the BVF participates in packet forwarding; otherwise, the BVF does not participate in packet forwarding.

3. Correlation with VRRP

VRRP Plus relies on VRRP, and runs in the following way:

- A master device in VRRP corresponds to a BVG in VRRP Plus.
- A standby device in VRRP corresponds to a BVF in VRRP Plus. Gateway addresses of hosts in a LAN are set to the virtual IPv4/IPv6 address of VRRP.

4. MAC Address Allocation

A BVG allocates virtual MAC addresses to BVFs. For an IPv4 VRRP Plus group, the BVG directly uses the virtual MAC address of VRRP to ensure compatibility between IPv4 VRRP Plus and IPv4 VRRP. That is, the virtual MAC address used by the BVG is 00-00-5E-00-01-{VRID} (VRID is the VRRP group number). The virtual MAC address used by a BVF is 00-1A-A9-16-{MemberID}-{VRID} (MemberID is the member ID of the BVF in the VRRP Plus group). Currently, a VRRP Plus group can have up to four members. The BVG uses the member ID 01, and the other BVFs use the member IDs 02 to 04.

For an IPv6 VRRP Plus group, the BVG directly uses the virtual MAC address of IPv6 VRRP to ensure compatibility between IPv6 VRRP Plus and IPv6 VRRP. That is, the virtual MAC address used by the BVG is

00-00-5E-00-02-{VRID} (VRID is the IPv6 VRRP group number). The virtual MAC address used by a BVF is 14-14-4B-72-{76 + MemberID }-{VRID}. The value range of MemberID is from 01 to 03.

5. Load Balancing Policies

The BVG responds to the gateway ARP/NS requests sent from hosts in a LAN. According to a specific load balancing policy, the BVG responds to hosts by using different virtual MAC addresses. The following load balancing policies are available:

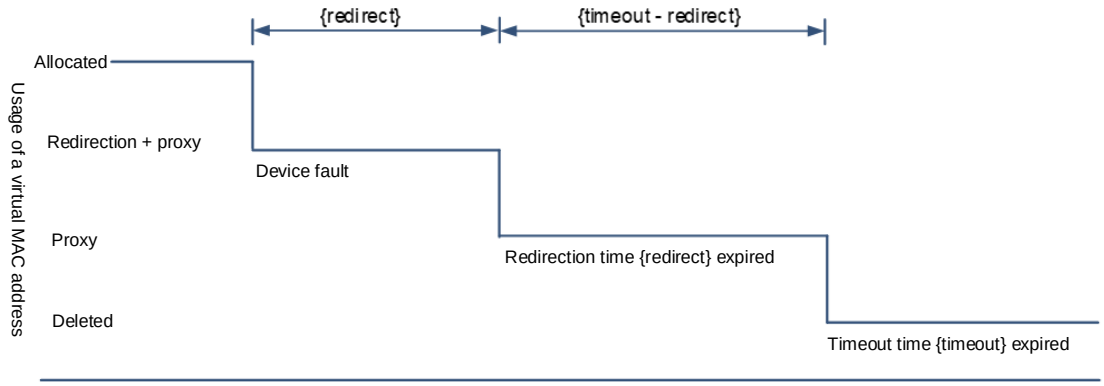
- Host-dependent policy: A specific virtual MAC address is used to respond to the requests sent by a specific host.
- Round-robin policy: Virtual MAC addresses in a standby group are used in a cyclic manner to respond to the gateway ARP/NS requests sent by hosts.
- Weighted policy: The ARP/NA requests are responded based on the forwarding capability of a device.

Policy switching is described below:

- If the load balancing mode is changed, load balancing is always implemented in the new load balancing mode. For example, if the round-robin load balancing mode is previously used, and later the weighted mode is used, load balancing is implemented in weighted mode. Load balancing cannot be implemented for hosts that have learned the VRRP virtual gateway addresses before the configuration of VRRP Plus. Therefore, if VRRP Plus is configured after a VRRP group switches to the master state, real load balancing cannot be implemented before aging of the ARP/ND entries learned by hosts. Load balancing is implemented only after the gateway ARP/ND entries learned by the hosts age and the hosts request new gateway addresses.
- Weight configuration means configuring different weights for different devices. In this way, more traffic is distributed to the device with a greater weight and less traffic is distributed to the device with a smaller weight, thereby fully utilizing the forwarding performance of different devices (if the total weight of virtual routers in a VRRP Plus group is 0, the ARP/NS requests are not responded). When the weight of a BVF in a standby group is smaller than the lower threshold, the BVF automatically exits the forwarding role. When the weight recovers and is greater than the upper threshold, the BVF automatically applies to the forwarding role. The forwarding role can be recovered when one or more remaining virtual MAC addresses or proxy virtual MAC addresses exist.
- The function of periodically sending of gratuitous ARP packets on an interface also affects the load balancing function of VRRP Plus. When VRRP Plus is enabled, the function of sending gratuitous ARP/NA packets of VRRP virtual IP addresses will be disabled. When a virtual IP address overlaps with an actual IP address, gratuitous ARP/NA packets of this address are no longer sent.
- When an address conflict occurs between a host and the local device, the ARP/NA module will broadcast gratuitous ARP/NA packets of this address. If a conflict occurs on the VRRP Plus virtual address, sending gratuitous ARP/NA packets results in re-learning of the host's gateway MAC address, which negatively affects the load balancing function of VRRP Plus. Therefore, the load balancing function of VRRP Plus is currently not supported in this scenario.

6. Proxy Virtual MAC Address

When a device with a virtual MAC address assigned becomes faulty in a standby group, traffic of hosts that use this virtual MAC address as the gateway MAC address will be interrupted. The BVG in the VRRP Plus standby group can quickly detect the fault, and automatically allocate the virtual MAC address of the faulty BVF to another device in the standby group. The new device acts as the proxy of the faulty device to forward packets of



the virtual MAC address. In addition, this proxy device takes over traffic of original hosts to prevent traffic interruption. The virtual MAC address allocated to a device in a standby group can be called a master virtual MAC address, and the virtual MAC address used by this device on behalf of another device is called a proxy virtual MAC address.

7. Redirection Interval and Timeout

VRRP Plus provides the virtual MAC address proxy function so that another device can take the place of a faulty device with a virtual MAC address assigned to forward packets. If a BVF recovers from the fault, its forwarding role should be restored and the BVF continues to forward packets of the virtual MAC address allocated to this BVF. If the faulty BVF does not recover all the time, the standby group stops redirecting traffic to this virtual MAC address. That is, when gateway ARP requests are received again, this virtual MAC address is no longer used to give responses. After a sufficient long period of time, it is believed that hosts that use the virtual MAC address as the gateway MAC address already update the ARP/ND table entry of the gateway address, and the traffic is already taken over by other devices. Now, this virtual MAC address can be deleted, and packets sent to this virtual MAC address should be discarded.

VRRP Plus allows configuring the redirection interval and timeout for a standby group. When a device is faulty, the standby group allocates the virtual MAC address of the faulty device to another device. Within the redirection interval, the standby group continues to use this virtual MAC address to respond to the ARP/NS requests. When the redirection time expires, the standby group no longer uses this virtual MAC address to respond to the requests. When the timeout time elapses, the standby group deletes this virtual MAC address and stops using it for proxy forwarding. Figure 1-1 shows the changes in the role of a virtual MAC address within the redirection interval and timeout time.

Figure 1-1 Diagram of Changes in the Role of an Allocated Virtual MAC Address

8. Correlation with Track

VRRP Plus supports correlation with bidirectional forwarding detection (BFD) and can adjust the weight based on the link status. Each device in a standby group can associate its weight with the link status. When a link is abnormal or unreachable, the device automatically decreases its weight. When the weight is too low, the device automatically exits the forwarding role. If a standby group is currently using the weighted load balancing policy, traffic can be distributed based on the new weight. When the associated link recovers, the device automatically restores its original weight and the forwarding role. If the standby group is currently using the weighted load balancing policy, traffic is distributed based on the restored weight.

9. Forwarding Preemption

VRRP Plus supports the function of preempting the forwarding role. In VRRP Plus, at most four devices can participate in load balancing. That is, a VRRP Plus standby group generates at most four virtual MAC addresses. If more than four devices are added to a VRRP Plus group, only four devices participate in packet forwarding. The remaining devices only listen to the statuses of other devices and do not participate in packet forwarding. Only when a device participating in packet forwarding is faulty, another device that originally does not participate in packet forwarding takes the place of the faulty device to forward packets. Assume that a VRRP Plus standby group already has four devices and all these devices participate in packet forwarding; a fifth device is added to the VRRP Plus group, and the forwarding capability of this device is strong or a device taking the forwarding role encounters a link failure and consequently the degradation of forwarding performance. In this case, if the preemption mode is enabled, the fifth device preempts the forwarding role from a device with a smaller weight (that is, with weaker forwarding capability). A greater weight is configured for a device with stronger forwarding capability. When the weight of a device in listening state is greater than that of a forwarding device, the device in listening state automatically preempts the forwarding role from the forwarding device. That is, the device with stronger forwarding capability forwards packets, whereas the device with lower forwarding capability is in listening state. This minimizes the waste of resources.

The BVG in a standby group is responsible for allocating virtual MAC addresses. Therefore, the BVG role cannot be preempted, and only the forwarding role of a BVF can be seized. If the BVG is faulty, VRRP re-elects a new master device, which assumes the BVG role.

1.1.2 Packet Structure

Figure 1-2 shows the structure of VRRP Plus packets.

Figure 1-2 Structure of VRRP Plus Packets

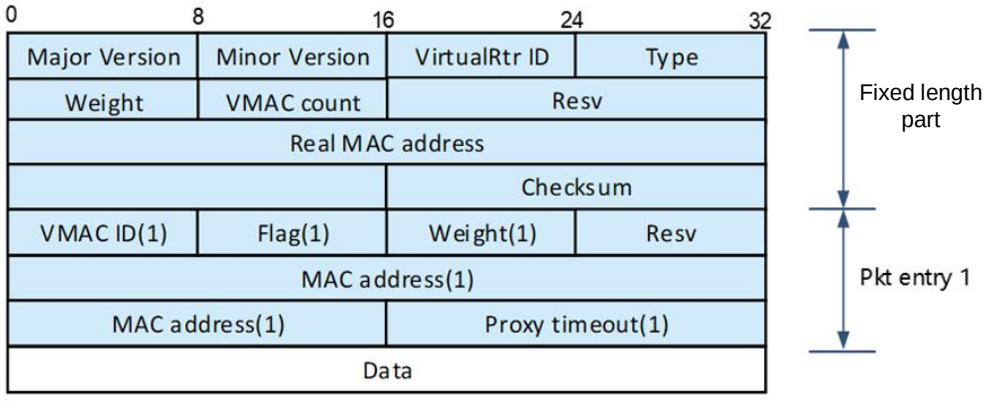


Table 1-1 Field Description of VRRP Plus Packets

Packet Field	Description
Major Version	Major version number. The current version is 1.
Minor Version	Minor version number. The current version is 0.
VirtualRtr ID	Virtual router ID, that is, the ID of a VRRP Plus standby group.

Packet Field	Description
Type	Type of VRRP Plus packets. Values and corresponding types are as follows: ● **0**: Indicates a tricky packet. ● **1**: Indicates a virtual MAC request packet. ● **2**: Indicates a keepalive packet of a BVF. ● **3**: Indicates the virtual MAC address release packet sent by the BVF to the BVG. ● **4**: Indicates the virtual MAC address allocation packet sent by the BVG to a BVF.
Weight	Weight of the device.
VMAC count	Number of virtual MAC addresses filled in the packet.
Resv	Reserved field in the fixed length part.
Real MAC address	Real MAC address of the interface on the local device.
Checksum	Packet checksum (including the fixed length part and filling part).
VMAC ID	Filled virtual MAC ID.
Flag	Flag information of the virtual MAC address.
Weight	Weight of the device to which the virtual MAC address is allocated.
Resv	Reserved field in the filling part.
MAC address	Real MAC address of the interface on the device to which the virtual MAC address is allocated.
Proxy timeout	Remaining time before timeout of the virtual MAC address filling in the case of a proxy virtual MAC address.

1.2 Configuration Task Summary

VRRP Plus configuration includes the following tasks:

(1) Configuring VRRP Plus

1.3 Configuring VRRP Plus

1.3.1 Overview

This section describes how to enable the VRRP Plus function and adjust the VRRP Plus weight based on the track object, to implement automatic balancing among multiple standby groups.

1.3.2 Restrictions and Guidelines

To enable the VRRP Plus function, you must configure a VRRP virtual IP address for the corresponding standby group.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

- Enter the VXLAN router interface configuration mode.

  interface overlayrouter *interface-number*

(4) Enable IPv4 VRRP.

vrrp-config *group-id* **ip** *ipv4-address* [**secondary**]

IPv4 VRRP is disabled on a port by default.

(5) Configure a priority for the IPv4 VRRP standby group.

vrrp-config *group-id* **priority** *Priority*

The default priority of an IPv4 VRRP standby group is **100**.

(6) Enable the VRRP Plus function on the interface.

vrrp-config [**ipv6**] *group-id* **balance**

The VRRP Plus function is disabled by default.

(7) Configure a VRRP Plus load balancing policy.

vrrp-config [**ipv6**] *group-id* **load-balancing** { **host-dependent** | **round-robin** | **weighted** }

By default, VRRP Plus uses the host-dependent load balancing policy, that is, host-dependent.

(8) Configure the redirection interval and timeout time for proxy virtual MAC addresses of the VRRP Plus standby group.

vrrp-config [**ipv6**] *group-id* **timers redirect** *redirect-interval redirect-timeout*

The default redirection interval of proxy virtual MAC addresses of a VRRP Plus standby group is **300** seconds and the default redirection timeout time is **14400** seconds.

(9) Configure the weight and upper and lower thresholds for the VRRP Plus standby group.

vrrp-config [**ipv6**] *group-id* **weighting** *weight-limit* [**lower** *min-weight-value*] [**upper** *max-weight-value*]

The default weight, default upper threshold, and default lower threshold of a VRRP Plus standby group are **100**, **1**, and **100** respectively.

(10) Configure the forwarding preemption function for the VRRP Plus standby group.

vrrp-config [**ipv6**] *group-id* **forwarder preempt**

The forwarding preemption function is enabled for a VRRP Plus standby group by default.

(11) Configure a track object for adjusting the weight for the VRRP Plus standby group.

vrrp-config [**ipv6**] *group-id* **weighting track** *object-number* [**reduce** *value*]

VRRP Plus tracking is not configured by default.

1.4 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

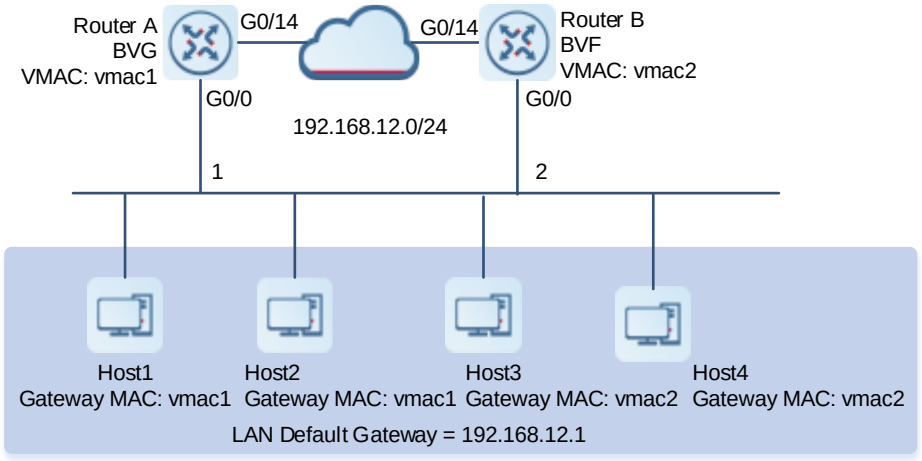
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-2 VRRP Plus Monitoring

Command	Purpose
display [**ipv6**] **vrrp-config balance**	Displays the brief or detailed information about VRRP Plus.
display [**ipv6**] **vrrp-config balance interface** *interface-type interface-number* [**brief**]	Displays the actions of a VRRP Plus group on a specified interface.
debugging [**ipv6**] **vrrp balance**	Debugs the VRRP Plus function.
debugging [**ipv6**] **vrrp balance error**	Debugs errors.
debugging [**ipv6**] **vrrp balance event**	Debugs events of a VRRP Plus group.
debugging [**ipv6**] **vrrp balance messages**	Debugs messages of VRRP Plus.
debugging [**ipv6**] **vrrp balance packets**	Debugs the VRRP Plus packets.
debugging [**ipv6**] **vrrp balance state**	Debugs the VRRP Plus group status.
debugging vrrp balance timer	Debugs the timers of a VRRP Plus group.
debugging [**ipv6**] **vrrp balance**	Debugs the VRRP Plus function.
debugging [**ipv6**] **vrrp balance error**	Debugs errors.

1.5 Configuration Examples



1.5.1 Configuring IPv4 VRRP Plus

1. Requirements

A load balancing policy needs to be enabled in an IPv4 VRRP group.

2. Topology

Figure 1-3 Configuring IPv4 VRRP Plus

3. Notes

- Configure a VRRP group and enable VRRP Plus on both routers A and B. Configure the local IP addresses so that router A becomes the BVG (master) device and router B becomes a BVF (standby) device.
- Configure the weighted load balancing policy for VRRP Plus. Configure a track object for adjusting the weight, and set the weight decrement value to 100.
- Retain default configurations for the weight, upper and lower thresholds, redirection interval, timeout time, and forwarding preemption function of the standby group.
- Set the default gateway addresses of hosts 1 to 4 in the LAN to the virtual IP address of VRRP, that is, 192.168.12.1.

4. Procedure

Perform the following configuration on router A:

```
RouterA> privilege
RouterA# config-system
RouterA(cfg)# interface GigabitEthernet0/0
RouterA(cfg-if-GigabitEthernet 0/0)# unset switch-port
RouterA(cfg-if-GigabitEthernet 0/0)# ip address 192.168.12.3 255.255.255.0
RouterA(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 ip 192.168.12.1
RouterA(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 balance
RouterA(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 load-balancing weighted
```

Perform the following configuration on router B:

```
RouterB> privilege
RouterB# config-system
RouterB(cfg)# interface GigabitEthernet0/0
RouterB(cfg-if-GigabitEthernet 0/0)# unset switch-port
RouterB(cfg-if-GigabitEthernet 0/0)# ip address 192.168.12.2 255.255.255.0
RouterB(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 ip 192.168.12.1
RouterB(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 balance
RouterB(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 load-balancing weighted
```

5. Verification

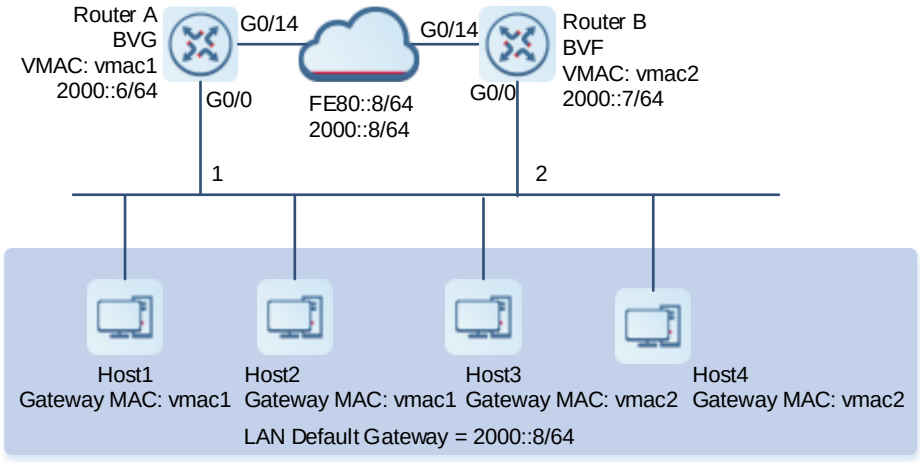
Run the **display vrrp-config balance** command on Router A to display the configuration of the VRRP Plus standby group. . If the standby group has packet forwarding tasks, **local** is displayed in the **Forwarder** column, and the virtual MAC address allocated to this standby group is also displayed.

```
RouterA# display vrrp-config balance interface GigabitEthernet0/0
State is BVG
  Virtual IP address is 192.168.12.1
  Hello time 1 sec, hold time 3 sec
  Load balancing: weighted
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 100 (configured 100), thresholds: lower 1, upper 100
  There are 2 forwarders
  Forwarder 1 (local)
    MAC address:
      0000.5e00.0101
    Owner ID is 0000.0001.0006
    Preemption disabled (BVG cannot be preempted)
  Forwarder 2
    MAC address:
001a.a916.0201
    Owner ID is 00d0.f822.33a3
Preemption enabled
```

Run the **display vrrp-config balance** command on Router B to display the configuration of the VRRP Plus standby group. If the standby group has packet forwarding tasks, **local** is displayed in the **Forwarder** field, and the virtual MAC address allocated to this standby group is also displayed.

```
RouterB# display vrrp-config balance interface GigabitEthernet0/0
  State is BVF
  Virtual IP address is 192.168.12.1
  Hello time 1 sec, hold time 3 sec
  Load balancing: weighted
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 100 (configured 100), thresholds: lower 1, upper 100
  There are 2 forwarders
  Forwarder 1
    MAC address:
      0000.5e00.0101
```

```
    Owner ID is 0000.0001.0006
    Preemption disabled (BVG cannot be preempted)
  Forwarder 2 (local)
    MAC address:
001a.a916.0201
    Owner ID is 00d0.f822.33a3
    Preemption enabled
```



1.5.2 Configuring IPv6 VRRP Plus

1. Requirements

A load balancing policy needs to be enabled in an IPv6 VRRP group.

2. Topology

Figure 1-4 Configuring IPv6 VRRP Plus

3. Notes

- Configure an IPv6 VRRP group and enable IPv6 VRRP Plus on both routers A and B. Configure the priorities so that router A becomes the BVG (master) device and router B becomes a BVF (standby) device.
- Configure the weighted load balancing policy for the IPv6 VRRP Plus standby group.
- Retain default configurations for the weight, upper and lower thresholds, redirection interval, timeout time, and forwarding preemption function of the standby group.
- Hosts 1 to 4 are hosts in the LAN. Set their IPv6 gateway addresses to 2000::8.

4. Procedure

Perform the following configuration on router A:

```
RouterA> privilege
RouterA# config-system
RouterA(cfg)# interface GigabitEthernet0/0
RouterA(cfg-if-GigabitEthernet 0/0)# unset switch-port
RouterA(cfg-if-GigabitEthernet 0/0)# ipv6 address 2000::6/64
```

```
RouterA(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 ipv6fe80::8
RouterA(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 ipv62000::8
RouterA(cfg-if-GigabitEthernet 0/0)# vrrp-config ipv6 1 priority 120
RouterA(cfg-if-GigabitEthernet 0/0)# vrrp-config ipv6 1 load-balancing weighted
RouterA(cfg-if-GigabitEthernet 0/0)# vrrp-config ipv6 1 balance
```

Perform the following configuration on router B:

```
RouterB> privilege
RouterB# config-system
RouterB(cfg)# interface GigabitEthernet0/0
RouterB(cfg-if-GigabitEthernet 0/0)# unset switch-port
RouterB(cfg-if-GigabitEthernet 0/0)# ipv6 address 2000::7/64
RouterB(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 ipv6fe80::8
RouterB(cfg-if-GigabitEthernet 0/0)# vrrp-config 1 ipv62000::8
RouterB(cfg-if-GigabitEthernet 0/0)# vrrp-config ipv6 1 load-balancing weighted
RouterB(cfg-if-GigabitEthernet 0/0)# vrrp-config ipv6 1 balance
```

5. Verification

Run the **display ipv6 vrrp-config balance** command on Router A to display the configuration of the VRRP Plus standby group. If the standby group has packet forwarding tasks, **local** is displayed in the **Forwarder** column, and the virtual MAC address allocated to this standby group is also displayed.

```
RouterA# display ipv6 vrrp-config balance interface GigabitEthernet0/0
GigabitEthernet 0/0 - Group 1
  State is BVG
  Virtual IPv6 address is as follows:
    FE80::8
    2000::8
  Hello time 1 sec, hold time 3 sec
  Load balancing: weighted
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 100 (configured 100), thresholds: lower 1, upper 100
  There are 2 forwarders
  Forwarder 1 (local)
    MAC address:
      0000.5e00.0201
    Owner ID is 00d0.f8fb.96f3
    Preemption disabled (BVG cannot be preempted)
  Forwarder 2
    MAC address:
      1414.4b72.7701
    Owner ID is 00d0.f8fb.6c42
    Preemption enabled
```

Run the **display ipv6 vrrp-config balance** command on Router B to display the configuration of the VRRP Plus standby group. If the standby group has packet forwarding tasks, **local** is displayed in the **Forwarder** field, and the virtual MAC address allocated to this standby group is also displayed.

```
RouterB# display ipv6 vrrp-config balance interface GigabitEthernet0/0
```

```
GigabitEthernet 0/0 - Group 1
  State is BVF
  Virtual IPv6 address is as follows:
    FE80::8
    2000::8
  Hello time 1 sec, hold time 3 sec
  Load balancing: weighted
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 150 (configured 150), thresholds: lower 1, upper 100
  There are 2 forwarders
  Forwarder 1
    MAC address:
      0000.5e00.0201
    Owner ID is 00d0.f8fb.96f3
    Preemption disabled (BVG cannot be preempted)
  Forwarder 2 (local)
    MAC address:
      1414.4b72.7701
    Owner ID is 00d0.f8fb.6c42
Preemption enabled
```

6. Common Errors

- VRRP Plus does not take effect because no VRRP virtual IP address is configured for a group.

1 Configuring BFD

1.1 Introduction

Bidirectional forwarding detection (BFD) provides a light-load and fast method for detecting the connectivity of the forwarding path between two adjacent routers. It quickly detects faults on the bidirectional forwarding path between two routers for upper layer protocols such as routing protocols and Multi-Protocol Label Switching (MPLS) so that measures can be taken in a timely manner to guarantee services. BFD minimizes the impact of faults on services and improves network availability.

1.1.1 Basic Concepts

1. Packet Format

Detection packets transmitted by BFD are User Datagram Protocol (UDP) packets, which are classified into two types:

- Control packets: The protocol defines a specific format, as shown in Figure 1-1. Currently, there are two versions (v0 and v1) for the format of control packets: v1 is adopted by default for establishing a BFD session; if a device receives packets of v0 from the peer system, the device automatically switches to v0.
- Echo packets: Echo packets are only used by the local system of a BFD session, and the protocol does not define a specific format.

Figure 1-1 BFD Packet Format

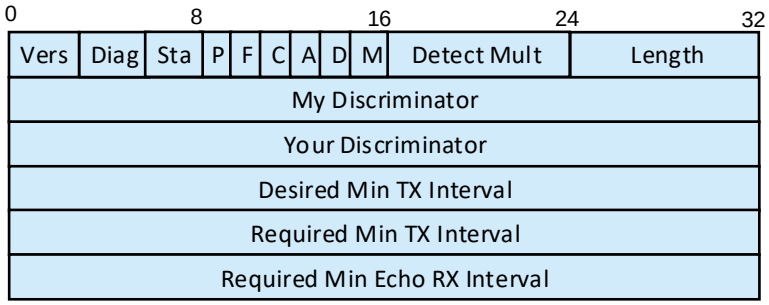

Table 1-1 Description of BFD Packet Fields

Field	Description
Vers	BFD protocol version number, which is 1 currently.

Field	Description
Diag	Causes for the local system to switch from up state to another state last time, including: **0**: Indicates no diagnostic information. **1**: Controls timeout detection. **2**: Indicates that the echo function failed. **3**: Indicates that a neighbor advertises session down. **4**: Indicates forwarding plane reset. **5**: Indicates that the path failed. **6**: Indicates that the connection path failed. **7**: Indicates that the local system enters the AdminDown state.
Sta	BFD local session states, including: **0**: Indicates the AdminDown state. **1**: Indicates the Down state. **2**: Indicates the Init state. **3**: Indicates the Up state.
P	The transmitter sets this flag to **1** in a BFD packet upon parameter changes. The receiver must immediately respond to this packet.
F	This flag must be set to **1** in the response packet for responding to the P flag that is set to **1**.
C	Forwarding/control separation flag. If it is set to **1**, the control plane changes do not affect BFD detection. For example, if the control plane is Open Shortest Path First (OSPF), when OSPF is restarted or experiences graceful restart (GR), BFD can continue to detect the link state.
A	Authentication flag. If it is set to **1**, a session needs to be authenticated.
D	Query request. If it is set to **1**, the transmitter desires the query mode for detecting links.
M	It is used in point-to-multipoint applications in the future. It must be set to **0** currently.
Detect Mult	Detection timeout multiplier. It is used by the detector to calculate the detection timeout time.
Length	Packet length.
My Discriminator	Discriminator of the local end of a BFD session.
Your Discriminator	Discriminator of the remote end of a BFD session
Desired Min Tx Interval	Minimum BFD packet transmission interval supported by the local end.

Field	Description
Required Min RX Interval	Minimum BFD packet receiving interval supported by the local end.
Required Min Echo RX Interval	Minimum echo packet receiving interval supported by the local end. It is set to **0** if the local end does not support the echo function.
Auth Type	Authentication type. It is an optional field and can be set to the following values: Simple Password Keyed MD5 Meticulous Keyed MD5 Keyed SHA1 Meticulous Keyed SHA1
Auth Length	Authentication data length.
Authentication Data	Authentication data area.

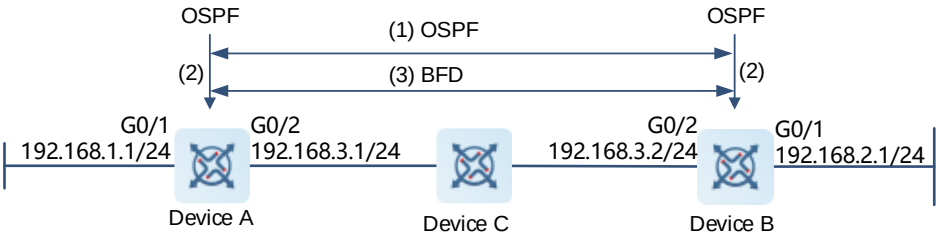
2. Session State

BFD migrates the state machine based on the local session state and the BFD packets received from the peer end. A BFD state machine is established and torn down using a three-way handshake mechanism, to ensure that both ends know the state change. A BFD session can be in any of the following four basic states:

- Down: Indicates that a session is in the down state or is established just now.
- Init: Indicates that the local system has communicated with the peer system and desires to bring the session to the up state.
- Up: Indicates that a session has been established successfully.
- AdminDown: Indicates that a session is in the AdminDown state.

3. Transmission Interval and Detection Time

During the establishment of a BFD session, both ends negotiate about BFD parameters to determine the transmission interval and detection time. After a BFD session is established, both ends dynamically negotiate about BFD parameters (for example, the minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.



1.1.2 Session Establishment

BFD detection starts from the establishment of a BFD session.

1. Session Establishment Process

BFD itself is unable to discover neighbors. It needs an upper-layer protocol to specify the neighbor, with which BFD needs to establish a session. As shown in Figure 1-2, two routers running OSPF and BFD are connected through an Layer 2 switch.

Figure 1-2 BFD Session Establishment

The BFD session establishment process is as follows:

- OSPF discovers a neighbor and establishes a connection with the neighbor.
- OSPF instructs BFD to establish a session with the neighbor.
- BFD establishes a session with the neighbor.

2. Session Establishment Mode

The BFD protocol specifies that a BFD session can be established in two modes:

- Active mode: Before the establishment of a session, BFD actively transmits a control packet for establishing a BFD session regardless of whether it receives a control packet for establishing a BFD session from the peer end.
- Passive mode: BFD does not actively transmit a control packet for establishing a BFD session before a session is established but waits till it receives a control packet for establishing a BFD session from the peer end.

Specification

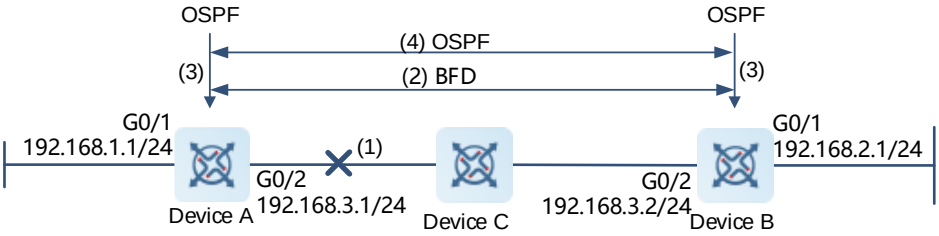
The passive mode is not supported currently.

3. Negotiation of Session Parameters

Both ends negotiate about BFD session parameters during the establishment of a BFD session, to determine the transmission interval and detection time. Pay attention to the following points:

- BFD session parameters (including the minimum transmission interval, minimum receiving interval, and detection timeout multiplier) must be set for interfaces at both ends. Otherwise, a BFD session cannot be established. If the BFD session is a multi-hop session, there is no need to configure BFD session parameters on the interface. The default global multi-hop session parameters will be used instead.
- Interfaces at both ends negotiate about BFD session parameters and detect the session based on the parameters during the establishment of a BFD session. If the BFD session is a multi-hop session, the default global multi-hop session parameters will be used for negotiation and session detection.
- After a BFD session is established, both ends dynamically negotiate about BFD parameters (for example, the minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.
- BFD session parameters can be updated only after all the original sessions on a port complete negotiation; otherwise an error is prompted. You can run a related command to query the negotiation status of the original

sessions.



1.1.3 Session Detection

Link detection starts after the establishment of a BFD session. BFD periodically transmits BFD control packets. If it fails to receive BFD packets from the peer end within the detection time, it deems that the session is down and instructs the associated application to accelerate the convergence.

1. Detection Process

As shown in Figure 1-3, two routers running OSPF and BFD are connected through an L2 switch.

Figure 1-3 Topology for BFD Session Detection

The handling process after a BFD session is down is as follows:

- The link between router A and the switch fails.
- The BFD session between routers A and B detects the failure.
- BFD notifies the local OSPF that the forwarding path to the neighbor is faulty.
- OSPF processes the neighbor down situation. If a backup forwarding path is available, it starts protocol convergence to enable the backup forwarding path.

2. Detection Mode

BFD supports the following detection modes:

- Asynchronous mode

  In asynchronous mode, systems transmit BFD control packets periodically to each other. If a system fails to receive BFD control packets from the peer end within the detection time, it advertises that the session is down.

- Query mode

  In query mode, it is assumed that each system has an independent method for confirming its connection with other systems. After a BFD session is established, the system stops transmitting BFD control packets unless it needs to explicitly verify the connectivity. In such a case, the system transmits a shot-sequence BFD control packet. If the system fails to receive a returned packet within the detection time, it advertises that the session is down. If it receives a response from the peer end, the forwarding path is reachable.

- Echo mode

  In echo mode, the local system periodically transmits BFD echo packets and a remote system receives and loops back the packets through the forwarding path. If the local system fails to receive several consecutive echo packets within the detection time, it advertises that the session is down. The echo function can be used together with the preceding two detection modes. The echo packet detection function does not require

the involvement of the control plane of the remote system. Packets are returned by the forwarding plane of the remote system, which reduces the delay and ensures faster fault detection in comparison with transmission of control packets. Enabling the echo function in asynchronous mode greatly reduces transmission of control packets because the detection is accomplished by the echo function. Enabling the echo function in query mode thoroughly cancels transmission of control packets after a session is established. The echo function must be enabled at both ends of a BFD session. Otherwise, the echo function does not take effect.

The echo mode includes the echo mode and one-armed echo mode. The one-armed echo mode is applicable to the single-hop IP link scenario and generally used in two directly connected devices, where one device supports the BFD function and the other does not. The echo mode requires that the echo mode be configured for both detection parties.

Specification

- The query mode is not supported and cannot be configured at present.
- Only BFD session version 1 supports the BFD echo mode.
- The echo mode is not supported for an IPv6 BFD session with the link-local address as the source or destination address.

1.1.4 BFD Support for Applications

By supporting BFD, the associated applications can utilize the fast fault detection of BFD to improve the protocol convergence performance. In general, the fault detection time can be shortened to less than 1 second. After BFD support for a certain application is enabled, BFD rapidly detects faults occurring on an established BFD session. When a link fault occurs, BFD can rapidly identify the fault and notify the associated application to process the fault, thereby improving its convergence. Currently, BFD supports the following applications:

1. BFD Support for RIP

After BFD support for the Routing Information Protocol (RIP) is enabled, RIP can utilize the faster fault detection feature of BFD than the hello mechanism of RIP to improve the protocol convergence. In general, the fault detection time can be shortened to less than 1 second.

Note

For more details about BFD support for RIP, see *Configuring RIP*.

2. BFD Support for OSPF

After BFD support for OSPF is enabled, OSPF can utilize the faster fault detection feature of BFD than the hello mechanism of OSPF to improve the protocol convergence. In general, the fault detection time can be shortened to less than 1 second.

Note

For more details about BFD support for OSPF, see *Configuring OSPFv2*.

3. BFD Support for OSPFv3

After BFD support for OSPFv3 is enabled, OSPFv3 can utilize the faster fault detection feature of BFD than the hello mechanism of OSPFv3 to improve the protocol convergence. In general, the fault detection time can be shortened to less than 1 second.

Note

For more details about BFD support for OSPFv3, see *Configuring OSPFv3*.

4. BFD Support for BGP

After BFD support for Border Gateway Protocol (BGP) is enabled, BGP can utilize the faster fault detection feature of BFD than the hello mechanism of BGP to improve the protocol convergence. In general, the fault detection time can be shortened to less than 1 second.

Note

For more details about BFD support for BGP, see *Configuring BGP*.

5. BFD Support for IS-IS

The Intermediate System to Intermediate System (IS-IS) protocol dynamically discovers neighbors through hello packets. After the BFD function is enabled on IS-IS, a BFD session is set up with a neighbor in up state. The BFD mechanism is used to detect the neighbor state. Once a neighbor failure is detected through BFD, IS-IS performs network convergence immediately. The convergence time can be reduced from 30s to less than 1s. By default, IS-IS hello packets are sent at an interval of **10** seconds in a P2P network, and the time required to detect a neighbor failure is three times the hello packet transmission interval.

Note

For more details about BFD support for IS-IS, see *Configuring IS-IS*.

6. BFD Support for Static Routing

After BFD support for static routing is enabled, BFD prevents routers from selecting an unavailable static route as the forwarding path during routing and enables routers to rapidly switch to an available backup forwarding path. Different from dynamic routing protocols, static routing does not have the ND mechanism. Therefore, after BFD support for static routing is configured, the next-hop reachability of a static route relies on the BFD session state. If a BFD session detects a fault, the next hop of a static route is unreachable and the static route is not added to the routing information base (RIB). If the remote system deletes a BFD session during the establishment of the BFD session, the BFD session becomes down. In this case, the system ensures that the forwarding behavior of static routing is not affected.

Note

For more details about BFD support for static routing, see *Configuring Static Routing*.

7. BFD Support for PBR

After BFD support for policy-based routing (PBR) is configured, BFD prevents routers from selecting an unavailable policy-based route as the forwarding path during routing and enables routers to rapidly switch to an available backup forwarding path. BFD support for PBR is equivalent to BFD support for static routing. BFD tracks and detects the forwarding path to a specified neighbor. When a BFD session fails, BFD notifies the PBR that the next hop is unreachable. Then, the policy-based route to the next hop does not take effect. If the remote system deletes a BFD session during the establishment of the BFD session, the BFD session becomes down. In this case, the system ensures that the PBR forwarding behavior is not affected.

Note

For more details about BFD support for PBR, see *Configuring PBR*.

8. BFD Support for VRRP

The BFD support for the Virtual Router Redundancy Protocol (VRRP) can replace the hello mechanism of VRRP to rapidly detect the running status of the active and standby routers. When a fault occurs, it accelerates the active/standby router switching and improves network performance. In general, the fault detection time can be shortened to less than 1 second. VRRP can also utilize BFD to track a specified neighbor. If a BFD session detects that the forwarding path to the neighbor fails, VRRP automatically lowers the VRRP priority to a certain extent to trigger active/standby router switching. This configuration takes effect only when a dynamic routing protocol or other applications notify BFD to establish a session with a neighbor.

Note

For more details about BFD support for VRRP, see *Configuring VRRP*.

9. BFD Support for VRRP Plus

The BFD support for VRRP Plus can replace the balancing virtual forwarder (BVF) detection conducted by the balancing virtual gateway (BVG) of VRRP Plus to rapidly detect the running status of BVFs. When a fault occurs, it accelerates the forwarding entity switching and improves network performance. In general, the fault detection time can be shortened to less than 1 second. VRRP Plus is based on the VRRP protocol. Therefore, no additional configuration is required for BFD support for VRRP Plus and only VRRP needs to be enabled on devices at both ends and a BFD session is correctly associated.

Note

For more details about BFD support for VRRP Plus, see *Configuring VRRP Plus*.

10. BFD Support for MPLS

The BFD support for Multiprotocol Label Switching (MPLS) enables label switched paths (LSPs) to use BFD to rapidly detect the neighbor status. The following detection modes are supported:

- BFD detects static LSPs.
- BFD detects LSPs generated by the Label Distribution Protocol (LDP).
- BFD detects reverse LSPs by using the IP addresses.

Note

For more details about BFD support for MPLS, see *Configuring MPLS Basics*.

11. BFD Support for Layer 3 Interfaces

BFD supports modifying the status of a Layer 3 interface. In interface configuration mode, run the **bfdbindpeer-ip** command to detect the address of a specified directly connected Layer 3 interface. After this CLI command is executed, a BFD session is created and the status of an Layer 3 interface can be changed based on the detection result of the BFD session, for example, BFD Down or BFD Up. This function is often used in various types of fast reroute (FRR), which use BFD to detect the interface status to implement FRR switching.

Note

Only LDP FRR switching is supported when BFD support for Layer 3 interfaces is configured.

12. BFD Support for AP Member Ports

After BFD support for aggregate port (AP) member ports is enabled, BFD can rapidly detect a fault occurring on a member port link so that traffic on this link is rapidly distributed to other effective member port links. In general, the fault detection time can be shortened to less than 1 second.

Note

For more details about BFD support for AP, see *Configuring Aggregate Interface*.

1.1.5 BFD Protection

If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets), BFD sessions will flap. You can enable the BFD protection to provide protection. If both BFD and BFD protection are enabled on a device, the device discards the BFD packets received from the previous-hop device, which affects the establishment of a BFD session between the previous-hop device and other devices.

1.1.6 BFD Flapping Advertisement Dampening

A BFD session may frequently switch between the down and up states due to link instability. As a result, an associated application (such as static routing) may frequently switch forwarding paths, causing the frequent switching of the BFD session between the down and up states. This function allows users to set the delay for status change advertisement. After a BFD session is up for a certain period of time, BFD informs an associated application of BFD up. Otherwise, BFD informs it of BFD down.

1.1.7 Protocols and Standards

- draft-ietf-bfd-base-09: Bidirectional Forwarding Detection
- draft-ietf-bfd-generic-05: Generic Application of BFD
- draft-ietf-bfd-mib-06: Bidirectional Forwarding Detection Management Information Base
- draft-ietf-bfd-v4v6-1hop-09: BFD for IPv4 and IPv6 (Single Hop)
- draft-ietf-bfd-multihop-07: BFD for IPv4 and IPv6 (Multihop)

- draft-ietf-bfd-mpls-07: BFD For MPLS LSPs

Specification

Currently, draft-ietf-bfd-mib-06 and draft-ietf-bfd-multihop-07 are not supported.

1.2 Restrictions and Guidelines

- You are advised to keep the parameter configuration consistent at both ends of a BFD session. The purpose is to ensure that application protocols associated with BFD take effect simultaneously and prevent occurrence of one-way forwarding path due to different dampening time at both ends.
- Transmission bandwidth differences of different interfaces need to be taken into account during parameter configuration. If the configured minimum Tx interval and minimum Rx interval are very small, BFD may occupy excessive bandwidth and affect data transmission.
- BFD session parameters can be configured only after all the sessions on the current port complete negotiation. Otherwise, a configuration error is prompted. Run the **display bfd adjacencies parm-consult** command to display the negotiation status of all the sessions.
- Ensure that BFD support is enabled on neighbors of a BFD session. Otherwise, a BFD session cannot be established. If a dynamic routing protocol or another application instructs BFD to establish a session with a neighbor, the BFD session can also be established.
- For a single-hop session whose source and destination IP addresses belong to the same network segment, if the interface specified by a BFD session is different from the actual BFD packet outbound interface because of IP routing, or if the interface specified during BFD session creation is different from the actual BFD packet inbound interface, a BFD session cannot be established. For a multi-hop session whose source and destination IP addresses belong to different network segments, associated applications do not need to specify an interface and BFD transmits and receives packets based on IP routing. Such BFD sessions can be established provided that returned BFD packets can be received.
- When BFD session traffic is sent and no BFD session parameters are configured on the device (the **display bfd adjacencies** command shows that the number of BFD sessions is 0), the CPU protect policy (CPP) entries are not delivered. Therefore, the BFD traffic sent to the local device is not matched with the CPP entries and not sent to the local device. In this case, BFD sessions must be configured for sending the traffic to the local device.
- In the process that the forwarding plane of the peer device returns echo packets transmitted by the local end to the local end, the echo packets may be lost due to congestion of the peer device, causing a session detection failure. In this case, you need to configure a quality of service (QoS) policy to ensure that echo packets are processed preferentially or disable the echo function.
- The echo detection function of BFD does not support multi-hop detection. Ensure that the echo function is disabled when configuring multi-hop detection.
- The echo mode takes effect only after it is enabled at both ends of a BFD session.
- Before enabling the echo mode of BFD, run the **unset ip redirects** command on the neighbors of a BFD session to disable the function of sending Internet Control Message Protocol (ICMP) redirection packets, and run the **unset ip deny land** command to disable the distributed denial of service (DDoS) function to prevent the land-based attack.

1.3 Configuration Task Summary

BFD configuration includes the following tasks:

(1) Configuring BFD Basic Functions

- Configuring BFD Parameters
- (Optional) Configuring the BFD Echo Mode
- (Optional) Configuring the BFD Slow Timer
- (Optional) Configuring BFD Support for Layer 3 Interfaces
- Configuring BFD Support for Applications

(2) (Optional) Configuring BFD Protection

(3) (Optional) Configuring BFD Flapping Advertisement Dampening

1.4 Notes

This section describes notes for configuring BFD functions.

Table 1-2 describes BFD functions supported by different products.

Table 1-2 BFD Functions Supported by Different Products

Function	Product Supporting the Function
Configuring the BFD Echo Mode	S6980-64QC, S6920-4C, S6580-48CQ8QC, S6580-24DC8QC, S6520-64CQ, S6510-32CQ, S6510-4C, S6510-48VS8CQ, S6250-48XS8CQ

1.5 Configuring BFD Basic Functions

1.5.1 Overview

You can establish BFD sessions and configure BFD support for applications to perform link fault detection.

1.5.2 Configuration Tasks

The basic function configuration of BFD includes the following tasks:

(1) Configuring BFD Parameters

(2) (Optional) Configuring the BFD Echo Mode

(3) (Optional) Configuring the BFD Slow Timer

(4) (Optional) Configuring BFD Support for Layer 3 Interfaces

(5) Configuring BFD Support for Applications

1.5.3 Configuring BFD Parameters

1. Overview

- Unless otherwise specified, for single-hop sessions, a BFD session should be established between routers

at both ends to be detected by BFD and BFD parameters must be configured at the egresses. Multi-hop sessions use global parameters for session establishment by default. If different negotiation parameters need to be configured for different multi-hop sessions, BFD templates need to be associated with the sessions.

- Transmission bandwidth differences of different interfaces need to be taken into account during parameter configuration. If the configured minimum Tx interval and minimum Rx interval are very small, BFD may occupy excessive bandwidth and affect data transmission.

2. Restrictions and Guidelines

- The fast forwarding function must be enabled before the BFD function is enabled on routers.
- Negotiation parameters can be configured only after all the original sessions on a port complete negotiation.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure parameters for the BFD multi-hop session.

bfd multi-hop min_tx_interval *milliseconds* **min_rx_interval** *milliseconds* **multiplier** *multiplier-value*

(4) By default, the minimum interval to send BFD control packets to BFD peers is 999 ms, the minimum interval to receive BFD control packets from BFD peers is 999 ms, and the multiplexer is 5.Enter the Layer 3 Ethernet interface configuration mode.

interface *interface-type interface-number*

(5) Configure BFD parameters.

bfd min_tx_interval *milliseconds* **min_rx_interval** *milliseconds* **multiplier** *interval-multiplier*

No BFD session parameters are configured by default.

1.5.4 Configuring the BFD Echo Mode

Note

BFD echo mode is supported by only the S6980-64QC, S6920-4C, S6580-48CQ8QC, S6580-24DC8QC, S6520-64CQ. S6510-32CQ, S6510-4C, S6510-48VS8CQ, S6250-48XS8CQ.

1. Overview

- (Optional) Ports run in asynchronous mode by default. If a BFD session needs to run in echo mode, the echo mode needs to be configured. The echo mode includes the echo mode and one-armed echo mode.
- Complete the configuration on ports of switches or routers.
- A BFD session runs in asynchronous mode as long as either of routers at both ends is configured to run in asynchronous mode. If routers at both ends are configured to run in echo mode by default, a BFD session finally runs in echo mode. This function is disabled by default and can be enabled after the **bfd echo** command is executed.
- Run the **bfd echo one-arm** command to enable the one-armed echo mode.

2. Restrictions and Guidelines

By default, when BFD session parameters are configured, the system automatically enables the echo mode. To disable the BFD echo function, run the **unset bfd echo** command in interface configuration mode. The minimum Tx interval and minimum Rx interval of echo packets adopt the **Interval milliseconds** and **min_rx_interval milliseconds** parameters configured for a session.

Before enabling the echo mode of BFD, run the **unset ip redirects** command on the neighbors of a BFD session to disable the function of sending ICMP redirection packets, and run the **unset ip deny land** command to disable the DDoS function to prevent the land-based attack.

The BFD one-armed echo function and **ip redirect-drop** cannot be configured at the same time, otherwise the function fails.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 3 Ethernet interface configuration mode.

interface *interface-type interface-number*

(4) Configure the BFD echo mode.

bfd echo [**one-arm**]

The echo mode is disabled for a BFD session by default.

1.5.5 Configuring the BFD Slow Timer

1. Overview

- The default slow timer is **3000** milliseconds. The value can be changed as required.
- Configure this function in global configuration mode of switches or routers.
- In BFD echo mode or during session establishment, control packets are sent based on the slow timer. A larger value indicates that the required time for negotiating and establishing a BFD session is longer and the time required for transmitting slow BFD packets in echo mode is longer.

2. Restrictions and Guidelines

This command is used to specify the slow timer in echo mode.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the BFD slow timer.

bfd slow-timer [*interval*]

The default slow timer time in the echo mode is **2000** milliseconds.

1.5.6 Configuring BFD Support for Layer 3 Interfaces

1. Overview

- Currently, this function is used only when MPLS LDP is used for FRR switching.
- Complete the configuration on ports of switches or routers.

2. Restrictions and Guidelines

This command is used to enable BFD support for Layer 3 interfaces so as to rapidly detect connectivity of Layer 3 interfaces.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure BFD support for Layer 3 interfaces.

bfd bind peer-ip *ipv4-address* [**source-ip** *ipv4-address*] **process-pst**

BFD support for interfaces is not configured by default.

1.5.7 Configuring BFD Support for Applications

1. Overview

- This function is disabled by default.
- The configuration command varies with the associated applications. For details, see their configuration guides.
- This function must be configured at both ends so that a BFD session can be established.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure BFD support.

bfd all interfaces

In RIP routing configuration mode, enable BFD support for RIP on all interfaces. For details, see *Configuring RIP*.

bfd all interfaces

In OSPF routing configuration mode, enable BFD support for OSPF on all interfaces. For details, see *Configuring OSPFv2*.

bfd all interfaces

In OSPFv3 routing configuration mode, enable BFD support for OSPFv3 on all interfaces. For details, see *Configuring OSPFv3*.

neighbor *address* **fall-over bfd**

In BGP routing configuration mode, enable BFD support for BGP. For details, see *Configuring BGP*.

bfd all interfaces

In IS-IS routing configuration mode, enable BFD support for IS-IS on all interfaces. For details, see *Configuring IS-IS*.

ip route-config static bfd [**vrf** *vrf-name*] *interface-type interface-number gateway* [**source** *ip-address*]

In global configuration mode, enable BFD support for static routing. For details, see *Configuring Static Routing*.

ipv6 route static bfd [**vrf** *vrf-name*] *interface-type interface-number gateway* [**source** *ipv6-address*]

In global configuration mode, enable BFD support for static IPv6 routing. For details, see *Configuring Static Routing*.

set ipnext-hopverify-availability next-hop-address **bfd** [**vrf** *vrf-name*] interface-type interface-number gateway

Enable BFD support for PBR. For details, see *Configuring PBR*.

set ipv6 next-hopverify-availability *next-hop-address* **bfd** [**vrf** *vrf-name*] *interface-type interface-number gateway*

Enable BFD support for IPv6 PBR. For details, see *Configuring PBR*.

vrrp bfd *interface-type interface-number ip-address*

Enable BFD support for VRRP. For details, see *Configuring VRRP*.

VRRP Plus is based on the VRRP protocol. Therefore, no additional configuration is required for BFD support for VRRP Plus and only VRRP needs to be enabled on devices at both ends and a BFD session is correctly associated.

1.6 Configuring BFD Protection

1.6.1 Overview

- If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets), BFD sessions flap. In this case, you can configure BFD protection to provide protection.

1.6.2 Restrictions and Guidelines

- The BFD basic functions must be configured.
- If both BFD and BFD protection are enabled on a device, the device discards the BFD packets received from the previous-hop device, which affects the establishment of a BFD session between the previous-hop device and other devices.

1.6.3 Prerequisites

Basic functions of BFD have been configured.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure BFD protection.

bfd cpp

Configure BFD protection on a switch in the network where attacks exist.

The BFD protection is enabled by default.

1.7 Configuring BFD Flapping Advertisement Dampening

1.7.1 Overview

- A BFD session may frequently switch between the down and up states due to link instability. As a result, a relevant application (such as static routing) may frequently switch forwarding paths and the running services are affected.
- Users can set a delay for status change advertisement, after which BFD informs an associated application of BFD up. After a BFD session is up for a certain period of time, BFD informs an associated application of BFD up. Otherwise, BFD informs it of BFD down. This aims to reduce flapping of associated protocols caused by unstable links.

1.7.2 Restrictions and Guidelines

- The BFD basic functions must be configured.
- If a BFD session does not frequently switch between the down and up states, enabling BFD flapping advertisement dampening will delay notifying an associated application of BFD up.
- Enabling BFD flapping advertisement dampening can relieve frequent processing of associated applications (such as route re-calculation) caused by frequent advertisement of BFD status changes. The larger the configured time is, the longer the required BFD stability time is. BFD notifies an application module of BFD up only after the stability time reaches the configured time.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure flapping dampening parameters.

bfd up-dampening { *milliseconds* }

The BFD flapping advertisement dampening is disabled on ports by default. If a BFD session frequently switches between the down state and up state, you are advised to enable this function.

1.8 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

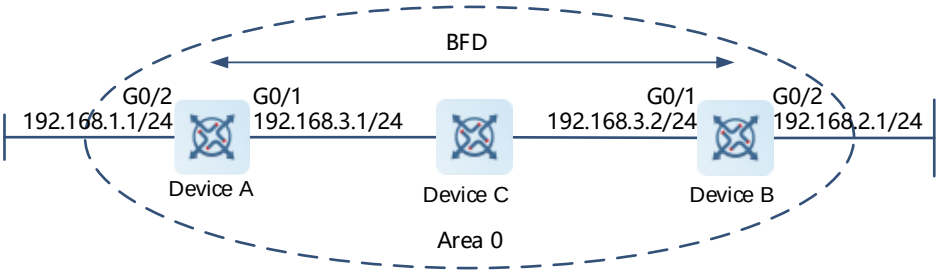
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-3 BFD Monitoring

Command	Purpose
display bfd adjacencies [**vrf** *vrf-name*] [**protocol** { **ap** | **backward**-**lsp**-**with**-**ip** | **bgp** | **bgp**-**lsp** | **dhcp** | **isis** | **ldp**-**lsp** | **openflow** | **ospf** | **ospfv3** | **pbr** | **pimdm** | **pimsm** | **pimsmv6** | **pst** | **rip** | **srp** | **srp-v6** | **static**-**lsp** | **static**-**route** | **vrrp** | **vrrp**-**balance** }] [**ipv4** *ipv4-address* | **ipv6** *ipv6-address*] [**details**] [**parm**-**consult** [*interface-type interface-number*]]	Displays BFD session information.
debugging bfd event [**interface** *interface-type interface-number* **| ipv4** *ipv4-address* **| ipv6** *ipv6-address*]	Debugs BFD events.
debugging bfd packet [**interface** *interface-type interface-number* **| ipv4** *ipv4-address* **| ipv6** *ipv6-address*]	Debugs BFD packets.

1.9 Configuration Examples



1.9.1 Configuring BFD Support for OSPF

1. Requirements

Three devices are used to build a network, the devices run the OSPF protocol, and BFD support for OSPF is enabled on two devices.

2. Topology

Figure 1-4 Configuring BFD Support for OSPF

3. Notes

- Configure IP addresses for ports connecting devices A and B.
- Run the OSPF protocol on devices A and B.
- Configure BFD parameters for the interconnected ports of devices A and B.
- Enable BFD support for OSPF on devices A and B.

4. Procedure

Perform the following configuration on device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitethernet0/1
DeviceA(cfg-if-GigabitEthernet0/1)# unset switch-port
DeviceA(cfg-if-GigabitEthernet0/1)# ip address 192.168.3.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet0/1)# bfd min_tx_interval 200 min_rx_interval 200 multiplier 5
DeviceA(cfg-if-GigabitEthernet0/1)# exit
DeviceA(cfg)# interface GigabitEthernet0/2
DeviceA(cfg-if-GigabitEthernet0/2)# unset switch-port
DeviceA(cfg-if-GigabitEthernet0/2)# ip address 192.168.1.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet0/2)# exit
DeviceA(cfg)# router-protocol ospf 123
DeviceA(cfg-router)# log-adj-changes detail
DeviceA(cfg-router)# network-advertise 192.168.3.0 0.0.0.255 area 0
DeviceA(cfg-router)# network-advertise 192.168.1.0 0.0.0.255 area 0
DeviceA(cfg-router)# bfd all-interfaces
```

Perform the following configuration on device B.

```
DeviceB# config-system terminal
DeviceB(cfg)# interface gigabitethernet2/1
DeviceB(cfg-if-GigabitEthernet0/1)# unset switch-port
DeviceB(cfg-if-GigabitEthernet0/1)# ip address 192.168.3.2 255.255.255.0
DeviceB(cfg-if-GigabitEthernet0/1)# bfd min_tx_interval 200 min_rx_interval 200 multiplier 5
DeviceB(cfg-if-GigabitEthernet0/1)# exit
DeviceB(cfg)# interface GigabitEthernet0/2
```

```
DeviceB(cfg-if-GigabitEthernet0/2)# unset switch-port
DeviceB(cfg-if-GigabitEthernet0/2)# ip address 192.168.2.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet0/2)# exit
DeviceB(cfg)# router-protocol ospf 123
DeviceB(cfg-router)# log-adj-changes detail
DeviceB(cfg-router)# network-advertise 192.168.3.0 0.0.0.255 area 0
DeviceB(cfg-router)# network-advertise 192.168.2.0 0.0.0.255 area 0
DeviceB(cfg-router)# bfd all-interfaces
```

5. Verification

Run the **display bfd adjacencies detail** command to check whether BFD support configuration is correct.

```
DeviceA# display bfd adjacencies detail
OurAddr          NeighAddr      LD/RD    RH/RS    Holdown(mult)  State     Int

```

6. Common Errors

- For a single-hop session, BFD parameters may not be configured for the port on the device at one end of the session.
- If different negotiation parameters need to be configured for different multi-hop sessions, templates need to be associated with the sessions and negotiation parameters need to be configured in the templates.
- For multi-hop BFD sessions, if the sessions use different templates, negotiation parameters in the template used by a session that becomes up first are used for transmitting and receiving packets.
- BFD support for applications is not configured.
- BFD support for applications is enabled only on the device at one end.

1 Configuring Track

1.1 Introduction

The reliable network service (RNS) tests the services provided by a peer device to monitor the service availability, integrity of the end-to-end connection, and service quality. With the RNS test results, you can learn the network performance in time and take measures accordingly to handle related network performance problems. Meanwhile, you can diagnose and locate network faults. The RNS test in this document is also called track test.

1.1.1 Basic Concepts

1. RNS Instance

An RNS instance can be treated as an RNS process. Before performing the RNS, you must create an RNS instance. In the RNS instance, you need to configure the RNS parameters, such as the test type, test destination address, and test frequency. The instance ID is globally unique.

2. RNS Test

RNS test aims to monitor the network connectivity, service availability, integrity of end-to-end connection, and service quality. For example, the RNS tests whether the domain name server (DNS) function of the device is normal. Currently, the RNS supports the following types of tests: RNS Test, DNS, TCP, UDP-Echo, and HTTP.

1.1.2 ICMP Echo Test

The Internet Control Message Protocol (ICMP) echo test is a basic function of the RNS, and is implemented in compliance with the RFC 2925. An ICMP packet is sent to check whether the destination is reachable and to calculate the network response time and packet loss rate.

An ICMP echo request packet is sent to the destination IP address based on the preset test time and frequency. Upon receipt of the ICMP echo request packet, an ICMP echo reply packet is returned from the destination IP address. Through the ICMP echo test, the response time and packet loss rate is calculated based on the information relating to the received ICMP echo reply packet, for example, the receipt time and number of packets. In this way, the current network performance and status are reflected. The ICMP echo test results and historical records are saved, and you can use the command line to display them.

 Caution

The prerequisite for a successful ICMP echo test is that destination devices can correctly respond to ICMP echo request packets.

1.1.3 UDP Echo Test

User Datagram Protocol (UDP) echo is used to test the network accessibility and delay. When UDP packets are used to test the network accessibility and delay, the RNS server must be enabled on the peer end with the UDP port enabled, or the RNS server must be able to respond to ICMP port unreachable packets.

A UDP packet is sent to the destination IP address based on the preset test time and frequency. Upon receipt of the UDP packet, the device of the destination IP address replies by using such packet. Through the UDP echo test, the time required for packet round trip and packet loss rate are calculated based on the information relating to the received UDP packet from the server to reflect the current network performance and network conditions. The UDP echo test results and historical records are saved, and you can use the command line to display them.

1.1.4 DHCP Test

The Dynamic Host Configuration Protocol (DHCP) test is used to test the DHCP service function of the peer device and the network accessibility and delay. When DHCP packets are used to test the network accessibility and delay, the RNS service must be enabled on the peer end.

After the detection time and frequency are set, the DHCP test process is as follows:

1. The client sends a DHCP discovery packet to the test destination IP address, and the destination server replies with an offer packet after receiving the DHCP discovery detection packet.
2. After receiving the offer packet, the client replies with a request packet. The destination server receives the request packet and replies with an ack packet.
3. After receiving the ack packet, the client deems that the detection succeeds, and sends a cancel packet to the server.

The detection client calculates the time required for the client to obtain the IP address and the packet loss rate according to the information of the received DHCP ack packet, reflecting the current network performance and network conditions. The DHCP test results and historical records are saved. You can run the **display ip rns configuration** command to view them.

1.1.5 TCP Test

The Transmission Control Protocol (TCP) test is used to test the availability of a TCP connection. A TCP connection can be established based on the configured destination IP address and port ID. If the TCP connection is established successfully, the test succeeds; otherwise, the test fails.

1.1.6 DNS Test

In a DNS test, a DNS client is simulated to send a domain name resolution request to a specified DNS server. You can determine whether the DNS server is available and the domain name resolution speed by checking the domain name resolution result and the time required for domain name resolution. In the DNS test, the domain name resolution process is simulated, and the mapping between the resolved domain name and the IP address is not saved. The DNS test results and historical records are saved in the test group. You can use the command line to view them.

The procedure for configuring an RNS instance test is as follows:

(1) Create an instance and configure the test based on the test type.

(2) Start the instance.

(3) Use the RNS instance to construct a packet of the specific test type and send the packet to the peer end.

(4) Upon receipt of the test packet, the peer end returns a reply packet of the corresponding type.

(5) The RNS instance calculates the packet loss rate and round trip time based on whether a reply packet is received and the time of reply packet receipt.

(6) Run the **display** or **debugging** command to view the test result.

1.1.7 Track Support for the RNS

Objects that can be tracked include: the test result of an RNS instance, RNS list status, link status on an interface, and track list status. When the track status changes, an action of other modules is triggered. The working process of track is described below by taking different track objects as examples.

- Configure a track object for tracking the test result of an RNS instance.
  - When the test result of the RNS instance changes, the RNS module sends a status change message to the track module.
  - The track module receives the test result. After the preset delay, if the test result remains unchanged, the status of the track object is modified, and the module of the track object is notified of the modification. If the test result recovers within the period, the status of the track object is not modified and the corresponding module is not notified.
- Configure a track object for tracking the link status of an interface.
  - If the link status of the interface is up, the status of the track object is also up.
  - If the link status of the interface is down, the status of the track object is also down.
- Configure a track object for tracking the test result of an RNS instance.
  - If the RNS test succeeds, the status of the track object is also up.
  - If the RNS test fails, the status of the track object is also down.
- Configure a track object for tracking the test result of an RNS list.
  - The result can be the AND or OR operation result of all member status.
  - If the result of this track object is set to the AND operation result of all member status, and the AND result of the status of all the track RNS objects is up, the status of this track object is up. So long as the RNS test result of one track RNS object is down, the status of this track object is also down.
  - If the result of this track object is set to the OR operation result of all member status, and the OR result of the status of all the track RNS objects is down, the status of this track object is down. So long as the RNS test result of one track RNS object is up, the status of this track object is also up.
- Configure a track object for tracking the status of a track list.
  - Set the result of the track object to the AND operation result of all member status.
  - When the AND operation result of all member status is up, the status of this track object is also up.
  - When the AND operation result of all member status is down the status of this track object is also down.
- Configure a track list member.

  Configure a track list member. The status of the member can be the same as or contrary to that of the corresponding track object.
- Adjust the delay for notifying the status change of a track object.
  - A longer delay indicates that it takes more time before the module that is concerned with the track object is informed of the status.
  - A shorter delay indicates that it takes less time before the module that is concerned with the track object is informed of the status.

1.2 Configuration Task Summary

RNS configuration includes the following tasks:

(1) Configuring Basic Features of RNS

(2) Configuring the ICMP Echo Test

(3) Configuring the DNS Test

(4) Configuring the TCP Connection Test

(5) Configuring the UDP Echo Test

(6) Configuring the DHCP Test

(7) Configuring the Track Support for the RNS

1.3 Configuring Basic Features of RNS

1.3.1 Overview

Configure details of an RNS test instance to complete basic configuration of the RNS instance. Brief configuration is also available. Configure and start an RNS instance at a time.

1.3.2 Restrictions and Guidelines

- In detailed configuration mode, if you do not configure the test type after entering the IP RNS mode by running the command, the RNS instance is not created.
- In detailed configuration mode, after configuring an RNS instance, you need to run the **ip rns schedule** command to configure the startup policy; otherwise, the test is not implemented.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Define an RNS operation object.

ip rns *operation-number* [{ **dns** *destination-hostname* **nameserver-config** *ipv4-address* | **icmp-echo** { *destination-ipv4-address* | *destination-ipv6-address* } | **tcp-connect** *destination-ipv4-address port-number* } [**frequency** *interval*] [**timeout** *interval*] [**threshold** *interval*]]

No track operation object is created by default.

(4) Configure the proactive threshold monitoring and triggering mechanism of the RNS test.

ip rns react-operation *operation-number* **react** { **allfail** | **rtt** | **timeout** } [**action track**] [**threshold-mode** { **average** [*number-of-measurements*] | **consecutive** [*occurrences*] | **immediate** | **never** | **xofy** [*x-value y-value*] }] [**threshold-value** *max-threshold min-threshold*]

The proactive threshold monitoring and triggering mechanism is not configured for the test by default.

(5) Enable an RNS instance to trigger another RNS instance.

ip rns trigger-operation *source-operation-number target-operation-number*

The trigger mechanism when the monitoring threshold exceeds the expectation is not configured for the test by default.

(6) Configure scheduling parameters of an RNS instance.

ip rns schedule *operation-number* [**lifetime** { **forever** | *period* }] [**start** { *hh:mm* [*:ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh*:*mm*:*ss* }] [**cycle**]

No scheduling policy is configured for the test by default.

(7) Configure the **ip rns restart** command to restart an RNS instance.

ip rns restart *operation-number*

To restart an IP RNS instance in pending status of scheduling, perform this configuration (or directly configure scheduling start: **ip rns schedule** *operation-number* **start now**).

The test restart function is not configured by default.

(8) Run the **ip rns reset** command to clear the RNS test configuration.

ip rns reset

Perform this configuration if you need to clear configurations of all the RNS instances, for example, when a lot of instances are configured but configuration errors are found.

The RNS test clearing function is not configured by default.

(9) Configure the **ip rns server** command to enable the server function.

ip rns-server udp-echo *port-number*

This configuration is mandatory when you need to enable the RNS server for UDP echo tests.

The server function of UDP echo test is not configured by default.

1.4 Configuring the ICMP Echo Test

1.4.1 Overview

Create an RNS test instance of ICMP echo type.

1.4.2 Restrictions and Guidelines

You must first configure the RNS basic features.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Create an RNS test instance of ICMP echo type.

icmp-echo oob { *destination-ipv4-address* | destination-ipv6-address | *destination-hostname* [**nameserver-config** { *ipv4-address* | *ipv6-address }*] } [**src-address** { *ipv4-address* | *ipv6-address* }] **via** *interface-name* **next-hop** { *ipv4-address* | *ipv6-address* }

icmp-echo { *destination-ipv4-address* | destination-*ipv6-address* | *destination-hostname* [**nameserver-config** *ipv4-address* | *ipv6-address*] } [**src-address** { *ipv4-address* | *ipv6-address* }] [[**af-direct**] **out-interface** *interface-name* [**next-hop** { *ipv4-address* | *ipv6-address* }]]

No test of ICMP echo type is created by default.

(5) (Optional) Configure the repeat test interval.

frequency *interval*

The default test interval is **60** seconds.

(6) (Optional) Configure the tag parameter.

tag *tag-name*

No test tag is configured by default.

(7) (Optional) Configure the time threshold parameter.

threshold *interval*

The default upper threshold of test is **5** seconds.

(8) (Optional) Configure the timeout period.

timeout *interval*

The default timeout interval of a test is **5** seconds.

(9) (Optional) Configure the type of service (TOS) parameter.

tos *tos-values*

The default TOS value for IPv4 packet of the test is **0**.

(10) (Optional) Configure the virtual routing and forwarding (VRF) of an RNS test.

vrf *vrf-name*

No VRF name is configured for the test by default.

(11) Configure the protocol payload size for the test.

request-data-size *bytes*

The default protocol payload size is **36** bytes for the tests of ICMP echo and UDP echo types.

1.5 Configuring the DNS Test

1.5.1 Overview

Create an RNS test instance of DNS type.

1.5.2 Restrictions and Guidelines

You must first configure the RNS basic features.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an RNS test instance of DNS type.

dns { **oob** *destination-hostname* **nameserver-config** *ipv4-address* [**src-address** *ipv4-address*] **via** *interface-type interface-number* **next-hop** *ipv4-address* } | { *destination-hostname* **nameserver-config** *ipv4-address* [**src-address** *ipv4-address*] [[**af-direct**] **out-interface** *interface-type interface-number* [**next-hop** *ipv4-address*]] }

dns *destination-hostname* **nameserver-config** *ipv4-address* [**src-address** *ipv4-address*] [[**af-direct**] **out-interface** *interface-type interface-number* [**next-hop** *ipv4-address*]]

No test of DNS type is created by default.

⚠ Caution

For the commands (**frequency, tag, threshold, timeout, and tos**) of configuring common optional parameters of a test, see 1.4 Configuring the ICMP Echo Test. They are omitted here.

1.6 Configuring the TCP Connection Test

1.6.1 Overview

Create an RNS test instance of TCP type to implement a TCP connection test.

1.6.2 Restrictions and Guidelines

- You must first configure the RNS basic features.
- The target host must be able to respond to the TCP connection request.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an RNS test instance of TCP type.

tcp-connect { *destination-ipv4-address* | *destination-hostname* [**nameserver-config** *ipv4-address*] } *port-number* [**source-ipaddr** *ipv4-address*] [[**af-direct**] **out-interface** *interface-type interface-number* **next-hop** *ipv4-address*]

No test of TCP type is configured by default.

⚠ Caution

For the commands (**frequency, tag, threshold, timeout, and tos**) of configuring common optional parameters of a test, see 1.4 Configuring the ICMP Echo Test. They are omitted here.

1.7 Configuring the UDP Echo Test

1.7.1 Overview

Create an RNS test instance of UDP echo type and implement the UDP echo test.

1.7.2 Restrictions and Guidelines

- You must first configure the basic features of the RNS and RNS server.
- The RNS server must be enabled to provide server functions.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an RNS test instance of UDP echo type.

udp-echo { **oob** *destination-ipv4-address port-number* [**via** *interface-type interface-number* **next-hop** *next-hop-ip*] | *destination-ipv4-address port-number* [**out-interface** *interface-type interface-number* **next-hop** *next-hop-ip*] }

udp-echo *destination-ipv4-address port-number* [**out-interface** *interface-type interface-number* **next-hop** *next-hop-ip*]

No test object of UDP echo type is configured by default.

⚠ Caution

For the commands (**frequency, tag, threshold, timeout, and tos**) of configuring common optional parameters of a test, see 1.4 Configuring the ICMP Echo Test. They are omitted here.

1.8 Configuring the DHCP Test

1.8.1 Overview

Create an RNS test instance of DHCP type to implement a DHCP test.

1.8.2 Restrictions and Guidelines

You must first configure the basic features of RNS and the IP address of the outbound port.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an RNS test instance of DHCP type.

dhcp *destination-ipv4-address* **out-interface** *out-interface* **next-hop** *next_ip_address*

Caution

For the commands (**frequency, tag, threshold, timeout, and tos**) of configuring common optional parameters of a test, see 1.4 Configuring the ICMP Echo Test. They are omitted here.

1.9 Configuring the Track Support for the RNS

1.9.1 Overview

Configure track support for RNS, including the test results of track RNS, the link status of the interface, the status of track list, and the status of RNS test list.

1.9.2 Restrictions and Guidelines

- To configure the track function to track the test result of an RNS instance, you need to configure the related RNS instance.
- To configure the track function to track the link status of an interface, you need to configure the related interface.
- To configure the track function to track the status of a track list, you need to configure the members for the related track list.
- To configure the track function to track the status of an RNS list, you need to configure the members for the related RNS list.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure the track object. Select at least one of the following to configure.

- Configure to track the link status of an interface.

track *object-number* **interface** *interface-type interface-number* **line-protocol**

- Configure to track the RNS test result.

track *object-number* **rns** *entry-number*

- Configure to track the status of a track list.

track *object-number* **list-object bool-calc** { **and** | **or** }

- Configure to track the status of an RNS list.

track *object-number* **rns-list** *men-list* { **and | or** }

(5) Configure the notification delay of a track object.

state-delay { **up** *interval* [**down** *interval*] **|** [**down** *interval*] **up** *interval* }

Configure the delay for notifying the tracking status change from up to down or from down to up, or configure both at the same time.

No delay is set by default for notifying the track object status change from up to down or from down to up.

(6) Configure a track member.

object *object-number* [**not**]

No member object is configured by default.

1.10 Monitoring

This section describes the **display** commands used for checking the running status of a configured function to verify the configuration effect.

Run the **debugging** command to display debugging information.

⚠ Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 RNS Monitoring

Command	Purpose
display ip rns configuration [*operation-number*]	Displays the configuration of one or more RNS instances.
display ip rns statistics-detail [*operation-number*]	Displays the detailed statistics of one or more RNS instances.
display ip rns state [*operation-number*]	Displays the current status of one or more RNS instances.
display ip rns-server udp-echo	Displays the RNS server configuration.
display ip rns react-operation [*operation-number*]	Displays the proactive threshold monitoring information of one or more RNS instances.
display ip rns trigger-operation [*operation-number*]	Displays information about the test triggered by one or more RNS instances.
display ip rns statistics [*operation-number*]	Displays the brief statistics of one or more RNS instances.
display track [*object-number*]	Displays the statistics of one or more track objects.
debugging track { **all	proc-event	rdnd-event	client** }	Debugs the track module.
debugging rns { **all	lib	rdnd-event	restart	rns_id** *rns_id* }	Debugs the RNS module.

Command	Purpose
debugging rns-server {udp-echo} { event | fail | packet }	Debugs the RNS server module.

1.11 Configuration Examples

1.11.1 Configuring the ICMP Echo Test

1. Requirements

Configure an RNS test of ICMP echo type, which must be started immediately and take effect permanently.

2. Topology

Figure 1-1 Configuring the ICMP Echo Test

3. Notes

Configure RNS instance 1 and related parameters on Device A.

4. Procedure

Perform the following configuration on Device A:

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip rns 1
DeviceA(cfg-ip-rns)# icmp-echo 10.2.2.2
DeviceA(cfg-ip-rns-icmp-echo)# exit
DeviceA(cfg)# ip rns schedule 1 start now lifetime forever
```

5. Verification

Run the **display ip rns configuration** command to display the instance configuration.

```
DeviceA# display ip rns configuration 1
Entry number: 1
Tag:
Type of operation to perform: icmp-echo
Operation timeout (milliseconds): 5000
Operation frequency (milliseconds): 60000
Threshold (milliseconds): 5000
Recurring (Starting Everyday): FALSE
Life (seconds): foerver
```

```
Next Scheduled Start Time:Start Time already passed
Target address/Source address: 10.2.2.2/0.0.0.0
Request size (ARR data portion): 36
```

1.11.2 Configuring the DNS Test

1. Requirements

Configure an RNS test of DNS type, which must be started immediately and take effect permanently.

2. Topology

Figure 1-2 Configuring the DNS Test

3. Notes

Configure RNS instance 1 and related parameters on Device A.

4. Procedure

Perform the following configuration on Device A:

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip rns 1
DeviceA(cfg-ip-rns)# dns www.abc.com nameserver-config 10.2.2.2
DeviceA(cfg-ip-rns-dns)# exit
DeviceA(cfg)# ip rns schedule 1 start now lifetime forever
```

5. Verification

Run the **display ip rns configuration** command to display the instance configuration.

```
DeviceA# display ip rns configuration 1
Entry number: 1
Tag:
Type of operation to perform: dns
Operation timeout (milliseconds): 5000
Operation frequency (milliseconds): 60000
Threshold (milliseconds): 5000
Recurring (Starting Everyday): FALSE
Life (seconds): foerver
Next Scheduled Start Time:Start Time already passed
Target host name: www.abc.com
Name Server: 10.2.2.2
```

6. Common Errors

The DNS IP address is incorrect.

1.11.3 Configuring the TCP Connect Test

1. Requirements

Configure an RNS test of TCP type, which must be started immediately and take effect permanently.

2. Topology

Figure 1-3 Configuring the TCP Connect Test

3. Notes

Configure RNS instance 1 and related parameters on Device A.

4. Procedure

Perform the following configuration on Device A:

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip rns 1
DeviceA(cfg-ip-rns)# tcp-connect 10.2.2.2 8000
DeviceA(cfg-ip-rns-tcp)# exit
DeviceA(cfg)# ip rns schedule 1 start now lifetime forever
```

5. Verification

Run the **display ip rns configuration** command to display the instance configuration.

```
DeviceA# display ip rns configuration 1
Entry number: 1
Tag:
Type of operation to perform: tcp-connect
Operation timeout (milliseconds): 5000
Operation frequency (millseconds): 60
Threshold (milliseconds): 5000
Recurring (Starting Everyday): FALSE
Life (seconds): foerver
Next Scheduled Start Time:Start Time already passed
Target Address: 10.2.2.2
Target Port: 8000
```

6. Common Errors

- The target host does not respond to the TCP connection request.
- The configured TCP port for the RNS test is incorrect.

1.11.4 Configuring the UDP Echo Test

1. Requirements

Configure an RNS test of UDP echo type, which must be started immediately and take effect permanently.

2. Topology

Figure 1-4 Configuring the UDP Echo Test

3. Notes

Configure RNS instance 1 and related parameters on Device A.

4. Procedure

Perform the following configuration Device A:

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip rns 1
DeviceA(cfg-ip-rns)# udp-echo 10.2.2.2 1025
DeviceA(cfg-ip-rns-udp-echo)# exit
DeviceA(cfg)# ip rns schedule 1 start now lifetime forever
```

Perform the following configuration on Device B:

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ip rns-server udp-echo 1025
```

5. Verification

Run the **display ip rns configuration** command to display the instance configuration.

```
DeviceA# display ip rns configuration 1
Entry number: 1
Tag:
Type of operation to perform: udp-echo
Operation timeout (milliseconds): 5000
Operation frequency (milliseconds): 60000
Threshold (milliseconds): 5000
Target Address: 10.2.2.2
Target Port: 1025
Request size (ARR data portion): 36
```

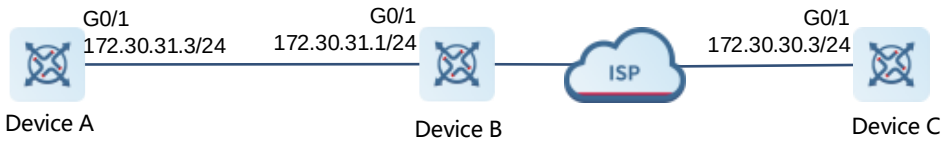
Run the **display ip rns-server udp-echo** command to display the RNS server configuration.

```
DeviceA# display ip rns-server udp-echo
```

```
UDP-Echo-Server:10000
Receive packets number: 0
Reflect packets success number: 0
Reflect packets fail number: 0
```

6. Common Errors

The UDP server port configured on the client is not correct.



1.11.5 Configuring the DHCP Test

1. Requirements

Configure an RNS test of DHCP type, which must be started immediately and take effect permanently.

2. Topology

Figure 1-5 Configuring the DHCP Test

3. Notes

Configure RNS instance 1 and related parameters on Device A.

4. Procedure

Perform the following configuration on Switch A:

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip rns 1
DeviceA(cfg-ip-rns)# dhcp 172.30.30.3 out-interface GigabitEthernet 1/0/1 next-hop 172.30.31.1
DeviceA(cfg-ip-rns-dhcp)# exit
DeviceA(cfg)# ip rns schedule 1 start now lifetime forever
```

5. Verification

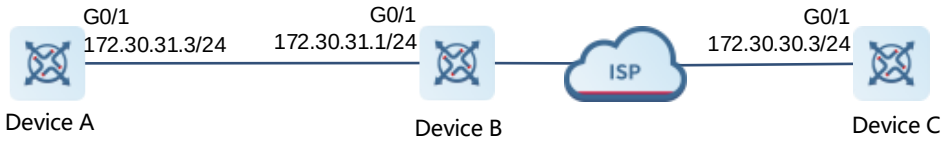
Run the **display ip rns configuration** command to display the instance configuration.

```
DeviceA# display ip rns configuration 1
Entry number: 1
Tag:
Type of operation to perform: dhcp
Operation timeout (milliseconds): 5000
Operation frequency (milliseconds): 60000
Threshold (milliseconds): 5000
Recurring (Starting Everyday): FALSE
Life (seconds): forever
Next Scheduled Start Time: Start Time already passed
```

```
Target address/Source address: 172.30.30.3/172.30.31.252
Out-interface: GigabitEthernet 1/0/1
Next-hop address: 172.30.31.1
```

6. Common Errors

- The DHCP service is not enabled on the server.
- No IP address is configured for the outbound interface of the client.



1.11.6 Configuring the Device to Track Link Status of an Interface

1. Requirements

Configure track object 3 to track the link status of the interface GigabitEthernet 0/1.

2. Topology

Figure 1-6 Configuring the Device to Track Link Status of an Interface

3. Notes

- Configure a track object to track the link status of an interface.
- Configure the delay for notifying the status change from up to down.

4. Procedure

Perform the following configuration on Device A:

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# track 3 interface gigabitethernet 0/1 line-protocol
DeviceA (cfg-track)# state-delay down 10
```

5. Verification

Disable the interface GigabitEthernet 0/1, namely, change the link status to down. Immediately check the status of the track object, and verify that the status is still up. Check the status of the track object 10s later, and verify that the status changes to down.

```
DeviceA# display track 3
Track 3
  Interface GigabitEthernet 0/1
  The state is Up, delayed Down (5 secs remaining)
    1 change, current state last: 300 secs
  Delay up 0 secs, down 10 secs
```

6. Configuration Files

```
track 3 Interface GigabitEthernet 0/1 line-protocol
 state-delay down 10
!
```

7. Common Errors

- The track object for tracking an RNS test is configured, but the RNS test is not configured.
- The track object for tracking the link status of an interface is configured, but the corresponding interface is not configured.
- The track object for tracking the status of a track list is configured, but no member of the RNS list is configured.
- The track object configured for tracking an RNS list is configured, but the RNS test is not configured.

1.11.7 Configuring the Device to Track the Status of Multiple Interfaces

1. Requirements

Configure track object 3. When track object 1 is up and object 2 is down, track object 3 is up.

2. Topology

Figure 1-7 Configuring the Device to Track the Status of Multiple Interfaces

3. Notes

- Configure track objects 1 and 2.
- Configure track object 3, and its members include track objects 1 and 2.

4. Procedure

Perform the following configuration on Device A:

```
DeviceA# config
DeviceA(cfg)# track 1 interface gigabitEthernet 0/0 line-protocol
DeviceA(cfg-track)# state-delay up 20 down 40
DeviceA(cfg-track)# exit
DeviceA(cfg)# track 2 interface gigabitEthernet 0/1 line-protocol
DeviceA(cfg-track)# state-delay down 30
DeviceA(cfg-track)# exit
DeviceA(cfg)# track 3 list Boolean and
DeviceA(cfg-track)# object 1
DeviceA(cfg-track)# object 2 not
```

5. Verification

```
DeviceA# display track 3
Track 3
   List boolean and
   Object 1
   Object 2 not
   The state is Down
      1 change,current state last:10 secs
   Delay up 0 secs,down 0 secs
```

6. Configuration Files

```
track 1 Interface GigabitEthernet 0/0 line-protocol
 state-delay up 20 down 40
!
track 2 Interface GigabitEthernet 0/1 line-protocol
 state-delay down 30
!
track 3 list boolean and
 object 1
 object 2 not
!
```

1.11.8 Configuring the Device to Track A Single RNS Instance

1. Requirements

Configure track object 5 to track the test result of RNS instance 7.

2. Notes

- Configure an RNS test.
- Configure a track object for tracking the test result of an RNS instance.
- Configure the delay for notifying the test result change from up to down and the delay for notifying the test result change from down to up.

3. Procedure

Perform the following configuration on Device A:

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ip rns 7
DeviceA(cfg-ip-rns)# icmp-echo 2.2.2.2
DeviceA(cfg-ip-rns-icmp-echo)# exit
DeviceA(cfg)# ip rns schedule 7 start now lifetime forever
DeviceA(cfg)# track 5 rns 7
DeviceA(cfg-track)# state-delay up 20 down 30
```

4. Verification

Make the test result of RNS instance 7 change from successful to unsuccessful. When the test result changes to unsuccessful, immediately check the status of track object 7, and verify that the status is still up. Check the status of the track object 30s later, and verify that the status changes to down.

```
DeviceA# display track 5
Track 5
  Reliable Network Service 7
  The state is Down
    2 change, current state last: 10 secs
  Delay up 20 secs, down 30 secs
```

5. Configuration Files

```
ip rns 7
 icmp-echo 2.2.2.2
!
ip rns schedule 7 start now lifetime forever
!
track 5 rns 7
 state-delay up 20 down 30
!
```

1.11.9 Configuring the Device to Track the Results of Multiple RNS Instances

1. Requirements

Configure track object 5 for tracking the test results of an RNS list (consisting of RNS instances 1, 2-5, and 8).

2. Notes

- Configure and start an RNS test.
- Configure a track object for tracking the test result of an RNS list.
- Configure the delay for notifying the test result change from up to down, and the delay for notifying the test result change from down to up.

3. Procedure

Perform the following configuration on Device A:

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# track 5 rns-list 1,2-5,8 and
DeviceA(cfg-track)# state-delay up 20 down 30
```

4. Verification

Make the test result of one of the RNS instances 1, 2-5, and 8 change from successful to unsuccessful. When the test result changes to unsuccessful, immediately check the status of track object 7, and verify that the status is still up. Check the status of the track object 30s later, and verify that the status changes to down.

```
DeviceA# display track 5
Track 5
```

```
   rns-list 1,2-5,8 and
   The state is Down
      2 change, current state last: 10 secs
Delay up 20 secs, down 30 secs
```

5. Configuration Files

```
track 5 rns-list 1,2-5,8 and
  state-delay up 20 down 30
!
```

1.5.1 Configuring IP Event Dampening on Layer 3 Interfaces....3

1 Configuring IP Event Dampening

1.1 Introduction

When a Layer 3 network interface frequently goes Up or Down due to manual enabling/disabling or other external causes, the routing table on the device flaps repeatedly. If a routing protocol is configured, the protocol may extend the flap to the entire network, causing repeated updates and recalculation of neighboring routes. As a result, this wastes network bandwidth and destabilizes the network. Repeated route updates and recalculation on devices consume many CPU resources, and thus affect the normal running of customer networks.

The function of IP Event Dampening detects abnormal Up/Down flapping and automatically suppresses frequent interface state changes, which prevents a routing protocol from propagating single-point link failures. When an interface is restored to stable, it is automatically released, thus reducing network flaps and CPU resource consumption while improving network stability.

1.1.1 Basic Concepts

1. Penalty

IP Event Dampening uses the penalty method to perceive and control interface changes. Whenever an interface goes Up or Down, the penalty accumulates, but when the interface is stable, the penalty decreases exponentially. In this way, interface behaviors can be sensed and processed intelligently.

2. Suppress threshold

To identify an interface flap event, the function of IP Event Dampening configures a suppress threshold. When the cumulative penalty of an interface exceeds a suppress threshold, the interface is considered to flap and is suppressed.

3. Half-life period

The half-life period is the period for the penalty to decrease to half of the original value when an interface becomes stable. It defines the speed at which the penalty decays exponentially. The shorter the half-life period, the faster the penalty decays, and the faster the interface is detected to be stable, but the flap detection sensitivity is reduced more greatly.

4. Reuse threshold

When an interface does not flap and its penalty decays to a certain degree (below the suppress threshold), the interface is considered to be stable and is released.

5. Maximum suppress time

When an interface keeps flapping and reaches a very large penalty, the interface is not usable for a long time. To avoid this problem, we define the maximum suppress time to ensure that the interface suppression duration is less than the maximum suppress time no matter how long the interface has flapped.

6. Interface flap suppression

- An interface configured with IP Event Dampening is assigned a penalty. The interface gets a penalty of 1000 whenever it goes Down, and the penalty decreases with time. If the interface goes Down again, the penalty

increases. When the cumulative penalty exceeds the suppress threshold, the interface is suppressed. For the affected upper-layer protocol, the suppressed interface is always Down regardless of the interface state. When the penalty decreases to the reuse threshold, the interface is released and restored to its real state.

- If a Layer 3 interface is not configured with IP Event Dampening or is not suppressed, the routing protocol or other protocols concerned about the interface state still work normally. When the interface is configured with IP Event Dampening and is suppressed, the upper-layer protocol considers the interface to be Down. During this process, any state change of the interface does not affect the routing table or the route calculation and advertisement performed by the upper-layer routing protocol until the interface is released.

1.1.2 Protocols and Standards

- RFC 2439: BGP Route Flap Damping

Note

The suppression algorithm core used by IP Event Dampening is the same as that used by Border Gateway Protocol (BGP) Route Flap Dampening stipulated in RFC 2439.

1.2 Restrictions and Guidelines

- The function of IP Event Dampening is supported only on Layer 3 interfaces.

1.3 Configuring IP Event Dampening

1.3.1 Overview

When an interface configured with IP Event Dampening keeps flapping until the predefined threshold is exceeded, the interface is set to Down.

1.3.2 Restrictions and Guidelines

- When a Layer 3 interface on a device is converted into a Layer 2 interface, the IP Event Dampening command configured on the interface is deleted.
- IP Event Dampening can be configured only on the primary interface of a router but takes effect to all subinterfaces related to the primary interface. IP Event Dampening cannot be configured on **virtual templates**.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

interface aggregateport *interface-number*

(4) Configure IP Event Dampening.

dampening [*half-life-period* [*reuse-threshold suppress-threshold max-suppress* [**restart** [*restart-penalty*]]]]

IP event dampening is disabled on an interface by default.

1.4 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

Run the **debugging** commands to output debugging information.

⚠ Caution

- Running the **cleanup** command during operation of the device may lose vital information and interrupt services.
- The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
cleanup counters	Clears interface statistics.
display dampened-interface interface	Displays statistics about interfaces with IP Event Dampening.
display interfaces [*interface-type interface-number*] **dampened-interface**	Displays IP Event Dampening configurations.
debugging dampening interface	Debugs IP Event Dampening.

1.5 Configuration Examples

1.5.1 Configuring IP Event Dampening on Layer 3 Interfaces

1. Requirements

Configure IP Event Dampening on Layer 3 interfaces.

2. Topology

Figure 1-1 Configuring IP Event Dampening on Layer 3 interfaces

3. Notes

- Enable IP event dampening on interface GigabitEthernet 0/1 on Routers A and B respectively, and set the half-time period to 30s, the reuse threshold to 1500, the suppress threshold to 10,000, and the maximum suppress time to 120s.

4. Procedure

Configure IP event dampening on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# summary gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# dampened-interface 30 1500 10000 100
```

Configure IP event dampening on Device B.

```
DeviceB# config-system terminal
DeviceB(cfg)# summary gigabitethernet 0/1
DeviceB(cfg-if-GigabitEthernet 0/1)# dampened-interface 30 1500 10000 100
```

5. Verification

Run the **display interfaces dampened-interface** command to display the detailed information about Event Dampening on an interface.

```
DeviceA# display interfaces dampened-interface
GigabitEthernet 0/1
  Flaps Penalty Supp      ReuseTm HalfL    ReuseV   SuppV    MaxSTm   MaxP      Restart
  0     0       FALSE     0       30       1500     1000     100      15119     0
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
summary GigabitEthernet 0/1
 unset switch-port
 dampened-interface 30 1500 10000 100
!
end
```

- Device B configuration file

```
hostname DeviceA
!
summary GigabitEthernet 0/1
```

```
 unset switch-port
 dampened-interface 30 1500 10000 100
!
end
```

7. Common Errors

- IP Event Dampening is configured for an interface on a Layer 3 device before the interface is converted to a Layer 3 interface by running the **unset swithport** command.

1 Configuring HAM 1

1.1 Introduction 1

1.2 HAM Application 1

1.2.1 Detection Process 1

1.3 Configuring the HA Service of One Frequently Restarting Process 1

1 Configuring HAM

1.1 Introduction

High availability module (HAM) is a self-developed system high availability (HA) technology. It monitors exceptional exit of software processes of a device to automatically start the processes or monitors frequent restart of a software process to automatically restart the device, thus quickly and automatically restore services. Used during patch upgrade, this function can prevent device reset due to patch upgrade exceptions.

1.2 HAM Application

HAM is mainly used for:

- Software process HA service: When a software process exits abnormally, HAM automatically starts the software process to restore services.
- Device restart service: When a software process restarts frequently, HAM attempts to automatically restart the device to restore services.

Typically, the HA service of one frequently restarting process is enabled on all devices. You can run command line interface (CLI) commands on the master device to enable/disable this service and synchronize the service status to other non-master devices. During a patch upgrade, a process may restart due to an abnormal process. If the device automatically restarts, traffic may be interrupted. Therefore, you must disable the HA service of one frequently restarting process. After a patch upgrade, you can enable the HA service of one frequently restarting process when confirming that no process restarts frequently.

⚠ Caution

If you disable the HA service of one frequently restarting process by running a command, services may not automatically be restored to normal because some processes frequently restart due to no automatic restarting of the device. As a result, failure time prolongs.

1.2.1 Detection Process

HAM monitors kernel advertisements to perceive the status of an abnormal process and automatically restores services based on the following rules:

- If one process exits five times within two minutes, HAM attempts to start the process five minutes later.
- If a process restarts twice within 10 minutes, services cannot be restored. In this case, you must restart the device to restore them.

1.3 Configuring the HA Service of One Frequently Restarting Process

1. Overview

When one process exits abnormally, you can automatically restore services by configuring the HA service of one process that restarts frequently. You can further determine the exception to check whether the device needs to be restarted to restore services.

2. Restrictions and Guidelines

If one process frequently restarts, disabling its HA service may lead to a longer failure time. Therefore, you are advised to enable the configuration in scenarios other than patch upgrades.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Disable the HA service of one frequently restarting process.

unset ham single-process-ha auto-restart enable

The HA service of one frequently restarting process is enabled by default.

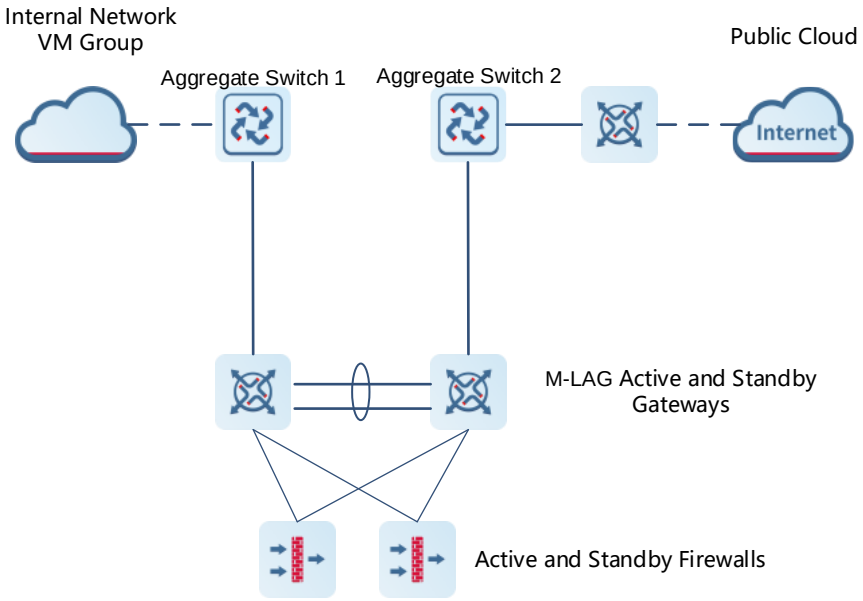
1.5 Configuration Examples 3
1.5.1 Configuring the M-LAG DAG 3

1 Configuring DAG

1.1 Introduction

1.1.1 Overview



Generally, the same default route is configured for all hosts in a network. The default route points to the egress gateway to allow the hosts to communicate with the external network. When errors occur in the egress gateway, the communication between hosts and the external network is interrupted.

In a dual-active gateway (DAG) mode, multiple gateways (typically two) are combined to form a virtual router. The IP address of the virtual router is used as the default gateway address to communicate with the external network. When one gateway fails, the communication between hosts and the external network is not interrupted. This improves the reliability of the entire network. When all devices run properly, the two gateways can forward traffic at the same time, which helps fully utilize the network bandwidth.

1.1.2 Principles

One common DAG mode is that, in multi-chassis link aggregation group (M-LAG) scenarios, M-LAG active and standby devices are used as a DAG, which is connected to downlink servers through downlink Layer 3 aggregate ports. This DAG mode is called M-LAG DAG.

Figure 1-1 M-LAG DAG in a Public Cloud Scenario

- M-LAG DAG

  In a public cloud scenario, virtual machine (VM) traffic flows through the M-LAG active and standby gateways to the active and standby firewalls. In the reverse direction, the firewalls send the traffic to the public network through the M-LAG active and standby gateways (Figure 1-1).

  M-LAG active and standby gateways connect to the downlink active and standby firewalls through Layer 3 aggregate ports in dual-homing mode. The gateways share the same IP address and MAC address and the

DAG mode is enabled. A static VXLAN tunnel is established between the M-LAG active and standby gateways and reverse path limited (RPL) is disabled. Floating static routes are created in a VRF instance, with one pointing to the firewalls and the other pointing to the peer end of the static VXLAN tunnel. Different administrative distances are configured to ensure that the route pointing to the firewalls has a higher priority. When the DAG runs properly, both gateways forward traffic. When the downlink of one gateway fails, traffic of the faulty gateway is switched to the static VXLAN tunnel (the traffic flows through the peer-link of the M-LAG) to ensure service continuity.

1.2 Configuration Task Summary

Configuring the DAG includes the following tasks:

- Configuring M-LAG DAG

1.3 Configuring M-LAG DAG

- Overview

You can configure the DAG mode on the downlink Layer 3 aggregate ports and use the existing floating static routing function to implement M-LAG DAG.

1.3.1 Restrictions and Guidelines

M-LAG active and standby devices connect to the active and standby firewalls as gateways to ensure the firewall stability. In addition, sub-interfaces of the Layer 3 aggregate ports can be configured to differentiate traffic and expand the capacity of the firewalls to process traffic.

- In normal cases, traffic from the M-LAG gateways is sent to the active firewall. DAG entries are synchronized through the peer-link of the M-LAG.
- When the active firewall fails, the traffic from the M-LAG gateways is switched to the standby firewall.
- When the downlink of one M-LAG gateway fails, the faulty M-LAG gateway sends traffic to the firewall through the peer-link between M-LAG gateways in the static VXLAN tunnel.

1.3.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 3 aggregate port configuration mode.

interface aggregateport *interface-number*

(4) Enable the DAG mode.

mlag dual-active-gateway enable

The DAG mode is disabled by default.

1.4 Monitoring

Run the **debugging** command to output debugging information.

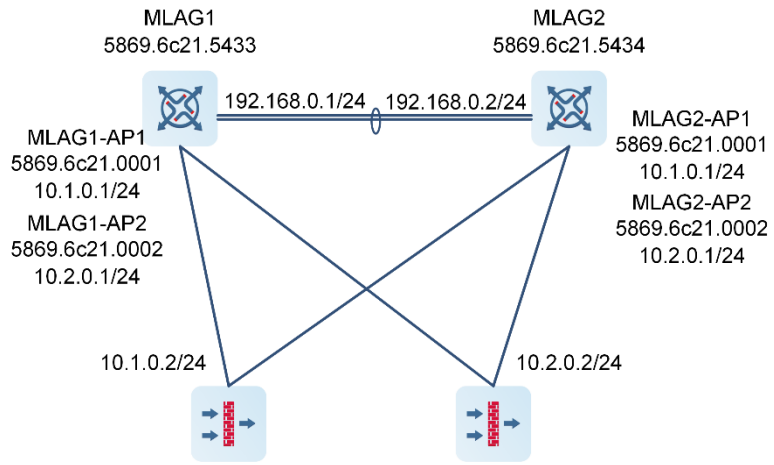
Caution

System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Table 1-1 Monitoring

Command	Purpose
debugging net mlag-dag	Debugs the M-LAG DAG mode.

1.5 Configuration Examples



1.5.1 Configuring the M-LAG DAG

1. Requirements

The ARP entries of the DAG can be synchronized, the DAG can respond to the ARP requests of the firewalls as a proxy, and the ARP broadcast requests are not flooded.

2. Topology

Figure 1-2 DAG Configuration Topology

3. Note

- Enable the DAG mode on the downlink Layer 3 aggregate ports.
- Configure the system ID to be used for LACP negotiation between the Layer 3 aggregate ports and downlink firewalls to achieve the dual-homing mode.
- Create a static VXLAN tunnel and two floating static routes.

4. Procedure

(1) On the downlink aggregate ports of M-LAG1, configure the DAG mode, MAC address, IP address, and system ID for LACP negotiation.

```
MLAG1> privilege
MLAG1# config-system terminal
MLAG1(cfg)# interface AggregatePort 1
MLAG1(cfg-if-AggregatePort 1)# mlag dual-active-gateway enable
MLAG1(cfg-if-AggregatePort 1)# mac-address 5869.6c21.0001
MLAG1(cfg-if-AggregatePort 1)# ip address 10.1.0.1/24
MLAG1(cfg-if-AggregatePort 1)# lacp system-id 5869.6c21.54333
MLAG1(cfg-if-AggregatePort 1)# exit
MLAG1(cfg)# interface AggregatePort 2
MLAG1(cfg-if-AggregatePort 2)# mlag dual-active-gateway enable
MLAG1(cfg-if-AggregatePort 2)# mac-address 5869.6c21.0002
MLAG1(cfg-if-AggregatePort 2)# ip address 10.2.0.1/24
MLAG1(cfg-if-AggregatePort 2)# lacp system-id 5869.6c21.54333
MLAG1(cfg-if-AggregatePort 2)# exit
```

(2) On M-LAG1, create a static VXLAN tunnel.

```
MLAG1(cfg)# interface overlaytunnel 1
MLAG1(cfg-if-OverlayTunnel 1)# tunnel source 192.168.0.1
MLAG1(cfg-if-OverlayTunnel 1)# tunnel destination 192.168.0.2
MLAG1(cfg-if-OverlayTunnel 1)# exit
MLAG1(cfg)# interface OverlayRouter 1
MLAG1(cfg-if-OverlayRouter 1)# anycast-gateway
MLAG1(cfg-if-OverlayRouter 1)# exit
MLAG1(cfg)# vxlan 1
MLAG1(cfg-vxlan)# symmetric
MLAG1(cfg-vxlan)# router-interface OverlayRouter 1
MLAG1(cfg-vxlan)# tunnel-interface overlayTunnel 1
MLAG1(cfg-vxlan)# exit
```

(3) On M-LAG1, create a floating static route.

```
MLAG1(cfg)# ip route-config 10.1.0.2 255.255.255.0 aggregatePort 1 10
MLAG1(cfg)# ip route-config 10.2.0.2 255.255.255.0 aggregatePort 2 10
MLAG1(cfg)# ip route-config 10.1.0.2 255.255.255.0 OverlayRouter 1 192.168.0.2 20 router-mac
5869.6c21.5434
MLAG1(cfg)# ip route-config 10.2.0.2 255.255.255.0 OverlayRouter 1 192.168.0.2 20 router-mac
5869.6c21.5434
```

(4) On the downlink aggregate ports of M-LAG2, configure the DAG mode, MAC address, IP address, and system ID for LACP negotiation.

```
MLAG2> privilege
MLA2# config-system terminal
MLAG2(cfg)# interface AggregatePort 1
MLAG2(cfg-if-AggregatePort 1)# mlag dual-active-gateway enable
MLAG2(cfg-if-AggregatePort 1)# mac-address 5869.6c21.0001
MLAG2(cfg-if-AggregatePort 1)# ip address 10.1.0.1/24
MLAG2(cfg-if-AggregatePort 1)# lacp system-id 5869.6c21.54333
MLAG2(cfg-if-AggregatePort 1)# exit
MLAG2(cfg)# interface AggregatePort 2
```

```
MLAG2(cfg-if-AggregatePort 2)# mlag dual-active-gateway enable
MLAG2(cfg-if-AggregatePort 2)# mac-address 5869.6c21.0002
MLAG2(cfg-if-AggregatePort 2)# ip address 10.2.0.1/24
MLAG2(cfg-if-AggregatePort 2)# lacp system-id 5869.6c21.54333
MLAG2(cfg-if-AggregatePort 2)# exit
```

(5) On M-LAG2, create a static VXLAN tunnel.

```
MLAG2(cfg)# interface overlaytunnel 1
MLAG2(cfg-if-OverlayTunnel 1)# tunnel source 192.168.0.2
MLAG2(cfg-if-OverlayTunnel 1)# tunnel destination 192.168.0.1
MLAG2(cfg-if-OverlayTunnel 1)# exit
MLAG2(cfg)# interface OverlayRouter 1
MLAG2(cfg-if-OverlayRouter 1)# anycast-gateway
MLAG2(cfg-if-OverlayRouter 1)# exit
MLAG2(cfg)# vxlan 1
MLAG2(cfg-vxlan)# symmetric
MLAG2(cfg-vxlan)# router-interface OverlayRouter 1
MLAG2(cfg-vxlan)# tunnel-interface overlayTunnel 1
MLAG2(cfg-vxlan)# exit
```

(6) On M-LAG2, create a floating static route.

```
MLAG2(cfg)#ip route-config 10.1.0.2 255.255.255.0 aggregatePort 1 10
MLAG2(cfg)#ip route-config 10.2.0.2 255.255.255.0 aggregatePort 2 10
MLAG2(cfg)# ip route-config 10.1.0.2 255.255.255.0 OverlayRouter 1 192.168.0.2 20 router-mac
5869.6c21.5434
MLAG2(cfg)# ip route-config 10.2.0.2 255.255.255.0 OverlayRouter 1 192.168.0.2 20 router-mac
5869.6c21.5434
```

1. Verification

Run the **display current-config** command to display the configuration.

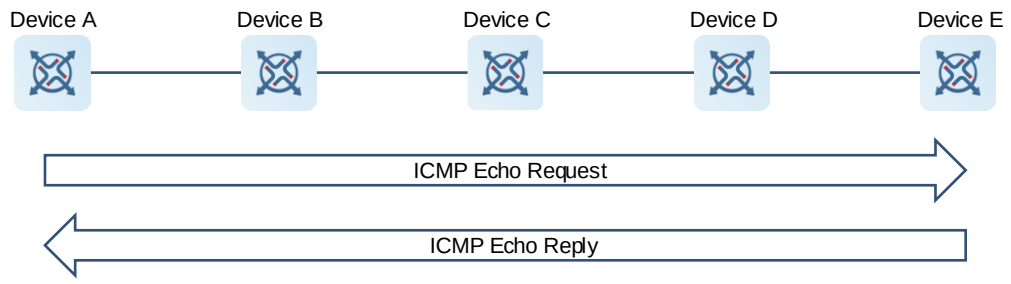
1 Configuring Network Connectivity Test

1.1 Introduction

1.1.1 Overview

The network connectivity test tool is used to check whether the network can be connected, and accurately find out the cause of the network failure. Common network communication test tools include packet Internet groper (Ping) and Traceroute. On a network device, the commands corresponding to these two tools are **ping** and **traceroute**.

- The Ping tool is often used to check the network connectivity between devices and the network delay. A larger delay indicates a slower network speed.
- The Traceroute tool helps users learn the topology of the physical and logical connections of the network and efficiency of data transmission.



1.1.2 Principles

1. Testing connectivity with Ping

The Ping tool sends an Internet Control Message Protocol (ICMP) Echo Request packet to the destination IP address, requesting the peer to return an ICMP Echo Reply packet to determine whether the two network devices are connected and what is the delay.

The sequence number of the ICMP Echo Request starts from 0. Each time an ICMP Echo Request is sent by the Ping tool, the sequence number increases by 1. The sender sends five ICMP Echo Request packets by default. You can also specify the number of sent ICMP Echo Request packets in the command. If two devices are connected, the receiver returns the same number of ICMP Echo Reply packets.

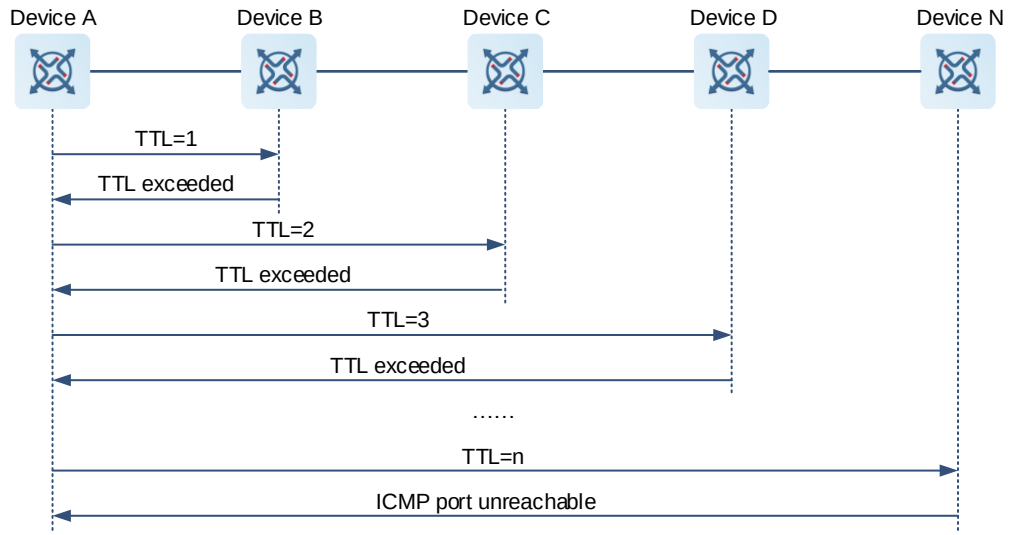


Figure 1-1 Testing Connectivity with Ping

2. Testing connectivity with Traceroute

The Traceroute tool uses the Time To Live (TTL) field in the header of ICMP and IP packets to complete the connectivity check. The process is as follows:

Figure 1-2 Testing Connectivity with Traceroute

(1) Device A sends an ICMP Request packet with the TTL set to 1 through the Traceroute tool. The UDP port number in the packet is an invalid destination port number (greater than 3000).

(2) When the first device, device B, on the path receives this packet, device B decreases the TTL by 1. Then, the TTL changes to 0, and the device discards the packet and returns an ICMP Time Exceeded message.

(3) When Traceroute on device A receives this message, it learns that device B exists on the path and therefore sends a packet with the TTL set to 2 to detect the second device, device C.

(4) Each time when device A sends a packet, Traceroute on device A increases the TTL by 1 to detect another device. This operation repeats until a packet arrives at the destination host. When the packet arrives at the destination host, the host returns an ICMP Port Unreachable message, instead of an ICMP Time Exceeded message. Finally, Traceroute stops the detection and displays the path from the network device to the destination host.

1.1.3 Protocols and Standards

- RFC 792: Internet Control Message Protocol
- RFC 4443: Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification

1.2 Restrictions and Guidelines

An IP address must be configured for the network device where the Ping and Traceroute operations are executed.

1.3 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Ping Connectivity Test
- Configuring a Traceroute Connectivity Test

1.4 Configuring a Ping Connectivity Test

1.4.1 Overview

You can use Ping connectivity test to check whether a network device is connected to the destination host and whether packets can be transmitted between these two devices.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Check whether the IP address is reachable.

(IPv4 network)

ping [**ip** | **vrf** *vrf-name*] { *hostname* | *ipv4-address* } [**8021p** *8021p* | **data** *data* | **detail** | **df-bit** | **dscp** *dscp* | **interval** *interval* | **length** *length* | **ntimes** *times* | **out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | [**source** *interface-type interface-number* | **source** *source-ipv4-address*] | **timeout** *time* | **validate**] *

ping oob { *hostname* | *ipv4-address* } [**data** *data* | **detail** | **df-bit** | **interval** *interval* | **length** *length* | **ntimes** *times* | **out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | [**source** *interface-type interface-number* | **source** *source-ipv4-address*] | **timeout** *time* | **validate** | **via** *mgmt-name*] *

(IPv6 network)

ping [**ipv6** | **vrf** *vrf-name*] { *hostname* | ipv6-*address* } [**8021p** *8021p* | **data** *data* | **detail** | **dscp** *dscp* | **interval** *interval* | **length** *length* | **ntimes** *times* | **out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | [**source** *interface-type interface-number* | **source** *source-ipv6-address*] | **timeout** *time*] *

ping oob { *hostname* | *ipv6-address* } [**data** *data* | **detail** | **interval** *interval* | **length** *length* | **ntimes** *times* | **out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | [**source** *interface-type interface-number* | **source** *source-ipv6-address*] | **timeout** *time* | **validate** | **via** *mgmt-name*] *

By default, five 100-byte packets are sent to the specified IP address within two seconds.

To run the **ping oob** command on a device (such as a VSU) with multiple MGMT interfaces, use the **via** field to specify the outbound MGMT interface. This ensures that the Ping function can be used properly.

1.5 Configuring a Traceroute Connectivity Test

1.5.1 Overview

You can use Traceroute connectivity test on a network device to learn the routing topology and the number of gateways between this device and the destination host.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Configure an IP packet for tracing.

(IPv4 network)

traceroute [**ip** | **vrf** *vrf-name*] { *hostname* | ipv4-*address* } [**out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | **probe** *probe* | [**source** *interface-type interface-number* | **source** *source-ipv4-address*] | **timeout** *time* | **ttl** *minimum maximum*] *

traceroute oob { *hostname* | *ipv4-address* } [**out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | **probe** *probe* | [**source** *interface-type interface-number* | **source** *source-ipv4-address*] | **timeout** *time* | **ttl** *minimum maximum* | **via** *mgmt-name*] *

(IPv6 network)

traceroute [**ipv6** | **vrf** *vrf-name*] { *hostname* | ipv6-*address* } [**out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | **probe** *probe* | [**source** *interface-type interface-number* | **source** *source-ipv6-address*] | **timeout** *time* | **ttl** *minimum maximum*] *

traceroute oob { *hostname* | *ipv6-address* } [**out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | **probe** *probe* | [**source** *interface-type interface-number* | **source** *source-ipv6-address*] | **timeout** *time* | **ttl** *minimum maximum* | **via** *mgmt-name*] *

By default, the timeout time is 3 seconds, the number of probe packets to be sent is 3, the minimum TTL is 1, and the maximum TTL is 255.

To run the **traceroute oob** command on a device (such as a VSU) with multiple MGMT interfaces, use the **via** field to specify the outbound MGMT interface of packets. This ensures that the Traceroute function can be used properly.

1.6 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

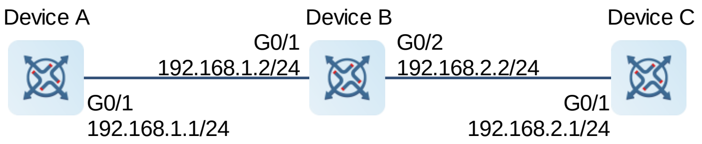
⚠ Caution

Running the **cleanup** commands may loss vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
cleanup rping table { **all** | **ping-object** *owner-index test-index* | **trace-object** *owner-index test-index* }	Clears the Rping table entries.
display rping detail	Displays detailed information of Rping table entries.

1.7 Configuration Examples



1.7.1 Configuring a Ping Connectivity Test

1. Requirements

Devices A, B, and C are connected to an IP network. It is required to check whether devices A and C can communicate with each other.

2. Topology

Figure 1-3 Configuring a Ping Connectivity Test

3. Notes

- Run the following command in privileged mode: **ping** 192.168.2.1.
- Run the following command in privileged mode: **ping** 192.168.2.1, and specify the length of the sent packet, number of sent packets, and TTL.

4. Procedure

- Use the common Ping function on device A.

  Display the brief Ping result.

```
DeviceA# ping 192.168.2.1
Sending 5, 100-byte ICMP Echoes to 192.168.2.1, timeout is 2 seconds:
< press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

  Display the detailed Ping result.

```
DeviceA# ping 192.168.2.1 detail
Sending 5, 100-byte ICMP Echoes to 192.168.2.1, timeout is 2 seconds:
  < press Ctrl+C to break >
Reply from 192.168.2.1: bytes=100 time=4ms TTL=64
Reply from 192.168.2.1: bytes=100 time=3ms TTL=64
Reply from 192.168.2.1: bytes=100 time=1ms TTL=64
Reply from 192.168.2.1: bytes=100 time=1ms TTL=64
Reply from 192.168.2.1: bytes=100 time=1ms TTL=64

Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms.
```

- Use the extended Ping function on device A.

  Display the brief Ping result.

```
DeviceA# ping 192.168.2.1 length 1500 ntimes 100 data ffff source 192.168.1.1 timeout 3
Sending 100, 1500-byte ICMP Echoes to 192.168.2.1, timeout is 3 seconds:
  < press Ctrl+C to break >
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
Success rate is 100 percent (100/100), round-trip min/avg/max = 2/2/3 ms
```

  Display the detailed Ping result.

```
DeviceA# ping 192.168.2.1 length 1500 ntimes 10 data ffff source 192.168.1.1 timeout 3 detail
Sending 20, 1500-byte ICMP Echoes to 192.168.2.1, timeout is 3 seconds:
```

```
  < press Ctrl+C to break >
Reply from 192.168.2.1: bytes=1500 time=1ms TTL=64
Reply from 192.168.2.1: bytes=1500 time=1ms TTL=64
Reply from 192.168.2.1: bytes=1500 time=1ms TTL=64
Reply from 192.168.2.1: bytes=1500 time=1ms TTL=64
Reply from 192.168.2.1: bytes=1500 time=1ms TTL=64
Reply from 192.168.2.1: bytes=1500 time=1ms TTL=64
Reply from 192.168.2.1: bytes=1500 time=1ms TTL=64
Reply from 192.168.2.1: bytes=1500 time=2ms TTL=64
Reply from 192.168.2.1: bytes=1500 time=1ms TTL=64
Reply from 192.168.2.1: bytes=1500 time=1ms TTL=64

Success rate is 100 percent (10/10), round-trip min/avg/max = 1/1/3 ms.
```

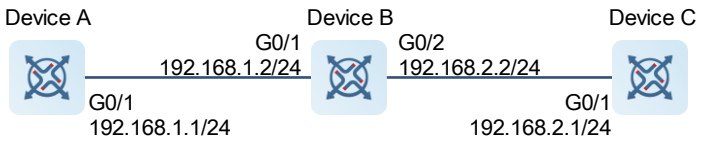
5. Verification

Common Ping function: By default, five 100-byte packets are sent to the specified IP address. Within the specified time (2 seconds by default), the detection information is displayed, and statistical information is output.

```
DeviceA# ping 192.168.2.1
Sending 5, 100-byte ICMP Echoes to 192.168.2.1, timeout is 2 seconds:
< press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

Extended Ping function: By default, ten 1500-byte packets are sent to the specified IP address. If there is a response within the specified time (3 seconds), the detection information is displayed, and statistical information is output.

```
DeviceA# ping 192.168.2.1 length 1500 ntimes 10 data ffff source 192.168.1.1 timeout 3
Sending 10, 1500-byte ICMP Echoes to 192.168.2.1, timeout is 3 seconds:
< press Ctrl+C to break >
!!!!!!!!!!
Success rate is 10 percent (10/10), round-trip min/avg/max = 2/2/3 ms
```



1.7.2 Configuring a Traceroute Connectivity Test

1. Requirements

Devices A, B, and C are connected to an IP network. Device A fails to communicate with device C. It is required to check whether the route between devices A and C is reachable. If the route is unreachable, confirm the faulty network node.

2. Topology

Figure 1-4 Configuring a Traceroute Connectivity Test

3. Notes

Run the following command in privileged mode: **traceroute** 192.168.2.1.

4. Procedure

(1) Configure an IP address on devices A, B, and C, respectively. (omitted)

(2) Configure a static route on device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA (cfg)# ip route-config 0.0.0.0 0.0.0.0 192.168.1.2
DeviceA (cfg)# exit
```

(3) Check whether the route between devices A and C is reachable.

```
DeviceA# ping 192.168.2.1
Sending 5, 100-byte ICMP Echoes to 192.168.2.1, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5).
```

(4) Check the faulty network node.

```
DEVICEA# traceroute ip 192.168.2.1
  < press Ctrl+C to break >
Tracing the route to 192.168.2.1
1       192.168.1.2          1 msec    1 msec    1 msec
2       *          *          *
3       *          *          *
4       *          *          *
```

5. Verification

The displayed result indicates that the route between devices A and C is unreachable. The packet sent from device A to device C has arrived at device B, but a fault occurs to the connection between devices B and C.

1 Configuring Tech-Support

1.1 Introduction

1.1.1 Overview

Tech-Support is an information collection function that provides diversified information collection triggering modes according to requirements of the administrator, and collects information on faulty equipment in different modes.

1.1.2 Principles

1. Basic collection

In basic collection mode, the directory files registered by the log framework are collected, including configuration files, Syslog, and CLI operations.

2. Full collection

In full collection mode, the following fault information is collected:

- All fault log files
- Coredump files
- Service realtime fault information

3. Hotkey collection

When the console fails, you can use the hotkey @@@@f to trigger one-click collection. For details about the collected content, see Full collection.

4. Reset key collection

Press the Reset key on the panel for less than 5s to collect the fault information. Five minutes later, the device is reset. For details about the collected content, see Full collection.

5. Storage of the collected content

The collected fault information is stored in the descending order of USB flash drive, **Flash:/**, and **Tmp:/**.

If the collected fault information is not stored on the USB flash drive, at most two compressed packages are stored.

6. Collection of real-time diagnostic information

When a fault occurs, you can run the **display system diag-info** command and necessary CLI commands in debugging support mode to collect the related fault information and save it in the **diag-info.txt** file on the Flash.

1.2 Enabling the Tech-Support Function

1.2.1 Overview

You can use the Tech-Support function to collect detailed fault information of a device and use it for fault location.

1.2.2 Restrictions and Guidelines

- When the device is connected to the console port, you can also use the hotkey **@@@@f** to collect detailed fault information of the device. The @@@@f hotkey operation is often performed when the console crashes. The fault information is packaged in a way similar to the **tech-support package** command.
- Before enabling the Tech-Support function, you are advised to check whether the device has sufficient space to store the fault information.
- To avoid an information collection failure due to insufficient storage space, you are advised to insert the USB flash drive into the device before enabling Tech-Support to avoid information loss. You can use the TFTP function to transfer the compressed packages of the final fault information to a PC.
- If the collected files are too large, it takes a long time to collect the information and services may be affected. To prevent this problem, if the collected coredump files exceed 200 MB or the number of files is too large, a collection failure notification will be displayed. In this case, you need to use other commands to collect coredump files separately.
- The specific procedure is as follows:

  a Run the **display coredump files** command to display the coredump file names.

```
Device# display coredump files
Directory of /xxx/xxx/xxx/ :
 core-xxx-xxx
```

  b Enter the debugging support mode, run the **execute diagnose-cmd copy** command to copy the coredump files to the **data** directory, and upload the files to the specified TFTP server.

```
Device# debugging support
Device(support)# execute diagnose-cmd copy xxx/xxx/xxx/core-xxx-xxx /data
This operation will modify file? [Y/N]:y
Device(support)# exit
Device# copy flash:/ xxx/xxx/xxx/core-xxx-xxx tftp://xxx.xxx.xxx.xxx/
This operation may overwrite file[tftp:// xxx.xxx.xxx.xxx /core-xxx-xxx]? [Y/N]:y
Press Ctrl+C to quit
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
Copy success.
```

- The compressed packages of fault information are stored as follows:
  - USB flash drive

    If a USB flash drive is inserted into the device, the compressed packages are stored in the root directory of the USB flash drive. You can run the **dir usb0:** command to view these compressed packages.
  - Flash directory

    If no USB flash drive is inserted into the device, the compressed packages are preferentially stored in the Flash directory. You can run the **dir flash:** command to view these compressed packages.
  - **Tmp** directory (memory)

    If no USB flash drive is inserted into the device and the Flash has insufficient space, the compressed packages are stored in the **Tmp** directory. You can run the **dir tmp:** command to view these compressed packages.
- To prevent excessive consumption of space on the storage media after the fault information is collected for

multiple times, a maximum of three compressed packages of fault information can be stored on the same storage medium.

1.2.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(1) Enter the debugging configuration mode.

debugging support

(2) Enable the Tech-Support function. The configuration tasks below are mutually exclusive. Please configure only one task.

- Run the following command to enable the Tech-Support function:

tech-support package [*component-name* | **basic**]

- Use the hotkey to enable the Tech-Support function.

@@@@f

This command takes effect only when the device is connected to the console port, and is invalid for remote connections, for example, Telnet or SSH connection.

(3) Run the diagnose command:

execute diagnose-cmd { [**device** *device-id*] [**slot all**] [**chip all** | **chip** *chip-id*] *shell-command* | **help** }

Note

- The **device** keyword is supported by only the S6520-64CQ, S6510-32CQ, S6510-4C, S6510-48VS8CQ, and S6250-48XS8CQ.

1.3 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
display system diag-info	Displays the diagnostic information when a fault occurs.

1 Configuring SPAN

1.1 Introduction

1.1.1 Overview

With the development of network technologies, the demand for high network availability is increasing. When exceptions occur in a network, the network node or device port needs to be analyzed for data traffic so that the network can return to normal fast. Meanwhile, the device traffic forwarding should not be affected.

The mirroring function copies messages from a specified port to another port connected to a network monitoring device. The device analyzes data traffic of a suspicious network node or device port, without affecting the traffic forwarding of the monitored device. Mirroring is mainly applied to network monitoring and troubleshooting to monitor network information for security and troubleshoot network failures.

1.1.2 Basic Concepts

1. Source Port

A source port is also called a monitored port. The data traffic of a source port is copied to a destination port for network analysis or troubleshooting.

2. Destination Port

A destination port is also called a monitoring port. A destination port is connected to a device to forward packets received from a source port to a monitoring device.

3. Session

A session is a logical concept, which consists of a source port and a destination port.

4. SPAN

Switch port analyzer (SPAN) is also called local port mirroring or local mirroring. In local port mirroring, the source port and the destination port in a mirroring session are in the same device.

5. RSPAN

Remote switch port analyzer (RSPAN) is an extension of SPAN. In RSPAN, the source port and the destination port in a mirroring session are in different devices.

6. ERSPAN

Encapsulated remote switch port analyzer (ERSPAN) is an extension of RSPAN. ERSPAN allows monitoring multiple devices across switched or routing networks.

7. RSPAN VLAN

An RSPAN VLAN is a special VLAN that only transmits mirrored packets to a destination device.

8. Output Port

An output port on a source device sends mirrored packets to a port on an intermediate device or a destination device.

9. Source Device

A source device is a role in RSPAN and has a source port. A source device copies the packets from a source port and outputs them through an output port on the source device to an intermediate device or destination device.

10. Destination Device

A destination device is a role in RSPAN and has a destination port. A destination device forwards the mirrored packets received from an intermediate or source device to a monitoring device through a destination port.

11. Intermediate Device

An intermediate device is a role in RSPAN and resides between a source device and a destination device. An intermediate device forwards mirrored packets to another intermediate device or a destination device. If a source device is directly connected to a destination device, there is no intermediate device.

12. SPAN Data Streams

SPAN data streams refer to mirrored packets. A SPAN session contains data streams in three directions:

- Input data streams

  All packets received by a source port are copied to a destination port. Users can monitor input packets of one or more source ports in a SPAN session.

- Output data streams

  All packets transmitted by a source port are copied to a destination port. Users can monitor output packets of one or more source ports in a SPAN session.

- Bidirectional data streams

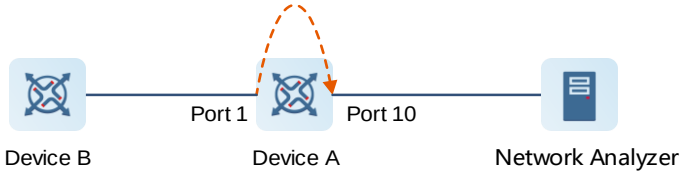
  Bidirectional data streams include input data streams and output data streams. In a SPAN session, users can monitor data streams of one or more source ports in the input and output directions.

1.1.3 Principles

1. SPAN Principles

As shown in Figure 1-1, all packets on port 1 are copied to port 10 through configuring SPAN on Device A. The network analyzer connected to port 10 receives all packets that pass through port 1 even if the network analyzer is not directly connected to port 1. Therefore the network analyzer can monitor the data streams that pass through port 1. The specific process is as follows:

(1) The device identifies and marks the incoming and outgoing packets of the source port 1.



(2) The device searches for the SPAN session to which port 1 belongs.

(3) The device searches for the destination port 10 corresponding to the SPAN session.

(4) The device copies both incoming and outgoing packets of port 1 and sends them to port 10.

(5) Port 10 sends the copied packets to the network analyzer.

Figure 1-1 SPAN Principles

2. RSPAN Working Process

As shown in Figure 1-2, an RSPAN VLAN is created for the source device, intermediate device, and destination device. All ports involved in an RSPAN session must be added to the RSPAN VLAN. Mirrored packets are broadcast in the RSPAN VLAN so that they are forwarded from the source device to the destination device. Then the destination device forwards the mirrored packets to the network analyzer. The following is the specific working process.

(1) Add all ports involved in an RSPAN session of a source device, intermediate device, and destination device to an RSPAN VLAN.

(2) The source device adds the VLAN ID of the RSPAN VLAN to the mirrored packets of the source port. Then the device copies the encapsulated packets to the output port.

Note

As shown in Figure 1-4, for 1:N port mirroring, enable the loopback function on the output port of the source device to make it a loopback port. Add the loopback port (port 1) and the interface of the intermediate device (port 2) to the RSPAN VLAN. The source port adds the VLAN ID of the RSPAN VLAN to the mirrored packets and copies the packets to the loopback port. The loopback port belongs to the RSPAN VLAN and this VLAN is forbidden to learn any MAC address. Therefore the reflected packets are broadcast in the RSPAN VLAN so that all ports in this VLAN can receive the mirrored packets to achieve 1:N port mirroring .

(3) The output port sends the mirrored packets to a port on an intermediate device or a destination device.

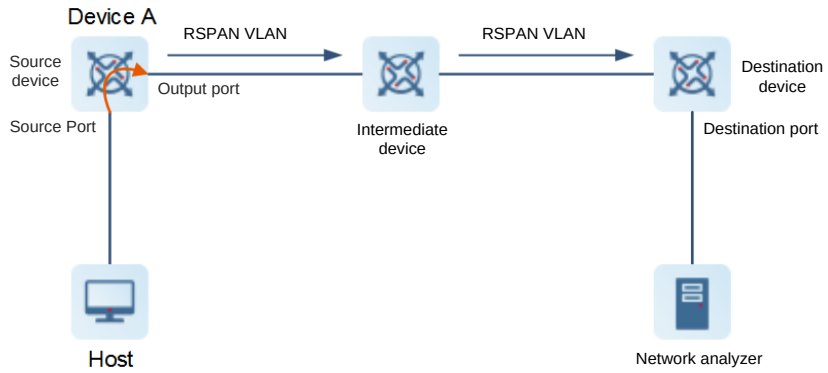
(4) The intermediate device broadcasts mirrored packets in the RSPAN VLAN to transparently transmit the packets to another intermediate device or a destination device.

Note

If a source device is directly connected to a destination device, there is no intermediate device.

(5) After receiving the packets, the destination device determines whether they are mirrored packets through the VLAN ID. If the VLAN ID carried by the packets is the same as the RSPAN VLAN ID, the device regards the packet as a mirrored packet and forwards the packet to the network analyzer through the destination port.

Figure 1-2 Principles of RSPAN



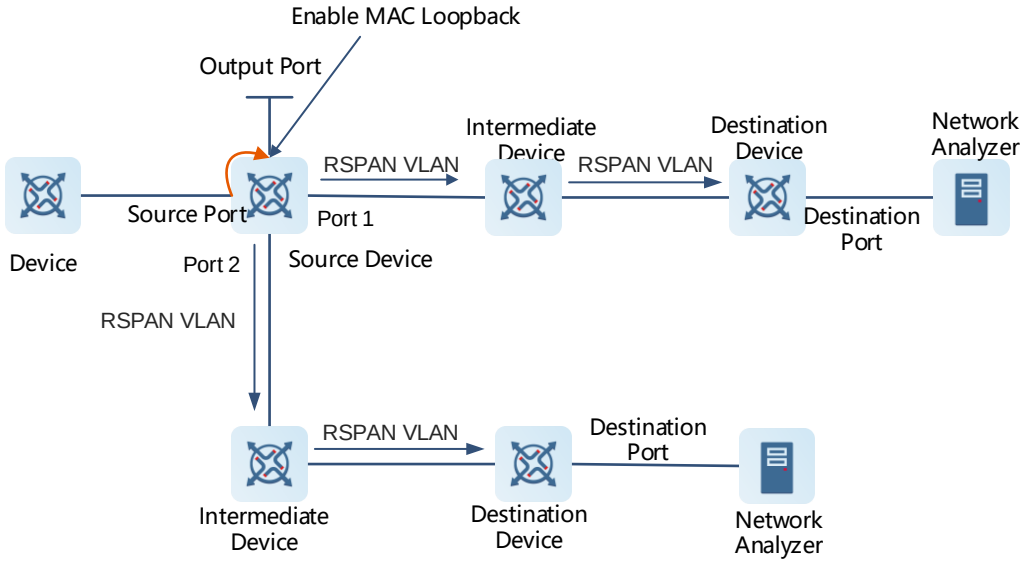


Figure 1-3 Principles of 1:N Port Mirroring Based on RSPAN

3. ERSPAN Working Process

In RSPAN, mirrored packets can be transmitted only at Layer 2 and cannot transmitted across routing networks. However, ERSPAN can encapsulate mirrored packets into IP packets through a generic routing encapsulation (GRE) tunnel and forward the mirrored packets to the destination port of the RSPAN device, thus transmitting mirrored packets across routing networks.

Figure 1-4 shows the specific working process of ERSPAN.

(1) The source device copies and encapsulates the incoming packets of the source port.

- Encapsulate the source and destination IP addresses of the GRE packet.
- Set the TTL and DSCP of the GRE packet.

Note

Figure 1-5 shows the header format of a packet encapsulated in ERSPAN.

(2) The source port forwards the mirrored packets to the destination device through the GRE tunnel.

(3) The destination device decapsulates GRE packets to remove the header encapsulated by ERSPAN, and forwards the packets to the destination port.

(4) The destination port forwards the mirrored packets to the netwokr analyzer.

Caution

The IP packets after GRE encapsulation must be normally routed to the destination device in the network. Therefore, the destination IP address is generally the next-hop IP address of the route. That is, the output port of the source device is the next-hop egress of the Layer 3 path where the destination IP address to be encapsulated is located. The output port must be reachable, and can be an SVI, Layer 3 aggregate interface, or Layer 3 Ethernet interface.

Figure 1-4 ERSPAN Principles

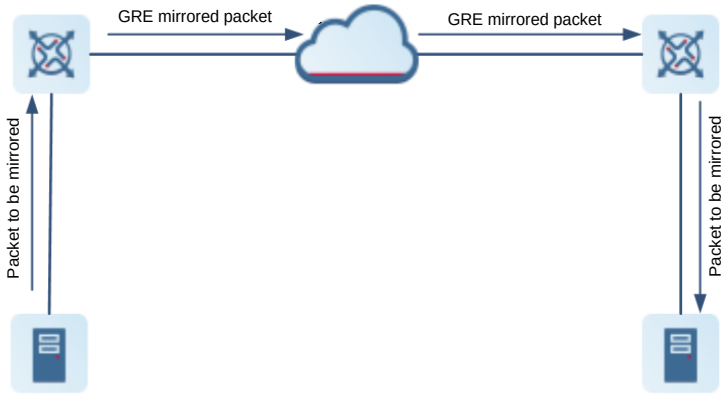

Figure 1-5 Format of an Encapsulated Packet in ERSPAN

MAC_HEADER(14/18B)	IP_HEADER(20B)	GRE_HEADER(48B)	L2_Mirrored_Packet(untagged)

4. Stream Mirroring Principles

Stream mirroring is to associate the source port with an ACL on the basis of SPAN, and filter packets based on the ACL rules, so as to mirror only specified packets. Only the packets matching the permit ACE in the ACL on the source port can be mirrored to the destination port. A source port can be associated with only one ACL. Currently, the standard ACL, extended ACL, MAC ACL, and custom ACL can be associated.

1.2 Restrictions and Guidelines

- A source port has the following features:
  - The source port and the output port cannot be the same one.
  - The source port can be a Layer 2 Ethernet interface, Layer 3 Ethernet interface, Layer 2 link aggregation or Layer 3 link aggregation.
  - Data streams on multiple source ports on the source device can be mirrored to a specified output port.

- When the source port is a Layer 3 link aggregation or Ethernet interface, the port monitors both Layer 2 and Layer 3 packets.
- Upon bidirectional monitoring of multiple ports, a packet is received from one port and output from another port, and monitoring is effective as long as one packet is monitored among these ports.
- When a port is STP enabled and in the block state, the incoming and outgoing packets of the port can also be monitored.
- The source port and the destination port can belong to the same VLAN or different VLANs.

  If a source port is added to a link aggregation, the source port exits the SPAN session. The source port acts as only a member port of the link aggregation.

- A destination port has the following features:
  - A destination port cannot be used as a source port simultaneously.
  - The destination port can be an Ethernet interface, link aggregation or an output group.
  - The SPAN destination port is used for the Spanning Tree Protocol (STP) calculation.
- A source port cannot be added to an output group.
- The destination port is not enabled with switching function and only receives SPAN packets by default. To allow the destination port to forward packets, enable switching function on the port. Otherwise, the packets passing through the port are dropped.
- Due to other reasons (such as port security), incoming packets of a source port may be discarded, but it does not affect the SPAN function, and these packets are still mirrored to the destination port. Due to other reasons, packets sent from other ports to a source port may be discarded, and these packets are not sent to the destination port.
- If the format of a packet output from the source port is changed, for example, the source MAC, destination MAC, VLAN ID, and TTL of the packet change, the format of the packet mirrored to the destination port will change as well.
- Configure the following types of ACL on the source port to mirror specified packets: standard ACL, extended ACL, MAC ACL, and custom ACL.

1.3 Configuration Task Summary

SPAN configuration includes the following tasks:

- Configuring SPAN
- Configuring RSPAN
- Configuring ERSPAN
  - a Configuring Basic Functions of ERSPAN
  - b (Optional) Configuring the ERSPAN Sampling Function
  - c (Optional) Configuring ERSPAN Attributes

1.4 Configuring SPAN

1.4.1 Overview

SPAN copies packets of the designated port or designated VLAN to the port connected to the data monitoring device, so that you can use the data monitoring device to analyze these copied packets for network monitoring and troubleshooting.

1.4.2 Restrictions and Guidelines

- When configuring the SPAN source port, you can specify the following items as the data source simultaneously: some VLANs, an interface, and specified streams on the specified port.
- When configuring the SPAN source port, if you specify a VLAN as the data source, you cannot specify an interface or streams on the specified port as the data source.
- When configuring the SPAN source port, if you specify some VLANs as the data source, you must also specify the source port.
- If you change the VLAN configuration on the source port or destination port, the configuration takes effect immediately.
- If you disable the source or destination port, the SPAN function does not take effect.
- If you configure a VLAN or a VLAN list as the SPAN source, ensure that the destination port has sufficient bandwidth for receiving mirrored data of the entire VLAN (or VLAN list).
- If you add or delete a VLAN source port to or from an effective SPAN session, you need to re-apply the entire SPAN session. Therefore, a few existing mirrored packets may be lost.
- If SPAN source and destination ports are both configured as LACP aggregate interfaces, the LACP flapping occurs repeatedly on the destination port and its peer port.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a SPAN source port. Configure at least one of the following tasks.

- Specify an interface as the data source of SPAN.

  mirror session-id *session-number* **source port** *interface-type interface-number* [**both** | **rx** | **tx**]

- Specify some streams of an interface as the data source of SPAN.

  mirror session-id *session-number* **source port** *interface-type interface-number* **rx acl** { *acl-name* | *acl-number* [**priority** *priority-number*] }

- (Optional) Exclude one or more VLANs as the data source of SPAN.

  mirror session-id *session-number* **filter vlan** *vlan-id-list* **rx**

  This command must be configured together with monitor session source **port** or monitor session source **port acl**

- Specify one or more VLANs as the data source of SPAN.

mirror session-id *session-number* **source vlanid** *vlan-id-list* **rx**

This function is mutually exclusive with the preceding three configurations.

By default, no source port is configured for a SPAN session.

(4) Configure a SPAN destination port.

mirror session-id *session-number* **destination** { **port** *interface-type interface-number* } [**switch**]

By default, no SPAN destination port is configured.

1.5 Configuring RSPAN

1.5.1 Overview

A device enabled with RSPAN can monitor packets acrorss networks for network monitoring and troubleshooting.

1.5.2 Restrictions and Guidelines

- All ports involved in RSPAN must be added to a remote VLAN.
- An RSPAN VLAN must be configured on each device and their VLAN IDs must be consistent. All ports involved in a session must be added to the VLAN. Do not add common ports to an RSPAN VLAN.
- Do not configure a port that is connected to an intermediate device or a destination device as an RSPAN source port. Otherwise, traffic on the network may be in chaos.
- To achieve 1:N port mirroring, configure a port on a source device as a loopback port. The loopback function on the output port will transmit mirrored packets to multiple intermediate devices or destination devices.
- The loopback port cannot serve as a normal port to forward packets. You are advised to configure a port in Down state as the loopback port, and not to add other configurations for this port.
- If RSPAN source and destination ports are both configured as LACP aggregate interfaces, the LACP flapping occurs repeatedly on the destination port and its peer port.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the VLAN configuration mode.

vlan *vlan-id*

(4) Configure a remote VLAN.

remote-probe

By default, no remote VLAN is configured.

(5) Exit the VLAN configuration mode.

exit

(6) Configure an RSPAN source device.

mirror session-id *session-number* **remote-source**

By default, no source device is configured for an RSPAN session.

(7) (Optional) Configure the MAC loopback function on the source device.

a Enter the Layer 2 or Layer 3 Ethernet interface configuration mode.

interface *interface-type interface-number*

b Enable the MAC loopback function of the interface.

mac-loopback

By default, MAC loopback is disabled for an interface.

(8) Exit the Layer 2 or Layer 3 Ethernet interface configuration mode.

exit

(9) Configure a source port on the source device.

mirror session-id *session-number* **source port** *interface-type interface-number* [{ **both** | **rx** [**acl** { *acl-name* | *acl-number* [**priority** *priority-number*] | **tx** } }]

By default, no source port on the source device is configured for an RSPAN session.

(10) Configure an RSPAN destination device.

mirror session-id *session-number* **remote-destination**

By default, no destination device is configured for an RSPAN session.

(11) Configure an output port on the source device or a destination port on the destination device.

mirror session-id *session-number* **destination remote vlan** *remote-vlan-id* **port** *interface-type interface-number* [**switch**]

By default, no output port on the RSPAN source device or no destination port on the RSPAN destination device is configured.

1.6 Configuring ERSPAN

1.6.1 Configuration Tasks

ERSPAN configuration includes the following tasks:

(1) Configuring Basic Functions of ERSPAN

(2) (Optional) Configuring the ERSPAN Sampling Function

(3) (Optional) Configuring ERSPAN Attributes

1.6.2 Configuring Basic Functions of ERSPAN

1. Overview

After ERSPAN is configured, a network analyzer can be used to monitor data streams of network devices. Devices can normally exchange data with each other.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an ERSPAN session.

mirror session-id *session-number* **erspan**

No ERSPAN session is configured by default.

(4) Specify an interface as the data source of ERSPAN.

source port *interface-type interface-number* [**both** | **rx** [**acl** { *acl-name* | *acl-number* } [**sample | priority** *priority-number*]] | **tx**]

By default, no source port is configured. If a source port is configured, the default mirroring direction is bidirectional.

When a sub-interface is configured as the source port, mirroring is supported only in the inbound direction.

(5) Configure all ports that support mirroring as the mirroring data source.

source port all rx acl { *acl-name* | *acl-number* } [**sample | priority** *priority-number*]

No mirroring source port is configured by default.

(6) Configure the source IP address for encapsulation.

original { **ip** | **ipv6** } **address** *address*

By default, no source IP address is configured for GRE encapsulation.

(7) Configure the destination IP address for encapsulation.

destination { **ip** | **ipv6** } **address** *address*

By default, no encapsulation type or destination IP address is configured.

1.6.3 Configuring the ERSPAN Sampling Function

1. Restrictions and Guidelines

The ERSPAN sampling function takes effect only when the sampling function is configured in an ERSPAN session or source port.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an ERSPAN session.

mirror session-id *session-umber* **erspan**

(4) Configure a source port.

source port { **all rx** { **acl** *acl-name* | **acl** *acl-number* } | *interface-type interface-numbere* [{ **both** | **rx** [**acl** *acl-name* | **acl** *acl-number* [**sample** | **priority** *priority-number*]] | **tx** }] }

By default, no source port is configured. If a source port is configured, the mirroring direction is **both** by default.

(5) Configure the source IP address for encapsulation.

original { **ip** | **ipv6** } **address** *address*

By default, no source IP address is configured for GRE encapsulation.

(6) Configure the destination IP address for encapsulation.

destination { **ip** | **ipv6** } **address** *address*

By default, no encapsulation type or destination IP address is configured.

(7) (Optional) Configure the sampling rate.

sampling-rate *rate*

The default sampling rate is **1:1**, that is, every packet is sampled.

1.6.4 Configuring ERSPAN Attributes

1. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an ERSPAN session.

mirror session-id *session-number* **erspan**

(4) Configure attributes of an ERSPAN session. The following configurations are optional. Select at least one of the configurations as actually needed.

- (Optional) Configure the TTL of the encapsulated IP packet.

  ip ttl *ttl-value*

  The default TTL of the encapsulated IP packet is **64**.

- (Optional) Configure the DSCP of the encapsulated IP packet.

  ip dscp *dscp-value*

  The default DSCP of the encapsulated IP packet is **0**.

(Optional) Configure the hop-limit value of encapsulated IPv6 packets.

ipv6 hop-limit *value*

The default hop-limit value of encapsulated IPv6 packets is 64.

Note

This command is supported by only the S6520-64CQ.

- (Optional) Configure the hop-limit value of encapsulated IPv6 packets.

  ipv6 max-hops *value*

  The default hop-limit value of encapsulated IPv6 packets is **64**.

- (Optional) Configure the traffic-class value of encapsulated IPv6 packets.

  ipv6 traffic-class *value*

  The default traffic-class value of encapsulated IPv6 packets is **0**.

Note

This command is supported by only the S6520-64CQ.

- (Optional) Associate ERSPAN with a VRF.

  vrf *vrf-name*

  By default, no VRF is associated with ERSPAN.

  When this function is configured, the VRF must be already configured.

- (Optional) Configure the header type value of ERSPAN packets.

  header type3

Note

This command is supported by only the S6580-48CQ8QC, and S6580-24DC8QC.

(5) (Optional) Shut down the ERSPAN session.

shutdown

The session is enabled by default.

1.7 Monitoring

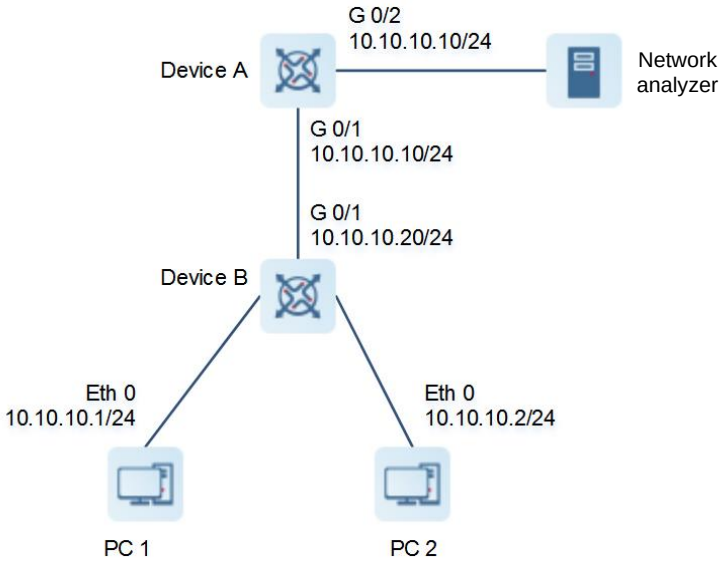
Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

Table 1-1 Monitoring

Command	Purpose
display mirror [**session-id** *session-number*]	Displays the SPAN session information.
debugging span	Debugs the SPAN.

1.8 Configuration Examples



1.8.1 Configuring SPAN

1. Requirements

As shown in Figure 1-6, after appropriate configuration, the network analyzer can monitor all data streams forwarded by device A to device B and specified data streams of device B (for example, data streams fromHost A and Host B).

2. Topology

Figure 1-6 SPAN Topology

3. Notes

- Add GigabitEthernet 0/1 and GigabitEthernet 0/2 of device A to VLAN 1. Create SVI 1 and set the address of SVI 1 to 10.10.10.10/24.
- Add GigabitEthernet 0/1 of device B to VLAN 1. Create SVI 1 and set the address of SVI 1 to 10.10.10.20/24.
- Set the IP addresses of PC 1 and PC 2 to 10.10.10.1/24 and 10.10.10.2/24, respectively.
- Configure SPAN for Device A and configure ports GigabitEthernet 0/1 and GigabitEthernet 0/2 as the source port and destination port of SPAN respectively. Monitor all data streams forwarded by device A to device B and specified data streams of device B.

4. Procedure

Add GigabitEthernet 0/1 and GigabitEthernet 0/2 of device A to VLAN 1.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# vlan 1
DeviceA(cfg-vlan)# exit
```

On device A, create SVI 1 and set the address of SVI 1 to 10.10.10.10/24.

```
DeviceA(cfg)# interface vlan 1
DeviceA(cfg-if-VLAN 1)# ip address 10.10.10.10 255.255.255.0
DeviceA(cfg-if-VLAN 1)# exit
```

Add GigabitEthernet 0/1 of device B to VLAN 1.

```
DeviceB# config-system terminal
DeviceB(cfg)# vlan 1
DeviceB(cfg-vlan)# exit
```

On device B, create SVI 1 and set the address of SVI 1 to 10.10.10.20/24.

```
DeviceB (cfg)# interface vlan 1
DeviceB(cfg-if-VLAN 1)# ip address 10.10.10.20 255.255.255.0
DeviceB(cfg-if-VLAN 1)# exit
```

On device A, configure an ACL to match packets with the source address 10.10.10.20.

```
DeviceA(cfg)# access-list 100 permit ip host 10.10.10.20 any
```

On device A, configure GigabitEthernet 0/1 as the SPAN source port, and monitor all data streams forwarded by device A to device B and specified data streams of device B.

```
DeviceA(cfg)# mirror session-id 1 source interface gigabitethernet 0/1 tx
DeviceA(cfg)# mirror session-id 1 source interface gigabitethernet 0/1 rx acl 100
```

On device A, configure GigabitEthernet 0/2 on device A as the SPAN destination port.

```
DeviceA(cfg)# mirror session-id 1 destination interface gigabitethernet 0/2
```

5. Verification

Run the **display mirror** command to check whether the SPAN configuration is correct.

```
DeviceA# display mirror
sess-num: 1
span-type: LOCAL_SPAN
src-intf:
   GigabitEthernet 0/1          frame-type TX Only
src-intf:
   GigabitEthernet 0/1          frame-type RX Only
rx acl id 100
dest-intf:
   GigabitEthernet 0/2
```

6. Configuration Files

- Device A configuration file

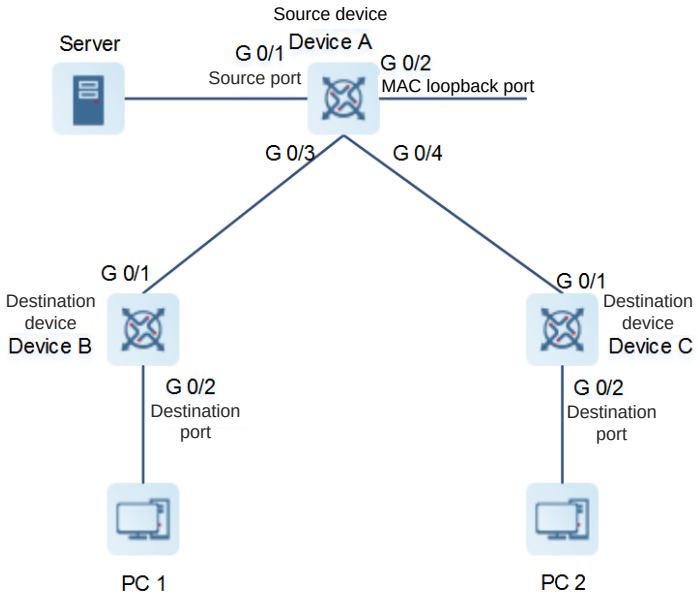
```
hostname DeviceA
!
ip access-control-list extended 100
  10 permit ip host 10.10.10.20 any
!
interface VLAN 1
  ip address 10.10.10.10 255.255.255.0
!
mirror session-id 1 destination interface GigabitEthernet 0/2
mirror session-id 1 source interface GigabitEthernet 0/1 tx
mirror session-id 1 source interface GigabitEthernet 0/1 rx acl 100
!
end
```

- Device B configuration file

```
hostname DeviceB
```

```
!
interface VLAN 1
 ip address 10.10.10.20 255.255.255.0
!
end
```

1.8.2 Configuring RSPAN to Realize One-to-Many SPAN



> **Caution**
>
> When deploying One-to-Many SPAN, you must run the **switch-port trunk allowed vlan remove** *vlan-list* command to remove the broadcast VLANs from a trunk interface on each SPAN device. Otherwise, the trunk interface may be fully occupied by the broadcast traffic, causing service interruption.

1. Requirements

As shown in Figure 1-7, the RSPAN function enables the network analyzer to monitor bidirectional data streams of the source device A from the destination devices B and C. The devices can normally exchange data with each other.

2. Topology

Figure 1-7 Configuring RSPAN to Realize One-to-Many SPAN

3. Notes

- Configure device A as the source device. Configure an RSPAN VLAN. Configure GigabitEthernet 0/1 as the source port, GigabitEthernet 0/3 and GigabitEthernet 0/4 connected to the destination device as the output ports, and GigabitEthernet 0/2 as the MAC loopback port to realize the reflection function of 1:N SPAN. Configure the switching function of the output port.
- Configure devices B and C as the destination devices. Configure an RSPAN VLAN. Configure

GigabitEthernet 0/1 connected to the source device as the source port. Configure a trunk port. Configure GigabitEthernet 0/2 connected to the network analyzer as the SPAN destination port, and configure the switching function for the SPAN destination port.

4. Procedure

(1) Configure device A as the source device.

a. Configure a remote VLAN.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# vlan 7
DeviceA(cfg-vlan)# remote-probe
DeviceA(cfg-vlan)# exit
```

b. Configure a source port.

```
DeviceA(cfg)# mirror session-id 1 remote-source
DeviceA(cfg)# mirror session-id 1 source interface gigabitethernet 0/1 both
```

c. Configure an output port.

```
DeviceA(cfg)# mirror session-id 1 destination remote vlan 7 interface gigabitethernet 0/2 switch
```

d. Configure a loopback port.

```
DeviceA(cfg)# port gigabitethernet 0/2
DeviceA(cfg-if)# mac-loopback
DeviceA(cfg-if)# switch-port  access vlan 7
DeviceA(cfg-if)# exit
DeviceA(cfg)# interface range gigabitethernet 0/3-4
DeviceA(cfg-if-list)# switch-port  mode trunk
```

(2) Configure device B as the destination device.

a. Configure a remote VLAN.

```
DeviceB> privilege
DeviceB# config-system
DeviceB(cfg)# vlan 7
DeviceB(cfg-vlan)# remote-probe
DeviceB(cfg-vlan)# exit
```

b. Configure a destination port.

```
DeviceB(cfg)# mirror session-id 1 remote-destination
DeviceB(cfg)# mirror session-id 1 destination remote vlan 7 port gigabitethernet 0/2 switch
DeviceB(cfg)# interface gigabitethernet 0/1
DeviceB(cfg-if)# switch-port  mode trunk
```

(3) Configure device C as the destination device.

a. Configure a remote VLAN.

```
DeviceC> privilege
DeviceC# config-system
DeviceC(cfg)# vlan 7
DeviceC(cfg-vlan)# remote-probe
DeviceC(cfg-vlan)# exit
```

b. Configure a destination port.

```
DeviceC(cfg)# mirror session-id 1 remote-destination
DeviceC(cfg)# mirror session-id 1 destination remote vlan 7 port gigabitethernet 0/2 switch
DeviceC(cfg)# interface gigabitethernet 0/1
DeviceC(cfg-if)# switch-port    mode trunk
```

5. Verification

Run the **display mirror** command on device A to view the SPAN source device configurations.

```
DeviceA# display mirror
sess-num: 1
span-type: SOURCE_SPAN
src-intf:
GigabitEthernet 0/1          frame-type Both
dest-intf:
GigabitEthernet    0/2
Remote vlan 7
mtp_switch on
```

Run the **display mirror** command on devices B and C to view the SPAN destination device configurations. Device B is taken as an example below:

```
DeviceB# display mirror
sess-num: 1
span-type: DEST_SPAN
dest-intf:
GigabitEthernet    0/2
Remote vlan 7
mtp_switch on
```

6. Configuration Files

- Device A configuration file of

```
hostname DeviceA
!
vlan 7
!
 remote-probe
!
interface GigabitEthernet 0/2
 mac-loopback
 switch-port    access vlan 7
!
interface GigabitEthernet 0/3
switch-port    mode trunk
interface GigabitEthernet 0/4
switch-port    mode trunk
!
mirror session-id 1 remote-source
```

```
mirror session-id 1 source interface GigabitEthernet 0/1 both
mirror session-id 1 destination remote vlan 7 interface GigabitEthernet0/2 switch
!
end
```

- Device B configuration file

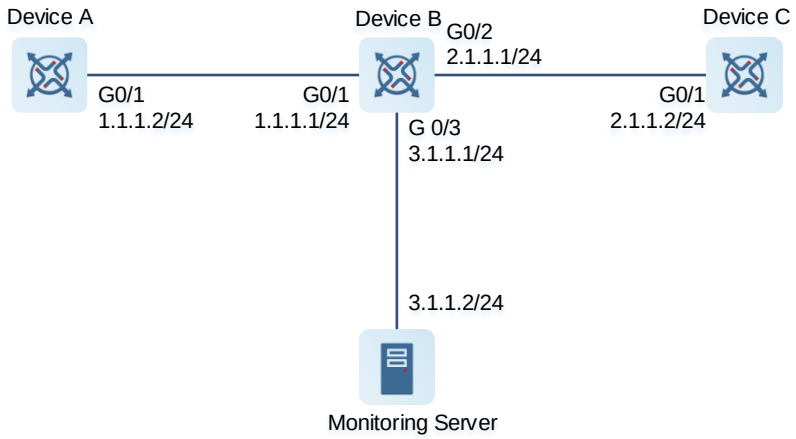
```
hostname DeviceB
!
vlan 7
 remote-probe
!
interface GigabitEthernet 0/1
 switch-port    mode trunk
!
mirror session-id 1 remote-destination
mirror session-id 1 destination remote vlan 7 interface GigabitEthernet0/2 switch
!
end
```

- Device C configuration file

```
hostname Device
!
vlan 7
 remote-probe
!
interface GigabitEthernet 0/1
 switch-port    mode trunk
 !
mirror session-id 1 remote-destination
mirror session-id 1 destination remote vlan 7 interface GigabitEthernet 0/2 switch
!
end
```

7. Common Errors

- A remote VLAN must be configured on the source device, intermediate device, and destination device, and their VLAN IDs must be consistent.
- Packet loss may occur if packets of a port with large bandwidth are mirrored to a port with small bandwidth.



1.8.3 Configuring Basic Functions of ERPSAN

1. Requirements

As shown in Figure 1-8, the network administrator wants to use the network analyzer to monitor traffic on devices A and C. The network administrator monitors bidirectional packets of device A. For device B, the network administrator monitors only some incoming packets. To make reasonable use of resources, the monitored packets are sampled at a sampling rate of 1000.

2. Topology

Figure 1-8 Configuring Basic Functions of ERSPAN

3. Notes

- Configure reachable Layer 3 routes between devices.
- Configure device B as the source device. Configure GigabitEthernet 0/1 and GigabitEthernet 0/2 as the source ports to mirror packets in both directions on GigabitEthernet 0/1, mirror packets with the destination IP address 2.1.1.1 on GigabitEthernet 0/2, and configure GigabitEthernet 0/3 as the output port.
- Set the sampling rate of mirrored packets to 1000.

4. Procedure

Configure the IP address of Device B.

```
DeviceB> privilege
DeviceB # config-system terminal
DeviceB(cfg)# interface gigabitethernet 0/1
DeviceB(cfg-if-GigabitEthernet 0/1)# ip address 1.1.1.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/1)# exit
DeviceB(cfg)# interface gigabitethernet 0/2
DeviceB(cfg-if-GigabitEthernet 0/1)# ip address 2.1.1.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/1)# exit
DeviceB(cfg)# interface gigabitethernet 0/3
DeviceB(cfg-if-GigabitEthernet 0/1)# ip address 3.1.1.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/1)# exit
```

Configure the IP address of device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# ip address 1.1.1.2 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
```

Configure the IP address of device C.

```
DeviceC> privilege
```

```
DeviceC# config-system terminal
DeviceC(cfg)# interface gigabitethernet 0/1
DeviceC(cfg-if-GigabitEthernet 0/1)# ip address 2.1.1.2 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/1)# exit
```

Configure an ACL on Device B.

```
DeviceB(cfg)#access-list 1 permit host 1.1.1.1
```

Create ERSPAN Session 1, and configure Device as the source device. Configure GigabitEthernet 0/1 as the source port, and mirror bidirectional packets. Configure GigabitEthernet 0/2 as the source port, and mirror packets with the destination IP address 1.1.1.1.

```
DeviceB(cfg)# mirror session-id 1 erspan-source
DeviceB(cfg-monitor-erspan)# source interface gigabitethernet 0/1 both
DeviceB(cfg-monitor-erspan)# source interface gigabitethernet 0/2 rx acl 1
DeviceB(cfg-monitor-erspan)# origin ip address 10.1.1.2
DeviceB(cfg-monitor-erspan)# destination ip address 3.1.1.2
```

Enable the sampling function and set the sampling rate to 1000.

```
DeviceB(cfg-monitor-erspan)# sample enable
DeviceB(cfg-monitor-erspan)# sample rate 1000
```

5. Verification

Check that the Layer 3 route between Device B and Device A is reachable.

```
DeviceB# ping 1.1.1.2
Sending 5, 100-byte ICMP Echoes to 1.1.1.2, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/3/8 ms.
```

Check that the Layer 3 route between Device B and Device C is reachable.

```
DeviceB# ping 2.1.1.2
Sending 5, 100-byte ICMP Echoes to 2.1.1.2, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/3/8 ms.
```

Check that the Layer 3 route between Device B and the network analyzer is reachable.

```
DeviceB# ping 3.1.1.2
Sending 5, 100-byte ICMP Echoes to 3.1.1.2, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/3/8 ms.
```

Run the **display access-lists** command to check that the ACL configuration takes effect.

```
DeviceB# display access-lists

ip access-control-list standard 1
  10 permit host 1.1.1.1
```

Run the **display mirror** command to check that the ERSPAN session is in Active state in the configuration result.

```
DeviceB# display mirror
sess-num: 1
span-type: ERSPAN_SOURCE
src-intf:
   GigabitEthernet 0/1          frame-type: Both          TX status: Active     RX status: Active
src-intf:
   GigabitEthernet 0/2          frame-type: RX Only       Rx acl id: 1
status: Active
original ip address: 2.1.1.2
destination ip address: 3.1.1.2
ip ttl: 64
ip dscp: 0
sample rate: 1000
vrf: reset
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 ip address 1.1.1.2 255.255.255.0
!
end
```

- Device C configuration file

```
hostname DeviceC
!
interface GigabitEthernet 0/1
 ip address 2.1.1.2 255.255.255.0
!
end
```

- Device B configuration file

```
hostname DeviceB
!
ip access-control-list standard 1
 10 permit host 1.1.1.1
!
interface GigabitEthernet 0/1
 ip address 1.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
 ip address 2.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/3
```

```
 ip address 3.1.1.1 255.255.255.0
!
mirror session-id 1 erspan-source
 source interface gigabitEthernet 0/1 both
 source interface gigabitEthernet 0/2 rx acl acl1
 origin ip address 10.1.1.2
 destination ip address 3.1.1.2
 sample enable
 sample rate 1000
!
end
```

7. Common Errors

- The session ID used to configure ERSPAN is already configured with RSPAN or LOCAL SPAN.
- The Layer 3 route between the source device and destination device is unreachable.

1 Configuring Packet Capture

1.1 Introduction

1.1.1 Overview

Packet capture (PCAP) captures packets sent or received by a network device to analyze network device faults. With network technology development, network deployment becomes more and more complex. The PCAP function configured on a device helps locate faults remotely, facilitating network maintenance.

After packets that meet a capture rule are captured, a network administrator can view the captured packets in the command line interface (CLI) or save them to the storage medium of the device using a *.pcap file and then download the file to a local directory and use software to view the packets. The PCAP function simplifies deployment of the packet analyzer and network monitoring devices and can analyze the causes of network faults, improving network maintenance efficiency and reducing network maintenance costs.

1.1.2 Principles

The device supports the following packet capture methods:

1. Capturing packets destined for the CPU

Configure the packet capture points, specify the packet capture location, direction, matching rule, captured packet quantity, and name of the file for saving captured packets, and analyze different types of captured packets destined for the central processing unit (CPU) to locate the causes of device faults and handle the faults in time to ensure proper network running.

2. Capturing forwarded packets

Associate a packet capture rule with an access control list (ACL) to filter packets and analyze specified packets captured to locate the cause for abnormal data forwarding in the network environment and handle the fault in time to ensure proper network running.

1.2 Configuration Task Summary

PCAP configuration includes the following tasks:

- Capturing Packets Destined for the CPU
- Capturing Forwarded Packets

1.3 Capturing Packets Destined for the CPU

1.3.1 Overview

When a type of packets fails to be sent or received during device running, configure rules to capture and analyze packets destined for the CPU to help locate the fault.

1.3.2 Restrictions and Guidelines

- To capture different types of packets simultaneously, you can define up to eight packet capture points with different names on the device.
- You can define packet capture rules to capture packets that meet requirements. Packet capture rules include:
  - Specifying the location for capturing packets. You can specify a physical port or the system CPU as the packet capture location. Each packet capture point can define only one packet capture location. However, different packet capture points can have the same packet capture location.
  - Specifying the direction for capturing packets. You can specify the outbound direction, inbound direction, or both directions to capture packets.
  - Matching packet feature information to capture specific packets. Packet feature information includes the source media access control (MAC) address, destination MAC address, layer-2 protocol type, source IP address, destination IP address, layer-3 protocol type, and Transmission Control Protocol (TCP)/User Datagram Protocol (UDP) port.
- Specify the name of the file used to save captured packets. Save captured packets to the storage medium of the device using a *.pcap file.
- Specify a condition for automatic stopping of packet capturing, such as the quantity of capture packets, size of the file used to save captured packets, packet capture duration, and less than 1/4 idle space of the PCAP file storage path. After the PCAP function is enabled and any of the conditions for automatic stopping of packet capturing is met, the device automatically stops packet capturing. After the **packet capture stop** command is run, the device stops packet capturing immediately regardless of whether the condition for automatic stopping of packet capturing is met.
- Multiple packet capture rules with different names can be defined on the device simultaneously. A packet capture rule takes effect only when it is referenced by a packet capture point.
- To delete a packet capture rule, you need to delete all the packet capture points referencing the rule.
- The PCAP function can be enabled only when the CPU usage of the device is less than or equal to 70%.
- The PCAP configuration cannot be saved.
- The PCAP configuration cannot be synchronized in VSU mode. Packet capture rules configured on the master device will be lost after a master/slave switchover.
- Rules for capturing packets destined for the CPU and forwarded packets cannot be configured simultaneously. For example, if a rule for capturing forwarded packets is configured, a rule for capturing packets destined for the CPU can be configured only after the previous rule is cleared.
- A switch virtual interface (SVI) cannot be configured as the location for capturing packets destined for the CPU.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Configure a packet capture rule.

packet capture rule *rule-name* **filter** [**dst-mac** *mac-address*] [**etype** *type*] [**icmpv4_code** *icmpv4-code*] [**icmpv4_type** *icmpv4-type*] [**icmpv6_code** *icmpv6-code*] [**icmpv6_type** *icmpv6-type*] [**ipv4_dip** { *ipv4-address wildcard*| **host** *ipv4-address* }] [**ipv4_dport eq** *port-number*] [**ipv4_sip** { *ipv4-address wildcard* | **host** *ipv4-address* }] [**ipv4_sport eq** *port-number*] [**ipv6_dip** *ipv6-address*] [**ipv6_dport eq** *port-number*] [**ipv6_sip** *ipv6-address*] [**ipv6_sport eq** *port-number*] [**src-mac** *mac-address*] [**v4_protocol** *protocl*] [**v6_protocol** *protocol*] [{ **acl** *acl-name* | **acl** *acl-number* } **interface** *interface-type interface-number* **in**]

No packet capture rule is configured by default.

(3) Configure a packet capture point.

packet capture point *name* **rule** *rule-name* **location** { **control-plane** | **interface** *interface-type interface-number* } { **in** | **out** | **both** }

No packet capture point is configured by default.

(4) Configure the name of the file used to save captured packets.

packet capture file { **flash:** | **tmp: | usb0:** } *filename* [**buffer-size** *size*] [**packet-num** *number*] [**timeout** *timeout*]

No file used to save captured packets is configured by default.

(5) Enable the PCAP function.

packet capture start

The PCAP function is disabled by default.

(6) (Optional) Manually disable the PCAP function.

packet capture stop

Packet capturing stops automatically when any of the conditions for stopping packet capturing is met.

(7) (Optional) Clear configured packet capture rules.

cleanup packet capture point *capture-point-name*

cleanup packet capture rule *rule-name*

1.4 Capturing Forwarded Packets

1.4.1 Overview

Associate a packet capture rule with an ACL to filter packets and analyze specified packets captured to locate the cause for abnormal data forwarding in the network environment and handle the fault in time to ensure proper network running.

1.4.2 Restrictions and Guidelines

- No packet capture point needs to be specified, and 7-tuple matching information is not supported.
- Specify the name of the file used to save captured packets. Save captured packets to the storage medium of the device using a *.pcap file.
- Specify a condition for automatic stopping of packet capturing, such as the quantity of capture packets, size of the file used to save captured packets, packet capture duration, and less than 1/4 idle space of the PCAP file storage path. After the PCAP function is enabled and any of the conditions for automatic stopping of

packet capturing is met, the device automatically stops packet capturing. After the **packet capture stop** command is run, the device stops packet capturing immediately regardless of whether the condition for automatic stopping of packet capturing is met.

- Multiple packet capture rules with different names can be defined on the device simultaneously.
- The PCAP function can be enabled only when the CPU usage of the device is less than or equal to 70%.
- To configure a rule for capturing forwarded packets, configure an ACL rule first. In addition, the permit rule needs to be configured for the ACL rule. Otherwise, packets cannot be captured.
- The PCAP configuration cannot be saved.
- The PCAP configuration cannot be synchronized in VSU mode. Packet capture rules configured on the master device will be lost after a master/slave switchover.
- Rules for capturing packets destined for the CPU and forwarded packets cannot be configured simultaneously. For example, if a rule for capturing packets destined for the CPU is configured, a rule for capturing forwarded packets can be configured only after the previous rule is cleared.
- Configuration requirements on the interface for capturing forwarded packets:
  - A physical interface can be configured as the location for capturing packets.
  - An MGMT interface or virtual switch link (VSL) interface cannot be configured as the location for capturing packets.
  - In a VSU environment, non-master device interfaces cannot be configured as the location for capturing packets. An aggregation port of the master device can be configured as the location for capturing packets even if a member interface of the aggregation port is not a master device interface.

1.4.3 Procedure

(1) Create an ACL and configure rules.

a Enter the privileged EXEC mode.

privilege

b Enter the global configuration mode.

config-system terminal

c Configure an ACL rule.

access-control-list *acl-number* { **permit** | **deny** } { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *time-range-name*]

No ACL rule is configured by default.

d Return to the privileged EXEC mode.

end

(2) Configure a packet capture rule.

packet capture rule *rule-name* **filter** { **acl** { *acl-name* | *acl-number* } [**interface** *interface-type interface-number*] { **in** | **out** | **both** } }

No packet capture rule is configured by default.

(3) Configure the name of the file used to save captured packets.

packet capture file { **flash:** | **tmp: | usb0:** } *filename* [**buffer-size** *size*] [**packet-num** *number*] [**timeout** *timeout*]

No file used to save captured packets is configured by default.

(4) Enable the PCAP function.

packet capture start

The PCAP function is disabled by default.

(5) (Optional) Manually disable the PCAP function.

packet capture stop

Packet capturing stops automatically when any of the conditions for stopping packet capturing is met.

(6) (Optional) Clear configured packet capture rules.

cleanup packet capture rule *rule-name*

1.5 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Purpose	Command
Displays packet capture information.	**display packet capture status**

1.6 Configuration Examples

1.6.1 Capturing Packets Destined for the CPU

1. Requirements

A TCP connection to GigabitEthernet 0/1 of the device fails. Capture TCP packets over the interface for 1 minute to analyze the cause.

2. Procedure

Configure a packet capture rule named **tcp** to match packets whose layer-2 protocol type is IPv4 and layer-3 protocol type is TCP.

```
Device> privilege
Device# packet capture rule tcp filter etype ip v4_protocol tcp
```

Configure a packet capture point named **tcppoint**, associate it with packet capture rule **tcp**, and capture packets in the inbound and outbound directions of GigabitEthernet 0/1.

```
Device# packet capture point tcppoint rule tcp location interface gigabitethernet 0/1 both
```

Save captured packets to the **tcp.pcap** file in the flash file system. Condition for automatic stopping of packet capturing: The size of the **tcp.pcap** file reaches 2 MB, the number of captured packets reaches 1,500, or the packet capture duration reaches 1 minute.

```
Device# packet capture file flash:tcp.pcap buffer-size 2 packet-num 1500 timeout 1
```

Enable the PCAP function.

```
Device# packet capture start
```

3. Verification

Run the **display packet capture status** command to display the PCAP configuration.

```
Device# display packet capture status

Capture rules:
  Capture rules tcp:
    Etype: 0x0800
    Protocol: 0x6

Capture points:
  Capture point tcppoint:
    Capture rules: tcp
    Location: Gi0/1
    Direction: all
    Packets captured (all): 0

Capture file:
  Filename: flash:tcp.pcap
  Buffer size: 2 (MB)

Capture Statistic:
  Status: running
  Start time: 2021-4-12 10:00:03 AM
  Timeout: 1 (minutes)
  Packets limit: 1500
  Write file packet count: 0
```

Run the **display packet capture status** command to display the packet capture status after packet capturing ends.

```
Device# display packet capture status

Capture rules:
  Capture rules tcp:
    Etype: 0x0800
    Protocol: 0x6

Capture points:
  Capture point tcppoint:
    Capture rules: tcp
    Location: Gi0/1
    Direction: all
    Packets captured (all): 60
```

```
Capture file:
  Filename: flash:tcp.pcap
  Buffer size: 2 (MB)

Capture Statistic:
  Status: stopped
  Stopped reason: Timeout
  Start time: 2021-4-12 10:00:03 AM
  End time: 2021-4-12 10:01:03
  Timeout: 1 (minutes)
  Packets limit: 1500
  Write file packet count: 60
```

1.6.2 Capturing Forwarded Packets

1. Requirements

Traffic over GigabitEthernet 0/1 of the device is abnormal. Capture forwarded packets over the interface for 10 minutes to confirm whether data streams are forwarded to the device.

2. Procedure

Run the packet capture command to save traffic over GigabitEthernet 0/1 that matches the ACL rule to the **tcp.pcap** file and upload the file to a PC to display the captured data.

Configure an ACL rule.

```
Device> privilege
Device(cfg)# config-system terminal
Device(cfg)# access-control-list 100 permit tcp host 1.1.1.1 any
Device(cfg)# exit
```

Configure a packet capture rule named **rule1**, associate it with the ACL rule, and capture packets in the inbound direction of GigabitEthernet 0/1.

```
Device# packet capture rule rule1 filter acl 100 interface gigabitethernet 0/1 in
```

Save captured packets to the **tcp.pcap** file in the flash file system. Condition for automatic stopping of packet capturing: The packet capture duration reaches 10 minutes.

```
Device# packet capture file flash:tcp.pcap timeout 10
```

Enable the PCAP function.

```
Device# packet capture start
```

3. Verification

Run the **display packet capture status** command to display the packet capture status.

```
Device# display packet capture status

Capture rules:
  Capture rules rule1:
```

```
acl_id: 100
acl_name:
acl_ifx: GigabitEthernet 0/1
Direction: in

Capture file:
   Filename: flash:tcp.pcap
   Buffer size: 2 (MB)

Capture Statistic:
   Status: running
   Start time: 2020-10-15 7:48:41 PM
   Timeout: 10 (minutes)
   Packets limit: 1024
   Write file packet count: 10
```

1 Configuring sFlow

1.1 Introduction

1.1.1 Overview

Sampled flow (sFlow) is a network monitoring technology based on message sampling. It is mainly used for traffic statistics analysis when the network traffic is huge.

sFlow has the following advantages:

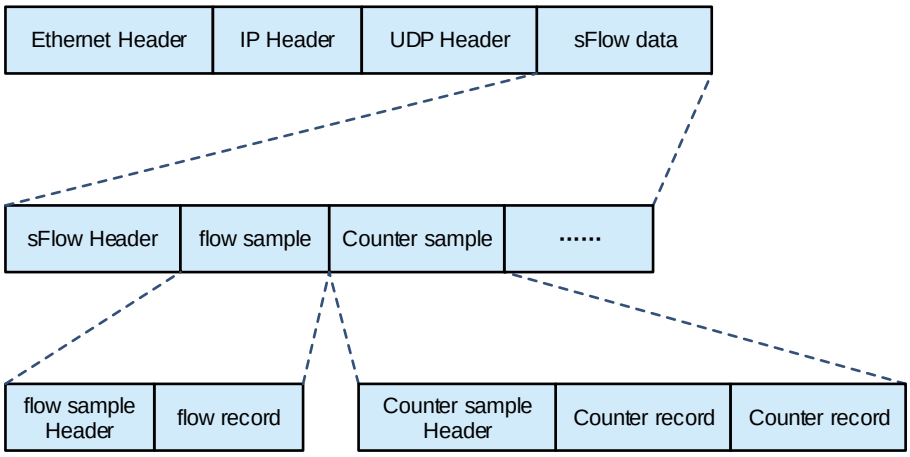
- Accurate: sFlow supports accurate monitoring of traffic on a Gigabit network or a network with higher bandwidth.
- Scalable: One sFlow Collector can monitor thousands of sFlow Agents, and it has high scalability.
- Low cost: sFlow Agent is embedded in a network device, and its cost is low.

1.1.2 Principles

The sFlow system consists of an sFlow Agent embedded in a device and a remote sFlow Collector. The sFlow Agent obtains interface statistics and data from the network device by using specific sampling technologies, encapsulates the information into sFlow packets, and sends them to the sFlow Collector. The sFlow Collector analyzes sFlow packets and displays the analysis results.

- **sFlow Agent**

  An sFlow Agent is embedded in a network device. Generally, one network device serves as an sFlow Agent.



- **sFlow Collector**

  An sFlow Collector can be a PC or server that receives and analyzes sFlow packets from the sFlow Agent. A PC or server installed with the software used for sFlow packet analysis can be regarded as an sFlow Collector.

  The sFlow Agent performs flow sampling and counter sampling, encapsulates sampled data into sFlow packets, and sends them to the sFlow Collector.

  sFlow packets are encapsulated in UDP. Figure 1-1 shows the sFlow packet format.

Figure 1-1 sFlow Packet Format

Note

One sFlow packet may contain one or more flow samples and counter samples.

Figure 1-2 sFlow Header

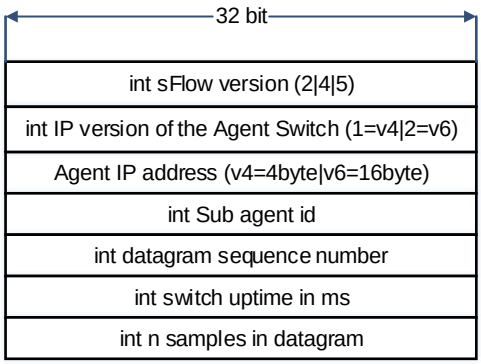


Table 1-1 sFlow Header Description

Field	Description
sFlow version	sFlow version. V2, V4, and V5 are available. Currently, the product supports V5 only.
IP version of the agent/switch	IP address version of the sFlow Agent
Agent IP address	IP address of the sFlow Agent
Sub agent id	Sub agent ID
Datagram sequence number	Serial number of an sFlow packet
Switch uptime	Duration from device startup to the current time

Field	Description
n samples in datagram	Number of samples in an sFlow packet. One sFlow packet contains one or more flow samples and counter samples.

1. Flow sampling

Based on the sampling rate configured for the specified interface, the sFlow Agent device performs flow sampling on packets through this interface, including copying the packet header, extracting the Ethernet header and IP header of each packet, and obtaining the route information of each packet. Then, the sFlow Agent encapsulates the flow sampling result into sFlow packets and sends them to the sFlow Collector for analysis.

Table 1-2 Description of Fields in the Flow Record Part of the sFlow Packet

Field	Description
Raw packet	All or part of the header of the original packet (the extracted length depends on the configuration) is extracted and encapsulated into an sFlow packet and then sent to the Collector.
Extended Switch Data	For an Ethernet packet, the Ethernet header is parsed and encapsulated into an sFlow packet and then sent to the Collector.
Extended VNI Data	VNI ID of a VXLAN packet

2. Counter sampling

In counter sampling, the sFlow Agent periodically obtains the statistics and CPU usage from a specified interface. The sFlow Agent periodically performs interface polling, obtains the statistics from an interface where the counter sampling timer expires, encapsulates the statistics into an sFlow packet, and sends it to the sFlow Collector for analysis.

Table 1-3 Description of Fields in the Counter Sampling Result

Field	Description
Generic Interface Counters	General interface statistics, including basic interface information and general interface traffic statistics
Ethernet Interface Counters	Ethernet-related traffic statistics of an Ethernet interface

1.1.3 Protocols and Standards

- sFlow Version 5: sFlow V5
- RFC 1014: XDR: External Data Representation standard

1.2 Configuration Task Summary

sFlow configuration includes the following tasks:

(1) Configuring Basic Functions of sFlow

(2) (Optional) Configuring Optional Parameters of sFlow

1.3 Configuring sFlow

1.3.1 Configuring Basic Functions of sFlow

1. Overview

- sFlow Agent and sFlow Collector can communicate with each other.
- Traffic flowing through the interface are sampled based on the default sampling rate and sent to the sFlow Collector for analysis.
- Statistics of the interface are periodically sent to the sFlow Collector based on the default sampling interval for analysis.

2. Restrictions and Guidelines

- The forwarding performance of an interface may be affected after flow sampling is enabled.
- To enable the sFlow Collector to analyze the flow sampling results, you must configure the IP address of the sFlow Collector on the sFlow Agent device.
- The sFlow Agent address must be a valid address. That is, the sFlow Agent address cannot be a multicast or broadcast address. It is recommended that the IP address of the sFlow Agent device be used.
- When the **vrf** parameter is configured, the corresponding VRF instance must exist. If you configure a VRF instance for an sFlow Collector address and later remove this VRF instance, the sFlow Collector address will be removed as well.
- When the **oob** parameter is configured, a packet is sent to the sFlow Collector through the management port.
- You can enable flow sampling on an Ethernet interface or a link aggregation.
- **sflow enable**
  - If the direction is not specified, flow sampling is enabled in both the inbound and outbound directions.
  - Counter sampling is enabled when flow sampling is enabled in any direction of an interface.
  - The ACL is supported only in the inbound direction. Configure the ACL before configuring this command.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the sFlow Agent address.

sflow agent { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **interface** [**ipv6**] *interface-type interface-number* }

No sFlow Agent address is configured by default.

(4) Configure the sFlow Collector address.

sflow collector *collector-id* **destination** { *ipv4-address* | **ipv6** *ipv6-address* } *udp-port-number* [**vrf** *vrf-name* | **oob** [**via mgmt** *mgmt-name*]] [**description** *collector-description*] [**source** { **address** *ip-address* | **interface** *interface-type interface-number* }]

No sFlow Collector address is configured by default.

(5) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 2 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 2 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

(6) Configure the ID of the sFlow Collector for flow sampling. Configure at least one of the following task.

- Configure the ID of the sFlow Collector for flow sampling.
  - **sflow flow collector** *collector-id*

  No ID of the sFlow Collector is configured for flow sampling by default.

- Configure the ID of the sFlow Collector for counter sampling.
  - **sflow counter collector** *collector-id*

  No ID of the sFlow Collector is configured for counter sampling by default.

(7) Enable the sampling functions.

sflow enable [{ **ingress** } [{ **ingress** | **egress** } [**acl** { acl-name | acl-number }]]

The sFlow sampling function is disabled by default.

1.3.2 Configuring Optional Parameters of sFlow

1. Overview

You can adjust the data sampling accuracy by modifying relevant parameter attributes of sFlow.

2. Restrictions and Guidelines

- You can run the **sflow collector** command to configure the payload size of an sFlow packet, excluding the Ethernet header, IP header, and UDP header. One or more flow samples and counter samples can be encapsulated to an sFlow packet. When the maximum sFlow packet size is configured, different numbers of sFlow packets may be output after the same number of flow samples or counter samples are processed. If the maximum size is greater than MTU, the output sFlow packet is segmented.
- The **sflow sampling-rate** command is used to configure the global flow sampling rate. This configuration applies to all interfaces. The flow sampling rate may affect the sFlow sampling accuracy. A lower sampling rate indicates a higher accuracy and a larger CPU consumption, which may affect the forwarding performance of the interface.
- You can run the **sflow flow max-header** command to modify the configuration of packets sent to the sFlow Collector. For example, if you are concerned about the IP header of a packet, set the length to 56 bytes. During flow sampling, the first 56 bytes of a sample packet are encapsulated to the sFlow packet.
- This command is used to configure the maximum number of bytes that can be copied from the header of the original packet. The copied content is recorded in the generated sample. The protocol requires byte alignment during packet encapsulation, that is, the actual length of a sent packet is a multiple of 4. Therefore, the length of a collected packet may exceed the configured length. For example, when the maximum length is set to any of 21, 22, 23, and 24, the actual output packet length is 24.
- The **sflow counter interval** command is used to configure the global sFlow counter sampling interval. This configuration applies to all interfaces.
- The **sflow source** command is used to configure the source IP address of output packets. The default source address of output sFlow packets is the local device IP address which is used to ping the destination IP address. If the source interface is specified, the primary address (or the first global IPv6 address if any) of the interface is the source IP address of output packets. If the source interface is not specified, the default source address is used.
- Run the **sflow enhance-mode enable** command to enable enhanced sFlow sampling. In the enhanced mode, sFlow packets are sent by the chip to the Collector server, which caters to requirements for high performance. The enhanced mode applies to the only ingress direction. In the enhanced mode, the sampling packets are not sent from the management port. In the enhanced mode, the length of the chip packets and of the copy packet header is fixed. The globally configured maximum length of the chip packets and of the copy packet header applies to only the software sFlow. In the enhanced mode, the sysuptime encrypted in the sFlow packet header uses the IEEE 1588 Time Of Day (TOD) clock, which is not compliant with the standard protocol but does not affect hardware sFlow packet parsing. In the enhanced mode, the ingress sampling on the sub-interface is not supported. When the enhanced mode is enabled on the line card of a modular device, ingress sampling on the sub-interface of the aggregate interface does not conflict with the enhanced mode based on the line card. If the member port of the aggregate interface is on the line card enabled with the enhanced mode, the member port uses the software sFlow actually. In the enhanced mode, sFlow supports only sample_type 1, namely, the sFlow packet does not contain the VLAN ID of the original packet. When the **sample pool** field in the sFlow packet header is 0, the server software (sflowtrend)

fails to parse packets.

- Run the **sflow tx-use-loop disable** command to configure the device to disable loopback mode for sFlow egress sampling. With loopback mode disabled, egress sampling occupies all mirroring resources, leading to conflicts with other mirroring resource-consuming services such as SPAN and IPFIX. With loopback mode disabled, ingress ACL sampling, ingress snoop sampling, or sFlow enhanced mode is not supported.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Configure the maximum size of the output sFlow packet.

sflow collector *collector-id* **max-datagram-size** *datagram-size*

By default, the maximum size of the output sFlow packet is **1400**.

(4) (Optional) Configure the sFlow flow sampling rate.

sflow sampling-rate *sampling-rate*

The default sFlow flow sampling rate is **8192**.

(5) (Optional) Configure the maximum length of the packet header copied during flow sampling.

sflow flow max-header *sampling-length*

By default, the maximum length of the packet header copied during sFlow flow sampling is **64**.

(6) (Optional) Configure the sampling interval.

sflow counter interval *sampling-interval-time*

The interface where counter sampling is enabled sends the interface statistics to the sFlow Collector at the sampling interval.

(7) (Optional) Configure the source address of output sFlow packets.

sflow source { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **interface** [**ipv6**] *interface-type interface-number* }

By default, the source address of output sFlow packets is the local device IP address which is used to ping the destination IP address.

(8) (Optional) Configure enhanced sFlow sampling.

sflow enhance-mode enable [**device** *devid*] [**slot** *slotid*]

1.4 Enhanced sFlow sampling is disabled by reset. Monitoring

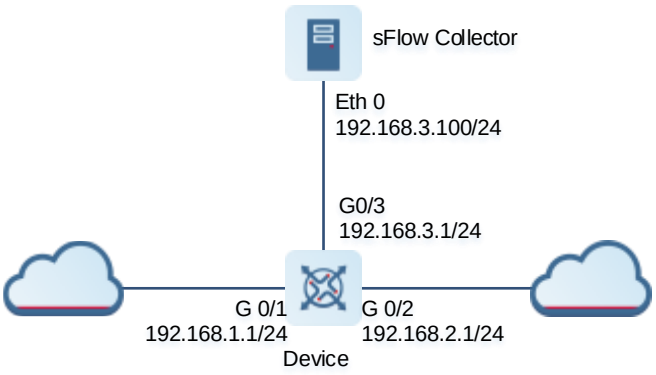
Run the **display** command to check the running status of a configured function to verify the configuration effect.

Table 1-4 sFlow monitoring

Command	Purpose
display sflow	Displays the sFlow configuration.

Command	Purpose
display sflow stats	Displays sFlow packet statistics.

1.5 Configuration Examples



1.5.1 Configuring Basic Functions of sFlow

1. Requirements

Start the device that serves as the sFlow Agent, enable flow sampling and counter sampling on port GigabitEthernet 0/1, monitor the traffic in the 192.168.1.0 network segment, encapsulate the sampling result into sFlow packets at regular intervals or when the buffer is full, and send these packets to the sFlow Collector for traffic analysis.

2. Topology

Figure 1-3 Configuring Basic Functions of sFlow

3. Notes

- Configure the Layer 3 network reachable between the sFlow Agent and the sFlow Collector.
- Configure the sFlow function.

4. Procedure

Configure the Layer 3 network reachable between the sFlow Agent and the sFlow Collector.

```
Device> privilege
Device#config-system terminal
Device(cfg)# interface GigabitEthernet 0/1
Device(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
Device(cfg)# interface GigabitEthernet 0/2
Device(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
Device(cfg)# interface GigabitEthernet 0/3
Device(cfg-if-GigabitEthernet 0/1)# ip address 192.168.3.1 255.255.255.0
```

Configure 192.168.1.1 as the sFlow Agent address.

```
Device(cfg)# sflow agent address 192.168.1.1
```

Configure 192.168.3.100 as the address of sFlow Collector 1, and 6343 as the port number.

```
Device(cfg)# sflow collector 1 destination 192.168.3.100 6343
```

Configure the interface GigabitEthernet 0/1 to output flow samples and counter samples to sFlow Collector 1, and enable sFlow sampling on this interface.

```
Device(cfg)# interface GigabitEthernet 0/1
Device(cfg-if-GigabitEthernet 0/1)# sflow flow collector 1
Device(cfg-if-GigabitEthernet 0/1)# sflow counter collector 1
Device(cfg-if-GigabitEthernet 0/1)# sflow enable
```

5. Verification

Run the **display sflow** command to check whether the command output is consistent with the configuration.

```
Device# display sflow
sFlow datagram version 5
Global information:

1 Configuring IPFIX

Note

This function is not supported by the S6980-64QC, S6520-64CQ, S6580-48CQ8QC, or S6580-24DC8QC.

1.1 Introduction

1.1.1 Overview

With the rapid development of network technology, stream-based technologies are highly valubale in QoS policy configuration, application deployment, and capacity planning. But there is no standard format for flow export.

IP Flow Information Export (IPFIX) is a standard protocol published by IETF for statistics and analysis of network traffic. It standardizes traffic monitoring, uses a single and unified model, and simplifies export structure so that network equipment and servers from different manufacturers can communicate with each other. Therefore, IPFIX is widely applied to network monitoring and analysis, security analysis and attack check, and traffic-based billing.

1.1.2 Basic Concept

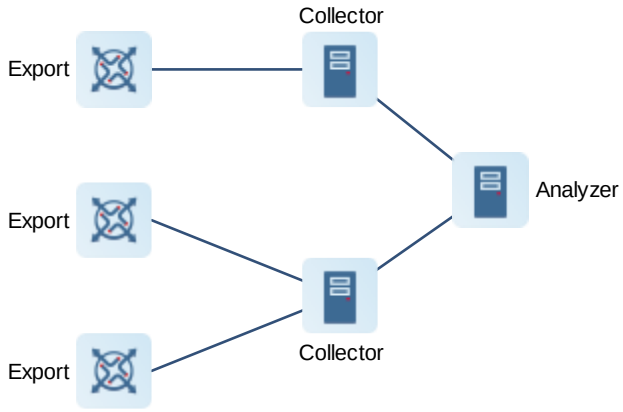
1. IPFIX System

The IPFIX system consists of an Export device, a collector, and an analyzer, as shown in Figure 1-1.

- Export: A network traffic exporter is responsible for analyzing and processing network traffic, extracting eligible traffic statistics, and exporting the statistics to a collector.
- Collector: A network traffic collector is a software specializing in processing traffic records. A collector is responsible for parsing packets received from the exporter and collecting statistics into a database that can be parsed by an analyzer. A collector can receive data from multiple exporters.
- Analyzer: A network traffic analyzer processes the statistical data extracted from a collector and provides a basis for various services. Usually, the analyzer has a graphical user interface to display the analysis results, which is convenient for users to obtain and analyze collected data. An analyzer can receive data from multiple collectors.

In practice, an exporter is a network device, such as a switch, a router and so on. A collector and an analyzer are usually integrated on an IPFIX server, as shown in Figure 1-2.

Figure 1-1 IPFIX System



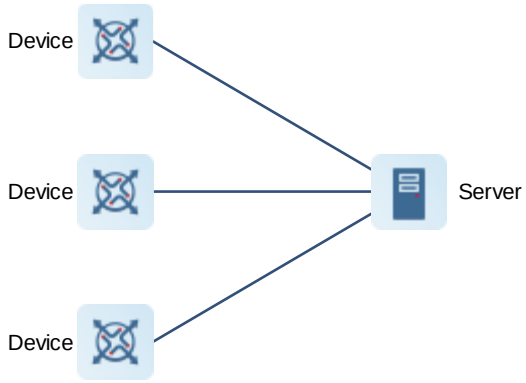


Figure 1-2 IPFIX Networking

2. IPFIX Sampling

When analyzing the traffic of an interface, IPFIX sets the sampling rate on a specified interface to sample the interface traffic and analyze the sample packets.

IPFIX sampling reduces the statistical analysis of packets and the impact on device performance.

You can enable IPFIX to sample the traffic in the inbound or outbound direction of the interface or the traffic in both directions.

3. IPFIX Flow

IPFIX is a flow-based protocol. After sampling traffic, IPFIX processes sampled packets and produces a flow based on the keywords in the packets. The flow is called as an IPFIX flow.

Note

The IPFIX flow here are also called the IPFIX basic flow or primary flow.

A packet consists of a series of attributes, such as the IP address and TCP port ID. Continuous packets that have the same attributes and flow through a detection point within a period of time are called a packet flow. Attributes used to determine whether packets belong to the same flow are called key attributes of the flow. If the key attributes of packets are the same, these packets belong to the same flow. A flow is determined by the common combination of the following key fields:

- Source IP address
- Destination IP address
- Source port ID
- Destination port ID
- L3 protocol type
- ToS
- Packet sampling interface index

These seven key fields determine a unique flow. Packets with the same seven fields belong to the same flow. If a packet has one key field that is different from that of another packet, they belong to different flows. A flow also contains other statistical fields, such as the number of packets, next-hop IP address, and total number of bytes in the flow. Flow information also includes:

- Flow start time
- Flow end time
- Total number of packets
- Total number of bytes
- Flow ingress interface index (for sampling in the ingress direction)
- Flow egress interface index (for sampling in the egress direction)

4. IPFIX Flow Table

A flow table stores measured IP flow information. For an IP packet, the device first looks up the corresponding flow record in the main cache based on key fields of its flow. If the flow record is not configured, the device creates a new flow record, and records the flow information. If the flow record is already configured, the device updates the flow statistics in the flow record, such as the number of packets and the number of bytes in the flow.

Note

The IPFIX flow table here is also called the IPFIX basic flow table or primary flow table, and used to store basic flows.

1.1.3 Principles

The basic functions of an IPFIX device include:

- Flow statistics: Obtains attributes from transmitted packets, and looks up the flow table based on the seven key fields. If no matched record is found in the flow table, the packet belongs to a new flow, and a flow record is created to record the flow statistics. If the packet belongs to an existing flow, the flow statistics is updated.
- Exporting flow information to the server: Sends the flow statistics to the server for analysis at the appropriate time.

Note

The IPFIX specification defines only how an IPFIX device exports flow records, but not how to save and analyze flow records.

1. IPFIX Flow Statistics

IPFIX flow statistics is used to build flow tables, extract information in packets, and count traffic in the network. Figure 1-3 shows the IPFIX flow statistics process.

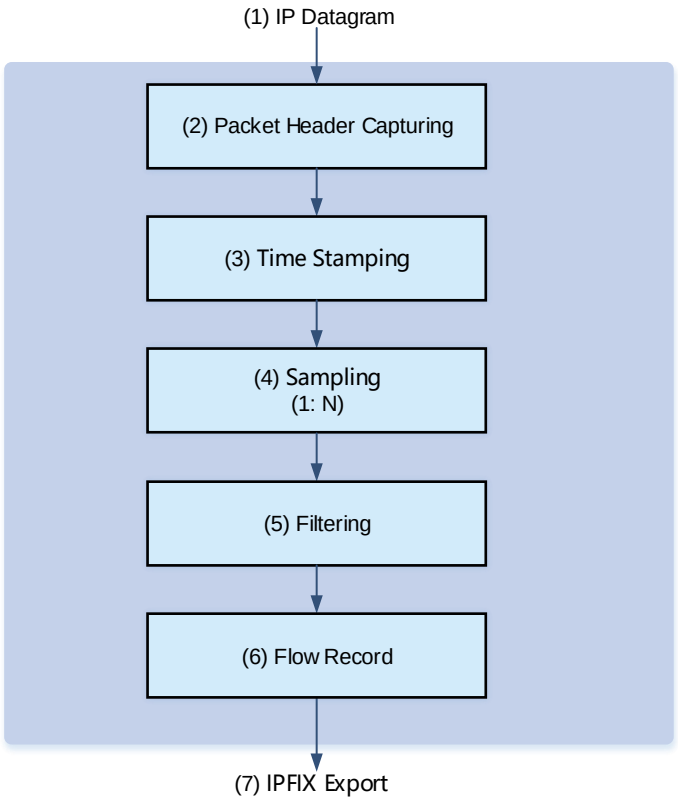
(1) A network device forwards packets normally. A packet is input from one interface and output from another interface after being forwarded.

(2) The IPFIX module of the device extracts the packet-related attributes, such as the IP address and packet length, from the packet header.

(3) It also adds a time stamp to the packet to record the start time, end time, and duration of the flow.

(4) The IPFIX module samples packets according to the sampling rate.

(5) IPFIX filters the packets as needed. IPFIX filters the packets by ACLs to process the specified packets only.



(6) The device save flow information. If the flow record is not configured, the device adds a flow record. If the flow record already is configured, the device updates the flow information, such as the number of packets and the number of bytes.

(7) When the flow ages, the device deletes the flow record and exports the flow record information to the IPFIX server.

Note

Step 4 and step 5 can be reversed, or cycled multiple times. The device can filter packets first and then sample the packets. Or the device can sample the packets first and then filter the packets. After that, the device can also sample the filtered packets again.

Figure 1-3 Flowchart of IPFIX Flow Statistics

2. IPFIX Flow Aging

Flow records are deleted from the flow table under certain circumstances. Before deletion, the statistical information is exported to the server. This process is called flow aging. Flow aging prevents the flow table from increasing indefinitely, while ensuring that the IPFIX server can obtain flow statistics. An IPFIX Flow has the following three types of aging.

- Inactive flow aging
  - When no packets of a flow is detected within a certain period of time (inactive aging time), the flow should be aged and exported. The device exports the flow information to the server. This is called inactive flow aging.
- Active flow aging
  - When packets of a flow is continuously collected for a long time, its information cannot be recorded indefinitely for saving resources. You can configure a period (active aging time), after which the flow should be aged and the device exports the flow information to the server. This is called active flow aging.
- Mandatory flow aging
  - When the IPFIX mode changes or the template configuration changes, a new template is used to analyze and collect packets and create new flow records, and the existing flow records are forced to age.
  - When the flow forced aging command is executed, related flow records are forced to age. The IPFIX

flow are not automatically aged because it does not meet the aging conditions, but you want to check the latest flow statistics. Or the flow cannot be automatically aged due to an exception of the flow statistics function. In this two cases, you can use the command line to force the flow to age.

Note

When a flow record is aged and deleted, and a packet with the same seven key fields as the aged flow is immediately received, no matched flow record exists in the flow table. Therefore, the packet is processed as a new flow, and a new flow record is created.

3. IPFIX Flow Export

IPFIX flow export means that aged flow records are exported to the IPFIX server for analysis.

IPFIX uses a template to transmit flow records. A template defines the format of data records, including a series of bit fields. Each bit field includes the data type and data length of the bit field.

- When an aged flow record needs to be exported to the server, the information of the flow record is encapsulated into a UDP or TCP packet based on the format defined in IPFIX, sent to the configured server, and processed by the collector on the server.
- When sending flow records, create a template containing the record format and send the template to the server. After receiving the template, the server learns the format of the subsequent flow records based on the template, and interprets the subsequent IPFIX flow records based on the flow record format defined in the template. The template and flow record information can co-exist in the same packet, or a packet can be accompanied by multiple flow records or templates.
- The IPFIX device can send only the key attributes of a flow, and the software on the server can also extract only the useful flow attributes from flow records, and ignore other flow attributes. For example, a device may determine that the TCP flag can be used to analyze network security, and therefore include the TCP flag in the flow export information. However, some server software support only traffic analysis, but not network analysis. Therefore, the software can ignore the TCP flag sent by the device. There is no compatibility issue between the device and the server. Similarly, when the network device expands a new field (attribute) in the flow record, it only needs to recreate the corresponding template. The server can interpret the flow record information based on the new template, without upgrading the server software. This greatly improves the scalability.

4. Flexible IPFIX Flow Sampling

A template and flow record can be selected based on configurations. The concept of flexible sampling is introduced based on the basic sampling function of IPFIX. You can flexibly configure keywords of the flow record and customize the template based on your requirements.

1.1.4 Protocols and Standards

- RFC 5470: Architecture for IP Flow Information Export
- RFC 5472: IP Flow Information Export (IPFIX) Applicability
- RFC 5103: Bidirectional Flow Export Using IP Flow Information Export (IPFIX)
- RFC 5153: IP Flow Information Export (IPFIX) Implementation Guidelines
- RFC 5102: Information Model for IP Flow Information Export

- RFC 5101: Specification of the IP Flow Information Export (IPFIX) Protocol for the Exchange of IP Traffic Flow Information
- RFC 3917: Requirements for IP Flow Information Export
- RFC 3954: Cisco Systems NetFlow Services Export Version 9

1.2 Configuration Task Summary

IPFIX configuration includes the following tasks:

(1) Configuring IPFIX Flow Statistics

(2) Configuring IPFIX Flow Export

(3) (Optional) Configuring Parameters of the IPFIX Flow TableConfiguring Flexible Sampling

1.3 Configuring IPFIX Flow Statistics

1.3.1 Overview

By configuring IPFIX flow statistics, you can obtain statistics of the following types of packets in the network:

- IP packets
- IPv6 packets
- MPLS packets

1.3.2 Restrictions and Guidelines

- Assume that the sampling function is configured under a link aggregation and link aggregation loading balancing is not configured. If the member ports of a link aggregation are not on the same line card, and packets with the same seven key attributes are collected from different line cards, the number of IPFIX packets received by the server from the link aggregation within the unit aging time is the same as the total number of IPFIX packets received by the member ports from different line cards. In addition, the flow aging time of the AP is the same as that on a single line card.
- If IPFIX ACL-based sampling is enabled on a port, the ACL is used to match the IP packets; otherwise, sampling does not take effect on the port. If IPFIX sampling based on the IPv4 ACL is enabled on a port, the ACL is used to match the IPv4 packets. If IPFIX sampling based on the IPv6 ACL is enabled on a port, the ACL is used to match the IPv6 packets. For more information about ACL configuration, see *Configuring ACL*.
- When configuring statistics about the outer VXLAN packets, If the inner and outer VXLAN packets are of different types, for example, one is an IPv4 packet and the other is an IPv6 packet, the inner and outer packets cannot be sampled at the same time. In this case, you can configure either sampling of inner IPv4 and IPv6 packets or sampling of outer IPv4 and IPv6 packets.
- The **netflow-sampling-map** command is configured in global configuration mode. You can enter the sampler configuration mode, and then configure the sampler. If you enter the sampler mode, but do not configure any sampler, the sampler configuration mode is not displayed when you run **display current-config**.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Enable global sampling of VXLAN outer packets.

{ **ip** | **ipv6** } **netflow vxlan out**

VXLAN inner packets are sampled by default.

(4) Configure a sampler map (sampling rule table).

netflow-sampling-map *sampler-map-name*

No sampler map is configured by default.

(5) Configure a random sampler.

mode random one-out-of *packet-interval*

No random sampler is configured by default.

(6) Exit the IPFIX sampler configuration mode.

exit

(7) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(8) Enable IPFIX in the ingress direction of an interface.

(IPv4 main mode)

ip netflow ingress

(IPv6 main mode)

ipv6 netflow ingress

By default, IPFIX is disabled in the ingress direction of an interface.

(9) Enable IPFIX in the egress direction of an interface.

(IPv4 main mode)

ip netflow egress

(IPv6 main mode)

ipv6 netflow egress

By default, IPFIX is disabled in the egress direction of an interface.

(10) Apply a sampler to an interface.

(IPv4 main mode)

netflow-sampling *sampler-map-name* [**egress**] [**acl** *acl-name* | **acl** *acl-number* }]

(IPv6 main mode)

ipv6 netflow-sampling *sampler-map-name* [**egress**] [**acl** { *acl-name* | **acl** *acl-number* }]

No sampler is applied to an interface by default.

1.4 Configuring IPFIX Flow Export

1.4.1 Overview

This section describes how to send the aged flow records to the server.

1.4.2 Restrictions and Guidelines

- The configured IPFIX server address must be reachable; otherwise, it cannot be displayed after the **display ip netflow export** or **display ipv6 netflow export** command is executed.
- If the type of interface used for exporting flow records is changed from port to VLAN and the interface is an SVI, you also need to configure IPFIX on the VLAN interface.
- Packets can be exported to a maximum of two IPFIX servers.
- You can configure an IPv4 or IPv6 address as the server address for IPv4 or IPv6 IPFIX. When the configured source port and the IPFIX server are not in the same VRF, the IP address of the specified source port cannot be used as the source IP address for packet transmission. The system obtains the best-matched local address as the source address based on the server address. The management port has a default VRF. If you want to use the management port to send packets, configure the source port and the management port in the same VRF.
- The **ip netnetflow-export template** and **ipv6 netnetflow-export template** commands are used to configure the template retransmission frequency. The IPFIX server parses the IPFIX packets based on the template. When the device just starts to use the IPFIX function, the template retransmission frequency can be decreased, so that the IPFIX server can receive the IPFIX template in a short time. For example, you can set the template retransmission frequency to 1 minute.
- The **ip netnetflow-export source** and **ipv6 netnetflow-export source** commands are used to configure the source IP address of an exported packet. By default, the source address of an exported IPFIX packet is the local device IP address which is used to ping the destination IP address. If the source interface is specified, the primary address (or the first global IPv6 address if any) of the interface is the source IP address of the exported IPFIX packet.
- If the source interface is not specified, the default source address is used. You can configure an IPv4 or IPv6 address, or both as the IPFIX server address. If you specify the source interface and configure an IPv6 or IPv4 address as the IPFIX server address, make sure that an IPv6 or IPv4 address is configured for the source interface. Otherwise, the system obtains the best-matched local address as the source address based on the server address. Make sure that the source interface and the IPFIX server are in the same VRF; otherwise, the system obtains the best-matched local address as the source address based on the server address.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the IPFIX server address.

(IPv4 main mode)

ip netnetflow-export target { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } *por-number* [**vrf** *vrf-name* | **oob** [**via mgmt** *mgmt-name*]

(IPv6 main mode)

ipv6 netnetflow-export target { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } *por-number* [**vrf** *vrf-name* | **oob** [**via mgmt** *mgmt-name*]

By default, no IPFIX flow record is exported to the server.

(4) (Optional) Configure the exported packet format.

(IPv4 main mode)

ip netnetflow-export version { **9** | **10** }

(IPv6 main mode)

ipv6 netnetflow-export version { **9** | **10** }

By default, the exported packet format is version 10.

(5) (Optional) Configure the source interface for packet export.

(IPv4 main mode)

ip netnetflow-export source *interface-type interface-number*

(IPv6 main mode)

ipv6 netnetflow-export source *interface-type interface-number*

By default, no destination address and port are configured, and the local interface address that best-matches the server address is adopted.

(6) (Optional) Configure parameters related to the export template.

(IPv4 main mode)

ip netnetflow-export template { **model** *model-id* | **options** { **export-stats** | **refresh-rate** *refresh-rate* | **timeout** *time* } | **refresh**-**rate** *refresh-rate* | **timeout** *timeout* }

(IPv6 main mode)

ipv6 netnetflow-export template { **model** *model-id* | **options** { **export-stats** | **refresh-rate** *refresh-rate* | **timeout** *time* } | **refresh**-**rate** *refresh-rate* | **timeout** *timeout* }

By default, the template retransmission frequency is 20 packets in 10 minutes.

1.5 Configuring Parameters of the IPFIX Flow Table

1.5.1 Overview

The parameters adjust the number of cache entries and the aging time of flow records in the IPFIX flow table.

1.5.2 Restrictions and Guidelines

- If the global IPFIX function is enabled, the modification of cache entries does not take effect immediately. To make the modification effective, you need to reconfigure the global IPFIX function or restart the device.
  a To disable the global IPFIX function, run the **unset ip netflow ingress** or **unset ip netflow egress** command.
  b To restart the IPFIX flow statistics function, run the **ip netflow ingress** command.
- IPv4 and IPv6 share the capacity for cache entries.
  - If only IPv4 or IPv6 packet sampling is enabled, the maximum number of IPv4 or IPv6 cache entries can reach the maximum capacity.
  - If both IPv4 and IPv6 packet sampling are enabled, the maximum number of IPv4 and IPv6 cache entries in total cannot exceed the maximum capacity.
- To modify the aging time of an active or inactive entry, run the **ip netflow-cache aging** command.
  - Modification of the aging time affects the duration that a flow record exists in the flow table. A longer aging time indicates that a flow record exists longer in the flow table, and it takes longer for the IPFIX server to receive the flow record information.
  - To display the flow information in real time on the server, you are advised to set the aging time to a small value. For example, set the aging time of an active entry to 1 minute.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Configure the number of cache entries in the flow table.

(IPv4 main mode)

ip netflow-cache entries *number*

(IPv6 main mode)

ipv6 netflow-cache entries *number*

(4) (Optional) Configure the aging time of a flow record.

(IPv4 main mode)

ip netflow-cache aging { **active** *active-time* | **inactive** *inactive-time* }

(IPv6 main mode)

ipv6 netflow-cache aging { **active** *active-time* | **inactive** *inactive-time* }

By default, the aging time is **30** minutes for an active entry and **15** seconds for an inactive entry.

1.6 Configuring Flexible Sampling

Note

The Flexible Sampling command is not supported by the S6980-64QC, S6580-48CQ8QC, and S6580-24DC8QC.

1.6.1 Overview

This section describes how to flexibly create flow entries and construct a template.

1.6.2 Restrictions and Guidelines

To enable the flow-key function, ensure that the IPFIX function is already enabled.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the netflow-key configuration mode.

(IPv4 main mode)

ip netflow-key

(IPv6 main mode)

ipv6 netflow-key

By default, the flow-key function is disabled.

(4) Configure the flow table matching conditions for flexible sampling.

match { **flow direction** | **interface** { **input** | **output** } | **ip** { **protocol** | **tos** } | **ipv4** { **destination-address** | **source-address** [**mask**] } } | **transport** { **destination-port** | **source-port** } | **vlan** }*

(5) Enter the template-key configuration mode.

(IPv4 main mode)

ip template-key

(IPv6 main mode)

ipv6 template-key

By default, the template-key function is disabled.

This command can be configured only after the collect function is enabled.

(6) Configure parameters of the IPFIX template for flexible sampling.

collect { **counter** { **bytes** | **packets** } | **timestamp sys-uptime** { **first** | **last** } | **transport tcp flags** }

By default, no parameter of the IPFIX template is configured for flexible sampling.

(7) Enable the flow-key and template-key modes.

enabled

In flow-key configuration mode, this command is used to enable the flexible sampling function. In template-key configuration mode, this command is used to enable the flexible template function.

1.7 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

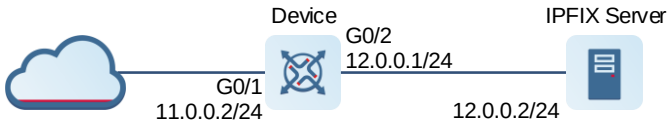
Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-1 IPFIX monitoring

Command	Purpose
cleanup { **ip** | **ipv6** } **netflow stats**	Clears the flow table information.
display { **ip** | **ipv6** } **netflow cache**	Displays the IPFIX flow table information.
display { **ip** | **ipv6** } **netflow export**	Displays the IPFIX server information.
display ip netflow interface	Displays the IPFIX configurations of an interface.

1.8 Configuration Examples



1.8.1 Configuring the IPv4 IPFIX Function

1. Requirements

The device is connected to the network through GigabitEthernet 0/1, and needs to monitor and analyze the IPv4 traffic passing through GigabitEthernet 0/1. Therefore, enable the IPv4 IPFIX function on the device, and configure the IPFIX sampling function in the ingress direction of GigabitEthernet 0/1.

2. Topology

Figure 1-4 Configuring the IPv4 IPFIX Function

3. Notes

- Configure the IP address of the device so that the device and the IPFIX server are mutually reachable at layer 3.
- Configure the sampling function.

- Export the IPv4 IPFIX flow records.
- Configure parameters of the IPv4 IPFIX flow table.

4. Procedure

(1) Configure the IP address of the device.

a. Set the IPv4 address of GigabitEthernet 0/1 to 11.0.0.2/24.

```
Device> privilege
Devcie# config terminal
Device(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-GigabitEthernet 0/1)# ip address 11.0.0.2 255.255.255.0
Device(cfg-if-GigabitEthernet 0/1)#exit
```

b. Set the IPv4 address of GigabitEthernet 0/2 to 12.0.0.1/24.

```
Device(cfg)# interface gigabitEthernet 0/2
Device(cfg-if-GigabitEthernet 0/2)# ip address 12.0.0.1 255.255.255.0
Device(cfg-if-GigabitEthernet 0/2)#exit
```

(2) Configure the IPFIX sampling function.

a. Configure a sampler map "zxw".

```
Device(cfg)#netflow-sampling-map zxw
```

b. Set the random sampling rate to 4096.

```
Device(cfg-sampler)#mode random one-out-of 4096
Device(cfg-sampler)#exit
```

c. Apply the sampler map to GigabitEthernet 0/1.

```
Device(cfg)# interface gigabitEthernet 0/1
Devcie(cfg-if-GigabitEthernet 0/1)#netflow-sampling zxw
```

d. Enable IPv4 packet sampling in the ingress direction of GigabitEthernet 0/1.

```
Devcie(cfg-if-GigabitEthernet 0/1)#ip netflow ingress
Devcie(cfg-if-GigabitEthernet 0/1)#exit
```

(3) Export the IPv4 IPFIX flow records to the server.

a. Export the flow records to the server with the IPv4 address 12.0.0.2 and port ID 9996.

```
Devcie(cfg)# ip netflow-export target 12.0.0.2 9996
```

b. Configure the IP address of GigabitEthernet 0/1 as the source IP address for packet export.

```
Devcie(cfg)# ip netflow-export source gigabitEthernet 0/2
```

c. Set the template retransmission frequency to 40 minutes.

```
Devcie(cfg)# ip netflow-export template timeout-rate 40
```

d. Configure the export option **export-stats**.

```
Devcie(cfg)# ip netflow-export template options export-stats
```

e. Set the export option **refresh-rate** to 35 packets.

```
Devcie(cfg)# ip netflow-export template options refresh-rate 35
```

f. Set the export option **timeout-rate** to 45 minutes.

```
Device(cfg)# ip netflow-export template options timeout-rate 45
```

g. Export packets using the standard format of Netflow V9.

```
Devcie(cfg)# ip netflow-export version 9
```

(4) Configure parameters of the IPv4 IPFIX flow table.

a. Set the number of cache entries in the flow table to 32768.

```
Device(cfg)# ip netflow-cache entries 32768
```

b. Set the aging time of an active entry to 2 minutes.

```
Device(cfg)# ip netflow-cache aging active 2
```

c. Set the aging time of an inactive entry to 20 seconds.

```
Device(cfg)# ip netflow-cache aging inactive 20
```

5. Verification

Run the **ping** command to verify L3 reachability between the device and the IPFIX server.

```
Device# ping 12.0.0.2
Sending 5, 100-byte ICMP Echoes to 12.0.0.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/2 ms.
```

Run the **display ip netflow export** command to display the IPFIX server information.

```
Devcie# display ip netflow export

IPV4 main Cache:
        Exporting flows to 12.0.0.2 (9996)
        Exporting using source IP address 12.0.0.1
        Version 9 flow records
        IPV4 Template ID = 266
        IPV4 Template ID = 292
                Template timeout = 40 Minute(s)
                Template refresh rate = 30
        0 flows exported in 0 udp datagrams
        0 flows failed to export
        0 messages failed to export
```

Run the **display ip netflow interface** command to display the IPFIX configurations of the interface.

```
Devcie# display ip netflow interface
interface GigabitEthernet0/1
  netflow-sampling zxw
  ip netflow ingress
```

Run the **display ip netflow cache** command to display the information about the IPv4 IPFIX flow table.

```
Devcie# display ip netflow cache
IPFIX CACHE(slot-0/1):
        IPV4 Flow Switching Cache, 0 bytes
        0 active, - inactive, 0 added
```

```
            0 flow alloc failures
            0 displayed
            Exporting flows to 12.0.0.2 (9996)

1.8.2 Configuring the IPv6 IPFIX Function

1. Requirements

The device is connected to the network through GigabitEthernet 0/1, and needs to monitor and analyze the IPv6 traffic passing through GigabitEthernet 0/1. Therefore, enable the IPv6 IPFIX function on the device, and configure the IPFIX sampling function in the ingress direction of GigabitEthernet 0/1.

2. Topology

Figure 1-5 Configuring the IPv6 IPFIX Function

3. Notes

- Configure the IP address of the device so that the device and the IPFIX server are mutually reachable at layer 3.
- Configure the sampling function.
- Export the IPv6 IPFIX flow records.
- Configure parameters of the IPv6 IPFIX flow table.

4. Procedure

(1) Configure the IP address of the device.

a. Set the IPv6 address of GigabitEthernet 0/1 to 11::1/64.

```
Device> privilege
Devcie# config-system terminal
Device(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-GigabitEthernet 0/1)# ipv6 address 11::1/64
Device(cfg-if-GigabitEthernet 0/1)#exit
```

b. Set the IPv6 address of GigabitEthernet 0/2 to 12::1/64.

```
Device(cfg)# interface gigabitEthernet 0/2
Device(cfg-if-GigabitEthernet 0/2)# unset switch-port
Device(cfg-if-GigabitEthernet 0/2)# ipv6 address 12::1/64
Device(cfg-if-GigabitEthernet 0/2)#exit
```

(2) Configure the IPFIX sampling function.

a. Configure a sampler map "zxw".

```
Device(cfg)#netflow-sampling-map zxw
```

b. Set the random sampling rate to 4096.

```
Device(cfg-sampler)#mode random one-out-of 4096
Device(cfg-sampler)#exit
```

c. Apply the sampler map to GigabitEthernet 0/1.

```
Device(cfg)# interface gigabitEthernet 0/1
Devcie(cfg-if-GigabitEthernet 0/1)#ipv6 netflow-sampling zxw
```

d. Enable IPv6 packet sampling in the ingress direction of GigabitEthernet 0/1.

```
Devcie(cfg-if-GigabitEthernet 0/1)#ipv6 netflow ingress
Devcie(cfg-if-GigabitEthernet 0/1)#exit
```

(3) Export the IPv6 IPFIX flow records to the server.

a. Export the flow records to the server with IPv6 address 12::2 and port ID 9996.

```
Devcie(cfg)# ipv6 netflow-export destination 12::2 9996
```

b. Configure the IP address of GigabitEthernet 0/1 as the source IP address for packet export.

```
Devcie(cfg)# ipv6 netflow-export source gigabitEthernet 0/2
```

c. Set the template retransmission frequency to 40 minutes.

```
Devcie(cfg)# ipv6 netflow-export template timeout-rate 40
```

d. Configure the export option **export-stats**.

```
Devcie(cfg)# ipv6 netflow-export template options export-stats
```

e. Set the export option **refresh-rate** to 35 packets.

```
Devcie(cfg)# ipv6 netflow-export template options refresh-rate 35
```

f. Set the export option **timeout-rate** to 45 minutes.

```
Device(cfg)# ipv6 netflow-export template options timeout-rate 45
```

g. Export packets using the standard format of Netflow V9.

```
Devcie(cfg)# ipv6 netflow-export version 9
```

(4) Configure parameters of the IPv6 IPFIX flow table.

a. Set the number of cache entries in the flow table to 32768.

```
Device(cfg)# ipv6 netflow-cache entries 32768
```

b. Set the aging time of an active entry to 2 minutes.

```
Device(cfg)# ipv6 netflow-cache timeout active 2
```

c. Set the aging time of an inactive entry to 20 seconds.

```
Device(cfg)# ipv6 netflow-cache timeout inactive 20
```

5. Verification

Run the **ping** command to verify L3 reachability between the device and the IPFIX server.

```
Device# ping 12::2
Sending 5, 100-byte ICMP Echoes to 12::2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/2 ms.
```

Run the **display ipv6 netflow export** command to display the IPFIX server information.

```
Devcie# display ipv6 netflow export

IPV6 main Cache:
        Exporting flows to 12::2 (9996)
        Exporting using source IP address 30::1
        Version 9 flow records
        IPV6 Template ID = 5000
        IPV6 Template ID = 5026
                Template timeout = 40 Minute(s)
                Template refresh rate = 30
        0 flows exported in 0 udp datagrams
        0 flows failed to export
        0 messages failed to export
```

Run the **display ip netflow interface** command to display the IPFIX configurations of the interface.

```
Devcie# display ip netflow interface
interface GigabitEthernet0/1
  ipv6 netflownetflow-sampling zxw
  ipv6 netflow ingress
```

Run the **display Ipv6 netflow cache** command to display the information about the IPv6 IPFIX flow table.

```
Devcie# display ipv6 netflow cache
IPFIX CACHE(slot-0/1):
        Ipv6 netflow Switching Cache, 0 bytes
        0 active, - inactive, 0 added
        0 flow alloc failures
        0 displayed
        Exporting flows to 12::2 (9996)
```

```
            0 ipv6 netflows exported in 0 udp datagrams, 0 failed
            And Exporting flows to 0.0.0.0 (0)
            0 ipv6 netflows exported in 0 udp datagrams, 0 failed
            Last cleanup of statistics 0 Days 00:00:18

SrcIf                           SrcIPAddress        DstIf                           DstIPAddress

1 Configuring the Function of Displaying Device Restart Reasons

1.1 Introduction

1.1.1 Overview

Diversified availability detection functions are implemented to ensure the availability of all system functions. While these functions ensure system availability by killing target processes or resetting cards, the following risks arise: The self-recovery behavior cannot be tracked or controlled in a unified manner. When a process is killed or a card is restarted, the service that triggers this self-recovery behavior cannot be located. If a process is frequently killed or a card is frequently reset due to the logic failure of a detection function, more serious system failure may occur. To solve these problems, a component is needed to track and control the service self-recovery behaviors of the system in a unified manner. The secondary protect and self-healing (PSH) module provides a method to check the device restart reason on the CLI interface. When a device restarts, you can view the device restart reasons by using the command provided by the PSH module, eventually improving the availability and quality of the device.

1.1.2 Principles

The PSH module collects information about the process that triggers restart of the device before the device restarts, and saves the restart reason locally. You can either run a command on a device to view the locally stored restart reason of the device, or run a command on the primary device of a cluster to view the restart reasons of all devices in the cluster.

1.2 Restrictions and Guidelines

The PSH module records only self-healing events of the system, and service components cannot use it as an internal logging tool to record logs of the running process in a log file.

1.3 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring of the Function of Displaying Device Restart Reasons

Command	Purpose
display reboot-reason [**all**]	Displays the device restart reason.

1 Configuring NTP

1.1 Introduction

1.1.1 Overview

Network Time Protocol (NTP) is an application-layer protocol that enables network devices to synchronize time. NTP enables network devices to synchronize time with their servers or clock sources and provides high-precision time correction (the difference from the standard time is smaller than one millisecond in a LAN and smaller than decades of milliseconds in a WAN). In addition, NTP can prevent attacks by using encrypted acknowledgment. NTP is implemented based on the transport protocol, User Datagram Protocol (UDP), and the UDP port used is 123.

Currently, Ruijie devices can be used both as NTP clients and NTP servers. In other words, a Ruijie device can synchronize time with a time server, or act as a time server to provide time synchronization for other devices. When a device is used as a server, it supports only the unicast server mode.

1.1.2 Principles

1. Basic Concepts

- NTP server

  A device uses a local clock as the reference clock source to provide time synchronization for other devices in the network.

- NTP client

  A device synchronizes time with an NTP server in the network.

- **Stratum**

  In NTP, "stratum" is used to describe the hops from a device to an authority clock source. An NTP server whose stratum is 1 has a directly connected atomic clock or radio controlled clock; an NTP server whose stratum is 2 obtains time from the server whose stratum is 1; an NTP server whose stratum is 3 obtains time from the server whose stratum is 2; and so on. Therefore, clock sources with lower stratum have higher clock precision.

- Hardware Clock

  A hardware clock operates based on the frequency of the quartz crystal resonator on a device and is powered by the device battery. After the device is shut down, the hardware clock continues running. After the device is started, the device obtains time information from the hardware clock as the software time of the device.

2. NTP Principles

As shown in Figure 1-1, a client exchanges NTP packets with a server to implement time synchronization.

(1) The client sends a time synchronization request packet to all servers every 64 seconds.

(2) After receiving response packets from the servers, the client filters these response packets, and synchronizes time with an optimum server.

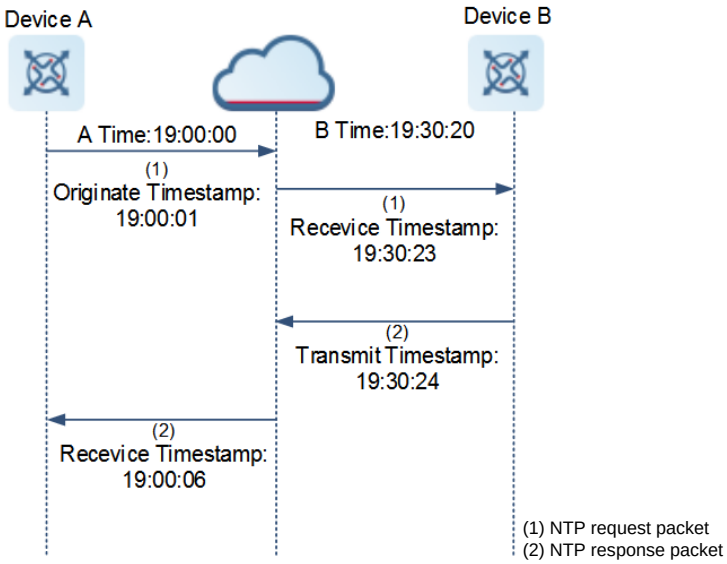
3. NTP Working Process

As shown in Figure 1-1, device B (B for short) acts as an NTP reference clock source, and device A (A for short) acts as an NTP client that synchronizes time with B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

(1) A sends an NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in **Originate Timestamp**.

(1) After a network delay of 2s, the local time (T1) when B receives the request packet is 19:30:23 and is filled in **Receive Timestamp**.

(2) B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in **Transmit Timestamp**.



(3) After a network delay of 2s, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

a A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula ((T1-T0)+(T2-T3))/2.

b A obtains the packet round-trip delay of 4 seconds between A and B by using the formula (T3-T0)-(T2-T1).

Figure 1-1 NTP Principles

- NTP working mode
  - External clock reference mode: In this mode, a device acts as both a server and a client. If receiving time synchronization requests from other clients, the device must synchronize time with the specified server, and then provide the time synchronization service for the clients only after successful synchronization with the specified server.
  - Local clock reference mode: In this mode, a device uses the default local clock as the reliable clock source and provides the time synchronization service directly for other clients.

4. NTP Security Mechanism

To prevent malicious damage to the time server and improve the security of time synchronization, NTP provides security authentication and access control functions.

- Security authentication

  NTP uses the authentication mechanism to check whether the time synchronization information really comes from the announced server and check the information return path to provide an anti-interference protection mechanism.

  An NTP client and an NTP server are configured with the same key. When sending request and response packets, a device calculates the hash values of the packets by using the MD5 algorithm based on the specified key and NTP packet content, and fills the hash values into the packet authentication information. The receiving device checks whether the packets are sent by a trusted device or modified based on the authentication information.

- NTP access control using the kiss-o-death (KoD) packet

  NTP provides a minimum security measure by using an ACL. Normally, the denial-of-service packets are discarded, and there is no operation other than incrementing the statistics counter. Sometimes a more proactive response is required. For example, the client is explicitly requested to stop sending packets to the server and to leave a message for the system operator. Therefore, open-source NTP proposes a KoD packet, which can be used to respond to special processing of the client when access control is configured on the server.

  The format of a KoD packet is the same as that of a common NTP packet, except that the **Leap Indicator** field is set to **clock unsynchronized**, the **Stratum** field is set to **0**, and the **Reference ID** field is set to a 4-byte ASCII code. The code is "RATE" if the limited flag is set and the rate threshold is exceeded. After the NTP client receives the KoD packet with the code "RATE", it limits the rate according to the minimum interval specified in the packet.

1.1.3 Protocols and Standards

- RFC 1305: Network Time Protocol (Version 3)
- RFC 5905: Network Time Protocol (Version 4)

1.2 Restrictions and Guidelines

- You cannot configure both the NTP and SNTP functions on the same device.
- Only Layer 3 Ethernet interfaces or link aggregations support NTP.
- To ensure accuracy of time synchronization, avoid configuring two or more clock sources whenever possible to prevent clock flapping.
- You can run the **ntp service disable** command to disable the NTP server function so that the device acts only as a client. This command cannot be configured together with **ntp master**.

1.3 Configuration Task Summary

NTP configuration includes the following tasks:

(1) (Optional) Configuring NTP Security Authentication

(2) Configuring NTP in Client/Server Mode

(3) (Optional) Configuring NTP-Related Parameters

(4) (Optional) Configuring NTP Access Control

1.4 Configuring NTP Security Authentication

1.4.1 Overview

- Synchronizing time from a trusted reference clock source: Use a device as a client to synchronize time only from a trusted external reference clock source to the local clock.
- Providing time synchronization for a trusted device: Use the local clock of a device as the NTP reference clock source to provide time synchronization for only a trusted device.

1.4.2 Restrictions and Guidelines

- The authentication keys of the client and server must be the same.
- To provide time synchronization for a trusted device, you must specify a trusted authentication key by using the key ID. Only one trusted key can be configured. The specified authentication key must be consistent with that of the trusted device.
- To synchronize time with a trusted reference clock source, you must specify a trusted authentication key by using the key ID. Each trusted reference clock source is mapped to an authentication key. The authentication keys must be consistent with the keys of trusted reference clock sources.
- By default, a client does not use a global security authentication mechanism. If no security authentication mechanism is used, communication will not be encrypted. A global security indicator is not enough to imply that the communication between the client and server is implemented in an encrypted manner. Other global keys and an encryption key for the server must also be configured for initiating encrypted communication between the client and server.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a global security authentication mechanism for NTP.

ntp-service authenticate

(4) Configure a global authentication key for NTP.

ntp-service auth-algorithm-key *authentication-key-id* **md5** *authentication-key-string* [**0** | **7**]

The NTP global authentication mechanism is disabled by default.

(5) (Optional) Configure a globally trusted key ID for NTP.

ntp-service trust *trusted-key-id*

(6) (Optional) Configure an authentication key ID for an external reference clock source.

ntp-service server [**oob** | **vrf** *vrf-name*] { *ipv4-address* | *ipv6-address* | *server-hostname* | **ip** *domain* | **ipv6** *domain* } [**key** *keyid* | **port** *port-number* | **prefer** | **source** *interface-type interface-number* | **version** *version*]* [**via** *mgmt-name*]

By default, no authentication key ID is configured for an external reference clock source.

1.5 Configuring NTP in Client/Server Mode

1.5.1 Restrictions and Guidelines

- When configuring the NTP server, you must specify at least one external reference clock source. A maximum of 20 different external reference clock sources can be configured.
- If it is necessary to configure an NTP key, you must configure NTP security authentication before configuring the NTP server. A device that acts as a client supports interaction with up to 20 NTP servers. You can configure an authentication key for each server (after configuring global authentication and the related key) to initiate encrypted communication with the servers.
- The default version of NTP for communicating with a server is NTP version 4. In addition, you can configure the source interface for transmitting NTP packets and specify that the NTP packets from a corresponding server can be received only on the transmitting interface.
- After a local clock is configured as the master clock (especially when a clock with a lower stratum is specified), the system does not synchronize with a clock source with a higher stratum, and therefore a real effective clock source may be overwritten. If this function is used for multiple devices in a network, the clock difference between the devices may cause unstable time synchronization of the network.
- Before a local clock is configured as the master clock, if the system never synchronizes time with an external clock source, you may need to manually calibrate the system clock to ensure that there is no excessive difference. For details about how to manually calibrate the system clock, refer to the basic management section in the Basic Configuration Commands.
- By default, if NTP works in client/server mode, after the NTP device synchronizes time from an external reliable clock source, the device acts as the time server to provide the time synchronization service for other devices. If you configure an NTP device only as a client, run the **ntp service disable** command to disable the external time synchronization service provided by NTP. After this command is configured, an external device cannot synchronize time from this NTP device.

1.5.2 Overview

This section describes how to configure a device as a client to synchronize time from an external reference clock source to the local clock. After successful time synchronization, the device can act as a time synchronization server to provide the time synchronization service.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an NTP server.

ntp-service server [**oob** | **vrf** *vrf-name*] { *ipv4-address* | *ipv6-address* | *server-hostname* | **ip** *domain* | **ipv6** *domain* } [**key** *keyid* | **port** *port-number* | **prefer** | **source** *interface-type interface-number* | **version** *version*]* [**via** *mgmt-name*]

1.6 Configuring NTP-Related Parameters

1.6.1 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Configure the interval for time synchronization with the external server.

ntp-service interval *synchronization-interval-time*

By default, the NTP synchronization interval is 64s.

(4) (Optional) Configure automatic update of the hardware clock.

ntp-service client-update-calendar

Automatic update of the hardware clock is not configured by default.

(5) (Optional) Configure the NTP master clock.

ntp-service master [*stratum*]

The NTP master clock is disabled by default.

stratum: specifies the stratum of a local clock, ranging from 1 to 15. The default value is 8.

(6) (Optional) Disable the NTP time synchronization service provided for other devices.

ntp-service global disable

The NTP time synchronization service is enabled by default.

(7) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(8) (Optional) Disable receiving of NTP packets on an interface.

ntp-service disable

The function of receiving NTP packets on an interface is enabled by default.

1.7 Configuring NTP Access Control

1.7.1 Overview

NTP access control provides a minimum security measure. A more secure method is to use the NTP authentication mechanism.

1.7.2 Restrictions and Guidelines

- If no access control rule is configured, all NTP services can be accessed. If access control rules are configured, only NTP services that comply with the access control rules can be accessed.
- The system currently does not support the access control query function.
- NTP service packets can only match some fields in an ACL rule, including:
  - Source IPv4 address/source IPv6 address
  - UDP number
- If the packet request interval of the NTP client is smaller than that allowed by the server, the NTP server discards the packets. This function takes effect only after the **ntp access-group limited access-list-number** | **access-list-name** [**kod**] command is configured. When the KoD-enabled NTP device acts as a client, it reduces the rate after receiving a KoD packet. A KoD-disabled device does not reduce the rate. Note that KoD cannot be triggered by specifying the interval in the **ntp interval** command.
- You can run the **ntp discard** command to configure the packet request interval allowed by the server. If the packet request interval of the NTP client is smaller than that allowed by the server, the NTP server discards the packets. This function takes effect only after the **ntp access-group limited access-list-number** | **access-list-name** [**kod**] command is configured.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Configure the NTP access control rights.

ntp-service access-apply { **limited** | **peer** | **serve** | **serve-only** | **query-only** } { *access-list-name* | *access-list-number* } [**kod**]

No NTP access control rule is configured by default.

(4) (Optional) Configure the minimum packet interval allowed by NTP.

ntp-service discard min-spacing *discard-min-spacing-interval* **avg-spacing** *avg-spacing-interval*

By default, the minimum packet request interval allowed by NTP is 2s, and the average packet request interval is 8s.

1.8 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

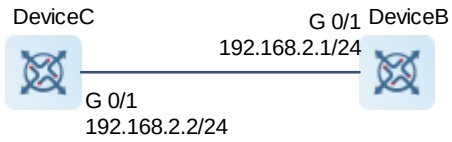
⚠ Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 NTP Monitoring

Command	Purpose
display ntp-service status	Displays the current NTP information.
display ntp-service packets	Displays the sent and received NTP packets.
display ntp-service server	Displays the NTP server information.
display ntp-service server	Displays the NTP server list.
debugging ntp-service	Debugs the DNS function.
view ntp-service peer	Displays the NTP configuration peer list.
unset debugging ntp-service	Disables the debugging function.

1.9 Configuration Examples



1.9.1 Configuring the Local Clock Reference Mode of NTP

1. Requirements

Use the local clock of a device as the NTP reference clock source to provide time synchronization.

2. Topology

Figure 1-2 Configuring the Local Clock Reference Mode of NTP

3. Notes

- Configure the local clock of device B as the NTP reference clock source.
- Device C synchronizes time from device B.

4. Procedure

Set the IP address of GigabitEthernet 0/1 on device B to 192.168.2.1/24.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on device C to 192.168.2.2/24.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/1)# exit
```

Configure device B as the NTP server.

```
DeviceB(cfg)# ntp-service master
```

Enable the NTP function on device C.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# ntp-service server 192.168.2.1
```

5. Verification

Run the **ping** command to verify L3 reachability between device B and device C.

```
DeviceB# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **clock set** command to modify the time on device B.

```
DeviceB# clock set 11:00:00
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **display clock** command on device C to check whether time synchronization is successful.

```
DeviceC# display clock
11:00:01 UTC Fri, Feb 26, 2021
```

6. Configuration Files

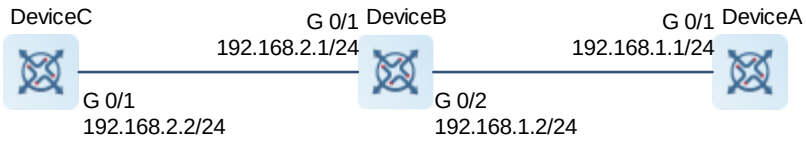
- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 ip address 192.168.2.1 255.255.255.0
ntp-service master
!
end
```

- Device C configuration file

```
hostname DeviceC
!
ntp-service server 192.168.2.1
!
interface GigabitEthernet 0/1
```

```
 ip address 192.168.2.2 255.255.255.0
!
end
```



1.9.2 Configuring the External Clock Reference Mode of NTP

1. Requirements

Use a device as a client to synchronize time from an external reference clock source to the local clock. After successful time synchronization, the device can act as a time synchronization server to provide the time synchronization service.

2. Topology

Figure 1-3 Configuring the External Clock Reference Mode of NTP

3. Notes

- Configure the NTP external clock reference mode on device B.
- Configure device A as the reference clock source of device B.
- Device C synchronizes time from device B.

4. Procedure

Set the IP address of GigabitEthernet 0/1 on device A to 192.168.1.1/24.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on device B to 192.168.2.1/24, and the IP address of GigabitEthernet 0/2 to 192.168.1.2/24.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/1)# exit
DeviceB(cfg)# interface gigabitEthernet 0/2
DeviceB(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on device C to 192.168.2.2/24.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/1)# exit
```

Configure device A as the reference clock source of device B.

```
DeviceA(cfg)# ntp-service master
```

Configure the NTP external clock reference mode on device B.

```
DeviceB(cfg)# ntp-service server 192.168.1.1
```

Enable device C to synchronize time from device B.

```
DeviceC(cfg)# ntp-service server 192.168.2.1
```

5. Verification

Run the **ping** command to verify L3 reachability between device B and device A.

```
DeviceB# ping 192.168.1.1
Sending 5, 100-byte ICMP Echoes to 192.168.1.1, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **ping** command to verify L3 reachability between device B and device C.

```
DeviceB# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **display ntp-service status** command to display the NTP configuration.

```
DeviceB# sh ntp-service status
Clock is synchronized, stratum 9, reference is 192.168.1.1
nominal freq is 250.000 Hz, actual freq is 250.000 Hz, precision is 2**18
reference time is E3527947.D5254A29 (14:03:51.000 UTC Sun, Nov 8, 2020)
clock offset is -0.00012 sec, root delay is 0.00282 sec
root dispersion is 0.01153 msec, peer dispersion is 0.00025 msec
system poll interval is 64, last update was 43 sec ago
system time(GMT) is E3527973.740AB522 (14:04:35.000 GMT Sun, Nov 8, 2020)
```

Run the **clock set** command to modify the time on device A.

```
DeviceA# clock set 11:00:00
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **display clock** command on device B to check whether time synchronization is successful.

```
DeviceB# display clock
11:00:01 UTC Fri, Feb 26, 2021
```

Run the **display clock** command on device C to check whether time synchronization is successful.

```
DeviceC# display clock
11:00:01 UTC Fri, Feb 26, 2021
```

6. Configuration Files

- Device A configuration file

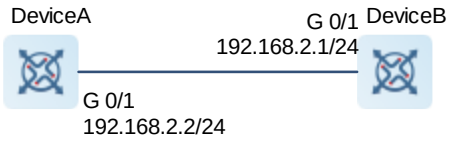
```
hostname DeviceA
!
interface GigabitEthernet 0/1
 ip address 192.168.1.1 255.255.255.0
ntp-service master
!
end
```

- Device B configuration file

```
hostname DeviceB
!
ntp-service server 192.168.1.1
!
interface GigabitEthernet 0/1
 ip address 192.168.2.2 255.255.255.0
!
interface GigabitEthernet 0/2
 ip address 192.168.1.2 255.255.255.0
!
end
```

- Device C configuration file

```
hostname DeviceC
!
ntp server 192.168.2.1
!
interface GigabitEthernet 0/1
 ip address 192.168.2.2 255.255.255.0
!
end
```



1.9.3 Configuring NTP Security Authentication

1. Requirements

Use a device as a client to synchronize time only from a trusted external reference clock source to the local clock. Use the local clock of a device as the NTP reference clock source to provide time synchronization for only a trusted device.

2. Topology

Figure 1-4 Configuring NTP Security Authentication

3. Notes

- Configure device A as the reference clock source of device B, enable device A to provide device B with the NTP service that requires security authentication, and set the authentication key to "abcd".

4. Procedure

Set the IP address of GigabitEthernet 0/1 on device A to 192.168.2.2/24.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
```

Configure device A as the reference clock source of device B, enable device A to provide the NTP service that requires security authentication, and set the authentication key to **abcd**.

```
DeviceA(cfg)# ntp master
DeviceA(cfg)# ntp authenticate
DeviceA(cfg)# ntp authentication-key 1 md5 abcd
DeviceA(cfg)# ntp trusted-key 1
```

Set the IP address of GigabitEthernet 0/1 on device B to 192.168.2.1/24.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/1)# exit
```

Configure device A as the reference clock source of device B, enable device A to provide the NTP service that requires security authentication, and set the authentication key to **abcd**.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# ntp master
DeviceA(cfg)# ntp authenticate
DeviceA(cfg)# ntp authentication-key 1 md5 abcd
DeviceA(cfg)# ntp trusted-key 1
```

Configure device B to synchronize time from device A, enable device B to provide the NTP service that requires security authentication, and set the authentication key to **abcd**.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# ntp-service trusted-key 1
DeviceB(cfg)# ntp-service server 192.168.2.2
```

5. Verification

Run the **ping** command to verify L3 reachability between device B and device A.

```
DeviceB# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **clock set** command to modify the time on device A.

```
DeviceA# clock set 11:00:00
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **display clock** command on device B to check whether time synchronization is successful.

```
DeviceB# display clock
11:00:01 UTC Fri, Feb 26, 2021
```

6. Configuration Files

- Device A configuration file

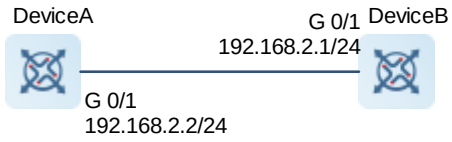
```
hostname DeviceA
!
interface GigabitEthernet 0/1
 ip address 192.168.2.2 255.255.255.0
ntp-service master
!
ntp authentication-key 1 md5 $10$23e$uYC4zg==$ 7
ntp authenticate
ntp trusted-key 1
end
```

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 ip address 192.168.2.1 255.255.255.0
!
ntp authentication-key 1 md5 $10$28a$x5aToA==$ 7
ntp authenticate
ntp trusted-key 1
ntp server 192.168.2.2 key 1
!
```

```
end
```

1.9.4 Configuring NTP Access Control Rights



1. Requirements

Configure the access control function to prevent malicious damage to the time server and improve the security of time synchronization.

Use a device as a client to synchronize time only from the specified external reference clock source to the local clock.

2. Topology

Figure 1-5 Configuring NTP Access Control Rights

3. Procedure

Set the IP address of GigabitEthernet 0/1 on device A to 192.168.2.2/24.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on device B to 192.168.2.1/24.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/1)# exit
```

Configure device A as the reference clock source of device B. Allow only the device with the IP address of 192.168.2.2 to send a time synchronization request to the local device.

```
DeviceB(cfg)# ntp-service server 192.168.2.2
DeviceB(cfg)# access-list 1 permit host 192.168.2.2
DeviceB(cfg)# ntp access-group serve-only 1
```

Configure device A as the NTP server, limit the request packet interval of the client, and send KoD packets.

```
DeviceA(cfg)# ip access-control-list standard limited1
DeviceA(cfg-stdacl)# 10 permit any
DeviceA(cfg)# exit
DeviceA(cfg)# ntp-service access-group limited limited1 kod
```

```
DeviceA(cfg)# ntp-service discard min-spacing 5 avg-spacing 5
DeviceA(cfg)# ntp-service master
```

4. Verification

Run the **ping** command to verify L3 reachability between device B and device A.

```
DeviceB# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **clock set** command to modify the time on device A.

```
DeviceA# clock set 11:00:00
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **display clock** command on device B to check whether time synchronization is successful.

```
DeviceB# display clock
11:00:01 UTC Fri, Feb 26, 2021
```

5. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ip access-control-list standard limited1
 10 permit any
!
interface GigabitEthernet 0/1
 ip address 192.168.2.2 255.255.255.0
ntp-service master
ntp-service access-group limited limited1 kod
!
end
```

- Device B configuration file

```
hostname DeviceB
!
ip access-control-list standard 1
 10 permit 192.168.2.2
!
ntp-service server 192.168.2.2
ntp-service access-group serve-only 1
!
interface GigabitEthernet 0/1
 ip address 192.168.2.1 255.255.255.0
!
end
```

1 Configuring SNTP

1.1 Introduction

1.1.1 Overview

NTP uses a complex algorithm for time synchronization, and raises high requirements for the system. As a simplified version of NTP, Simple Network Time Protocol (SNTP), inherits the protocol specification and implementation process of NTP, and adopts the same packet format and interaction mode as NTP. By setting some fields in the packet to predetermined values, SNTP simplifies the time synchronization algorithm and lowers the requirements for system performance. Although the precision of SNTP time synchronization is compromised while the algorithm is simplified, SNTP can generally achieve a precision of about 1s. Therefore, when the time precision requirements are not very high, you can choose to use SNTP. SNTP packets are the same as NTP packets, and therefore the SNTP client is fully compatible with the NTP server.

1.1.2 Principles

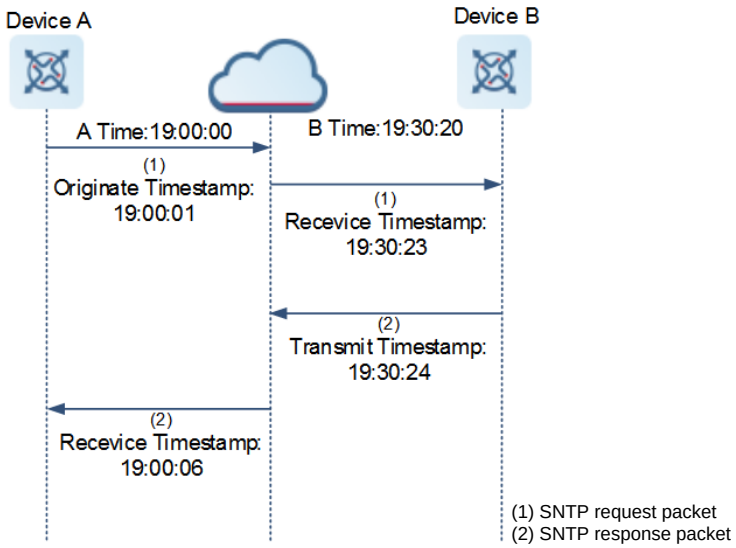
Like NTP, SNTP also uses the client/server mode for SNTP/NTP message interaction. The client sends a time synchronization packet to the server at a certain interval (half an hour by default). After receiving a response packet from the server, the client synchronizes time.

As shown in Figure 1-1, device B (B for short) acts as an NTP reference clock source, device A (A for short) acts as an SNTP client that synchronizes time with B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

(1) A sends an SNTP/NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in Originate Timestamp.

(2) After a network delay of 2s, the local time (T1) when B receives the request packet is 19:30:23 and is filled in Receive Timestamp.

(3) B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in Transmit Timestamp.



(4) After a network delay of 2s, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

a A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula ((T1-T0)+(T2-T3))/2.

b A obtains the packet round-trip delay of 4 seconds between A and B by using the formula (T3-T0)-(T2-T1).

Figure 1-1 SNTP Principles

1.1.3 Protocols and Standards

- RFC 2030: Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI

1.2 Restrictions and Guidelines

You cannot configure both the NTP and SNTP functions on the same device.

1.3 Configuring SNTP

1.3.1 Overview

An SNTP client accesses an NTP server regularly to calibrate the clock.

1.3.2 Restrictions and Guidelines

All time obtained through SNTP communication is Greenwich Mean Time (GMT). To obtain precise local time, you need to set the local time zone for alignment with GMT.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable SNTP.

sntp enable

The SNTP function is disabled by default.

(4) Configure the IP address of an SNTP server.

sntp server [**oob**] { *ipv4-address* | *domain* } [**via** *mgmt-name*] [**source** *source-ipv4-address*]

No SNTP server is configured by default.

(5) (Optional) Configure the SNTP time synchronization interval.

sntp interval *synchronization-interval-time*

The default interval for clock synchronization between an SNTP client and SNTP/NTP server is 1800s.

1.4 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

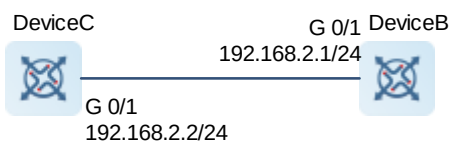
⚠ Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 SNTP Monitoring

Command	Purpose
display sntp	Displays SNTP-related parameters.
debugging sntp	Debugs the DNS function.

1.5 Configuration Examples



1.5.1 Configuring Basic Functions of SNTP

1. Requirements

- Use the local clock of device B as the NTP reference clock source to provide time synchronization for device C.
- Use device C as an SNTP client to synchronize time from device B.

2. Topology

Figure 1-2 Configuring Basic Functions of SNTP

3. Notes

- Configure device B as the SNTP server of device C.
- Enable the SNTP function on device C.

4. Procedure

Set the IP address of GigabitEthernet 0/1 on device B to 192.168.2.1/24.

```
DeviceB> privilege
DeviceB# config-system terminal
DeviceB(cfg)# interface gigabitEthernet 0/1
DeviceB(cfg-if-GigabitEthernet 0/1)# unset switch-port
DeviceB(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceB(cfg-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on device C to 192.168.2.2/24.

```
DeviceC> privilege
DeviceC# config-system terminal
DeviceC(cfg)# interface gigabitEthernet 0/1
DeviceB(cfg-if-GigabitEthernet 0/1)# unset switch-port
DeviceC(cfg-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceC(cfg-if-GigabitEthernet 0/1)# exit
```

Configure device B as the NTP server.

```
DeviceB(cfg)# ntp master
```

Enable the SNTP function on device C.

```
DeviceC(cfg)# sntp server 192.168.2.1
DeviceC(cfg)# sntp enable
```

5. Verification

On device B, run the **ping** command to verify L3 reachability between device B and device C.

```
DeviceB# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

On device C, run the **display sntp** command to display the SNTP status and check whether the server is successfully configured.

```
DeviceC# display sntp
 SNTP state              : Enable
 SNTP oob mode           : Disable
 SNTP server             : 192.168.2.1
 SNTP sync interval      : 1800
 Time zone               : -0
```

Run the **clock set** command to modify the time on device B.

```
DeviceB# clock set 11:00:00
```

```
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **display clock** command on device C to check whether time synchronization is successful.

```
DeviceC# display clock
11:00:01 UTC Fri, Feb 26, 2021
```

6. Configuration Files

- Device B configuration file

```
DeviceB# diaplay current-config
hostname DeviceB
!
interface GigabitEthernet 0/1
 ip address 192.168.2.1 255.255.255.0
ntp master
!
end
```

- Device C configuration file

```
DeviceC# display current-config
hostname DeviceC
!
sntp server 192.168.2.1
sntp subscribe
!
interface GigabitEthernet 0/1
 ip address 192.168.2.2 255.255.255.0
!
end
```

1.9 Configuration Examples 7

1.9.1 Providing the FTP Service in a LAN 7

1 Configuring the FTP Server

1.1 Introduction

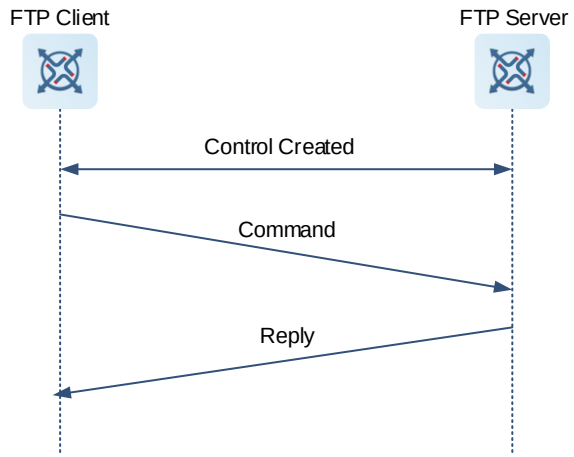
1.1.1 Overview

File Transfer Protocol (FTP) is a standard application layer protocol formulated by the IETF Network Working Group. It implements file transfer based on Transmission Control Protocol (TCP). FTP is a major method for transferring files on the Internet.

FTP adopts the client/server model. As shown in Figure 1-1, a device can act as an FTP server to provide remote client access and program operations. By issuing commands to the server through the client, you can view the files in the FTP server directory, copy files from a remote computer to the local device, and transfer local files to the server. In addition, FTP provides functions, such as login authentication and read/write access control.

Figure 1-1 FTP Client/Server Mode

1.1.2 Principles



1. FTP Connection

FTP sets up two TCP connections between the client and the server, namely the control connection and the data connection.

- The control connection uses port 21 to transmit control commands, and is always in enabled state.
- The data connection uses port 20 to transmit data. The server can proactively enable or disable the data connection. It sets up a new data connection every time a file or directory is transferred.

For some simple sessions, only the control connection needs to be enabled, the client sends a command to the server, and the sever returns a response after receiving the command. The process is shown in Figure 1-2.

Figure 1-2 Control Connection

When the client sends a command for uploading or downloading data, both the control connection and data connection must be established.

2. User Login and Authentication

To access files on the FTP server, the FTP client must have a user account authorized by the FTP server. By default, a device supports configuration of up to 10 users, 2 connections per user, and 10 connections with the server.

In addition, the read and write permissions of files can be defined to effectively prevent unauthorized users from accessing internal files. When the number of a user's FTP login failures reaches the upper limit, the IP address or username used for login is locked. Within a certain period of time, all users cannot log in to the FTP server properly using this IP address or username.

3. Supported FTP Commands

After receiving an FTP connection request, the FTP server requires the client to provide the username and password for authentication.

If the client passes the authentication, the FTP client commands can be executed. The following table lists the FTP client commands supported by the FTP server.

Table 1-1 FTP Client Commands Supported by the FTP Server

ascii	close	mdelete	mput	quit	size
bin	delete	mdir	nlist	recv	system
bye	dir	mget	passive	rename	type
cd	get	mkdir	put	rmdir	user
cdup	ls	mls	pwd	send	

For how to use these FTP client commands, refer to the documentation of the FTP client software used. In addition, many FTP client tools, such as CuteFTP and FlashFXP, provide the graphic user interface (GUI), which allows users to perform operations without configuring FTP commands.

1.1.3 Protocols and Standards

- RFC 959: File Transfer Protocol (FTP)
- RFC 3659: Extensions to FTP
- RFC 2228: FTP Security Extensions
- RFC 2428: FTP Extensions for IPv6 and NATs
- RFC 1635: How to Use Anonymous FTP

1.2 Configuration Task Summary

FTP server configuration includes the following tasks:

(1) Configuring Basic Functions of the FTP Server

(2) (Optional) Configuring FTP Session Management

(3) (Optional) Configuring the FTP Lock Function

(4) (Optional) Enabling AAA on the FTP Server

(5) (Optional) Configuring Read/Write Permission Control of FTP Users

1.3 Configuring Basic Functions of the FTP Server

1.3.1 Overview

This section describes how to enable the FTP server and configure the username, password, and top-level directory to provide the FTP service for the FTP client.

1.3.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the FTP server.

ftp-server enable

The FTP server is disabled by default.

(4) Configure the top-level directory of the FTP server.

ftp-server topdir *directory*

By default, no top-level directory under which the FTP client can read and write files is configured, that is, the client is prohibited from accessing any directory on the FTP server.

(5) Configure a username and password for server login.

ftp-server username *username* [**privilege level**] **password** [*type*] *password*

By default, no username and password are configured for login to the FTP server, that is, no login users are restricted.

1.4 Configuring FTP Session Management

1.4.1 Overview

- The FTP login times refers to the number of times that the user's account and password can be verified when the user logs in to the FTP server.
- The FTP login timeout refers to the maximum time that the user can stay online after the username and password are verified. If the username and password are not verified again before login timeout, the session will be terminated to ensure that other users can log in to the FTP server.
- The idle timeout refers to the time from the completion of the last FTP operation to the start of the next FTP operation in an FTP session. After the server responds to an FTP client command (for example, after a file is completely transferred), the server starts to count the idle time again, and stops counting when the next FTP client command arrives. Therefore, the configuration of the idle timeout does not affect time-consuming file transfer operations.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure FTP session management. Configure at least one of the following tasks.

- Configure the FTP login times.

  ftp-server login times *times*

  By default, the FTP login times is 1, that is, a session will be terminated once you enter an incorrect username or password so that other users can go online.

- Configure the FTP login timeout.

  ftp-server login timeout *time*

  By default, the FTP login timeout is 2 minutes.

- Configure the idle timeout.

  ftp-server timeout *time*

  By default, the idle timeout of an FTP session is 10 minutes.

- Configure the maximum number of FTP sessions.

  ftp-server max-session-num *number*

  By default, the maximum number of FTP sessions is 20.

1.5 Configuring the FTP Lock Function

1.5.1 Overview

- After the IP address lock function is enabled, if the cumulative number of login failures caused by entry of the incorrect username or password reaches the configured upper limit, the FTP session is terminated and the user's IP address is locked. In addition, all users cannot log in to the FTP server properly using this IP address or username.
- After the username lock function is enabled, if the cumulative number of login failures caused by entry of the incorrect password reaches the configured upper limit, the FTP session is terminated and the username is locked. The user cannot log in to the FTP server, but other users are not affected.
- The FTP lock time refers to the duration that a user needs to wait for automatic unlocking after the user is locked because the number of the user's login failures reaches the upper limit. The locked user can log in to the FTP server only after the login silence time expires.
- The maximum number of login verification times allowed by the FTP lock function refers to the maximum number of times that the username and password of a user can be verified after the FTP lock function is enabled. The default value is 3. If the number of verification failures exceeds the configured upper limit, the session is terminated and the user is locked.

1.5.2 Restrictions and Guidelines

After the IP address lock function is enabled, if the number of locked IP addresses reaches the upper limit, the full lock function is enabled. Then, the FTP server no longer accepts the connection request from any user until the number of locked IP addresses is smaller than the upper limit.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the FTP lock function. Configure at least one of the following tasks.

- Disable the IP address lock function.

  ftp-server login ip-block disable

  The IP address lock function is enabled by default.

- Configure the username lock function.

  ftp-server login username-block disable

  The username lock function is enabled by default.

- Configure the FTP lock time.

  ftp-server login silence-time *time*

  By default, the FTP lock time is 10 minutes.

- Configure the maximum number of IP addresses that can be locked after the IP address lock function is enabled.

ftp-server login max-block-limit *limit*

By default, up to 30 IP addresses can be locked.

- Configure the maximum number of login verification times allowed by the FTP lock function.

  ftp-server login block failed-times *times*

  By default, the maximum number of login verification times allowed by the FTP lock function is 3.

1.6 Enabling AAA on the FTP Server

1.6.1 Overview

By default, FTP does not support AAA login authentication. However, you can enable AAA on the FTP server through configuration.

1.6.2 Restrictions and Guidelines

This command takes effect only after FTP is enabled.

1.6.3 Prerequisites

Enable the AAA function before configuring this command. For details about how to enable AAA, see *Configuring AAA*.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable AAA on the FTP server.

ftp-server authentication { **default** | *name* }

By default, FTP does not support AAA login authentication.

1.7 Configuring Read/Write Permission Control of FTP Users

1.7.1 Overview

After the user read/write permission control function is enabled, the configured FTP user levels or AAA username levels can be used to control read/write permissions. By default, users of all levels have the read/write permissions. After permission control is enabled, if the user level is not configured, it is set to 1 by default and the user has only the read permission, that is, the user can only download data. You can configure FTP users of different levels as required for read/write permission control.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable read/write permission control of FTP users.

ftp-server login permission enable

By default, read/write permission control of FTP users is disabled.

1.8 Monitoring

Run the display commands to check the running status of a configured function to verify the configuration effect.

Run the debugging command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the cleanup commands to clear information.

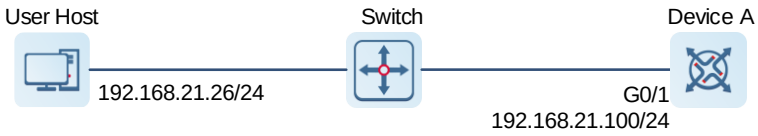
Caution

Running the **cleanup** command may lose vital information and thus interrupt services.

Table 1-2 FTP Server Monitoring

Command	Purpose
cleanup ftp-server block-list { **all** | **ip-address** { *ipv4-address* | *ipv6-address* } [**vrf** *vrf-name*] | **username** *user* }	Clears the user lock entries in the FTP lock list.
display ftp-server	Displays the FTP server status information.
display ftp-server { **ip-block** | **username-block** } **list**	Displays the user lock entries in the FTP lock list.
debugging ftp-server err	Debugs the FTP server error events.
debugging ftp-server pro	Debugs the FTP server message events.

1.9 Configuration Examples



1.9.1 Providing the FTP Service in a LAN

1. Requirements

As shown in Figure 1-3, a device in a LAN acts as the FTP server to provide the upload and download services for users. The switch is an access device. The required session idle timeout is 5 minutes.

2. Topology

Figure 1-3 Configuring the FTP Service on a LAN

3. Notes

Configure device A as follows:

(1) Enable the FTP server function.

(2) Configure the top-level directory **/syslog**.

(3) Set the username to **user** and password to **password**.

(4) Set the session idle timeout to **5** minutes.

4. Procedure

(1) Configure device A.

a. Configure an IP address.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# ip address 192.168.21.100 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
```

b. Enable the FTP server function.

```
DeviceA(cfg)# ftp-server enable
```

c. Configure the top-level directory **/syslog**.

```
DeviceA(cfg)# ftp-server topdir /syslog
```

d. Set the username to **user** and password to **password**.

```
DeviceA(cfg)# ftp-server user-account user password password
```

e. Set the session idle timeout to **5** minutes.

```
DeviceA(cfg)# ftp-server timeout 5
```

(2) Configure the user host.

Set the IP address of the user host to 192.168.21.26/24.

5. Verification

Run the **display ftp-server** command to view the FTP server configurations.

```
DeviceA# display ftp-server
      ftp-server information
==================================
enable : Y
```

```
topdir : /syslog
timeout: 5min
total connect: 0
username:user
password:(PLAINT)password
connect num[0]
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
ip address 192.168.21.100 255.255.255
!
ftp-server enable
ftp-server topdir /syslog
ftp-server timeout 5
ftp-server username user password password
!
```

7. Common Errors

- No username is configured.
- No password is configured.
- No top-level directory is configured.

1 Configuring FTP Client

1.1 Introduction

1.1.1 Overview

File Transfer Protocol (FTP) is an application of TCP/IP. By setting up a connection-oriented and reliable TCP connection between the FTP client and server, a user can access a remote computer that runs the FTP server program.

An FTP client enables file transfer between a device and the FTP server over FTP. A user uses the client to send a command to the server. The server responds to the command and sends the execution result to the client. By means of command interaction, the user can view files in the server directory, copy files from a remote computer to a local computer, and transfer local files to a remote computer.

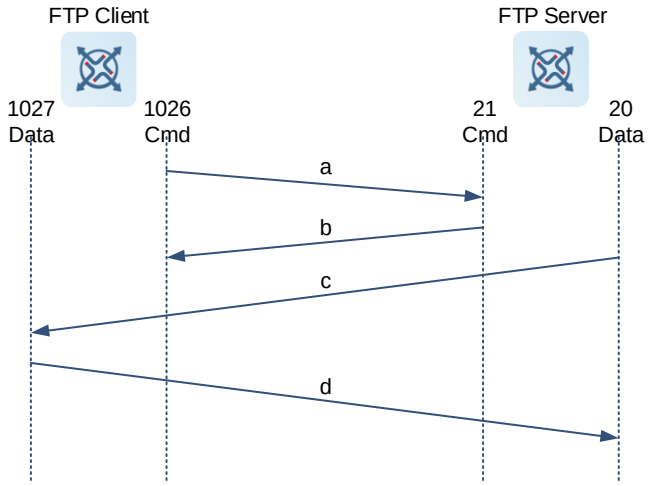
FTP facilitates sharing of program/data files and remote use of computers. Users can transfer data in an efficient and reliable manner without caring about differences between files systems on different hosts.

You enter the copy command in the CLI to automatically run commands related to the control connection, such as **open**, **user**, and **pass**. After a control connection is established, the file transfer process starts. Then, a data connection is established to upload or download files.

Note

For the principles of the connection between the FTP client and server, see *Configuring FTP Server*.

The following sections introduce only the FTP client.



1.1.2 Principles

1. FTP Connection Mode

FTP supports two data connection modes: active (PORT) and passive (PASV). The two modes differ only in the way that a data connection is established, and the control connection is the same.

- In PORT mode, when a data connection is established, the FTP server initiates a request to establish a new connection with the client for data transmission. This mode cannot be used if the firewall is deployed on the FTP client. The connection establishment process is as follows:
  a The FTP client establishes a control channel through port 1026 and port 21 of the FTP server, and sends control commands through this channel.
  b The client sends the **PORT** command through this channel when it needs to receive data. The **PORT** command contains the port information (1027) of the client data channel.
  c When transmitting data, the server connects to port 1027 of the client through port 20 on the server to establish a data channel for data transmission and reception.
  d The client sends a response. Data transmission ends.

Figure 1-1 PORT Mode

- In PASV mode, the FTP client initiates a request when a data connection is established. The connection establishment process is as follows:

  a The FTP client establishes a control channel through port 1026 and port 21 of the FTP server, and sends control commands through this channel.

  b The client sends the **PASV** command through this channel when it needs to receive data.

  c After receiving the **PASV** command, the FTP server randomly opens a high-end port 2024 and notifies the client of data transmission to this port.

  d The client uses port 1027 to connect to port 2024 of the FTP server, and then sends or receives data on this channel. The FTP server does not need to establish a new connection with the client.

Figure 1-2 PASV Mode

Note

The control connection for command and feedback transmission is always present whereas the data connection is established as required. Only the FTP client can select the PASV or PORT mode. The FTP mode supported by an FTP client depends on the actual FTP client software. A Ruijie FTP client uses the PASV mode by default.

2. FTP File Transmission Modes

FTP provides two file transmission modes:

- Binary transmission mode: It is used to transfer program files (for example, .app, .bin and .btm files), executable files, compressed files, image files, and all ASCII values. In this transmission mode, data is not processed, and therefore the transmission rate is faster than that of the text transmission mode.
- Text transmission mode (ASCII mode): It is used to transfer text files (such as .txt, .bat, and .cfg files). This mode is different from the binary mode in carriage return and line feed processing. In ASCII mode, carriage return and line feed are converted to local CRC characters. For example, \n in Unix is \r\n in Windows or \r in Mac. Assume that a file copied by a user contains ASCII text. If a remote computer does not run Unix, FTP automatically converts the file format accepted by the remote computer during file transfer.

3. Specifying the Source IP Address for FTP Transmission

You can configure a source IP address for the FTP client and use it to communicate with an FTP server. With this IP address, the FTP client can connect to the server and share files with the server.

4. Checking Sizes of Files Downloaded from an FTP Server

When the FTP client downloads a file, it checks the file size by default to detect file transfer errors (if any). You can also disable the file size check when downloading files from FTP servers that cannot reply to FTP clients with file sizes.

1.1.3 Protocols and Standards

- RFC 959: FILE TRANSFER PROTOCOL (FTP)

1.2 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring basic functions of the FTP client
  - Enabling the FTP Client to Upload Files
  - Enabling the FTP Client to Download Files
- Configuring extended functions of the FTP client
  - Configuring the FTP Connection Mode
  - Configuring the Transmission Mode of the FTP Client
  - Configuring the Source IP Address for FTP Connection

1.3 Enabling the FTP Client to Upload Files

1.3.1 Overview

You can use the FTP client to upload files to the FTP server.

1.3.2 Restrictions and Guidelines

During file transfer, do not insert or remove a storage medium or transmission medium to or from the device to avoid transmission errors.

When you transfer the file through the FTP client:

(1) The username is up to 32 characters long and cannot contain special characters such as : / @ or spaces. The username is required.

(2) The password is up to 32 characters long and cannot contain special characters such as : / @ or spaces. The password is required.

1.3.3 Prerequisites

The user must have an account with the read and write permissions for the FTP server, and can use this account to access the target folder on the FTP server.

1.3.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Upload files.

copy flash:*local-file* { **ftp: | oob_ftp:** }***//****account-information@remote-file*

1.4 Enabling the FTP Client to Download Files

1.4.1 Overview

You can use the FTP client to download files from the FTP server.

1.4.2 Restrictions and Guidelines

During file transfer, do not insert or remove a storage medium or transmission medium to or from the device to avoid transmission errors.

When you transfer the file through the FTP client:

(1) The username is up to 32 characters long and cannot contain special characters such as : / @ or spaces. The username is required.

(2) The password is up to 32 characters long and cannot contain special characters such as : / @ or spaces. The password is required.

1.4.3 Prerequisites

The user must have an account with the read permission for the FTP server, and can use this account to access the target files on the FTP server.

1.4.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) (Optional) Disable the size check of files downloaded from the FTP server.

- Enter the global configuration mode.

  config-system terminal

- Disable the size check of files downloaded from the FTP server.

  ftp-client disable-size-check

  By default, the sizes of files downloaded from the FTP server are checked.

- Exit the global configuration mode.

  exit

(3) Download files.

copy { **ftp:** | **oob_ftp:** }***//****account-information@remote-file* **flash:***local-file*

1.5 Configuring the FTP Connection Mode

1.5.1 Overview

You can download or upload files in the specified FTP connection mode. The default FTP connection mode is PASV. You can set the FTP connection mode to PORT, in which the FTP server initiates a connection request to the client.

1.5.2 Restrictions and Guidelines

If you need to specify the **vrf** *vrf-name* parameter when configuring the FTP client, configure the VRF first. For details about the VRF, see *Configuring VRF*.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Set the connection mode to **PORT**.

ftp-client [**vrf** *vrf-name*] **port**

The default FTP connection mode is PASV.

1.6 Configuring the Transmission Mode of the FTP Client

1.6.1 Overview

You can download or upload files in the specified transmission mode of the FTP client. The default transmission mode is Binary. You can also set the transmission mode to ASCII according to your requirements.

1.6.2 Restrictions and Guidelines

If you need to specify the **vrf** *vrf-name* parameter when configuring the FTP client, configure the VRF first. For details about the VRF, see *Configuring VRF*.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Set the transmission mode to ASCII.

ftp-client [**vrf** *vrf-name*] **ascii**

The default transmission mode is Binary.

1.7 Configuring the Source IP Address for FTP Connection

1.7.1 Overview

You can download or upload files using the specified IP address of the FTP client. The FTP client is bound to the IP address of a port so that the client can use this IP address to connect to the server.

1.7.2 Restrictions and Guidelines

If you need to specify the **vrf** *vrf-name* parameter when configuring the FTP client, configure the VRF first. For details about the VRF, see *Configuring VRF*.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the source IP address for FTP connection.

ftp-client [**vrf** *vrf-name*] **source** { *ipv4-address* | *ipv6-address* | *interface-type interface-number* }

By default, no source IP address is bound to the FTP client. Instead, an IP address is selected for the client based on the route.

1.8 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

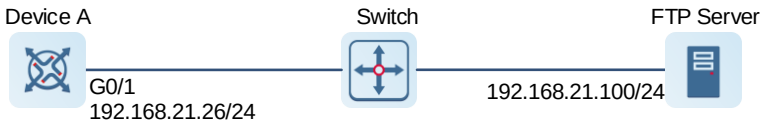
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
display ftp-client	Displays the FTP client configurations.
debugging ftp-client	Debugs the FTP client.

1.9 Configuration Examples



1.9.1 Configuring the FTP Client

1. Requirements

As shown in Figure 1-3, in a LAN, a local device needs to share files with a remote FTP server, and FTP is required to work in the specified connection mode and transmission mode.

2. Topology

Figure 1-3 Configuring the FTP Client

3. Notes

- Set the FTP connection mode to PORT.
- Set the transmission mode to ASCII.
- Use the username **user** and password **pass** to log in to the FTP server, upload the **local-file** file in the **home** directory of the local device to the **root** directory of the FTP server, and rename the file **remote-file**.
- Use the username **user** and password **pass** to log in to the FTP server, download the **remote-file** file from the **root** directory of the FTP server to the **home** directory of the local device, and rename this file **local-file**.

4. Procedure

(1) Configure the FTP server.

Set the IP address of the FTP server to 192.168.21.100/24.

(2) Configure device A.

a. Configure the IP address of device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# ip address 192.168.21.26 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
```

b. Set the transmission mode to ASCII.

```
DeviceA(cfg)# ftp-client ascii
```

c. Set the FTP connection mode to PORT.

```
DeviceA(cfg)# ftp-client port
DeviceA(cfg)# exit
```

d. Upload the file.

```
DeviceA# copy flash: home/local-file ftp://user:pass@192.168.21.100/root/remote-file
```

e. Download the file.

```
DeviceA# copy ftp://user:pass@192.168.21.100/root/remote-file flash: home/local-file
```

5. Verification

Run the **display ftp-client** command to view the FTP client configurations.

```
DeviceA# display ftp-client
        ftp-client information
==================================
type: ASCII
mode: PORT
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
 interface GgigabitEethernet 0/1
 ip address 192.168.21.26 255.255.255
!
 ftp-client ascii
 ftp-client port
!
```

7. Common Errors

- The command formats for uploading and downloading are incorrect.
- The username or password is incorrect.

1 Configuring TFTP Server

1.1 Introduction

1.1.1 Overview

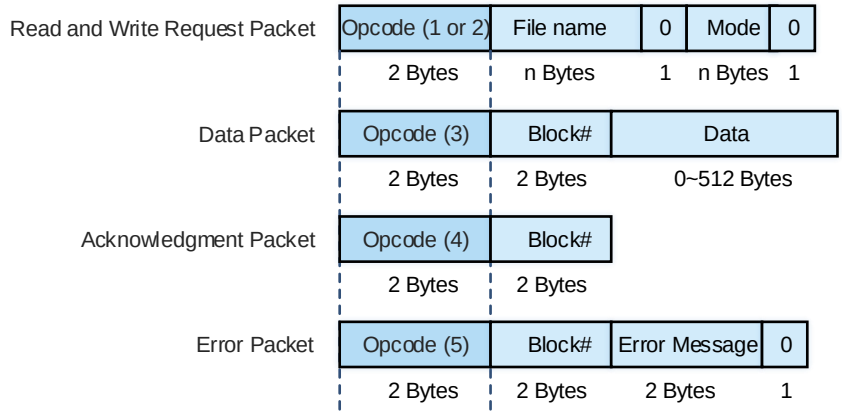
Trivial File Transfer Protocol (TFTP) is a standard application layer protocol formulated by the IETF Network Working Group. TFTP uses User Datagram Protocol (UDP) as its transport protocol, and the well known UDP port for TFTP traffic is 69.

TFTP provides the uncomplicated and inexpensive file transfer service. Many commonly used FTP features are unavailable in TFTP. TFTP can only upload or download files, but not list directories, perform authentication, or provide a security mechanism. TFTP employs a timeout and retransmission strategy to ensure data transmission. TFTP is described in RFC1350.

A TFTP client can conveniently download files (such as upgrade packages) on the device from the TFTP server, or upload files directly to the file system of the TFTP server.

1.1.2 Principles

1. TFTP Packet



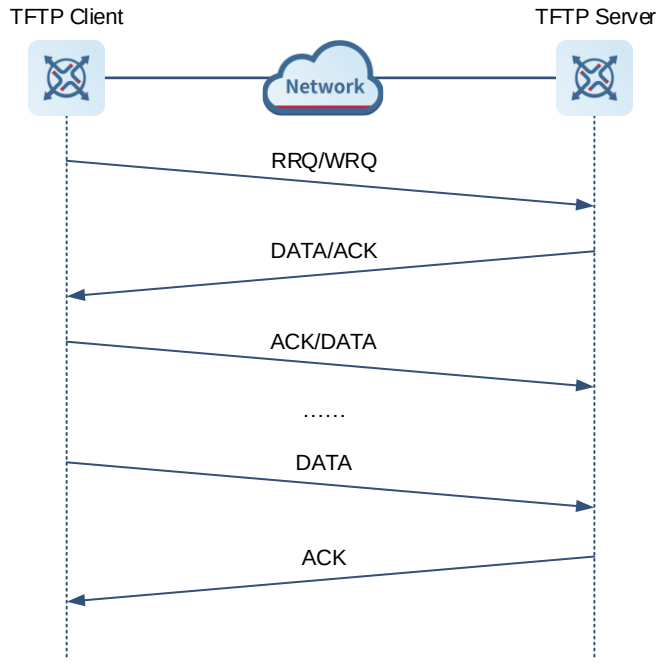
After the TFTP client initiates a file read or write request, and the TFTP server approves the request, TFTP transmits the data in 512-byte packets. A packet with less than 512 bytes indicates that the transmission is completed.

Each packet contains a data block, and the next packet can be sent only after an acknowledgment (ACK) packet is received from the peer. If the ACK packet is not received within the specified time, the last packet sent is retransmitted.

The header of a TFTP packet contains an Opcode field, which indicates the packet type. Opcodes 1 to 5 represent five types of packets:

- 1: Read Request (RRQ)
- 2: Write Request (WRQ)
- 3: Data (DATA)
- 4: Acknowledgment (ACK)
- 5: Error (ERROR)

Figure 1-1 TFTP Packet



The Error Message in an error packet contains 2 bytes in ASCII code. TFTP provides the following error codes:

- 0: Not defined;
- 1: File not found;
- 2: Access violation;
- 3: Disk full;
- 4: Illegal TFTP operation;
- 5: Unknown port;
- 6: File already exists;
- 7: No such user.

2. TFTP Working Modes

Figure 1-2 TFTP Working Modes

(1) The TFTP client initiates a read request (RRQ) or write request (WRQ) to the TFTP server.

(2) If the TFTP server receives an RRQ, it checks whether the read conditions are met (whether the file exists and whether the TFTP client has the access permission). If yes, the TFTP server sends a data packet (DATA) to the TFTP client. If the TFTP server receives a WRQ, it checks whether the write conditions are met (whether there is enough space and whether the FTP client has the write permission). If yes, the TFTP server sends an ACK packet to the TFTP client.

(3) If the TFTP client receives a DATA packet when preparing to download a file, it replies with an ACK packet. If the TFTP client receives an ACK packet when preparing to upload a file, it continues to send the DATA packet.

(4) The process of sending the ACK packet repeats until the last DATA packet with less than 512 bytes is received and indicates the end of the transmission.

(5) If an error is encountered in the transmission process, an ERROR packet is sent to the peer.

3. TFTP File Transmission Modes

TFTP supports the following transmission modes:

- Binary mode for transmitting program files
- ASCII mode for transmitting text files

1.1.3 Protocols and Standards

- RFC 1350: The TFTP Protocol (revision 2)
- RFC 2347: TFTP Option Extension
- RFC 2348: TFTP Blocksize Option
- RFC 2349: TFTP Timeout Interval and Transfer Size Options

1.2 Configuring Basic Functions of the TFTP Server

1.2.1 Overview

This section describes how to configure the TFTP server to provide the upload and download service for the TFTP client.

1.2.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the top-level directory of the TFTP server.

tftp-server topdir *directory*

By default, the TFTP client can read and write files in the Flash directory.

(4) Enable the TFTP server function.

tftp-server enable

The TFTP server is disabled by default. After the TFTP server is enabled, files can be transmitted only through the MGMT port.

1.3 Monitoring

Run the **display** commands to check the running status of a configured function to verify the configuration effect.

Run the **debugging** command to output debugging information.

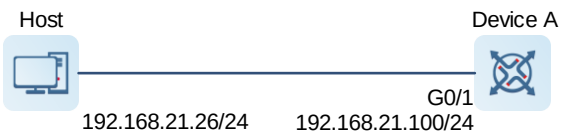
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
display tftp-server	Displays the TFTP server configurations.
display tftp-server updating-list	Displays the file download progress on the client.
debugging tftp-server	Debugs the server.

1.4 Configuration Examples



1.4.1 Configuring the TFTP Server

1. Requirements

Configure a TFTP server in a LAN so that users can upload and download files.

2. Topology

Figure 1-3 Configuring the TFTP Server

3. Notes

Configure device A as follows:

(1) Enable the TFTP server.

(2) Configure the top-level directory.

4. Procedure

(1) Configure device A.

Configure the IP address of the Ethernet interface.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-gigabitethernet 0/1)# ip address 192.168.21.100 255.255.255.0
DeviceA(cfg-if-gigabitethernet 0/1)# exit
```

Configure the top-level directory of the TFTP server.

```
DeviceA(cfg)# tftp-server topdir /tmp
```

Enable the FTP server function.

```
DeviceA(cfg)# tftp-server enable
```

(2) Configure the host.

Set the IP address of the host to 192.168.21.26/24.

5. Verification

Run the **display tftp-server** command to view the FTP server configurations.

```
DeviceA# display tftp-server
      tftp-server information
==================================
enable : Y
topdir : /tmp
```

6. Configuration Files

TFTP server configuration file

```
hostname DeviceA
!
interface gigabitethernet 0/1
ip address 192.168.21.100 255.255.255.0
!
tftp-server enable
tftp-server topdir /tmp
!
```

7. Common Errors

- No top-level directory is configured.

1.8.1 Configuring the TFTP Client....4

1 Configuring TFTP Client

1.1 Introduction

1.1.1 Overview

Trivial File Transfer Protocol (TFTP) is a specific application of Transmission Control Protocol/Internet Protocol (TCP/IP). File transfer between TFTP client and server is implemented based on User Datagram Protocol (UDP), and the default port number is **69**. Compared with the TCP-based FTP protocol, TFTP does not require authentication or have complex packets. It is suitable for a stable network environment and small file transfer.

Note

TFTP is suitable for small file transfer, and FTP supports transfer of large files.

1.1.2 Principles

1. Specifying the Source Interface IP Address for TFTP Transmission

You can configure a source IP address for the TFTP client and use it to communicate with a TFTP server. With this IP address, the TFTP client can connect to the server and share files with the server. Specifying the egress interface of packets facilitates interface management.

2. Specifying a Port Number for Connection with the TFTP Server

You can specify a port number on the TFTP client to connect with the TFTP server and transfer files. Specifying a port number also prevents attacks.

1.1.3 Protocols and Standards

- RFC 783: Trivial FILE TRANSFER PROTOCOL (TFTP)

1.2 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

- Basic functions of the TFTP client
  - Enabling the TFTP Client to Upload Files
  - Enabling the TFTP Client to Download Files
- Extended functions of the TFTP client
  - Binding the Source IP Address to the TFTP Client
  - Configuring a Port Number for TFTP Connection

1.3 Enabling the TFTP Client to Upload Files

1.3.1 Overview

You can upload files from the TFTP client to the TFTP server.

1.3.2 Restrictions and Guidelines

During file transfer, do not insert or remove a storage medium or transmission medium to or from the device to avoid transmission errors.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Upload files.

copy flash:*local-file* { **tftp: | oob_tftp:** }***//****remote-file*

1.4 Enabling the TFTP Client to Download Files

1.4.1 Overview

You can download files from the TFTP server to the TFTP client.

1.4.2 Restrictions and Guidelines

During file transfer, do not insert or remove a storage medium or transmission medium to or from the device to avoid transmission errors.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Download files.

copy { **tftp:** | **oob_tftp:** }***//****remote-file* **flash:***local-file*

1.5 Binding the Source IP Address to the TFTP Client

1.5.1 Overview

You can bind a source IP address to the TFTP client so that the client can use this IP address to communicate with the server for file upload or download.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Bind a source IP address to the TFTP client.

tftp-client source { **ip** *ipv4-address* | **ipv6** *ipv6-address* | interface-type interface-number }

By default, no source IP address is bound to the TFTP client. Instead, an IP address is selected for the client based on the route.

1.6 Configuring a Port Number for TFTP Connection

1.6.1 Overview

You can specify the port number used by the TFTP client to connect with the TFTP server for file upload and download.

1.6.2 Restrictions and Guidelines

The range of the port number configured for the TFTP client is from 20000 to 65534.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the port number used by the TFTP client to connect with the TFTP server.

tftp-client port *port-number*

The default port number used by the TFTP client to connect with the TFTP server is **69**.

1.7 Monitoring

Run the **debugging** command to output debugging information.

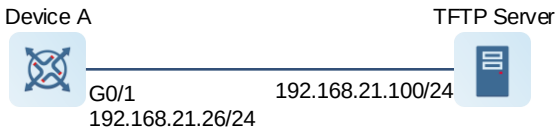
⚠ Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
debugging tftp	Debugs the TFTP client.

1.8 Configuration Examples



1.8.1 Configuring the TFTP Client

1. Requirements

A local device needs to upload a file to a remote TFTP server, and download another file from the TFTP server.

2. Topology

Figure 1-1 Configuring the TFTP Client

3. Notes

- Upload the **local-file** file in the **Flash** directory on device A to the **root** directory of the TFTP server with an IP address 192.168.21.100, and rename the file **remote-file**.
- Download the **remote-file** file from the **root** directory of the TFTP server with the IP address 192.168.21.100 to the **Flash** directory on device A, and save the file as **download-file**.

4. Procedure

(1) Configure the TFTP server.

Set the IP address of the TFTP Server to 192.168.21.100/24.

(2) Configure device A.

a. Configure an IP address.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitethernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# unset switch-port
DeviceA(cfg-if-GigabitEthernet 0/1)# ip address 192.168.21.26 255.255.255
DeviceA(cfg-if-GigabitEthernet 0/1)# exit
```

b. Upload the file.

```
DeviceA# copy flash:local-file tftp://192.168.23.69/root/remote-file
```

c. Download the file.

```
DeviceA# copy tftp://192.168.23.69/root/remote-file flash: download-file
```

5. Verification

Check whether the **remote-file** file is configured on the TFTP server.

Run the **dir** command on device A to check whether the **download-file** file is configured in the **home** directory of the Flash.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
 interface GigabitEthernet 0/1
 ip address 192.168.21.26 255.255.255.0
!
```

7. Common Errors

- The format of the uploaded or downloaded file is incorrect.

1 Configuring SNMP

1.1 Introduction

1.1.1 Overview

The Simple Network Management Protocol (SNMP) is used for network monitoring and management. Because many vendors support SNMP, SNMP has become a network management standard and applies to the interconnected environment of systems of multiple vendors. By using SNMP, the network administrator can implement information query for network nodes, network configuration, fault locating, and capacity planning.

1.1.2 SNMP Versions

- SNMPv1

  SNMPv1 is the first official version of SNMP and is defined in RFC 1157. Based on community names, SNMPv1 has simple structure of management information (SMI) and simple management information base (MIB) and lower security.

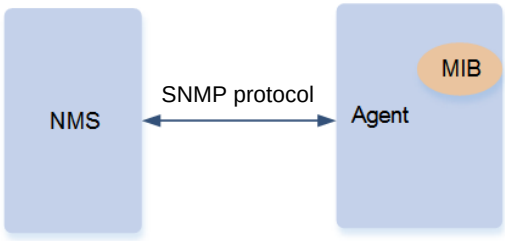
- SNMPv2C

  SNMPv2 is a community-based SNMP management architecture and is defined in RFC 1901. SNMPv2 is compatible with SNMPv1. Compared with SNMPv1, SNMPv2 has two more protocol operations Get-Bulk and Inform and supports more data types and error code information.

- SNMPv3

  SNMPv3 defines security extension capability and provides the following security features by identifying and encrypting data.

  - Ensuring that data is not tampered during transmission.
  - Ensuring that data is transmitted from legal data sources.
  - Encrypting packets and ensuring data confidentiality.



1.1.3 Principles

1. Basic Concepts

The SNMP management system has the following components:

- SNMP network manager
- SNMP agent
- MIB

Figure 1-1 Relationship Between the NMS and Network Management Agent

- SNMP network manager

  The SNMP network manager is a system that controls and monitors the network based on SNMP and is also called the network management system (NMS).

- SNMP agent

  The SNMP agent (" agent") is software running on the managed devices. It is responsible for receiving, processing, and responding to monitoring and control packets from the NMS. The agent may also actively send messages to the NMS.

- MIB

  The MIB is a virtual network management information base. The managed network devices contain lots of information. To uniquely identify a specific management unit among SNMP packets, the MIB adopts the tree hierarchical structure. Nodes in the tree indicate specific management units. A string of digits are used to uniquely identify a management unit system among network devices. The MIB is a set of unit identifiers of network devices.

- Operation types

  Six operation types are defined for information exchange between the NMS and the agent based on SNMP:

  - Get-Request: The NMS extracts one or more parameter values from the agent.
  - Get-Next-Request: The NMS extracts the parameter value next to one or more parameters from the agent.
  - Get-Bulk: The NMS extracts a batch of parameter values from the agent.
  - Set-Request: The NMS sets one or more parameter values of the agent.
  - Get-Response: The agent returns one or more parameter values, which are the operations of the agent in response to the three operations performed by the NMS.
  - Trap: The agent actively sends a message to notify the NMS of the situation happening in the agent.

  The first four packets are sent by the NMS to the agent and the last two packets are sent by the agent to the NMS. The first three operations of the NMS and the response operations of the agent are based on UDP port 161. The Trap operation performed by the agent is based on UDP port 162. For details, see Figure 1-2.

Caution

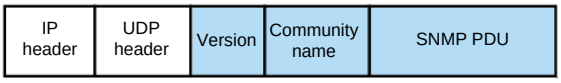
SNMPv1 does not support the Get-Bulk operation.

Figure 1-2 SNMP Packet Interaction

2. Basic SNMP Functions

SNMP interaction is response interaction (for interaction of packets, see Figure 1-2). The NMS actively sends requests to the agent, including Get-request, Get-next-request, Get-bulk, and Set-request. The agent receives the requests, completes operations, and returns a Get-response. Sometimes, the agent actively sends a Trap message and an Inform message to the NMS. The NMS does not need to respond to the Trap message but needs to return an Inform-response to the agent. Otherwise, the agent re-sends the Inform message.

3. Principles of SNMPv1 and SNMPv2C



SNMPv1 and SNMPv2C adopt the community-based security architecture. The administrator who can perform operations on the MIB of the agent is limited by defining the host address and authentication name (community string).

SNMPv1 and SNMPv2 determine whether the administrator has the right to use MIB objects by using the authentication name. To be able to manage devices, the NMS must ensure that its authentication name is the same as an authentication name defined in devices.

In SNMPv2C, the Get-bulk operation enables more detailed error message types to be returned to the NMS. The Get-bulk operation allows all information from a table or lots of data to be obtained at a time, so as to reduce the request-response times. The enhanced error handling capabilities of SNMPv2C include extension of error codes to differentiate error types. In SNMPv1, however, only one error code is provided for the errors. In SNMPv2C, the error codes can be used to differentiate error types. Because management workstations on the network may support SNMPv1 and SNMPv2C at the same time, the SNMP agent must be able to identify SNMPv1 packets and SNMPv2C packets and return packets of the corresponding versions.

SNMPv1 and SNMPv2c packets are composed of version, community name, and SNMP protocol data unit (PDU). Figure 1-3 shows the structure of the packets.

Figure 1-3 Structure of SNMPv1 and SNMPv2c Packets

- The main fields in packets are as follows:
  - Version: Indicates an SNMP version. For SNMPv1 packets, the corresponding field value is 0. For SNMPv2c packets, the field value is 1.
  - Community name: It is used for authentication between the agent and NMS. The field value is a string that can be customized. The community names include readable and writable community names. During Get-Request and Get-Next-Request operations, a readable community name is used for authentication. During Set operations, a writable community name is used for authentication.
  - SNMP PDU: Includes information such as PDU type, request identifier, and variable binding list. SNMPv1 PDUs include GetRequest PDU, GetNextRequest PDU, SetRequest PDU, Response PDU, and Trap PDU. Compared with SNMPv1, SNMPv2c has GetBulkRequest PDU and InformRequest PDU.
- Security

  An authentication name has the following attributes:
  - Read-only: Provides the read permission of all MIB variables for authorized management workstations.
  - Read-write: Provides the read/write permission of all MIB variables for authorized management workstations.

4. Principles of SNMPv3

SNMPv3 redefines the SNMP architecture and includes functions of SNMPv1 and SNMPv2 into the SNMPv3 system.

The NMS and SNMP agent are SNMP entities. In the SNMPv3 architecture, SNMP entities consist of the SNMP engine and SNMP applications. The SNMP engine is used to send and receive messages, identify and encrypt information, and control access to managed objects. SNMP applications refer to internal applications of SNMP, which work by using the services provided by the SNMP engine.

SNMPv3v determines whether a user has the right to use MIB objects by using the user-based security model (USM). The security level of the NMS user must be the same as that of a specified SNMP user defined in devices so as to manage devices.

SNMPv3 requires the NMS to obtain the SNMP agent engine IDs on devices when the NMS manages devices. SNMPv3 defines the Discover and Report operation mechanisms. When the NMS does not know the agent engine ID, the NMS may first send a Discover message to the agent and the agent returns a Report message carrying an engine ID. Later, management operations between the NMS and the agent must carry the engine ID.

SNMPv3 defines a new packet format, which is shown in Figure 1-4.

Figure 1-4 Structure of SNMPv3 Packets

- The main fields in SNMP packets are as follows:
  - Version: Indicates an SNMP version. For SNMPv3 packets, the field value is 2.

- Header data: Mainly includes description information such as the maximum message size supported by the message sender and the security model of the message.
- Security parameter: Includes such security information as SNMP engine-related information, username, authentication parameter, and encryption parameter.
- Context EngineID: A unique identifier of SNMP. This field and the PDU type decide the application to which the packets are sent.
- Context name: Decides the MIB view of the managed devices based on the Context EngineID.
- SNMP PDU: Includes information such as PDU type, request identifier, and variable binding list. SNMPv3 PDUs include GetRequest PDU, GetNextRequest PDU, SetRequest PDU, Response PDU, Trap PDU, GetBulkRequest PDU, and InformRequest PDU.

- Security

  SNMPv3 determines the data security mechanism based on the security model and security level. At present, security models include SNMPv1, SNMPv2C, and SNMPv3. SNMPv3 includes SNMPv1 and SNMPv2C into the security model.

Table 1-1 Security Models and Security Levels of SNMPv1 and SNMPv2C

Security Model	Security Level	Authentication	Encryption
SNMPv1	noAuthNoPriv	Authentication name	N/A
SNMPv2c	noAuthNoPriv	Authentication name	N/A

Table 1-2 Security Model and Security Level of SNMPv3

Security Model	Security Level	Authentication	Encryption	Description
SNMPv3	noAuthNoPriv	Username	N/A	Data validity is confirmed through username.
SNMPv3	authNoPriv	MD5 or SHA	N/A	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA is provided.
SNMPv3	authPriv	MD5 or SHA	DES	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA and the data encryption mechanism based on CBC-DES are provided.

- Engine ID

  An engine ID is used to uniquely identify an SNMP engine. Because each SNMP entity includes only one SNMP engine, the SNMP engine uniquely identifies an SNMP entity in a management domain. Therefore, the SNMPv3 agent as an entity must has a unique engine ID, that is, SnmpEngineID.

  An engine ID is an octet string that consists of 5 to 32 bytes. RFC 3411 defines the format of an engine ID:

  - The first four bytes indicate the private enterprise ID (allocated by the Internet Assigned Numbers Authority (IANA)) of a vendor, which is expressed in hexadecimal.

- The fifth byte indicates remaining bytes.
- 0: Reserved.
- 1: The later four bytes indicate an IPv4 address.
- 2: The later 16 bytes indicate an IPv6 address.
- 3: The later six bytes indicate a MAC address.
- 4: Text consisting of up to 27 bytes, which is defined by the vendor.
- 5: Hexadecimal value consisting of up to 27 bytes, which is defined by the vendor.
- 6-127: Reserved.
- 128-255: Formats specified by the vendor.

1.1.4 Protocols and Standards

- RFC 1157, Simple Network Management Protocol (SNMP)
- RFC 1901, Introduction to Community-based SNMPv2
- RFC 2578, Structure of Management Information Version 2 (SMIv2)
- RFC 2579, Textual Conventions for SMIv2
- RFC 3411, An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks
- RFC 3412, Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)
- RFC 3413, Simple Network Management Protocol (SNMP) Applications
- RFC 3414, User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)
- RFC 3415, View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)
- RFC 3416, Version 2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)
- RFC 3417, Transport Mappings for the Simple Network Management Protocol (SNMP)
- RFC 3418, Management Information Base (MIB) for the Simple Network Management Protocol (SNMP)

RFC 3419, Textual Conventions for Transport Addresses

1.2 Configuration Task Summary

SNMP configuration includes the following tasks:

(1) Configuring Basic SNMP Features

(2) (Optional) Configuring the Trap Function

(3) (Optional) Configuring the Agent Shielding Function

(4) (Optional) Configuring SNMP Control Parameters

1.3 Configuring Basic SNMP Features

1.3.1 Overview

After the basic SNMP function is configured, users can access the agent through the NMS.

1.3.2 Restrictions and Guidelines

- When an authentication name is configured, the default access permission is read-only if no access permission is specified.
- When the view-based access control model (VACM) is used, an SNMP user group must be configured. By associating specified users with a group and associating the group with a view, you can ensure that the users in the group have the same access permission. In this way, you can determine whether managed objects associated with an operation are in the allowable range of a view. Only managed objects in the range of a view can be accessed.
- When you configure users in SNMPv3, you can specify the security level, authentication algorithm (MD5 or SHA), authentication password, encryption algorithm (DES at present), and encryption password.
- After the SNMP attack prevention and detection function is configured, the corresponding action can be taken after authentication fails consecutively.
- The permanently forbidden source IP addresses can be authenticated for access again only after the administrator manually unlocks the IP addresses. The source IP addresses that are forbidden in a period of time can be authenticated for access again after the period expires or after the administrator manually unlocks the IP addresses.
- Password dictionary check for communities and users is disabled by default. This function must be used with the **password policy info** command in global configuration mode.
- The SNMP logging function records the Get, Get-Next, and Set operations performed by the NMS on the SNMP Agent. When the Get and Get-Next operations are performed, the agent records the IP address of the NMS user, operation type, and OID of the operation node. When the Set operation is performed, the agent records the IP address of the NMS user, operation type, OID of the operation node, and set value. These logs are sent to the information center of devices. The level of these logs is informational, that is, the logs are used as prompt information of devices. A large number of logs will affect device performance. In normal conditions, you are advised to disable the SNMP logging function.
- SNMP ACL will be associated with the ACL-based filtering rule to prevent unauthorized users from sampling SNMP information.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Configure an SNMP view.

snmp-agent view *view-name oid-tree* { **include** | **exclude** }

An SNMP view needs to be configured when the View-based Access Control Model (VACM) function is used.

The default view allows access to all MIB objects.

(4) (Optional) Configure an SNMP user group.

snmp-agent group *groupname* { **snmpv1** | **snmpv2c** | **snmpv3** { **auth** | **noauth** | **priv** } } [**read** *readview*] [**write** *writeview*] [**access-apply** {

[**ipv6** *ipv6-acl-name*]

acl-name | *acl-number* }]

No user group is configured by default.

(5) Configure an authentication name and access permission.

snmp-agent community [**0** | **7** | **secret** [**0** | **8**]] *community* [**view** *view-name*] [**ro** | **rw**] [**host** *ipv4-address* | **host** *ipv6-address*]

[**ipv6** *ipv6-acl-name*]

[*acl-name* | *acl-number*]

No authentication name is configured and the access permission of all communities is read-only by default.

When SNMPv1 and SNMPv2C are used to manage network devices, an authentication name must be configured on the agent.

(6) Configure an SNMP user.

snmp-agent user *username groupname* { **snmpv1** | **snmpv2c** | **snmpv3** [**crypto** | **interactive**] [**authentication** { **md5** | **sha** | **sha2-256** | **sha2-512** } *auth-password*] [**priv** { **des56 | acs128** } *priv-password*] } [**access-apply** {

[**ipv6** *ipv6-acl-name*]

| *acl-name* | *acl-number* }]

No SNMP user is configured by default.

When SNMPv3 is used to manage network devices, a user must be configured.

(7) (Optional) Enable the agent function.

enable-server service snmp-agent

The SNMP agent function is enabled by default.

(8) (Optional) Enable the SNMP attack prevention and detection function.

snmp-agent authentication attempt *attempt-times* **exceed** { **lock** | **lock-time** *lock-time* | **unlock** }

SNMP attack defense is enabled by default. The maximum number of consecutive SNMP authentication failures is 3 by default. The account is locked for 10 minutes after three consecutive SNMP authentication failures.

(9) (Optional) Configure password dictionary check for communities.

snmp-agent subscribe secret-dictionary-check

Password dictionary check for communities and users is disabled by default.

(10) (Optional) Configure the SNMP logging function to record the Get, Get-Next, and Set Operations performed by the NMS on the SNMP Agent.

snmp-agent logging { **authentication** { **fail | success** } | **get-operation** | **set-operation** | **trap-info** }

By default, the function of logging the Get and Get-Next Operations performed by the NMS on the SNMP agent is disabled and the function of logging the Set Operation is enabled.

(11) (Optional) Configure a global ACL filtering rule for the SNMP server.

snmp-agent ip access-apply {*aclnum* | *aclname*}

snmp-agent ipv6 access-apply *aclv6name*

No ACL filtering rule is configured for the SNMP server by default.

1.4 Configuring the Trap Function

1.4.1 Overview

After the Trap function is configured, the agent actively sends Trap messages to the NMS.

1.4.2 Restrictions and Guidelines

- The host address of the NMS must be configured when the agent actively sends Trap messages to the NMS. That is, the **snmp-agent host** command is used with the **snmp-agent subscribe traps** command in the global configuration mode.
- Multiple SNMP hosts can be configured to receive Trap messages. A host can combine different types of Trap messages, ports, and VRF forwarding tables. If a host is configured with the same port and VRF in multiple configurations, the last configuration is combined with the previous configurations. To send different Trap messages to the same host, configure different types of Trap messages each time. These configurations are finally combined.
- The system reboot notification function must be enabled on the agent so that the RGOS system sends Trap messages to the NMS to notify system reboot before reloading or rebooting of the device.
- After the Link Trap message sending function is enabled on an interface, the SNMP sends a Link Trap message if the link status on the interface changes. Otherwise, the SNMP does not send the message.
- By default, the IP address of an interface that sends SNMP packets is used as the source address of the SNMP packets. If you want to use a fixed local IP address as the source address to facilitate management, configure the source address for sending Trap messages on the agent.
- The **snmp-agent trap**-**format private** command can be run to include private fields in Trap messages. The supported private field is the alarm generation time. For the specific data types and data ranges of the fields, see the Ruijie-TRAP-FORMAT-MIB.mib file.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) (Optional) Configure an NMS host address.

snmp-agent host [**oob**] { *ipv4-address* | **ipv**6 *ipv6-address* **| domain** *domain-name* } [**vrf** *vrf-name*] [**traps** | **informs**] [**version** { { **1** | **2c** } [**0** | **7**] *community* | **3** { **auth** | **noauth** | **priv** } *username* }] [**udp-port** *port-number*] [**via** *mgmt-name*] [*notification-type*]

No SNMP host address is configured by default.

(4) (Optional) Enable the agent to actively send Trap messages to the NMS.

snmp-agent subscribe traps [*notification-type*]

The SNMP agent is forbidden to send Trap messages to the NMS by default.

(5) (Optional) Configure the system reboot trap sending function.

snmp-agent reload-trap

The SNMP system reboot notification function is disabled by default.

(6) (Optional) Configure a source address for Trap messages.

snmp-agent trap-source-interface *interface-type interface-number*

The IP address of the interface that sends SNMP packets is used as the source address by default.

(7) (Optional) Include private fields in sent Trap messages.

snmp-agent trap-format private

SNMP Trap messages do not include private fields by default.

(8) Configure Inform message sending attempts and timeout time.

snmp-agent inform { **retries** *retry-number* | **timeout** *timeout* }

The number of default Inform message sending attempts is **3** and the default Inform message timeout time is **15** seconds.

(9) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

(10) (Optional) Enable the Link Trap message sending function on an interface.

snmp-agent enable linktrap

The Link Trap message sending function is enabled on an interface by default.

(11) (Optional) Enable heartbeat Trap.

snmp heartbeat on

Heartbeat Trap is enabled by default.

(12) (Optional) Enable the heartbeat Trap interval.

snmp heartbeat period *time*

The default heartbeat Trap interval is 300 seconds.

1.5 Configuring the Agent Shielding Function

1.5.1 Overview

After the agent shielding function is enabled, the port access frequency and network attack probability are reduced.

1.5.2 Restrictions and Guidelines

The SNMP agent function is disabled by default. When SNMP agent parameters (for example, NMS host address, authentication name, and access permission) are configured, the SNMP agent service is automatically enabled. The **enable-server service snmp-agent** command must be run so that the SNMP agent service can take effect. If the SNMP agent service is disabled or the **enable-server service snmp-agent** command is not run, the SNMP agent service does not take effect. The **unset snmp-agent** command is used to shield all SNMP agent service configurations. In this case, running the **display current-config** command will not display the configurations. The configurations can be restored after the SNMP agent service is enabled again. The **unset enable-server service snmp-agent** command is used to disable the SNMP agent service. In this case, the SNMP agent function is disabled and packets and trap messages are not sent and received, but the SNMP agent configurations are not shielded.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the SNMP agent shielding function.

unset snmp-agent

The SNMP agent function is enabled by default.

(4) Disable the SNMP agent function of a device.

unset enable-server service snmp-agent

The SNMP agent function is enabled by default.

1.6 Configuring SNMP Control Parameters

1.6.1 Overview

After basic parameters such as device contact mode, device location, serial number, and Trap message sending are configured, the NMS can obtain information such as the contact person and physical location of the device by accessing the parameters.

1.6.2 Restrictions and Guidelines

- When too many SNMP request packets cause SUMP tasks to occupy a large CPU space, you can configure SNMP traffic control to limit the number of request packets processed per second in each SNMP task to control the CPU usage.
- SNMP contains three versions: v1, v2C, and v3. If only a specified version is used for MIB interaction management in practice, you can disable unused SNMP versions by running the **unset snmp-agent subscribe version** [**snmpv1** | **snmpv2c** | **snmpv3**] command.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the contact mode of the system.

snmp-agent contact *contact-text*

The contact mode of the system is empty by default.

(4) Configure the system location.

snmp-agent location *location-text*

The system location is empty by default.

(5) Configure the system serial number.

snmp-agent chassis-id *chassis-id-text*

The default system serial number is 60FF60.

In general, the device serial number is used as the SNMP serial number to facilitate identification of the device.

(6) Configure NE information of a device.

snmp-agent net-id *net-id-text*

The NE code information of a device is empty by default.

(7) Configure the maximum packet length of the SNMP agent.

snmp-agent packetsize *packetsize*

The maximum packet length of the SNMP agent is 1,472 bytes by default.

(8) Configure the UDP port ID of the SNMP service.

snmp-agent udp-port *port-number*

The default UDP port ID of the SNMP service is **161**.

(9) Configure the source port of the device on which the SNMP service is deployed.

snmp-agent source-interface *interface-type interface-number*

The source port of a device with a valid IP address is used to receive SNMP packets by default.

(10) Configure the queue length of Trap messages.

snmp-agent trap queue-length *queue-length*

The default queue length of the Trap messages is **100**.

(11) Configure the sending interval of Trap messages.

snmp-agent trap-send-interva *trap-timeout-time*

The Trap messages are resent with a timeout time of **300** milliseconds by default.

(12) Configure SNMP traffic control.

snmp-agent flow-control pps *packet-count*

About 300 SNMP request packets are processed every second by default.

(13) Configure the status of SNMP versions.

unset snmp-agent subscribe version { **snmpv1** | **snmpv2c** | **snmpv3** }

SNMPv1 and SNMPv2c are disabled and SNMPv3 is enabled by default.

1.7 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

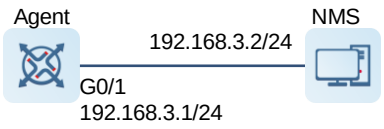
⚠ Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-3 Monitoring

Command	Purpose
cleanup snmp locked-ip [**ipv4** *ipv4-address* | **ipv6** *ipv6-address*] **cleanup snmp locked-ip ipv4** *ipv4-address*	Clears the list of source IP addresses that are locked after authentication fails consecutively.
display snmp [**group** | **host** | **locked-ip** | **process-mib-time** | **mib** | **user** | **version** | **view**]	Displays the SNMP status information.

1.8 Configuration Examples



1.8.1 Configuring Basic Functions of SNMPv2c

1. Requirements

Network devices are managed and monitored through the SNMP network manager, as shown in Figure 1-5.

2. Topology

Figure 1-5 Configuring Basic Functions of SNMPv2c

3. Procedure

Enable the SNMP agent function.

```
Device> subscribe
Device# config-system terminal
Device(cfg)# enable-server service snmp-agent
```

Configure a read/write community with the name comm_v1.

```
Device(cfg)# snmp-agent community comm_v2 rw
```

Configure an IP address for the agent. Set the address of GigabitEthernet 0/1 to 192.168.3.1/24.

```
Device(cfg)# interface gigabitethernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
Device(cfg-if-gigabitEthernet 0/1)# ip address 192.168.3.1 255.255.255.0
Device(cfg-if-gigabitEthernet 0/1)# exit
```

4. Verification

Run the **ping** command to verify that the agent and NMS are mutually reachable via L3 routes.

```
Device# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **display service** command to check whether the SNMP agent function is enabled.

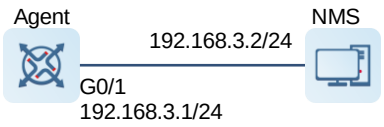
```
Device# display service
snmp-agent       : enabled
ssh-server       : disabled
telnet-server : enabled
```

5. Configuration Files

Agent configuration file

```
interface GigabitEthernet 0/1
  ip address 192.168.2.1 255.255.255.0
!
snmp-agent community comm_v2 rw
!
end
```

1.8.2 Configuring Basic Functions of SNMPv3



1. Requirements

The network management station is connected to the managed network devices. On the network management station, users access the MIB on the network devices through the SNMP network manager and receive messages actively sent by the network devices to manage and monitor the network devices.

- The management workstation (NMS) manages network devices (agents) based on the authentication and encryption mode of users.
- Network devices can control the operation permission of users to access MIB objects.
- Network devices can actively send authentication and encryption messages to the NMS.

2. Topology

Figure 1-6 Configuring Basic Functions of SNMPv3

3. Notes

- Configure an MIB view and an SNMP user group.
- Configure an SNMP user.
- Configure an SNMP host.
- Configure an IP address for the agent.

4. Procedure

Create an MIB view with the name view1, which includes the associated MIB object 1.3.6.1.2.1.1. Create an MIB view with the name view2, which includes the associated MIB object 1.3.6.1.2.1.1.4.0.

```
Device> subscribe
Device# config-system terminal
Device(cfg)# snmp-agent view view1 1.3.6.1.2.1.1 include
```

Create an MIB view with the name view2, which includes the associated MIB object 1.3.6.1.2.1.1.4.0.

```
Device(cfg)# snmp-agent view view2 1.3.6.1.2.1.1.4.0 include
```

Create an SNMP user group with the name g1, select v3 as the version, and configure an authentication and encryption mode with the security level priv. Configure view1 as a readable view and view2 as a writable view.

```
Device(cfg)# snmp-agent group g1 v3 priv read view1 write view2
```

Configure an SNMP user. Create a user with the name **user1** under the group g1, select v3 as the version, and set the authentication mode to md5, authentication password to 123, encryption mode to DES56, and encryption password to 321.

```
Device(cfg)# snmp-agent user user1 g1 v3 authentication md5 123 priv des56 321
```

Configure the SNMP host: Set the host address to 192.168.3.2, and the version to v3, configure an authentication and encryption mode with the security level priv, and associate the username **user1**.

```
Device(cfg)# snmp-agent host 192.168.3.2 traps version 3 priv user1
```

Enable the agent to actively send Trap messages to the NMS.

```
Device(cfg)# snmp-agent subscribe traps
```

Configure an IP address for the agent. Set the address of GigabitEthernet 0/1 to 192.168.3.1/24.

```
Device(cfg)# interface gigabitethernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
Device(cfg-if-gigabitEthernet 0/1)# ip address 192.168.3.1 255.255.255.0
Device(cfg-if-gigabitEthernet 0/1)# exit
```

5. Verification

Run the **ping** command to verify that the agent and NMS are mutually reachable via L3 routes.

```
Device# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **display snmp user** command to display the SNMP user.

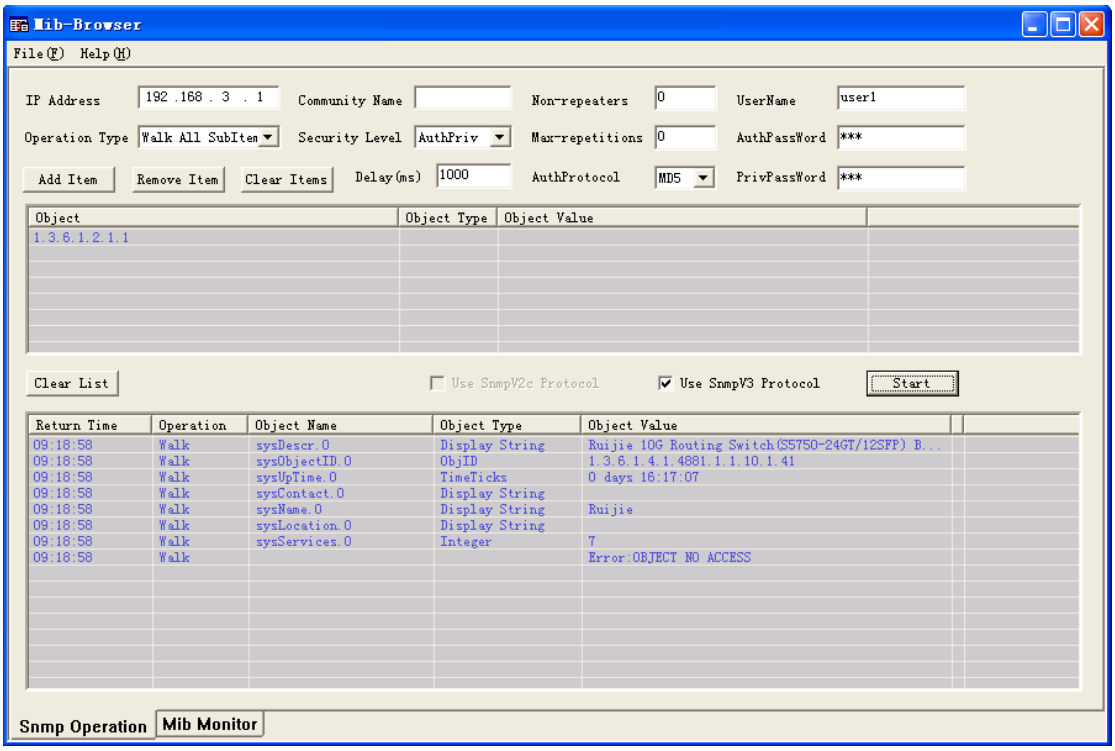
```
Device# display snmp user
User name: user1
Engine ID: 800013110300d0f8221120
storage-type: permanent         active
Security level: auth priv
Auth protocol: MD5
Priv protocol: DES
Group-name: g1
```

Run the **display snmp view** command to display the SNMP view.

```
Device# display snmp view
view1(include) 1.3.6.1.2.1.1
view2(include) 1.3.6.1.2.1.1.4.0
default(include) 1.3.6.1
```

Run the **display snmp group** command to display the SNMP group.

```
Device# display snmp group
groupname: g1
securityModel: v3
securityLevel:authPriv
readview: view1
writeview: view2
notifyview:
```



Run the **display snmp host** command to display the host information configured by the user.

```
Device# display snmp host
Notification host: 192.168.3.2
udp-port: 162
type: trap
```

```
user: user1
security model: v3 authPriv
```

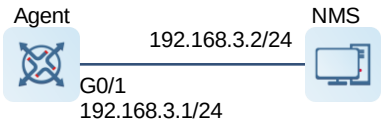
Install the MIB browser query. Enter the IP address 192.168.3.1 in IP Address and **user1** in UserName, select AuthPriv for Security Level, enter 123 in AuthPassWord, select MD5 for AuthProtocol, and enter 321 in PrivPassWord. Click **Add Item** and select an MIB management unit to be queried, for example, System. Click **Start** to query the MIB of the network devices. The query results are displayed in the lowest pane of the dialog box, as shown in Figure 1-7.

Figure 1-7 MIB-browser Query Example

6. Configuration Files

Agent configuration file

```
interface GigabitEthernet 0/1
 ip address 192.168.2.1 255.255.255.0
!
snmp-agent view view1 1.3.6.1.2.1.1 include
snmp-agent view view2 1.3.6.1.2.1.1.4.0 include
snmp-agent user user1 g1 v3 crypto authentication md5 DE8E9D1158A057A69EF73D1C12C51CC5 priv
des56 C767B705F9B261E6D359D4BFBDAF9CF4
snmp-agent group g1 v3 priv read view1 write view2
snmp-agent host 192.168.3.2 traps version 3 priv user1
snmp-agent subscribe traps
!
end
```



1.8.3 Configuring Basic Functions of Trap

1. Requirements

The network management station (NMS) manages network devices (agents) based on the community authentication mode, and the network devices can actively send messages to the network management station.

2. Topology

Figure 1-8 Configuring Basic Functions of Trap

3. Procedure

Set the agent and NMS to be reachable via L3 routes, and set the IP address of GigabitEthernet 0/1 on the agent to 192.168.3.1.

```
Device> subscribe
Device# config-system terminal
Device(cfg)#interface gigabitethernet 0/1
Device(cfg-if-gigabitEthernet 0/1)# unset switch-port
Device(cfg-if-GigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0
Device(cfg-if-GigabitEthernet 0/1)#exit
```

Set the SNMP host address to 192.168.3.2, the message format to Version 2c, and the authentication name to user1. Enable the agent to actively send Trap messages to the NMS.

```
Device> subscribe
Device# config-system terminal
Device(cfg)# snmp-agent host 192.168.3.2 traps version 2c user1
Device(cfg)# snmp-agent subscribe traps
```

4. Verification

Run the **ping** command to verify that the agent and NMS are mutually reachable via L3 routes.

```
Device# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **display snmp** command to display the SNMP status.

```
Device# display snmp
Chassis: 1234567890
0 SNMP packets input
        0 Bad SNMP version errors
        0 Unknown community name
        0 Illegal operation for community name supplied
```

```
        0 Encoding errors
        0 Number of requested variables
        0 Number of altered variables
        0 Get-request PDUs
        0 Get-next PDUs
        0 Set-request PDUs
0 SNMP packets output
        0 Too big errors (Maximum packet size 1472)
        0 No such name errors
        0 Bad values errors
        0 General errors
        0 Response PDUs
        0 Trap PDUs
SNMP global trap: enabled
SNMP logging: disabled
SNMP agent: enabled
```

5. Configuration Files

Agent configuration file

```
interface GigabitEthernet 0/1
  ip address 192.168.2.1 255.255.255.0
!
snmp-agent host 192.168.3.2 traps version 2c user1
snmp-agent subscribe traps
!
end
```

1 Configuring RMON

1.1 Introduction

1.1.1 Overview

The Remote Network Monitoring (RMON) protocol is a network management protocol that is built on the Simple Network Management Protocol (SNMP) architecture. RMON provides statistics and alarm functions for a managing device to remotely monitor and manage devices. he statistics function means that a managed device can trace and calculate different types of traffic information on a network segment that is connected to the port of the device regularly or continuously. For example, the device can trace and calculate the total number of packets or the total number of excessively long packets received on a network segment in a period. The alarm function means that a managed device can monitor specified management information base (MIB) variables and automatically record an event and send Trap messages to the managing device when one of the variables reaches the alarm threshold, for example, the port rate or the ratio of broadcast packets reaches a specified value.

Both RMON and SNMP are used for remote network management. Compared with SNMP, RMON has the following advantages:

- RMON notifies the managing device of alarm variable abnormality in Trap messages by using the SNMP Trap message sending mechanism. Though the Trap function is also defined in SNMP, this function is used to notify the managing device of the function running status of a managed device and physical state change of an interface. SNMP and RMON have different monitored objects, trigger conditions, and report content.
- Compared with SNMP, RMON can monitor remote network devices more effectively and actively, thus providing an efficient means of monitoring subnet running. According to RMON, a managed device can automatically send Trap messages when a value reaches the alarm threshold. This frees the managing device from frequently obtaining and comparing values of MIB variables and thus reduces the communication between the managing device and managed device. As a result, large interconnected networks are being managed simply yet effectively.

1.1.2 Principles

RMON defines different RMOM groups, and the company’s devices support the statistics group, history group, alarm group, and event group. The four groups are as follows:

1. Statistics Group

A statistics group is used to monitor and calculate traffic data on an Ethernet interface. The traffic data consists of cumulative values and is calculated from the time of entry creation to the current time. Statistical objects include discarded packets, broadcast packets, CRC errors, over-small or over-large packets, and conflicts. The statistical results are saved in the Ethernet statistical table for the administrator to view at any time.

2. History Group

A history group is used to collect network traffic periodically and records cumulative values of the traffic and bandwidth usage in each period. The data is saved in the history control table for the administrator to process. A history group includes two sub-groups:

- The HistoryControl sub-group is used to configure control information such as sampling interval and sampling data sources.
- The EthernetHistory sub-group provides the administrator with history data of a specific network segment, including traffic, error packets, broadcast packets, usage, and hit times.

3. Alarm Group

The alarm group is used to monitor specified MIB objects. When the value of an MIB object exceeds the set upper limit or lower limit, an alarm is triggered and processed as an event.

4. Event Group

An event group is used to define processing methods of events. When a monitored MIB object reaches the alarm condition, an event is triggered. The event can be processed with one of the following methods:

- None: The event is ignored.
- Log: The event related information is recorded in a log table for the administrator to view at any time.
- Snmp-trap: The Trap message is sent to the network management station to notify the occurrence of the event.
- Log-and-trap: The event-related information is recorded in a log table and the Trap message is sent to the network management station.

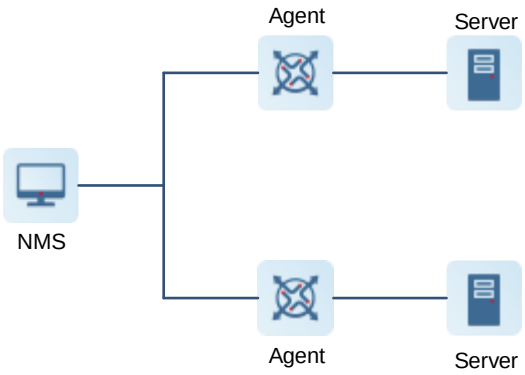
5. Working Process of RMON

RMON allows multiple monitor authorities to collect data with the following two methods: use the special RMON probe to collect data so that the NMS can obtain all MIB information from the RMON probe; embed the RMON agent into a network device (for example, switch or router) so that the device possesses the function of an RMON probe. The NMS uses basic commands of SNMP to exchange data with the network device and collect network management information. Limited by the device resources, this method does not obtain all data of the RMON MIB. Generally, only four groups of information are collected.

Through the RMON agent running on the managed network device, the NMS can obtain information such as traffic, error statistics, and performance statistics on the network segment that is connected to the port of this network device, to remotely manage this network device. Figure 1-1 displays the communication network between the NMS and RMON agent.

- RMON Ethernet statistics function

  Make the statistics of network traffic on the Ethernet interface from the time of entry creation to the current time.



- RMON history statistics function

  Record cumulative statistical values of traffic on the Ethernet interface in each period.

- RMON alarm function

  Monitor changes of alarm variable values periodically. If an alarm variable value exceeds the specified upper or lower limit, corresponding event is triggered, for example, a Trap message is sent or a LogTable entry record is created. Continuous excess of an upper or a lower limit triggers an event only once and the event can be triggered again by excess of the opposite limit.

Figure 1-1 Communication Network Between the NMS and RMON Agent

1.1.3 Protocols and Standards

- STD 0059 / RFC 2819: Remote Network Monitoring Management Information Base
- RFC 4502: Remote Network Monitoring Management Information Base Version 2
- RFC 3919: Remote Network Monitoring (RMON) Protocol Identifiers for IPv6 and Multi Protocol Label Switching (MPLS)
- RFC 3737: IANA Guidelines for the Registry of Remote Monitoring (RMON) MIB Modules
- RFC 3434: Remote Monitoring MIB Extensions for High Capacity Alarms
- RFC 3395: Remote Network Monitoring MIB Protocol Identifier Reference Extensions
- RFC 3287: Remote Monitoring MIB Extensions for Differentiated Services
- RFC 3273: Remote Network Monitoring Management Information Base for High Capacity Networks
- RFC 2896: Remote Network Monitoring MIB Protocol Identifier Macros
- RFC 2895: Remote Network Monitoring MIB Protocol Identifier Reference

1.2 Configuration Task Summary

RMON configuration includes the following tasks:

- Configuring the Ethernet Statistics Function
- Configuring the History Statistics Function
- Configuring the Alarm Function

1.3 Configuring the Ethernet Statistics Function

1.3.1 Overview

With the Ethernet statistics function of RMON, you can learn the cumulative statistical values of traffic generated on the monitored Ethernet interface from the time of entry creation to the current time.

1.3.2 Restrictions and Guidelines

- To calculate and monitor a specified interface, you must configure the Ethernet statistics function on this interface.

- After the statistics entry is created on the specified interface, the statistics group calculates the traffic of this interface. That is, make the statistics of variables defined by the Ethernet statistics table and record the cumulative values of variables that are generated from the creation time of the RMON statistics table to the current time.
- This function cannot be configured in the batch interface configuration mode.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 2 or Layer 3 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

(4) Configure statistical items of RMON.

rmon collection statistics *collection-stats-table-index* [**owner** *owner-name*]

The Ethernet statistics function is not configured on an Ethernet interface by default.

1.4 Configuring the History Statistics Function

1.4.1 Overview

With the history statistics function of RMON, you can learn the cumulative statistical values of traffic generated in each period and the bandwidth utilization on the monitored interface.

1.4.2 Restrictions and Guidelines

- The history group makes the statistics of variables defined by the history statistics function and records cumulative values of variables in each period.
- To collect network statistics on a specified interface, you must configure the history control function on the interface. This function cannot be configured in the batch interface configuration mode.
- It is not allowed to modify parameters of the configured history statistics function.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 2 or Layer 3 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

(4) Configure the history statistics function of an Ethernet interface.

rmon collection history-stats *collection-history-table-index* [**buckets** *bucket-number*] [**interval** *period-time*] [**owner** *owner-name*]

The history statistics function is not configured on an Ethernet interface by default.

1.5 Configuring the Alarm Function

1.5.1 Overview

The alarm function of RMON monitors whether the values of alarm variables vary within the valid range periodically.

1.5.2 Restrictions and Guidelines

- If alarm variables are MIB variables defined by the RMON statistical group or history group, the RMON statistics function or history statistics function must be configured on the monitored Ethernet interface. Otherwise, the alarm table fails to be created.
- The alarm function is implemented by the alarm table and event table. After an alarm event is triggered, the SNMP agent must be configured so that Trap messages can be sent to the managing device. For more information about SNMP agent configuration, see *Configuring SNMP*.
- Configured event table parameters, including event type, Trap community name, event description, and event creator, can be modified.
- Configured alarm table parameters, including alarm variable, sampling type, table creator, sampling interval, upper/lower limit, and event, can be modified.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an event table.

rmon event-instance *event-table-index* [**description** *description-string* | **log** | **owner** *owner-name* | **trap** *community*]*

No RMON event is configured by default.

(4) Configure the alarm function.

rmon alarm-instance *alarm-table-index alarm-variable sampling-interval* { **absolute** | **delta** } **upper-threshold** *sampling-rising-threshold-value* [*event-number*] **lower-threshold** *falling-threshold-value* [*event-number*] [**owner** *owner-name*]

The RMON alarm function is not configured by default.

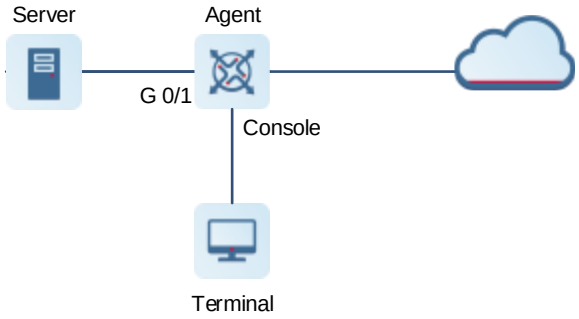
1.6 Monitoring

Run the **displaydisplay** command to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
display rmon-instance	Displays all RMON configurations.
display rmon-instance statistics	Displays the Ethernet statistics table information.
display rmon-instance history	Displays the history control table information.
display rmon-instance alarm	Displays the alarm table information.
display rmon-instance event	Displays the event table information

1.7 Configuration Examples



1.7.1 Configuring the Ethernet Statistics Function

1. Requirements

The RMON agent is connected to a server. The network administrator uses the RMON statistics group to calculate the performance of received packets on GigabitEthernet 0/1. Thus, the network administrator can understand the data of packets received on an interface at any time by viewing data, and take timely actions to process network abnormalities.

2. Topology

Figure 1-2 Configuring the Ethernet Statistics Function

3. Procedure

Configure a statistics table instance on GigabitEthernet 0/1 of the device on which the RMON agent is deployed to make the statistics of traffic on this interface.

```
Device> privilege
Device# config-system terminal
Device(cfg)# interface gigabitEthernet 0/1
```

```
Device(cfg-if-GigabitEthernet 0/1)# rmon collection stats 1 owner admin
```

4. Verification

Run the **display rmon-instance statistics** command to display Ethernet statistics information.

```
Device# display rmon-instance statistics
ether statistic table:
                    index = 1
                    interface = GigabitEthernet 0/1
                    owner = admin
                    status = 1
                    dropEvents = 0
                    octets = 25696
                    pkts = 293
                    broadcastPkts = 3
                    multiPkts = 0
                    crcAlignErrors = 0
                    underSizePkts = 0
                    overSizePkts = 0
                    fragments = 0
                    jabbers = 0
                    collisions = 0
                    packets64Octets = 3815
                    packets65To127Octets = 1695
                    packets128To255Octets = 365
                    packets256To511Octets = 2542
                    packets512To1023Octets = 152
                    packets1024To1518Octets = 685
```

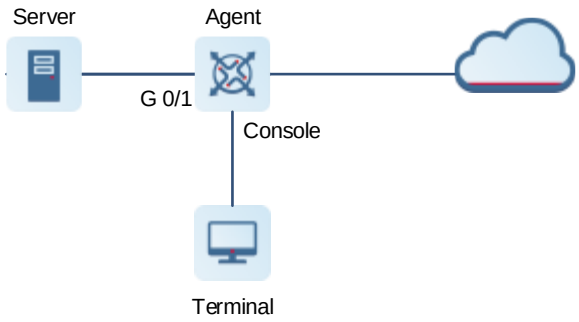
5. Configuration Files

Agent configuration file

```
hostname Device
!
interface GigabitEthernet 0/1
 rmon collection stats 1 owner admin
!
end
```

6. Common Errors

The parameters of configured statistics entries are reconfigured or modified.



1.7.2 Configuring the History Statistics Function

1. Requirements

The RMON agent is connected to a server. The network administrator uses the history group to make the statistics of received packets on GigabitEthernet 0/1 every minute so as to monitor the network and master emergencies.

2. Topology

Figure 1-3 Configuring the History Statistics Function

3. Procedure

Configure a history control table on GigabitEthernet 0/1 of the device on which the RMON agent is deployed to make the statistics of traffic on this interface periodically.

```
Device> privilege
Device# config-system terminal
Device(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-GigabitEthernet 0/1)# rmon collection history 1 buckets 5 interval 300 owner admin
```

4. Verification

Run the **display rmon-instance history** command to display history group statistics.

```
Device# display rmon-instance history
rmon history control table:
                        index = 1
                        interface = GigabitEthernet 0/1
                        bucketsRequested = 5
                        bucketsGranted = 5
                        interval = 60
                        owner = admin
                        stats = 1

rmon history table:
                        index = 1
                        sampleIndex = 786
                        intervalStart = 6d:18h:37m:38s
                        dropEvents = 0
                        octets = 2040
                        pkts = 13
                        broadcastPkts = 0
                        multiPkts = 0
                        crcAlignErrors = 0
                        underSizePkts = 0
```

```
overSizePkts = 0
fragments = 0
jabbers = 0
collisions = 0
utilization = 0

index = 1
sampleIndex = 787
intervalStart = 6d:18h:38m:38s
dropEvents = 0
octets = 1791
pkts = 16
broadcastPkts = 1
multiPkts = 0
crcAlignErrors = 0
underSizePkts = 0
overSizePkts = 0

                    collisions = 0
                    utilization = 0
```

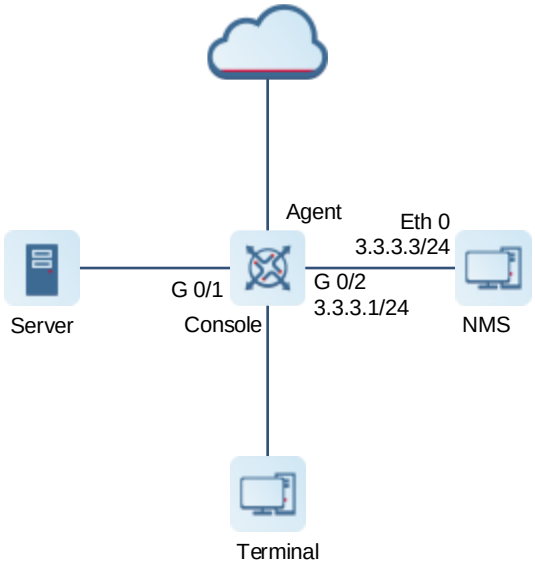
5. Configuration Files

Agent configuration file

```
hostname Device
!
interface GigabitEthernet 0/1
 rmon collection history-stats 1 buckets 5 interval 300 owner admin
!
end
```

6. Common Errors

The parameters of configured history control entries are reconfigured or modified.



1.7.3 Configuring the Alarm Function

1. Requirements

The RMON agent is configured on a terminal device and connected to the NMS device for communication. The port GigabitEthernet 0/1 is connected to the server and must be monitored the number of received packets with unknown protocols. The sampling interval is 60 seconds. When the absolute collection value is smaller than 10, only a log record is generated. When the absolute sampling value is greater than 100, a log record is generated and a notification is sent to the NMS in a Trap message.

2. Topology

Figure 1-4 Configuring the Alarm Function

3. Notes

- Run SNMPv1 on the NMS, configure a community name public1, set the attribute to RW, and set the Trap message receiving address to 3.3.3.3.
- Monitor the number of packets with unknown protocols, received on GigabitEthernet0/1, and check whether the OID value is 1.3.6.1.2.1.2.2.1.15.3, sampling method is relative sampling, and sampling interval is 60 seconds. Check whether event 1 or event 2 is triggered when the relative sampling value is greater than 100 or smaller than 10. For event 1, a Trap message is sent and a log record is generated. For event 2, a log record is generated.

4. Procedure

Set the IP address of GigabitEthernet0/2 on the agent to 3.3.3.1.

```
Device> enabel
Device# config-system terminal
Device(cfg)# interface gigabitEthernet 0/1
Device(cfg-if-GigabitEthernet 0/1)# ip address 3.3.3.1 255.255.255.0
Device(cfg-if-GigabitEthernet 0/1)# exit
```

Configure an event group to process alarms.

```
Device(cfg)# snmp-server community public1 rw
Device(cfg)# snmp-server host 3.3.3.3 trap public1
Device(cfg)# rmon event 1 description rising-threshold-event log trap public owner admin
Device(cfg)# rmon event 2 description falling-threshold-event log owner admin
```

Configure the alarm function.

```
Device(cfg)# rmon alarm 1 1.3.6.1.2.1.2.2.1.15.3 60 delta rising-threshold 100 1 falling-threshold 10 2 owner admin
```

5. Verification

Run the **ping** command to verify that the agent and NMS are mutually reachable via L3 routes.

```
Device# ping 3.3.3.3
Sending 5, 100-byte ICMP Echoes to 3.3.3.3, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/3 ms.
```

Run the **display rmon-instance event** command to display the event table information.

```
Device# display rmon-instance event
rmon event table:
                        index = 1
                        description = rising-threshold-event
                        type = 4
                        community = public
                        lastTimeSent = 0d:0h:0m:0s
                        owner = admin
                        status = 1

                        index = 2
                        description = falling-threshold-event
                        type = 2
                        community =
                        lastTimeSent = 6d:19h:21m:48s
                        owner = admin
                        status = 1

rmon log table:
                        eventIndex = 2
                        index = 1
                        logTime = 6d:19h:21m:48s
                        logDescription = falling-threshold-event
```

Run the **display rmon-instance alarm** command to display the alarm table information.

```
Device# display rmon-instance alarm
rmon alarm table:
            index: 1,
            interval: 60,
            oid = 1.3.6.1.2.1.2.2.1.15.3
            sampleType: 2,
            alarmValue: 0,
            startupAlarm: 3,
            risingThreshold: 100,
            fallingThreshold: 10,
            risingEventIndex: 1,
            fallingEventIndex: 2,
```

```
        owner: admin,
        stauts: 1
```

6. Configuration Files

Agent configuration file

```
hostname Device
!
interface GigabitEthernet 0/1
 ip address 3.3.3.1 255.255.255.0
!
rmon alarm 1 1.3.6.1.2.1.2.2.1.15.3 60 delta rising-threshold 100 1 falling-threshold 10 2 owner admin
rmon event 1 description rising-threshold-event log trap public1 owner admin
rmon event 2 description falling-threshold-event log owner admin
!
snmp-server host 3.3.3.3 traps public1
snmp-server community public1 rw
!
end
```

7. Common Errors

- The entered object OID is improper. For example, the variable corresponding to this OID does not exist or the OID type is not an integer or unsigned integer.
- The upper limit is smaller than or equal to the lower limit.

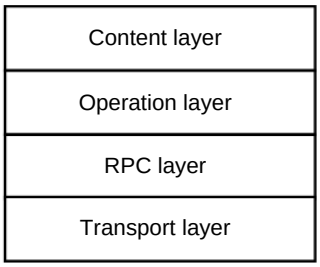
1 Configuring NETCONF

Note

NETCONF is not supported by only the S6520-64CQ, and S6920-4C.

1.1 Introduction



1.1.1 Overview

As network scale, complexity, and heterogeneity increase, it becomes more and more difficult for the traditional IP network management protocol Simple Network Management Protocol (SNMP) to manage the complicated network. In particular, SNMP cannot meet the requirements for configuration management and application system development of a large network. To overcome the shortcomings of SNMP, the Internet Engineering Task Force (IETF) formulates an extensible markup language (XML) based network management protocol – Network Configuration Protocol (NETCONF). NETCONF provides a programmable method to configure and manage network devices. This protocol configures parameters and obtains parameter values and statistics in XML packets and supports scalability, making network device configuration and management easy and efficient.

1.1.2 Structure of NETCONF

NETCONF supports the client/server (C/S) communication mode, in which a device runs the server of the protocol and a client runs the client program of the protocol. NETCONF packets, including all configuration data and protocol messages, follow the XML format. With a hierarchical similarity to the ISO/OSI system, NETCONF consists of four layers from down to up: transport layer, remote procedure call (RPC) layer, operation layer, and content layer, as shown in Figure 1-1.

Figure 1-1 Structure of NETCONF

1. Transport Layer

The transport layer provides secure transmission channels for NETCONF and supports security protocols such as Secure Shell (SSH), Simple Object Access Protocol (SOAP), and Blocks Extensible Exchange Protocol (BEEP). Now, SSH is preferred.

2. RPC Layer

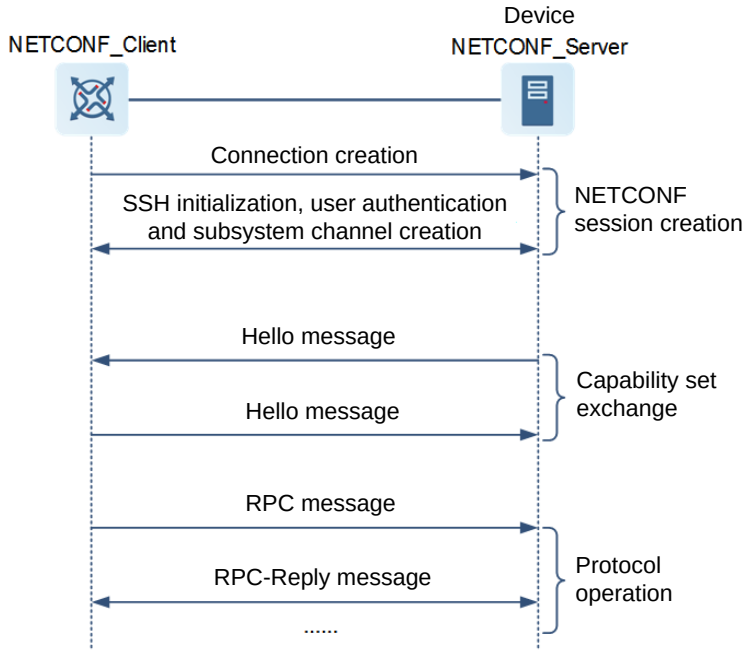
The RPC layer provides a simple transmission-irrelevant mechanism. The client uses the <rpc> element to encapsulate the NETCONF request message, and the server uses the <rpc-reply> element to encapsulate the NETCONF reply message. RPC defines three message types:

- Hello: The hello messages are used to complete capability set exchange when a session is created between the NETCONF client and server.
- RPC and RPC-Reply: RPC are request messages sent by the NETCONF client to the NETCONF server, and RPC-Reply are reply messages returned by the NETCONF server to the NETCONF client. The reply messages are returned only when the NETCONF server receives RPC request messages; the reply messages and the received RPC request messages must contain the same message ID.
- Notification: The notifications are sent by means of subscription.

3. Operation Layer

Based on the basic primitive operation sets applied in RPC, 9 types of basic operation methods are defined:

- Data acquisition: Get and Get-Config
- Configuration: Edit-Config, Copy-Config, and Delete-Config
- Protection for critical resource (for example, configuration file) concurrency: Lock and Unlock
- Session ending: Close-Session and Kill-Session



4. Content Layer

The content layer is a set of managed data objects. The content layer is the only layer that is not standardized and does not have a unified data model in NETCONF.

Note

The products use YANG for data modeling and XML for data transmission.

Figure 1-2 NETCONF Session Message Interaction

1.1.3 NETCONF Session Interaction Procedure

Figure 1-2 shows the NETCONF session interaction procedure, which falls into three parts.

1. Session Creation

(1) The transport layer of NETCONF relies on SSH. After the NETCONF server on a device starts the NETCONF process, a monitoring port is created.

(2) The NETCONF server monitors port 830 and creates an SSH channel. The SSH channel is created after a series of transport algorithm negotiations (including key agreement, compression algorithm, hash algorithm, encryption algorithm, and signature algorithm) and client authentication.

(3) After a session is created on the transport layer, the NETCONF client can exchange with the NETCONF server through this session.

Note

According to NETCONF, the default SSH TCP port ID is 830, which is customized based on the particular situation.

2. Capability Set Exchange

After the session is created, the NETCONF server and client send hello messages mutually to provide respective realized capability sets and ignore capabilities that are not understandable or realizable. The basic capability (urn:ietf:params:netconf:base:1.1) must be supported by the NETCONF server and client. To be compatible with earlier versions of NETCONF, the NETCONF server and client must support the basic capability (urn:ietf:params:netconf:base:1.0) of the earlier versions of NETCONF The NETCONF server and client finally obtain the intersected capabilities to perform subsequent data operation and management.

Caution

- In addition to the exchange capabilities defined in NETCONF RFC, developers can design other capabilities based on the specifications and formats described in NETCONF RFC.
- Capability exchange messages sent by the NETCONF client to the NETCONF server do not contain the session ID node (<session-id>).

3. Protocol Operation

- Get: Obtains device status or configuration data.

The packets sent by the client follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<get>
<filter type="subtree">
        Configuration data (or status data) filtering rule
</filter>
</get>
</rpc>
```

The replies returned by the server follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
Obtained configuration data (or status data)
</data>
</rpc-reply>
```

If all subsets of status data on the device fail to match the filtering rule, an empty data node is returned as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="Message ID " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"/>
</rpc-reply>
```

- Get-config: Obtains configuration data based on the filtering node.

The packets sent by the client follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<get-config>
<source>
<running/>
</source>
<filter type="subtree">
        Protocol-based filtering rule
</filter>
</get-config>
</rpc>
```

The replies returned by the server follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
Obtained configuration data
</data>
</rpc-reply>
```

If all subsets of configuration data on the device fail to match the filtering rule, an empty data node is returned as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"/>
</rpc-reply>
```

Note

The Get-config operation can obtain configuration data subsets through different subtree filtering rules but cannot obtain device status.

- Edit-config: Configures a device based on the model definitions and operation attributes.

  In the edit-config packet, there are five operation attributes which are given in the description of the operation attribute of the XML packet. These five attributes are as follows:

  - Merge: Merges the configuration data that includes this attribute in the Edit-config packets to the specified configuration file or database. If this configuration data does not exist, create this configuration data.
  - Replace: Replaces the configuration data node in the specified configuration file or database with the configuration data that includes this attribute in the Edit-config packets. If this configuration data does not exist, create this configuration data based on the delivered content.
  - Create: Creates configuration data that includes this attribute in the Edit-config packets in the specified configuration file or database. If the configuration data does not exist, deliver content to create this configuration data. If the configuration data exists, a reply, corresponding to the RPC-error packet, is returned and contains the value of error-tag "data-exists".
  - Delete: Deletes configuration data that includes this attribute in the Edit-config packets from the specified configuration file or database. If the configuration data does not exist, a reply, corresponding to the RPC-error packet, is returned and contains the value of error-tag "data-missing". If the configuration data exists, corresponding configuration is deleted.
  - Remove: Removes configuration data that includes this attribute in the Edit-config packets from the specified configuration file or database. If the configuration data does not exist, this operation is ignored and OK is returned. If the configuration data exists, corresponding configuration is removed.

  The packets sent by the client follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<edit-config>
```

```
<target> <running/> </target>
<config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
        Configuration data
</config>
</edit-config>
</rpc>
```

The replies returned by the server follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="Message ID " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<ok/>
</rpc-reply>
```

The Edit-config packet includes the Error-option node. The values of the Error-option node are of the enumerated type, including:

- **Continue-on-error**: During an Edit-config operation, if a configuration error occurs, the current error node is recorded and configuration continues. But an error message is returned finally (In the case of any configuration error, the final reply message is RPC-error).
- **Stop-on-error**: This is the default value of the Error-option. During an Edit-config operation, if a first configuration error occurs, the Edit-config operation stops immediately. The data configured before this error occurs takes effect.

The packets generally follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<edit-config>
<target> <running/> </target>
Acton option when a configuration error occurs
<config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
        Configuration data
</config>
</edit-config>
</rpc>
```

Specification

Currently, Ruijie devices do not support the Replace operation. If this operation is delivered, it is processed as a Merge operation.

Note

- If the Edit-config packet does not include the error-option node, the default value of the error-option node is stop-on-error. Once a configuration error occurs on a node, the remaining configuration in the Edit-config packet stops immediately and an RPC-error is returned.
- If the Edit-config packet does not include the test-option node, the default value of the test-option node is **test-then-set**.
- If the Edit-config packet does not include the default-operation node, the default value of the default-operation node is **merge**.

- The digit type of configuration data in edit-config packets does not support the octal or hexadecimal format. For data in octal format, the 0 before the digit will be removed by default and processed as decimal data. If hexadecimal data carries 0x, an error is returned to the client.

- Copy-config: Copies the configuration file. For example, candidate configuration is copied to the configuration file, startup configuration is copied to the running configuration file, and running configuration is written into the startup configuration file. The copies can be successful if the target files support the write capability.

The packets sent by the client follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx"    xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <copy-config>
      <target>
         <startup/>
      </target>
      <source>
         <running/>
      </source>
   </copy-config>
</rpc>
```

The replies returned by the server follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx"    xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
</rpc-reply>
```

- Delete-config: Deletes the configuration file. It is not allowed to delete the running file.

The packets sent by the client follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <delete-config>
     <target>
        <startup/>
     </target>
  </delete-config>
</rpc>
```

The replies returned by the server follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
</rpc-reply>
```

Specification

Now, only the startup configuration can be synchronized to the running configuration file.

- Lock: Locks the configuration file. The configuration file can be accessed or modified through the current client, but cannot be accessed or modified by other clients or non-NETCONF clients (for example, SNMP or CLI). The packets sent by the client follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
 <lock>
    <target>
       <running/>
    </target>
 </lock>
</rpc>
```

The replies returned by the server follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx "    xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

Note

According to RFC 6241, the Lock operation is used to lock the configuration database (configuration files) and prevent multiple sources (for example, CLI, SNMP, and NETCONF sessions) from concurrently revising the configuration files. This avoids introducing other irrelevant configuration revisions. The device removes some functions of the operation, and can only prevent concurrent modifications (running configuration) from multiple NETCONF.

- Unlock: Unlocks the configuration database (configuration file, which indicates the running configuration file in a device). This operation is opposite to the Lock operation.

The packets sent by the client follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx "    xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
 <unlock>
    <target>
       <running/>
    </target>
 </unlock>
</rpc>
```

The replies returned by the server follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx "    xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

- Close-session: Closes the current session, including resource and lock release and disconnection.

The packets sent by the client follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
```

```
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <close-session/>
</rpc>
```

The replies returned by the server follow the format below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx"    xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

Note

Before the Close-session operation closes the current session, ensure that proceeding business has been completed and no new business request is received.

- Kill-session: Forcibly closes the current session, including resource and lock release and disconnection.

Caution

- Before using the Kill-session operation to forcibly close the current session, ensure that proceeding business has been stopped and unfinished business is rolled back to original state.
- The Kill-session operation cannot close the current session.

1.1.4 Authentication Mechanism

The NETCONF authentication mechanism is used to manage the NETCONF operations of specific clients and the access to NETCONF resources, allowing the clients to perform operations and access data nodes stipulated by NETCONF.

1. Access Permissions Supported by the NETCONF Authentication Mechanism

The NETCONF authentication function is not configured by default. Therefore, authorized clients have all NETCONF permissions. Access permissions supported by the NETCONF authentication mechanism are as follows:

- Create: Permits or denies new data nodes to be added.
- Read: Permits or denies data nodes to be read.
- Update: Permits or denies data nodes to be updated.
- Delete: Permits or denies data nodes to be deleted.
- Execute: Permits or denies all protocol operations.

2. Content Supported by the NETCONF Authentication Mechanism

The NETCONF authentication function supports RPC method authentication and data node authentication.

- RPC method authentication

  RPC method authentication of NETCONF is used to control permissions of the operation methods stipulated by NETCONF. Table 1-1 lists the RPC methods and default permissions.

Table 1-1 RPC Methods and Default Permissions

RPC Method	Function	Default Permission (R: read; W: write; X: execute)
get	Obtains data.	X→R
get-config	Obtains configuration.	X→R
edit-config	Edits configuration.	X→W
copy-config	Replaces the target configuration with the source configuration.	X
delete-config	Deletes configuration.	X
validate	Performs syntax check.	X
commit	Validates the candidate configuration and runs the configuration.	X
cancel-commit	Cancels the confirmed-commit operation.	X
discard-changes	Discards candidate configuration that has not taken effect.	X
lock/unlock	Locks or unlocks configuration.	X
close-session	Closes the current session.	X
kill-session	Closes other sessions.	X
get-schema	Obtains the YANG file.	X

Note

- All RPC methods require the execution permission by default. The Get, Get-config, and Edit-config methods require the check of read/write permission for the data node.
- The Close-session method is permitted by default and cannot be denied.
- The Delete-config and Kill-session methods are denied by default, and can be configured as Permitted. Other RPC methods are permitted by default.
- The Lock and Unlock methods must be paired. If the Lock permission is configured, the Unlock permission is available as well.

- Data node authentication

  Data node authentication of NETCONF is used to control permissions of NETCONF data nodes. It can control the permissions of all modules, single module, and specific data nodes.

  - If only the slash (/) is configured, the authentication of NETCONF can control the permissions of the data nodes of all modules.

- If a module name is configured, for example, / snmp:snmp, the authentication of NETCONF can control the permissions of the data nodes of the single module.
- In other configuration conditions, permission control is applied to the data nodes of specific modules.

1.1.5 Protocols and Standards

- RFC 4741: NETCONF Configuration Protocol
- RFC 4742: Using the NETCONF Configuration Protocol over Secure Shell (SSH)
- RFC 4743: Using NETCONF over the Simple Object Access Protocol (SOAP)
- RFC 4744: Using the NETCONF Protocol over the Blocks Extensible Exchange Protocol (BEEP)
- RFC 5277: NETCONF Event Notifications
- RFC 5381: Experience of Implementing NETCONF over SOAP
- RFC 5539: NETCONF Over Transport Layer Security (TLS)
- RFC 5717: Partial Lock RPC for NETCONF
- RFC 6022: NETCONF Monitoring Schema
- RFC 6241: Network Configuration Protocol
- RFC 6242: Using the Network Configuration Protocol over Secure Shell
- RFC 6243: With-defaults capability for NETCONF
- RFC 6470: NETCONF Notification Events
- RFC 6536: NETCONF Access Control Model (NACM)

Note

RFC 4741 and RFC 4742 have been replaced by RFC 6241 and RFC 6242 respectively.

1.2 Configuration Task Summary

NETCONF configuration includes the following tasks:

(1) Configuring Communication Between the NETCONF Server and Client

(2) (Optional) Configuring NETCONF Authentication

1.3 Configuring Communication Between the NETCONF Server and Client

1.3.1 Overview

After the NETCONF function is enabled on the NETCONF server, the NETCONF server can communicate with the NETCONF client to manage network devices.

1.3.2 Restrictions and Guidelines

- The **netconf yang multi-revision** command must be configured before the capability packet (Hello packet) of the NETCONF server is advertised.

- The **unset netconf yang multi-revision** command must be configured before the capability packet (Hello packet) of the NETCONF server is advertised and one YANG module can advertise only its current latest version in the capability notification packet.
- In strict check mode, some XML packets that can be delivered in lightweight check mode may be intercepted.

1.3.3 Prerequisites

The NETCONF protocol is based on the SSH protocol. Before the NETCONF protocol is enabled, the SSH protocol must be configured. For the configuration procedure, see *Configuring SSH*.

1.3.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the attribute parameters of the NETCONF server. The configuration tasks below are optional. Select tasks as required.

- (Optional) Enable the NETCONF service.

  netconf enable

  The NETCONF function is enabled by default.

- (Optional) Configure the maximum number of session connections supported by NETCONF.

  netconf netconf max-session-num *max-sessions-numbers*

  The maximum number of session connections supported by NETCONF is **1** by default.

- (Optional) Configure the timeout time of the Edit-config operation in a NETCONF session.

  netconf timeout *timeout*

  The default timeout time of the Edit-config operation in a NETCONF session is **120** seconds.

- (Optional) Enable the YANG module multi-version notification function.

  netconf yang multi-revision

  The YANG module multi-version notification function of NETCONF is enabled by default.

- (Optional) Configure the NETCONF capabilities.

  netconf capability{ **candidate** | **rollback** | **validate** }

  The NETCONF-related capabilities are not configured by default.

- (Optional) Configure the NETCONF check mode.

  netconf calibration-mode { **lightweight** | **strict** }

  The default NETCONF check mode is lightweight check.

- (Optional) Enable the NETCONF logging function.

  netconf log { **capability** | **edit** | **get** | **session** }

  The NETCONF logging function is disabled by default.

- (Optional) Configure the port ID of the NETCONF server.

netconf port *port-number*

The default port ID of the NETCONF server is 830.

- (Optional) Configure the timeout time of a NETCONF session.

  netconf session-idle-time *num*

  No timeout time is configured for a NETCONF session by default. That is, a session will not be disconnected due to a timeout time by default.

- (Optional) Configure an ACL filtering rule for NETCONF.

  - **netconf access-apply** { **ipv4** *acl-name* | **ipv4** *acl-number* | **ipv6** *acl-name* }

  No ACL filtering rule is configured for NETCONF by default.

- (Optional) Configure the device to save configuration automatically upon the NETCONF commit operation.

  netconf commit auto-save delay-time *time* **delay-count** *count*

  The device does not save configuration automatically upon the NETCONF commit operation by default.

- (Optional) Configure the DSCP value of NETCONF packets.

  netconf dscp { ip | ipv6 } ssh dscp-value

1.4 The default DSCP value of NETCONF packets is 2.Configuring NETCONF Authentication

1.4.1 Overview

The NETCONF authentication mechanism is configured to manage the NETCONF operations of specific clients and the access to NETCONF resources, allowing the clients to perform operations and access data nodes stipulated by NETCONF.

1.4.2 Restrictions and Guidelines

- A user group cannot be named with the asterisk (*), because the symbol indicates all user groups.
- For a single rule list, the rules are successively matched based on the rule configured by users. When an operation matches a permit rule, the operation is permitted. When an operation matches a deny rule or does not match a rule, the operation is denied in the current rule list.
- For multiple rule lists, the rules in the lists are matched based on the rule configuration sequence. When an operation matches a permit rule in a rule list, the operation is permitted. When an operation matches a deny rule, the operation is denied. When an operation does not match any rule in the list, the operation matches the rules of the next list.
- RPC operation methods include Get, Get-Config, Edit-Config, Copy-Config, Delete-Config, Validate, Commit, Cancel-Commit, Discard-Changes, Lock, Kill-Session, and Get-Schema.
- If no rule type is configured, permission control is applied to both RPC operation methods and data node rules.
- Rule control for enabling RPC operation methods can be configured. If the Execute permission is included in the access operation permissions configured under the rules, the rules are matched during RPC operation method check. Otherwise, such rule matching does not occur.

- Rule control for enabling data nodes can be configured. If at least one of the Create, Read, Update and Delete permissions is included in the access operation permissions configured under the rules, the rules are matched during data node check. Otherwise, such rule matching does not occur.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the authentication configuration mode.

netconf acm

(4) Configure a user group and enter the user group mode.

user-group-name *name*

No user group is configured by default.

(5) Associate users with the user group.

user-name *name*

No user is associated with a user group by default.

(6) Quit the authentication configuration mode.

exit

(7) Configure a rule list and enter the rule list mode.

rule-list *name*

No rule list is configured by default.

(8) Associate the user group with the rule list.

user-group { *name* | ***** }

No user group is associated with a rule list by default.

(9) Configure rules and enter the rule mode.

rule *name* { **action deny** | **action permit** }

No rule is configured by default.

(10) Configure rule types.

rule-type { **path** *path* | **rpc-name** { *name* | ***** }

No rule type is configured by default.

(11) Configure access permissions of the rules.

access-operation { * | { create | delete | exec | read | update } * }

No access permission of a rule is configured by default.

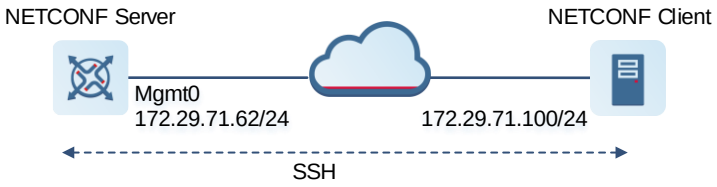
1.5 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Table 1-2 Monitoring

Command	Purpose
display netconf-server authorization user-name *name* { **rule-list** [**detail**] | **user-group** }	Displays a rule list that users are associated with, list details, and user group information.
display netconf-server session-info	Displays all session information of NETCONF.
display netconf-server statistics	Displays global statistics of NETCONF.
display netconf-server yang file	Displays all YANG files supported currently.
display netconf-server yang node-path [*module-name*]	Displays all node paths supported currently.
display netconf-server yang tree [*module-name*]	Displays all YANG model trees supported currently.

1.6 Configuration Examples



1.6.1 Configuring NETCONF

1. Requirements

NETCONF can be used as a network management tool to meet the high security and scalability requirements for network device management. NETCONF is based on SSH. As a security protocol of the application layer, SSH ensures security of NETCONF. As shown in Figure 1-3, the NETCONF network management software is used to manage and monitor network devices.

2. Topology

Figure 1-3 Configuring NETCONF

3. Notes

- Configure an IP address for the network management interface of the NETCONF server to ensure that the NETCONF server and client are mutually reachable via L3 routes.
- Enable the SSH function on the NETCONF server.
- Configure NETCONF related parameters on the NETCONF server to meet requirements of actual scenarios.
- Connect the NETCONF server to the NETCONF client through SSH to manage and monitor network

devices.

4. Procedure

Configure an IP address for the network management interface of the NETCONF server.

```
Hostname> privilege
Hostname# config-system terminal
Hostname(cfg)# interface mgmt 0
Hostname(cfg-if-Mgmt 0)# ip address 172.29.71.62 255.255.255.0
Hostname(cfg-if-Mgmt 0)# gateway 172.29.71.1
```

Enable the SSH function and generate a local key. For more information about the rule of selecting a key type, see the Usage Guidelines in the **crypto key generate** command in *SSH Commands*.

```
Hostname> privilege
Hostname# config-system terminal
Hostname(cfg)# enable-server service ssh-server
Hostname(cfg)# ssh-crypto key generate rsa
% You already have RSA keys.
% Do you really want to replace them? [yes/no]:y
Choose the size of the rsa key modulus in the range of 512 to 2048
and the size of the dsa key modulus in the range of 360 to 2048 for your
Signature Keys. Choosing a key modulus greater than 512 may take
a few minutes.
Choose the size of the ecc key modulus from (256, 384, 521)

How many bits in the modulus [1024]:2048
% Generating 2048 bit RSA1 keys ...[ok]
% Generating 2048 bit RSA keys ...[ok]
Hostname(cfg)#
```

Create an SSH user with the username **netconf** and set the password to netconf_1234.

```
Hostname(cfg)# username netconf privilege 15 password netconf_1234
```

Caution

To ensure security, you are advised to regularly modify the username and password.

Configure local user authentication of a VTY line.

```
Hostname(cfg)# line vty 0 35
Hostname(cfg-line)# login local
```

Enable the NETCONF service on the NETCONF server.

```
Hostname(cfg)# netconf enable
```

Set the maximum number of session connections supported by the NETCONF server to 6.

```
Hostname(cfg)# netconf max-session-num 6
```

Set the timeout time of the Edit-config operation in a NETCONF session to 100 seconds on the NETCONF server.

```
Hostname(cfg)# netconf timeout 100
```

Enable the YANG module multi-version notification function on the NETCONF server.

```
Hostname(cfg)# netconf yang multi-revision
```

Enable the candidate capability on the NETCONF server.

```
Hostname(cfg)# netconf capability candidate
```

Configure the check mode as lightweight check on the NETCONF server.

```
Hostname(cfg)# netconf calibration lightweight
```

Enable the syslog function related to the NETCONF sessions on the NETCONF server.

```
Hostname(cfg)# netconf log session
```

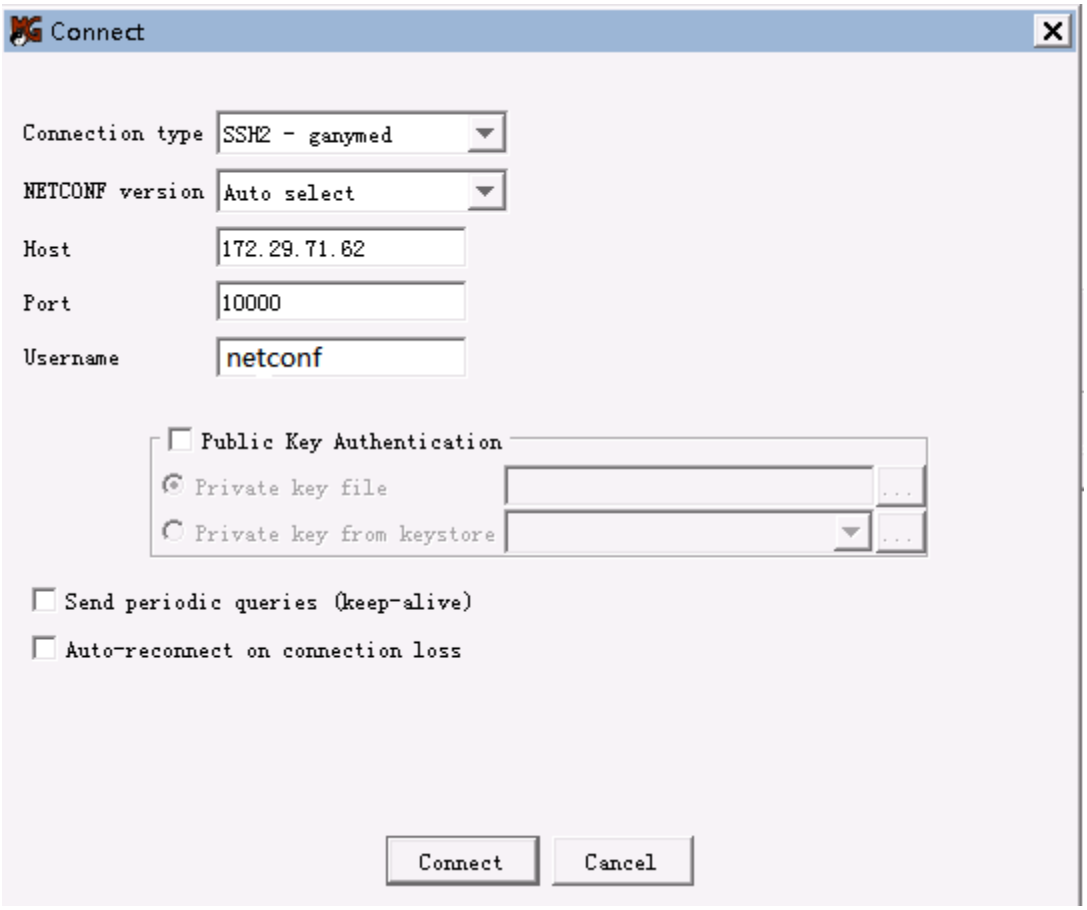
Set the port ID of the NETCONF service to 5000 on the NETCONF server.

```
Hostname(cfg)# netconf port 5000
```

Set the timeout time of a NETCONF session to 120 seconds on the NETCONF server.

```
Hostname(cfg)# netconf session-idle-time 120
```

Configure IPv4 ACL 1 on the NETCONF server.



```
Hostname(cfg)# netconf access-class ipv4 1
```

Configure the NETCONF server to save configuration automatically after the NETCONF commit operation.

```
Hostname(cfg)# netconf commit auto-save
```

Log in to the NETCONF server through the SSH protocol by using the NETCONF client software and manage and monitor network devices, as shown in Figure 1-4.

Figure 1-4 Device Login Example Through the NETCONF Client Software

5. Verification

Run the **ping** command to check whether the NETCONF server and client are mutually reachable via L3 routes.

```
Hostname# ping oob 172.29.71.100
Sending 5, 100-byte ICMP Echoes to 172.29.71.100, timeout is 2 seconds:
   < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/3 ms.
Hostname#
```

Run the **display service** command to check whether the SSH service is enabled.

```
Hostname# display service
snmp-agent       : enabled
ssh-server       : enabled
telnet-server : enabled
```

Run the **display netconf session** command to check whether the NETCONF server is connected to the NETCONF client software through the SSH protocol.

```
Hostname# display netconf-server session-info
**********session information**********
                                Session count: 1
```

```
**********************************************************************

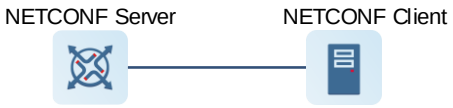
netconf port 5000
netconf access-apply ipv4 1
netconf dscp ip ssh 30
netconf netconf max-session-num 6
netconf session-idle-time 120
netconf yang multi-revision
!
enable-server service ssh-server
!
interface GigabitEthernet 0
unset switch-port
  ip address 172.29.71.62 255.255.255.0

!
```

```
line vty 0 35
 line-login local
!
end
```



1.6.2 Configuring NETCONF Authentication

1. Requirements

The user **user1** has the permission to get all modules, and the user **user2** has the permission to create SNMP modules.

2. Topology

Figure 1-5 Configuring NETCONF

3. Notes

Configure the Get permission for all modules for **user1**.

Configure the Create permission for SNMP modules for **user2**.

4. Procedure

(1) Configure the Get permission for all modules for **user1**.

Configure a user **user1**.

```
Device> privilege
Device# config-system terminal
Device(cfg)# username user1 password test12345
```

Enter the authentication mode.

```
Device(cfg)# netconf acm
```

Configure a user group **guser1**.

```
Device(cfg-nacm)# user-group-name guser1
```

Associate **user1** with **guser1**.

```
Device(cfg-nacm-user-group)# user-name user1
Device(cfg-nacm-user-group)# exit
```

Configure a rule list rule-list1.

```
Device(cfg-nacm)# rule-list rule-list1
```

Associate **guser1** with rule-list1.

```
Device(cfg-nacm-rule-list)# user-group guser1
```

Configure a permit rule rule1.

```
Device(cfg-nacm-rule-list)# rule rule1 action permit
```

Configure the RPC method as Get.

```
Device(cfg-nacm-rule-list-rule)# rule-type rpc-name get
Device(cfg-nacm-rule-list-rule)# end
```

(2) Configure the Create permission for SNMP modules for **user2**.

Configure a user **user2**.

```
Device# config-system terminal
Device(cfg)# username user2 password test12345
```

Enter the authentication mode.

```
Device(cfg)# netconf acm
```

Configure a user group **guser2**.

```
Device(cfg-nacm)# user-group-name guser2
```

Associate a user group **user2** with a user **guser2**.

```
Device(cfg-nacm-user-group)# user-name user2
```

Configure a rule list rule-list2.

```
Device(cfg-nacm-user-group)# exit
```

Associate a user group **guser2** with a rule list rule-list2.

```
Device(cfg-nacm)# rule-list rule-list2
Device(cfg-nacm-rule-list)# user-group guser2
```

Configure a permit rule rule2.

```
Device(cfg-nacm-rule-list)# rule rule2 act permit
```

Configure a data node type and configure the data node as an SNMP module name.

```
Device(cfg-nacm-rule-list-rule)# rule-type path /snmp:snmp
```

Configure the access permission as Create.

```
Device(cfg-nacm-rule-list-rule)# access-operation create
```

5. Verification

Run the **display netconf-server authorization user-name user1 user-group** command to display user group information of a user **user1**.

```
Device # display netconf-server authorization user-name user1 user-group
UserGroup: guser1
```

Run the **display netconf-server authorization user-name user2 user-group** command to display user group information of a user **user2**.

```
Device # display netconf-server authorization user-name user2 user-group
UserGroup: guser2
```

Run the **display netconf-server authorization user-name user1 rule-list detail** command to display details of the rule list associated with a user **user1**.

```
Device# display netconf-server authorization user-name user1 rule-list detail
RuleList: rule-list1
  ------------------------------------------------------------------
  Rule                 Action    AccessOperation    Type        Entity
  ------------------------------------------------------------------
```

```
  rule1                permit     RCUDX                RPC          get
  [R:Read C:Create U:Update D:Delete X:Exec]
```

Run the **display netconf-server authorization user-name user2 rule-list detail** command to display details of the rule list associated with a user **user2**.

```
Device# display netconf-server authorization user-name user2 rule-list detail
RuleList: rule-list2
  ------------------------------------------------------------------
  Rule                 Action     AccessOperation     Type         Entity
  ------------------------------------------------------------------
  rule2                permit     -C---               PATH         /snmp:snmp
  [R:Read C:Create U:Update D:Delete X:Exec]
```

6. Configuration Files

Device configuration file

```
hostname Device
!
username user1 password test12345
username user2 password test12345
!
netconf acm
 user-group-name guser1
  user-name user1
 user-group-name guser2
  user-name user2
 rule-list rule-list1
  user-group guser1
  rule rule1 action permit
   rule-type rpc-name get
 rule-list rule-list2
  user-group guser2
  rule rule2 action permit
   access-operation create
   rule-type path /snmp:snmp
!
end
```

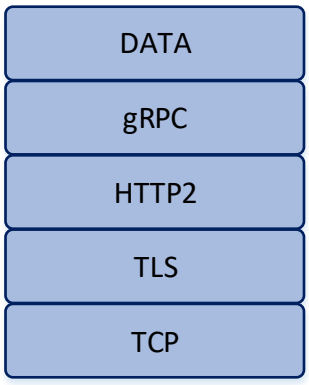
1 Configuring gRPC

1.1 Introduction



1.1.1 Overview

The Google Remote Procedure Calls (gRPC) is a high-performance open source software framework developed by Google using the Hyper Text Transfer Protocol 2 (HTTP2) as a data transmission protocol. gRPC provides a network configuration and management method that supports multiple programming languages. On the gRPC framework, secondary development can be performed.

1.1.2 Principles

1. Protocol Structure

Figure 1-1 Protocol Stack Layers

As shown in Figure 1-1, gRPC stack has five layers. The function description of each layer is as follows.

- DATA

  The layer is also known as the data content layer. It contains data from both sides of the communication. Based on specific service definitions, the layer consists of the following two elements.

  - Encoding format: The layer usually uses GPB and JSON as the encoding format. Currently the device only supports JSON.
  - Data abstraction: The YANG model is usually used to define the data format. The device also supports defining the data format based on the event ID.

- gRPC

  RPC interaction format is defined based on gRPC protocol. RPC is defined in the **proto** file, such as **gnmi.proto**, **dial-out.proto**, and so on.

- HTTP/2

  gRPC runs on HTTP/2, mainly using HTTP/2 features such as the bidirectional flow, flow control, header compression, multiplexing requests on a single connection.

- TLS

A gRPC protocol that uses TLS encryption.

- TCP

  An underlying communication protocol based on TCP connections.

2. Telemetry Mode

Figure 1-2 A gRPC Connection

(1) As shown in Figure 1-2, the network management system establishes connection with the device through gRPC. The network management system collects device data through gRPC to monitor and manage the device remotely.

The device supports the following two telemetry modes:

- Dial-in mode

  The device acts as a gRPC server and the network management system acts as a gRPC client. The network management system initiates connection to the device to subscribe to device data or deliver configurations.

  Dial-in mode applies to small networks and the scenarios where the network management system needs to deliver configurations through gRPC connections.

- Dial-out mode

  The device acts as a gRPC client and the network management system acts as a gRPC server. The device initiates connection to the network management system and pushes subscribed data to the network management system.

  Dial-out mode applies to larger networks where there are multiple devices.

3. Data Abstraction

The device supports the following two methods to define the data format.

- Yang data modeling

  The device can get, set and subscribe Yang model data. Yang model defines the data grammar and displays the data using the JSON format. The device supports both OpenConfig Yang and customized private RGOS Yang. See gRPC data format description document for Yang models supported by current devices. You are advised to use Yang model to define the data format because it is common and comprehensive.

- Event data modeling

  The device supports formatting data base on events. One event corresponds to a JSON data group. See gRPC data format description document for events supported by current devices. The event data modeling has been applied to multiple customer scenarios. It is easier to use the event data modeling than Yang data modeling. The customers who want to establish and use gRPC connections fast are advised to adopt the event data modeling.

(1) Proto files based on Yang data modeling

Yang data consists of Yang paths and JSON data. The following describes the basic data format in the proto definition.

```
message Path {
   repeated string element = 1 [deprecated=true]; // Abandoned.
   string origin = 2;                                  // A reserved field.
   repeated PathElem elem = 3;                         // Node names of a path.
   string target = 4;                                  // A reserved field.
}

message PathElem {
   string name = 1;                                    // Node names of a path.
   map<string, string> key = 2;                        // A keyword can be added if it is a list. node.
}

message Update {
   Path path = 1;                                      // A YANG path.
   Value value = 2 [deprecated=true];                  // Abandoned.
   TypedValue val = 3;                                 // JSON data of a YANG path.
   uint32 duplicates = 4;                              // A reserved field.
}

message TypedValue {
   oneof value {
      string string_val = 1;
      int64 int_val = 2;
      uint64 uint_val = 3;
bool bool_val = 4;
      bytes bytes_val = 5;
      float float_val = 6;
      Decimal64 decimal_val = 7;
      ScalarArray leaflist_val = 8;
      google.protobuf.Any any_val = 9;
      bytes json_val = 10;                             // Only supports json_val.
      bytes json_ietf_val = 11;
      string ascii_val = 12;
      bytes proto_bytes = 13;
   }
}
```

- Proto files based on Yang data modeling are all open source files. Proto files of the dial-in mode are gnmi.proto files and those of the dial-out mode are dial-out.proto files.

Note

gRPC Network Management Interfac (gnmi) is an interface developed by Google based on OpenConfig.

- Proto files based on the dial-in mode of Yang data modeling

The device can use the following three RPC types to implement the gnmi.proto definition.

- Get RPC: It is used to obtain current device data. The implementation and content description of request and response messages are as follows.

```
message GetRequest {
  Path prefix = 1;                                  // A shared prefix of multiple Yang paths.
  repeated Path path = 2;                           // Multiple Yang paths.
  enum DataType {
    ALL = 0;                                        // All data elements.
    CONFIG = 1;                                     // Config (rw) only elements.
    STATE = 2;                                      // State (ro) only elements.
    OPERATIONAL = 3;
  }
  DataType type = 3;                                // Only supports ALL.
  Encoding encoding = 5;                            // Only supports json.
  repeated ModelData use_models = 6;                // A reserved field.
  repeated gnmi_ext.Extension extension = 7;        // A reserved field.
}

message GetResponse {
  repeated Notification notification = 1;     // Data values.
  Error error = 2 [deprecated=true];          // Errors that occurred in the Get.
  repeated gnmi_ext.Extension extension = 3;
}

message Notification {
  int64 timestamp = 1;              // A nanosecond timestamp.
  Path prefix = 2;                  // A shared prefix of multiple Yang paths.
  string alias = 3;
  repeated Update update = 4;       // Pushed data.
  repeated Path delete = 5;         // A reserved field.
  bool atomic = 6;
}
```

- Set RPC: It is used to deliver configurations to devices. The implementation and content description of request and response messages are as follows.

```
message SetRequest {
  Path prefix = 1;                      // A shared prefix of multiple Yang paths.
  repeated Path delete = 2;             // A Yang path to be deleted.
  repeated Update replace = 3;          // A Yang path to be updated with path and val to be added into.
  repeated Update update = 4;           // A Yang path to be updated with path and val to be added into.
  repeated gnmi_ext.Extension extension = 5;          // A reserved field.
}

message SetResponse {
  Path prefix = 1;                              // A shared prefix of multiple Yang paths.
```

```
  repeated UpdateResult response = 2;     // If the delivery succeeds, the device sends the response
       message. If not, the device sends a gRPC error message.
  Error message = 3 [deprecated=true];                 // Abandoned. If the delivery fails, the device uses the
 failure mechanism of gRPC.
  int64 timestamp = 4;                                 // A nanosecond timestamp.
  repeated gnmi_ext.Extension extension = 5;       // A reserved field.
}
```

- Subscribe RPC: It is used to subscribe to a device to collect data. The implementation and content description of request and response messages are as follows.

```
message SubscribeRequest {
  oneof request {
    SubscriptionList subscribe = 1;                // Subscription information.
    Poll poll = 3;                                 // A reserved field.
    AliasList aliases = 4;                         // A reserved field.
  }
  repeated gnmi_ext.Extension extension = 5;     // A reserved field.
}
message SubscriptionList {
  Path prefix = 1;                                 // A shared prefix of multiple Yang paths.
  repeated Subscription subscription = 2;          // Subscription information.
  bool use_aliases = 3;                            // A reserved field.
  QOSMarking qos = 4;                              // A reserved field.
  enum Mode {
    STREAM = 0;
    ONCE = 1;
    POLL = 2;
  }
  Mode mode = 5;                                   // A reserved field.
  bool allow_aggregation = 6;                      // A reserved field.
  repeated ModelData use_models = 7;               // A reserved field.
  Encoding encoding = 8;                           // Only supports JSON.
  bool updates_only = 9;                           // A reserved field.
}

message Subscription {
  Path path = 1;                                   // A YANG path.
  SubscriptionMode mode = 2;                       // Interval or triggered subscription.
  uint64 sample_interval = 3;                      // Intervals of interval subscription. The field is
unnecessary for triggerd subscription.
```

```
  bool suppress_redundant = 4;                  // A reserved field.
  uint64 heartbeat_interval = 5;                // A reserved field.
}

message SubscribeResponse {
  oneof response {
    Notification update = 1;                    // Notification, same to the returned Get messages.
    bool sync_response = 3;                     // A reserved field.
    Error error = 4 [deprecated=true];          // Abandoned.
  }
  repeated gnmi_ext.Extension extension = 5;    // A reserved field.
```

- Proto files based on the dial-out mode of Yang data modeling

  Dial-out.proto is a proto provided by SONIC based on gnmi and has only one publish RPC. The request message is SubscribeRespone. The collected data should be the same to the data collected by Get and Subscribe PRC. The response message is defined as follows.

```
message PublishResponse {
  int64 timestamp = 1;          // A nanosecond timestamp. Currently the device does not process the collected data. The field can be omitted.
  Path prefix = 2;              // A shared prefix of multiple Yang paths. Currently the device does not process the collected data. The field can be omitted.
  string alias = 3;             // An alias. Currently the device does not process the collected data. The field can be omitted.
  repeated Path path = 4;       // A YANG path. Currently the device does not process the collected data. The field can be omitted.
}
```

(2) Proto files based on the event data modeling

- Proto files based on the dial-in mode of the event data modeling

  Proto files based on the dial-in mode of the event data modeling are private definitions. The file name is Ruijie-subscr.proto. The method supports SubscrAuthSend PRC for authentication, SubscrGetSend PRC for collecting data and SubscrSetSend PRC for setting. The definition and description of proto are as follows.

```
syntax = "proto3";

package Ruijie_subscr;

service Subscr {
  rpc SubscrAuthSend (SubscrAuthRequest) returns (SubscrAuthReply) {}
  rpc SubscrGetSend (SubscrGetRequest) returns (stream SubscrGetReply) {}
  rpc SubscrSetSend (SubscrSetRequest) returns (stream SubscrSetReply) {}
}

message SubscrDeviceMsg {
```

```
  string producer_name = 1;                  // Manufacture name.
  string device_name = 2;                    // Device name.
  string device_model = 3;                   // Device model.
}

message SubscrAuthInfo {
  string username = 1;                       // Username of the subscribed server.
  string password = 2;                       // Password of the subscribed server.
}

message SubscrGetInfo {
  string username = 1;                       // Username of the subscribed server.
}

message SubscrAuthRequest {
  SubscrAuthInfo info = 1;                   // Authentication information of the subscribed server.
  bool is_login = 2;                         // The field of login is true and the field of logout is false.
}

message SubscrAuthReply {
  SubscrDeviceMsg device_info = 1;           // Device information.
  sint32 ret = 2;                            // Indicates whether the authentication succeeds. 0 stands for
success and 1 stands for failure.
  string detail = 3;                         // An authentication information string.
}

message SubscrGetRequest {
  SubscrGetInfo info = 1;                    // Authentication information of the subscribed server.
  uint32 json_event = 2;                     // A specific event.
  string json_string = 3;                    // Event parameters in the standard JSON format.
}

message SubscrGetReply {
  SubscrDeviceMsg device_info = 1;           // Device information.
  sint32 ret = 2;                            // Indicates whether the data processing succeeds. 0 stands for
success and 1 stands for failure.
  uint32 json_event = 3;                     // A specific event.
  string json_string = 4;                    // Reported information strings in the standard JSON format.
}

message SubscrSetRequest {
  SubscrGetInfo info = 1;                    // Authentication information of the subscribed server.
  uint32 json_event = 2;                     // A specific event.
  string json_string = 3;                    // Event parameters in the standard JSON format.
}
```

```
message SubscrSetReply {
  SubscrDeviceMsg device_info = 1;          // Device information.
  sint32 ret = 2;                           // Indicates whether the data processing succeeds. 0 stands for
success and 1 stands for failure.
  uint32 json_event = 3;                    // A specific event.
  string json_string = 4;                   // The reason for the result of data processing in the standard
JSON format.
}
```

- Proto files based on the dial-out mode of the event data modeling

  Proto files based on the dial-in mode of the event data modeling are private definitions. The file name is Ruijie-subscr.proto. The method supports SubscrAuthSend PRC for authentication, SubscrGetSend PRC for collecting data and SubscrSetSend PRC for setting. The definition and description of proto are as follows.

```
syntax = "proto3";

package Ruijie_json;

service Json {
  rpc JsonSend (JsonRequest) returns (JsonReply) {}
  rpc JsonStreamSend (stream JsonRequest) returns (stream JsonReply) {}
}

message JsonDeviceMsg {
  string producer_name = 1;                 // Manufacture name.
  string device_name = 2;                   // Device name.
  string device_model = 3;                  // Device model.
  string device_ip = 4;                     // Device IP
  string device_vendor = 5;                 // Device vendor
  string device_version = 6;                // Device version
}

message JsonRequest {
  JsonDeviceMsg device_info = 1;            // Device information.
  uint32 json_event = 2;                    // A specific event.
  string json_string = 3;                   // Reported information strings in the standard JSON format.
  int64 timestamp = 4 [deprecated=true];
  string sensor_path = 5 [deprecated=true];
}

message JsonReply {
  sint32 ret = 1;                           // Indicates whether the data processing succeeds. 1 stands for
success and 0 stands for failure.
}
```

1.2 Configuration Task Summary

gRPC configuration includes the following tasks:

(1) Configuring Basic Functions of gRPC

(2) Configuring the gRPC Response Timeout Time

(3) Enabling Stream-based RPC for Events

(4) Configuring the DSCP Value of gRPC Packets

(5) Configuring Event Types Supported by gRPC

(6) Configuring gRPC Server Attributes

- Configuring gRPC to Pre-configure a Subscription Server and Event
- Configuring gRPC to Support User Login Information of the Functional Server

(7) Configuring a YANG Model Path

(8) Configuring the gRPC Subscription Function

- (Optional) Configuring gRPC to Specifying a Source Interface to Send Data
- Configuring gRPC Destination Server
- Configuring gRPC Subscription

(9) (Optional) Configuring gRPC to Support the Login and Logout Function

(10) Configuring a Third-party Defined RPC Method

(11) Configuring a Dial-out RPC Method

1.3 Configuring Basic Functions of gRPC

1.3.1 Overview

The gRPC function is enabled, and the gRPC Client and gRPC Server are created. The gRPC Client uploads data to the server, and the gRPC Server parses authentication messages sent from the server and obtains the message content.

1.3.2 Restrictions and Guidelines

- The connection between the device and server must be normal.
- The port number of the local gRPC Server is 50051.
- A gRPC instance is created by running a **gRPC** command, the gRPC function is enabled, and the gRPC process configuration mode is enabled.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the gRPC function.

grpc

The gRPC function is disabled by default.

1.4 Configuring the gRPC Response Timeout Time

1.4.1 Overview

The data response timeout time is configured for the gRPC Server.

1.4.2 Restrictions and Guidelines

- After the data response timeout time is configured for the gRPC process and the collector delivers a Get or Set operation, a timeout message is returned if the server does not obtain corresponding data within the timeout time.
- The value of the timeout time should be configured based on the actual scenario. If the configured timeout time is too short, part of the required data may not be returned in the timeout period during a Get operation.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure the gRPC data response timeout time.

reply-timeout *time*

The default data authentication timeout time on the gRPC Server is **10** seconds.

1.5 Enabling Stream-based RPC for Events

1.5.1 Overview

Configure events to push gRPC packets through stream-based RPC.

1.5.2 Restrictions and Guidelines

- Events push gRPC packets through JsonSend RPC of ruijie-json.proto by default. After stream-based RPC is enabled, events push gRPC packets through JsonStreamSend RPC of ruijie-json.proto.
- After the RPC mode is changed, the current gRPC channel will be disconnected and a new session will be set up.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Enable stream-based RPC for events.

event stream enable

Stream-based RPC is disabled by default.

1.6 Configuring the DSCP Value of gRPC Packets

1.6.1 Overview

Configure the DSCP value of communication packets for the gRPC server and the gRPC client.

1.6.2 Restrictions and Guidelines

- After the DSCP value of gRPC communication packets is modified, the gRPC server and gRPC client services on the device are restarted. To ensure successful session establishment, you are advised to reconnect the gRPC server after it is restarted. The gRPC client automatically reconnects after it is restarted. The DSCP value takes effect after the gRPC server and gRPC client are reconnected and a session is established between them.
- If the **dscp** command does not carry the **ipv6** keyword, the DSCP value of IPv4 gRPC communication packets is configured. If the command carries the **ipv6** keyword, the DSCP value of IPv6 gRPC communication packets is configured.
- The range of the DSCP value is from 0 to 63.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure the DSCP value of gRPC communication packets.

dscp [**ipv6**] *dscp-value*

The default DSCP value of gRPC communication packets is **0**.

1.7 Configuring Event Types Supported by gRPC

1.7.1 Overview

- The device is configured with all realtime events of concern which are subscribed to.
- The device is configured with all periodic events of concern which are subscribed to.
- The timer time of the periodic events is modified.

1.7.2 Restrictions and Guidelines

- The event which the server subscribes to cannot effect unless a specified event which is subscribed to is configured on the device.
- If the device subscribes to a realtime event, a realtime packet is generated and sent to the subscription server when the threshold of the realtime events is triggered. If the threshold of the realtime events is triggered frequently, many same packets are generated within a short time and sent to the subscription server. As a result, the cost of the server and the device is added. To prevent such threshold from being triggered frequently, Run the **subscr-realtime-interval** command to suppress realtime events to generate new packets within a period.
- When any periodic events of concern which are subscribed to is configured and the NETCONF manager sends periodic events which are subscribed to, the corresponding periodic timer starts and gRPC data is sent to the subscription server.
  - If the NETCONF manager does not subscribe to any periodic time, the timer period is determined by the **subscr-sample-interval** command.
  - If the NETCONF manager subscribes to both the periodic events and period time, the period time is subject to the subscription time of the NETCONF manager.
- After any events of concern which are subscribed to are configured by the gRPC process, the gRPC process waits for the NETCONF manager to send the subscription events:
  - If the received subscription message matches the local subscription event, the event triggering gRPC reporting server function is enabled.
  - When the NETCONF manager sends an unsubscription event and the received unsubscription message matches the local subscription event, the event triggering gRPC reporting server function is disabled.
- If no events of concerns which are subscribed to are configured by the gRPC process, the gRPC process ignores the subscription events and unsubscription events sent by the NETCONF manager.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure an event of concern which is subscribed to on the device.

subscr [**realtime** | **sample**] **enable**

No events of concern which are subscribed to are configured by default.

(5) (Optional) Configure the timer time of the periodic events.

subscr-**sample**-**interval** *subscr-sample-interval-second* [**millisecond** *subscr-sample-interval-millisecond*]

The default periodic event timer time is **10** seconds.

(6) (Optional) Configure the realtime event suppression time.

subscr-realtime-interval { **all** *subscr-realtime-time* | **realtime** *json-event subscr-realtime-time* }

The realtime event suppression function is not enabled by default.

1.8 Configuring gRPC Server Attributes

1.8.1 Configuration Tasks

gRPC server attribute configuration includes the following tasks:

- Loading an SSL/TLS Certificate
- Loading a CA Certificate
- Configuring an ACL Filtering Rule
- Configuring GZIP Format for Compressed Data Transmission

1.8.2 Loading an SSL/TLS Certificate

1. Overview

After an SSL/TLS certificate is loaded, TLS encryption is enabled.

2. Restrictions and Guidelines

Before loading an SSL/TLS certificate, copy the certificate to the flash partition of the device.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Load the SSL/TLS certificate of the gRPC server.

server certificate load { pem *cert-filename* **private-key** *key-filename* **} | { pfx** *cert-filename* **} [password** *password-text* **]**

No SSL/TLS certificate is loaded by default.

1.8.3 Loading a CA Certificate

1. Overview

After a CA certificate is loaded, certificate authentication is performed for the client.

2. Restrictions and Guidelines

Before loading a CA certificate, copy the certificate to the flash partition of the device.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Load the CA certificate of the gRPC server.

server trusted-ca load *cert-filename*

No gRPC server CA certificate is loaded by default.

1.8.4 Configuring an ACL Filtering Rule

1. Overview

Packet filtering will be performed on the connected clients based on the configured ACL.

2. Restrictions and Guidelines

Create an ACL before specifying it as a filtering rule.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configuring the ACL filtering rule.

server access-class { **ipv4** *acl-name* | **ipv4** *acl-number* | **ipv6** *acl-name* }

No ACL filtering rule is configured by default.

1.8.5 Configuring GZIP Format for Compressed Data Transmission

1. Overview

Configure the gRPC server to transmit data in GZIP format.

2. Restrictions and Guidelines

After being configured with GZIP format for data transmission, the gRPC server will be restarted. You are advised to reconnect the client after the gRPC server is restarted. The gRPC server will transmit data in GZIP format upon session creation.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure the gRPC server to transmit data in GZIP format.

server compression gzip

No compression format is configured for the gRPC server by default.

1.9 Configuring gRPC to Support Pre-configuration Functions

1.9.1 Configuration Tasks

gRPC configuration includes the following tasks:

- Configuring gRPC to Pre-configure a Subscription Server and Event
- Configuring gRPC to Support User Login Information of the Functional Server

1.9.2 Configuring gRPC to Pre-configure a Subscription Server and Event

1. Overview

- After a server and event which are subscribed to is pre-configured, gRPC packets of corresponding events can be reported to the server.
- After a subscribing standby server is pre-configured, its services can be switched over to the standby server and packets are automatically sent to the standby server when the active server becomes faulty.
- After the GZIP format is configured for event data reporting, the gRPC clients associated with the subscription server will set up new sessions and report event data in GZIP format.
- If the user server is specified with a source IP address or a VRF, the device does not use the IP address or the VRF of the source interface for gRPC server connection.

2. Restrictions and Guidelines

- The address and port number of the subscription server must be legitimate.
- The events and parameters which are subscribed to must be correct and valid.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure gRPC to support a subscription server.

user-server { *ipv4-address* | **ipv6** *ipv6-address* } *port-number* **[source ip** <*source-ipv4-address*> **| ipv6 <** *source-ipv6-address*>] [**vrf** <*vrf_name*>]

No subscription server is pre-configured by default.

(5) Configure gRPC to support a subscription event.

type *json-event* **value** *value-interval* [**value-extend** *value-extend-interval*]

The event subscription function for a specified server is not enabled by default.

(6) (Optional) Configure gRPC to support the heartbeat detection function.

heartbeat inform [**interval** *interval*] [**keepalive-times** *keepalive-times*]

The heartbeat sending function is not enabled by default.

(7) (Optional) Configure gRPC to pre-configure a standby server for the subscription server.

standby-server *ipv4-address port-number*

No standby server is pre-configured for the subscription server by default.

Before configuring a standby server, enable the heartbeat detection function. When an active server becomes faulty, data can be automatically sent to the standby server.

(8) (Optional) Configure the gRPC protocol for the destination server.

protocol grpc { **tls** | **no-tls** }

The default protocol is the cleartext gRPC.

(9) (Optional) Configure the subscription server to report event data in GZIP format.

compression gzip

No format is specified for event data reporting by default.

(10) Exit the gRPC subscription server mode.

exit-user-server

1.9.3 Configuring gRPC to Support User Login Information of the Functional Server

1. Overview

After user login information is pre-configured for the server, the specified server can obtain correct information after initiating an obtainment event request.

2. Restrictions and Guidelines

- Running a configured command, the device can pre-create user login information of the server that passes authentication, simulate the server to initiate a login request, pass the authentication, and save the user login information.
- Running a configured command, the device can delete user login information of the server that passes authentication, simulate the server to initiate a logout request, and delete the user login information.
- The address of the server must be legitimate.
- The sequence number of the login user must be unique.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure gRPC to pre-configure user login information of the server.

user-client *user-id username* { *ipv4-address* | **ipv6** *ipv6-address* }

No user login information is pre-configured for the server by default.

1.10 Configuring a YANG Model Path

1.10.1 Overview

After the YANG model path and data source are collected, data can be sent to the corresponding server based on the path in the subscription association relationship.

1.10.2 Restrictions and Guidelines

- The YANG model path must be legitimate and corresponding data is available on the path.
- In the YANG model path group, a specific YANG model path is configured. For the detailed compilation method of the path, see the displayed information of the **display grpc yang tree** and **display grpcnode-path** commands in **gRPC Command Reference**.
- After a gRPC YANG model is configured, the system switches to the gRPC YANG model configuration group mode.
- Multiple YANG model paths can be configured for this group in this mode.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure a YANG model path group.

sensor-group *sensor-group-id*

No YANG model path group is configured by default.

(5) Configure a gRPC YANG model path and its group.

sensor-**path** *sensor-path*

No YANG model path is configured by default.

(6) Exit the gRPC YANG model configuration group mode.

exit-sensor-group

1.11 Configuring the gRPC Subscription Function

1.11.1 Overview

After a subscription association relationship is configured, data of the associated YANG model path group is collected and sent to the destination server of the associated destination group.

1.11.2 Restrictions and Guidelines

A YANG model path group must be configured in advance.

1.11.3 Configuration Tasks

gRPC subscription configuration includes the following tasks:

(1) (Optional) Configuring gRPC to Specifying a Source Interface to Send Data

(2) Configuring gRPC Destination Server

(3) Configuring gRPC Subscription

1.11.4 Configuring gRPC to Specifying a Source Interface to Send Data

1. Overview

gRPC is configured to send packets based on the IP address of a specified interface.

2. Restrictions and Guidelines

- The bound interface must be up and be configured with an IP address.
- If a server receives only packets from a specified source address, this command can be used to configure the specified source interface.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) (Optional) Configure a source interface of realtime data and periodic data.

subscr-source-interface *interface-type interface-number*

The source interface of realtime data and periodic data is a random value by default.

1.11.5 Configuring gRPC Destination Server

1. Overview

The address of a destination server is configured for the server to subscribe to a YANG model path in the subscription association relationship.

2. Restrictions and Guidelines

- The address and port number of the server must be legitimate.
- After a gRPC destination group is configured, the system switches to the gRPC destination group configuration mode.
- Multiple destination addresses can be configured for this group in this mode.
- After the GZIP format is configured for gNMI data reporting, the gRPC clients in the destination configuration

group mode will set up new sessions and report gNMI data in GZIP format.

- If the gRPC destination address is specified with a source IP address or a VRF, the device does not use the IP address or the VRF of the source interface for gRPC server connection.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure a gRPC destination group.

destination-group *destination-group-id*

No destination group is configured for the subscription association relationship by default.

(5) Configure a gRPC destination address.

- Configure an IPv4 destination address.

  ip *ipv4-address* **port** *port-number* ***[source ip*** *<source-ipv4-address>* ***] [vrf*** *<vrf_name>* ***]***

  No IPv4 address or port is configured for the destination server by default.

- Configure an IPv6 destination address.

  ipv6 *ipv6-address* **port** *port-number* ***[source ipv6*** *<source-ipv6-address>* ***] [vrf*** *<vrf_name>* ***]***

  No IPv6 address or port is configured for the destination server by default.

(6) Configure a protocol for the destination server.

protocol grpc { **tls** | **no-tls** }

The default protocol is the gRPC protocol that supports plain text transmission.

(7) Configure the destination group to report gNMI data in GZIP format.

compression gzip

No format is specified for gNMI data reporting by default.

(8) Exit the gRPC destination group configuration mode.

exit-destination-group

1.11.6 Configuring gRPC Subscription

1. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure a subscription association relationship group.

subscription *subscriptionid*

No subscription association relationship is configured between the YANG model path group and destination group by default.

(5) Configure the associated YANG model path group and its period interval.

sensor-group *sensor-group-id* [**sample-interval** *sample-interval*]

(6) Configure a destination group of the subscription association relationship.

destination-**group** *destination-group-id*

No destination group is configured for the subscription association relationship by default.

(7) Exit the gRPC subscription association relationship configuration mode.

exit-grpc-subscription

1.12 Configuring gRPC to Support the Login and Logout Function

1.12.1 Overview

The authentication mode of the gRPC login and logout function is configured as authentication-exemption, AAA local authentication, or AAA server authentication (timeout time and retry times are configurable).

1.12.2 Restrictions and Guidelines

- If the authentication mode is configured as AAA server authentication, the new-model must be enabled.
- The authentication-exemption mode is not recommended.
- You are not advised to modify the timeout time and retry times. During server login in the AAA server authentication mode, if the retry times exceed a limit or the timeout time is too long, AAA may be locked for 15 minutes. The lock time can be canceled by running the AAA command **cleanup aaa local user lockout all**.
- Upon receiving a login request from the server, the device selects one of the three modes based on the configured authentication mode. After the server passes the authentication, the user login information, namely, IP address and username of the server, is recorded. The device returns responses to the obtainment event requests of the server that passes the authentication.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure an authentication mode of the gRPC login and logout function.

authen login { **local** | **authentication** *mlist* }

The local authentication mode, namely, **authen login local** is used by default.

(5) (Optional) Configure the AAA server authentication attribute of the gRPC login and logout function.

authen aaa-config { **retry** *retry-times* | **timeout** *timeout-time* }

The retry times and timeout time of AAA server authentication are 1 and 4 seconds, respectively, by default.

This authentication mode can be configured only after AAA configuration (aaa new-model) is completed.

1.13 Configuring a Third-party Defined RPC Method

1.13.1 Overview

After a third-party defined RPC method is configured, the RPC method can be used to collect device information and data or perform RPC-related operation.

1.13.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure a third-party defined RPC method.

rpc { **gnmi** | **openr** } **enable**

No RPC defined by gNMI or openR is configured by default.

1.14 Configuring a Dial-out RPC Method

1.14.1 Overview

An RPC method is configured for dial-out so that the RPC method can be selected to receive and send messages.

1.14.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure a dial-out RPC method.

dial-out rpc { **sonic** | **custom** }

The RPC method defined by the open source of Sonic is used by default.

1.15 gRPC Packet Retransmission Timeout

1.15.1 Overview

After the gRPC packet retransmission timeout is configured, gRPC can identify connection exception upon timeout.

1.15.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure the gRPC packet retransmission timeout.

tcp_user_timeout *value*

The default gRPC packet retransmission timeout is 30 seconds.

1.16 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** commands to clear information.

Caution

Running the **cleanup** commands may lose vital information and thus interrupt services.

Table 1-1 gRPC Monitoring

Command	Purpose
cleanup grpc channel [*ipv4-address port-number*] [**counter**]	Clears statistics about the server which gRPC subscribes to.
cleanup grpc subscr [**sample**] [**counter**]	Clears data about periodic events and realtime events of gRPC.
display grpc channel [**counter**]	Displays server address, port number, subscription events, and different statistics.
display grpc client	Displays gRPC server login information.
display grpc event subscription	Displays subscription delivered through events.
display grpc server information	Displays information related to the gRPC server.
display grpc status	Displays gRPC running status information.

Command	Purpose
display grpc subscr [**realtime** | **sample**]	Displays status and statistics of events which are subscribed to.
display grpc openconfig subscription	Displays information about static subscription association relationship (openconfig-telemetry.proto definition) of the device.
display grpc gnmi subscription	Displays information about subscription association relationship generated with the RPC method defined by gnmi.proto.
display grpc openr support-rpc	Displays openR RPC methods supported by the device.
display grpc yang tree [*module-name*]	Displays the YANG model tree that is loaded by gRPC.
display grpc yang node-path [*module-name*]	Displays paths corresponding to YANG nodes.

1.17 Configuration Examples

1.17.1 Configuring Basic Functions of gRPC

1. Requirements

A tested device is connected to a server and reports gRPC data.

2. Topology

Figure 1-3 Configuring Basic Function of gRPC

3. Notes

- Ensure that the device and the PC are mutually reachable via the Layer 3 route.
- Enable the gRPC function on the device.
- On the device, configure events in which the server must be reported.

4. Procedure

(1) Configure that the device and the PC are mutually reachable via the Layer 3 route.

```
Device> privilege
Device#config-system terminal
Device(cfg)#interface gigabitEthernet 0/1
Device(cfg-if-GigabitEthernet 0/1)# ip address 192.168.1.100 255.255.255.0
Device(cfg-if-GigabitEthernet 0/1)# exit
```

(2) Configure the gRPC function.

Enable the gRPC function.

```
Device(cfg)# grpc
```

Configure gRPC to bind a specified interface to send packets.

```
Device(cfg-grpc)# subscr-source-interface GigabitEthernet 0/1
```

(3) Configure events in which the server must be reported.

Configure the aaa new-model and the appropriate mlist test.

```
Device(cfg-grpc)# authen login authentication test
```

Configure the realtime event of concern subscribed to by gRPC.

```
Device(cfg-grpc)# subscr realtime enable
```

Configure the gRPC data response timeout time.

```
Device(cfg-grpc)# reply-timeout 30
```

Configure stream-based RPC for events.

```
Device(cfg-grpc)# event stream enable
```

Configure the DSCP value of IPv4 gPRC communication packets.

```
Device(cfg-grpc)# dscp 45
```

Enable the heartbeat mechanism, configure a heartbeat period and an interval, and specify a channel and subscription type, and specify a data compression format.

```
Device(cfg-grpc)# heartbeat inform interval 1 keepalive-times 1
Device(cfg-grpc)# user-server 192.168.1.1 12345
Device(cfg-grpc-us)# type 0x10000000 value 10
Device(cfg-grpc-us)# compression gzip
Device(cfg-grpc-us)# exit
```

Load the SSL/TLS certificate of the gRPC server.

```
Device(cfg-grpc)# server certificate load pem server.pem private-key server.key
```

Load the CA certificate of the gRPC server.

```
Device(cfg-grpc)# server trusted-ca load ca.pem
```

Configure IPv4 and IPv6 ACL filtering rules.

```
Device(cfg-grpc)# server access-class ipv4 ip4_acl
Device(cfg-grpc)# server access-class ipv6 ip6_acl
```

Configure the gRPC server to transmit data in GZIP format.

```
Device(cfg-grpc)# server compression gzip
```

Configure user login information of the specified server.

```
Device(cfg-grpc)# user-client 12345 test-user 192.168.1.100
```

Configure a YANG model path.

```
Device(cfg-grpc)# sensor-group 1
Device(cfg-grpc-us)# sensor-path /bridge:bridge/vlan/entry[id='1']/swport-list
Device(cfg-grpc-us)# exit-sensor-group
```

Configure a destination group.

```
Device(cfg-grpc)# destination-group 1
```

Configure an IPv4 address and port number of the destination group.

```
Device(cfg-grpc-destination)# ip 192.168.0.1 port 12345
```

Configure the destination group to report data in GZIP format.

```
Device(cfg-grpc-destination)# compression gzip
```

Enable the destination group to use the gRPC protocol that supports TLS encryption.

```
Device(cfg-grpc-destination)# protocol grpc tls
Device(cfg-grpc-destination)# exit-destination-group
```

Configure the subscription association relationship group, associated YANG model group and period interval, associated destination group, and data encoding format json-ietf.

```
Device(cfg-grpc)# subscription 1
Device(cfg-grpc-subscription)# sensor-group 1 sample-interval 1000
Device(cfg-grpc-subscription)# destination-group 1
Device(cfg-grpc-subscription)# exit-grpc-subscription
```

Configure an RPC method defined by gnmi.proto.

```
Device(cfg-grpc)# rpc gnmi enable
```

Configure an RPC method defined by openR.

```
Device(cfg-grpc)# rpc openr enable
```

Configure a private RPC method to receive and send messages.

```
Device(cfg-grpc)# dial-out rpc gnmi-ext
```

5. Verification

Run the **ping** command to check whether the device and the PC are reachable via the L3 route.

```
Device# ping oob 192.168.1.1
Sending 5, 100-byte ICMP Echoes to 192.168.1.1, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/3/5 ms.
```

Run the **display grpc status** command to check whether the gRPC function is enabled.

```
Device# display grpc status
GRPC:
  Uptime: 00h:28m:21s
```

Run the **display grpc client** command to display the user login information of the gRPC server.

```
Device# display grpc client
Client information all:
  1      : test-user@192.168.1.100, ID 12345
```

Run the **display grpc channel counter** command to display the statistics about the subscription server.

```
Device# display grpc channel counter
Server subscr all:
  server ip 192.168.1.1 port 50051
    state TRANSIENT_FAILURE
```

```
    heartbeat state FAILURE
  json list count: 0
  json send count: 1
  json drop count: 0
  call list count: 0
  call send count: 1
  call drop count: 0
```

Run the **display grpc channel counter** command to display the address, port number, and subscribing events of the subscription server.

```
Device# display grpc channel
Server subscr all:
  server ip 192.168.1.1 port 50051
    state TRANSIENT_FAILURE
    heartbeat state FAILURE
  subscr event:
    none
```

Run the **display grpc server information** command to display the gRPC server status, port number, TLS status, configured ACL, and certificate.

```
Device# display grpc server information
server information:
  status                  : enable
  port                    : 50051
  tls status              : enable
  ipv4 access-apply : ip4_acl
  ipv6 access-apply : ip6_acl
  certificate cn      : grpc
  ca certificate      : /O=RJ/emailAddress=1@123.com/C=CN/ST=FJ/L=FZ/OU=Ruijie/CN=ROOT
```

Run the **display grpc event subscription** command to display subscription delivered through events.

```
Device# display grpc event subscription
dynamic subscriptions:
  send count              : 405
  drop count              : 8
  call list count      : 0
  client(172.20.92.195:49340):
    subriptions:
      subription:
        json_event 0x10020001
        value 0
        value-extend 100
```

Run the **display grpc openconfig subscription** command to display the subscription relationship implemented according to openconfig-telemetry.yang.

```
Device# display grpc openconfig subscription
all subscriptions:
  subscription 1:
    sensor group 1:
      sample interval:1000
      sample timer count:858
      sensor path: /bridge:bridge/vlan/entry[id='1']/swport-list
        state: NORMAL
        recv count: 858
    destination group 1:
      destination: 192.168.1.100:12345
        state: TRANSIENT_FAILURE
        task list count: 0
        task drop count: 0
        send request count: 0
        send update count: 0
        recv response count: 0
      destination: [1::1]:12345
        state: TRANSIENT_FAILURE
        task list count: 0
        task drop count: 0
        send request count: 0
        send update count: 0
        recv response count: 0
```

6. Configuration Files

- Device configuration file

```
hostname Device
!
interface gigabitEthernet 0/1
 unset switch-port
 ip address 192.168.1.100 255.255.255.0
!
grpc
 dial-out rpc custom
 rpc gnmi enable
 rpc openr enable
 subscr enable
 reply-timeout 30
dscp 45
event stream enable
 subscr-source-interface Mgmt 0
 user-client 12345 test-user 192.168.1.100
 heartbeat inform interval 1 keepalive-times 100
```

```
server certificate load pem server.pem private-key server.key
server compression gzip
server trusted-ca load ca.pem
server access-apply ipv4 ip4_acl
server access-apply ipv6 ip6_acl
 sensor-group 1
  sensor-path /bridge:bridge/vlan/entry[id='1']/swport-list

1 Configuring OpenFlow

1.1 Introduction

1.1.1 Overview

OpenFlow is a network transmission protocol defined between a controller and the forwarding layer in the software defined network (SDN) architecture. OpenFlow allows the controller to directly access and operate network devices on the forwarding plane. These devices may be physical or virtualized.

OpenFlow separates the control plane from the forwarding plane of the network devices through standard communication protocols. Thus, the network devices focus on forwarding, and the control of an entire network focuses one controller. An OpenFlow connection is established between a controller and a device. The controller generates and delivers forwarding rules to the network device in a flow table through the OpenFlow connection, thereby centrally manage the control plane and reducing maintenance and management costs.

1.1.2 Principles

1. Basic Concepts

- Flow table

  A flow table is a core data structure for a device to control forwarding policies. Based on the flow table, the device determines an action to be taken for network traffic that enters the device.

  A device can have one or multiple flow tables. At present, a device supports only one flow table. A flow table is composed of multiple flow entries.

  According to the OpenFlow protocol, a flow entry consists of three parts: **header**, **counter**, and **action**.

  - **header**: It defines the index of a flow entry and consists of various packet fields such as source Media Access Control (MAC) address, destination MAC address, Ethernet protocol type, source IP address, destination IP address, IP protocol type, source port, and destination port. If a packet matches the header field of a flow entry, the packet matches this flow entry.
  - **counter**: It counts the number of packets and bytes that match this flow entry.
  - **action**: It defines an action taken for the packet that matches the flow entry, for example, discarding, broadcasting, or forwarding the packet.

- Message

  The OpenFlow protocol supports three categories of messages: **controller-to-switch**, **asynchronous**, and **symmetric**. Each category of messages include several subtypes of messages. The three categories of messages are described as follows:

  - **controller-to-switch**: This category of messages are initiated by the controller to manage and obtain network device statuses. For the subtypes of messages, see Table 1-1.
  - **asynchronous**: This category of messages are initiated by a network device to update network events or network device status changes (most commonly link up/down of a network port) to the controller. For the subtypes of messages, see Table 1-2.
  - **symmetric**: This category of messages are initiated either by a device or a controller to achieve an

initial handshake of the protocol and detect connection statuses. For the subtypes of messages, see Table 1-3.

Table 1-1 Subtypes of controller-to-switch Messages

Subtype	Description
Features	Used by a controller to send Features requests to understand device capabilities and responses.
Configuration	Used by a controller to query device configuration and make responses.
Modify-State	Used to manage device statuses, for example, flow entry and port statuses. This type of messages are used to add, delete, and modify flow entries, group entries, and port attributes of a device.
Multipart	Used by a controller to request device information, for example, current configuration and statistics.
Packet-Out	Used by a controller to send packets to a device.
Barrier	Used to check whether an action taken before a barrier message is successful. A controller sends a barrier request message. If a device confirms that the preceding action is successful, the device returns a barrier response message.
Role-Request	Used by a network device to request the role of a controller.
Asynchronous-Configuration	Used by a controller to set an asynchronous message filter and filter out unwanted asynchronous messages or query this filter.

Table 1-2 Subtypes of Asynchronous Messages

Subtype	Description
Packet-in	Used by a device to send packets to the controller.
Flow-Removed	Used to notify a controller of removing a flow entry from the flow table.
Port-Status	Used to notify a controller of the change in the device port status or configuration.
Error	Used to notify a controller of a device fault or error.

Table 1-3 Subtypes of Symmetric Messages

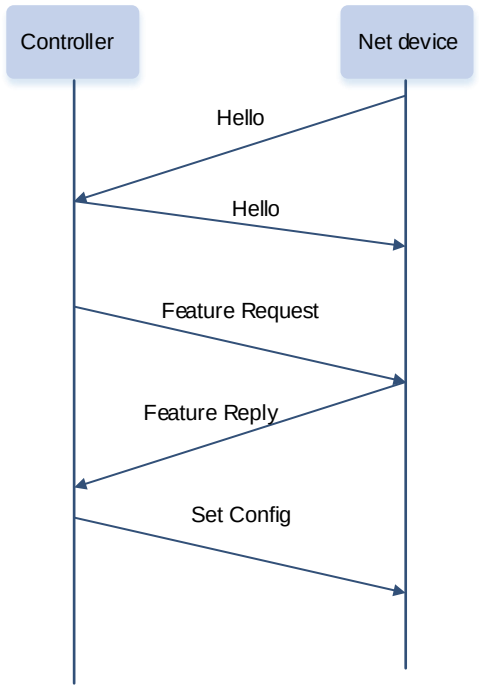
Subtype	Description
Hello	A message for interaction sent by between a controller and a device when an OpenFlow connection is established.

Subtype	Description
Echo	Keep-alive (echo request/reply) messages sent by a controller and a device.
Experimenter	A message reserved for new features.

2. Roles of the Controller

Table 1-4 Roles of the Controller

Role	Permission
Master	The controller in this role has all the permissions to control devices, deliver a flow table, query statistics, and receive status messages reported by the devices. In the cluster deployment mode, only one controller plays the master role.
Equal	The controller in this role has all the permissions of the controller. Compared with the master role, the equal role can be played by multiple controllers.
Standby	The controller in this role has partial permissions, and it is not permitted to deliver flow entries, group entries, or meter entries. The controller is not permitted to modify device configuration or perform packet out operation.



3. Separating Control from Forwarding

OpenFlow enables centralized management of the network control plane, so that the entire network can be centrally managed at ease (as compared with the status quo of the network), reducing maintenance and management costs.

The controller sends flow table information to the network devices, so as to control the method for forwarding network data packets and configuration parameters. Each network device will send a notification message to the controller when its link is interrupted or when the network device receives a data packet in which no forwarding action has been specified. In this way, the interaction between the controller and the network devices is implemented to eventually control the transmission of the entire network.

The mutual discovery between a controller and a network device must be completed before the controller and the network device interact with each other. Figure 1-1 shows the specific actions involved in this process.

Figure 1-1 Principle of the Controller and Network Device Interaction

Hello packets are sent between a controller and a network device to achieve a handshake. After the handshake is completed, the controller requests specific information about the device, including the number of ports on the network device and the capability of each port (such as the Feature Request/Reply shown in Figure 1-1). Then the controller delivers configurations (such as Set Config shown in Figure 1-1) to the specific network device. After a connection is established, the controller defines various flows and corresponding actions for the flows, and delivers them in a flow table to the network device. When a data packet enters the network device, the network device matches the data packet with the flow table according to present flow table rules and performs a corresponding action (including forwarding, discarding, and modifying the packet). At the same time, a corresponding counter is updated. If no match is found in the flow table, the network device forwards the data packet to the controller.

The network device locally maintains the flow table delivered from the controller. If the data packet to be forwarded is already defined in the flow table, the network device directly forwards the data packet. Otherwise, the data packet is sent to the controller to confirm the transmission path (which can be understood as control plane parsing to generate the flow table) and then forwarded based on the flow table delivered from the controller.

1.1.3 Protocols and Standards

- OpenFlow Switch Specification Version 1.0.0
- OpenFlow Switch Specification Version 1.3.0

1.2 Restrictions and Guidelines

- Only the Table 0 flow table is supported.
- A maximum of three controllers can be connected.

1.3 Configuration Task Summary

OpenFlow configuration includes the following tasks:

(1) Configuring OpenFlow

(2) (Optional) Configuring the OpenFlow Multi-controller Mode

(3) (Optional) Configuring the VLAN Tag for Packets Sent to the Controller

(4) (Optional) Configuring the Table-Lookup Mode

(5) (Optional) Configuring the OpenFlow Source IP Address

1.4 Configuring OpenFlow

1.4.1 Overview

As a network transmission protocol, OpenFlow runs over Transport Layer Security (TLS) or unprotected TCP connections, and defines the interaction between a controller and a network device.

1.4.2 Configuring OpenFlow

1. Overview

After the OpenFlow function is enabled on a device, packet forwarding control policies are generated and delivered by a controller.

2. Restrictions and Guidelines

- Before switching the address of a controller, disable and then enable the OpenFlow function again.
- When the OpenFlow function is enabled, the LLDP function on the device must be disabled. Otherwise, the LLDP packets delivered by a controller cannot be sent out.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the OpenFlow function.

of controller-ip *ipv4-address* [**port** *port-number*] [**aux**] **interface** *interface-type interface-number*

The OpenFlow function is disabled by default.

1.4.3 Configuring the OpenFlow Multi-controller Mode

1. Overview

After the multi-controller mode is configured, multiple controllers can be connected once.

2. Restrictions and Guidelines

Before the multi-controller mode is configured, the OpenFlow function must be disabled first. The multi-controller mode can take effect after the OpenFlow function is enabled again.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Connect an OpenFlow device to the controller.

of mode { **single** | **multiple** }

An OpenFlow device works in multi-controller mode by default.

(4) (Optional) Configure the interval at which an OpenFlow device reconnects to a controller.

of connect-interval *interval*

The default interval at which an OpenFlow device reconnects to a controller is 6 seconds.

(5) (Optional) Configure the echo request sending interval of an OpenFlow device.

of echo-interval *interval*

The default echo request sending interval of an OpenFlow device is 5 seconds.

1.4.4 Configuring the VLAN Tag for Packets Sent to the Controller

1. Overview

This function is used to configure a VLAN tag for packets sent to a controller by a device. Packets sent to a controller by a device contain the VLAN tag by default.

2. Restrictions and Guidelines

The configuration takes effect immediately.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a VLAN tag for packets sent by an OpenFlow device to a controller.

of packet vlantag

Packets sent to a controller by an OpenFlow device contain the VLAN tag by default.

1.4.5 Configuring the Table-Lookup Mode

1. Overview

This function is used to enable the table-lookup mode for received packets. A device looks up the flow table for the received packets by default, and processes the packets based on the matched entry. If no entry is matched, the packets are discarded.

2. Restrictions and Guidelines

The configuration takes effect immediately.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Connect an OpenFlow device to a controller.

of packet table-lookup { **enable** | **disable** }

The table-lookup mode is enabled for a network device by default.

1.4.6 Configuring the OpenFlow Source IP Address

1. Overview

The IP address of a device is configured as a source IP address for connecting to a controller. The default source IP address is the IP address of the connection port.

2. Restrictions and Guidelines

The configuration takes effect immediately and the network device is disconnected from the controller. Then, the source IP address is used for reconnection.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a source IP address for connecting an OpenFlow device to a controller.

of source-ip *ipv4-address*

The IP address of the connection port is the source IP address for connecting to a controller by default.

1.5 Monitoring

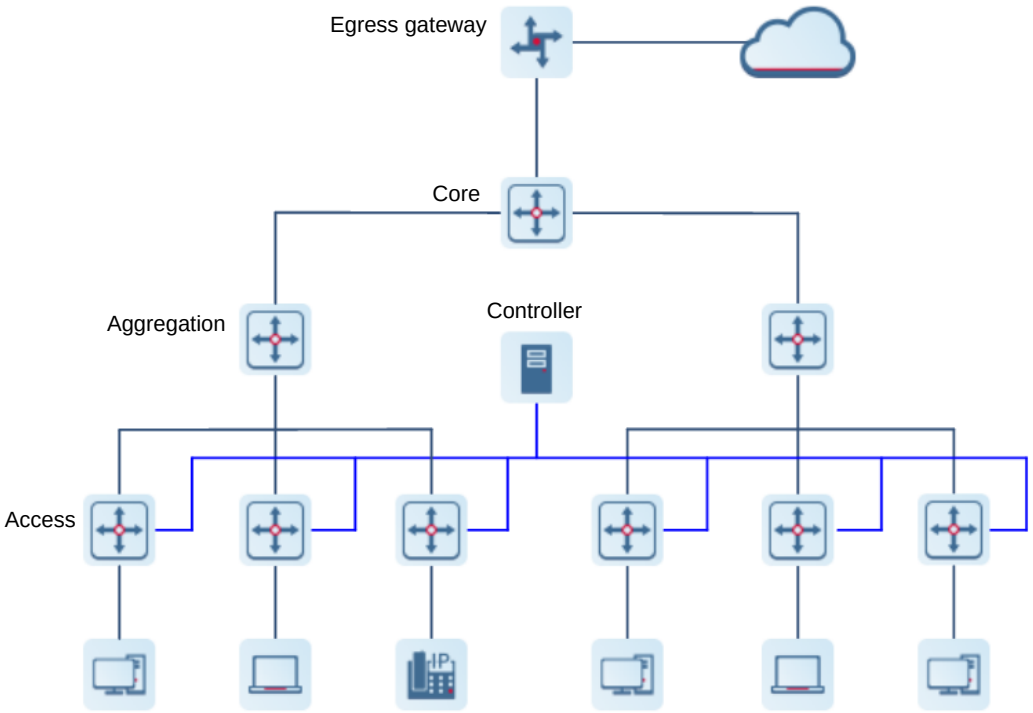
Run the **display** command to check the running status of a configured function to verify the configuration effect.

Table 1-5 Monitoring

Command	Purpose
display of	Displays the connection between the OpenFlow device and the controller.
display of port	Displays the port status of the current OpenFlow device.
display of flowtable	Displays the flow table of the current OpenFlow device.
display of group (only available in OpenFlow 1.3)	Displays the group table of the current OpenFlow device.

Command	Purpose
display of meter (only available in OpenFlow 1.3)	Displays the meter table of the current OpenFlow device.
display of mergedflow(only available in OpenFlow 1.3)	Displays the merged flow table of the current OpenFlow device.

1.6 Configuration Examples



1.6.1 Configuring Central Control

1. Requirements

OpenFlow can be used to perform centralized management of access device authentication. As displayn in Figure 1-2, a controller is deployed on an access device to authenticate and control the access device, so that the authentication function (on the control plane) is shifted from the access device to the controller.

2. Topology

Figure 1-2 Topology of Central Control

3. Notes

- Enable the OpenFlow function on a device and establish an OpenFlow management channel with a controller.

- Run OpenFlow Client on the access device to interconnect with the controller.
- The controller asks the access device to send an authentication packet to itself over the OpenFlow protocol.
- The controller completes the authentication process, and sends authentication results to the access device over the OpenFlow protocol to complete admission control on end users.

4. Procedure

Enable the OpenFlow function on a device, set the IP address of a controller to 172.18.2.36/24 and the port number to 65535, and disable the LLDP function on the device.

```
Device> privilege
Device# config-system terminal
Device(cfg)# unset lldp enable
Device(cfg)# interface GigabitEthernet 0/1
Device(cfg-if-GigabitEthernet 0/1)# unset switch-port
Device(cfg-if)# ip address 172.18.2.36 255.255.255.0
Device(cfg-if)# exit
Device(cfg)# of controller-ip 172.18.2.35 port 65535 interface mgmt 0
```

Configure the single-controller mode on the device.

```
Device(cfg)# of mode single
```

Remove the VLAN tag from packets sent to the controller.

```
Device(cfg)# no of packet vlantag
```

Configure the table-lookup mode on the device.

```
Device(cfg)# ofpacket table-lookup enable
```

Set the OpenFlow source IP address for the device to 192.168.197.25.

```
Device(cfg)# of source-ip 192.168.197.25
```

5. Verification

Display the connection status of OpenFlow 1.3.

```
Device# display of
[0] Controller ID=0 Info=tcp:172.18.2.35 port=6653 interface Mgmt 0, Main is Connected, Aux is Disabled
```

Display the port status of OpenFlow 1.3.

```
Device# display of port
ID   IFX  INTERFACE            SPEED    LINK  DUPLEX   TX_PKT  RX_PKT  CONFIG
1    1    GigabitEthernet 0/1  Unknown  DOWN  Unknown  0       0       NA
2    2    GigabitEthernet 0/2  Unknown  DOWN  Unknown  0       0       NA
3    3    GigabitEthernet 0/3  Unknown  DOWN  Unknown  0       0       NA
4    4    GigabitEthernet 0/4  Unknown  DOWN  Unknown  0       0       NA
5    5    GigabitEthernet 0/5  Unknown  DOWN  Unknown  0       0       NA
6    6    GigabitEthernet 0/6  Unknown  DOWN  Unknown  0       0       NA
7    7    GigabitEthernet 0/7  Unknown  DOWN  Unknown  0       0       NA
8    8    GigabitEthernet 0/8  Unknown  DOWN  Unknown  0       0       NA
9    9    GigabitEthernet 0/9  Unknown  DOWN  Unknown  0       0       NA
10   10   GigabitEthernet 0/10 Unknown  DOWN  Unknown  0       0       NA
```

11	11	GigabitEthernet 0/11 Unknown	DOWN	Unknown	0	0	NA
12	12	GigabitEthernet 0/12 Unknown	DOWN	Unknown	0	0	NA
13	13	GigabitEthernet 0/13 Unknown	DOWN	Unknown	0	0	NA
14	14	GigabitEthernet 0/14 Unknown	DOWN	Unknown	0	0	NA
15	15	GigabitEthernet 0/15 Unknown	DOWN	Unknown	0	0	NA
16	16	GigabitEthernet 0/16 Unknown	DOWN	Unknown	0	0	NA

Display the flow table status of OpenFlow 1.3.

```
Device# display of flowtable
/****************** openflow flow table[0]---flow number[2] ******************/

{table="0", duration_sec="5222", priority="0", flags ="0x1",idle_timeout="0", hard_timeout="0", cookie="0x0",
packet_count="0", byte_count="0". match=oxm{all match} instructions=[apply{acts=[output{port="controller",
max_len="3333"}] }] }
xid=472, sync_flag=0x0, ss_index=0x7b6

{table="0", duration_sec="5222", priority="66", flags ="0x1",idle_timeout="0", hard_timeout="0", cookie="0x0",
packet_count="0", byte_count="0". match=oxm{eth_dst="00:25:64:c4:54:e4", eth_type="0x800",
ipv4_dst="1.1.0.0", ipv4_dst_mask="255.255.240.0"} instructions=[apply{acts=[output{port="controller",
max_len="65535"}] }] }
xid=473, sync_flag=0x0, ss_index=0x7b1

/****************************** openflow flow table end ***************************************/
flow total number = 2
```

Configure the single-controller mode on the device. The device can be connected to only one controller. If more controllers are connected, a notification will be displayed.

```
Device(cfg)# unset of controller-ip
Device(cfg)# of mode single
Device(cfg)# of controller-ip 172.18.122.24 interface gigabitEthernet 0/1
Device(cfg)# of controller-ip 172.18.122.25 interface gigabitEthernet 0/1
Controller Mode is Single, can't connected
```

Run the **display of** command to check whether the current mode is the table-lookup mode and whether the source IP address is 192.168.197.25.

```
Device# display of
version:openflow1.3, controller[0]:tcp:172.18.105.11 port 6653 interface GigabitEthernet 1/0/7, main is
connected, aux is disable, role is master.
Current controller mode : multiple.
Current packet process mode : Lookup all flow.
Datapath id = 897516188948
Source IP = 192.168.197.25
```

6. Configuration Files

```
hostname Device
unset lldp enable
!
of source-ip 192.168.197.25
```

```
of controller-ip 172.18.2.35 port 65535 interface Mgmt 0
unset of packet vlantag
!
interface GigabitEthernet 0/1
unset switch-port
 ip address 172.18.2.36 255.255.255.0
```

7. Common Errors

- The controller IP address is incorrectly configured.
- The TCP port of the controller is incorrectly configured.
- The IP address of the local management channel is not configured.

1 Configuring SEM

1.1 Introduction

1.1.1 Overview

The smart embedded manager (SEM) is a network management tool. The tool can be separately deployed through commands, independent from external network management tools, which makes the tool easy to deploy.

Traditional external network management tools must be connected to devices over a network to manage the devices. If a network fails, affecting network connection, the external network management tools lose effect. SEM can directly manage devices under any circumstance and troubleshoot different types of network or device faults or capture key information.

SEM detects configuration events in real time. When an event occurs, SEM takes preset actions. The entire procedure is highly customizable. SEM provides fault detection and processing and automatic management functions, which improves the availability of the device and network.

SEM supports a variety of events, including key events of a device such as key syslog, trap and time point, or input operations such as Command Line Interface (CLI) commands and Simple Network Management Protocol (SNMP) operations, or threshold excess such as interface statistics, SNMP object values, and system resource statistics. SEM supports many actions, including user command running, log sending, and active device reset.

1.1.2 Basic Concepts

- Event

  An event indicates an event that a user cares about. It is configured by users and attached to a policy. One or multiple events can be configured. Each type of events are detected by a specific detector. When conditions are met, corresponding event is triggered by the event detector. For example, to detect the inclusion of the **shutdown** command in the privileged EXEC mode, run the **event tag** *example* **cli pattern** *shutdown* **mode** *exec* command to configure this event to the corresponding command line event detector.

- Action

  An action indicates a measure taken after an event occurs. It is configured by users and attached to a policy. One or multiple actions can be configured. Each type of actions correspond to a type of action configurations. When an event occurs, the policy corresponding to this event runs configured actions in order. For example, to restart a device after an event occurs, run the **act** *example* **reload** command.

- Policy

  A policy organizes relationships between events and between events and actions. A policy must be submitted after it is configured. When an event corresponding to this policy meets a preset rule, this policy is triggered and runs actions in order.

- Event detector

  An event detector is embedded in specific business and monitors the business based on user configuration. When the business complies with the user configuration, corresponding event is triggered. The event detector sends an event notification to the smart management server.

- Smart management server

  A smart management server receives the event notification from the event detector and determines whether to trigger a policy based on the event. After the policy is triggered, the smart management server runs the policy in policy management.

- Policy manager

  A policy manager manages SEM policies and runs actions in the policies that are triggered by the smart management server.

- SEM environmental variable

  It indicates a variable that is used by an action of a policy during SEM running. There are three types of SEM environmental variables:

  - Global variable
  - Local system variable
  - Local user variable

  The words and signs located between the United States Dollar sign ($) and the first non-letter, non-digit, and non-underline character are used as the name of a variable to be replaced. Global variables can be used in all policies. Local system variables and local user variables are local variables and can be used in specific policies only. The local system variables are read-only. The local user variables are defined by the actions in the policies during policy running. Therefore, the local system variables start with the underline (_) to avoid confusion with the local user variables.

- Specific application event of SEM

  SEM supports specific application events in the SEM system. These events are used to trigger a policy during running of another policy. Subsets and types are used to distinguish specific application events. Specific application events of SEM are detected by the specific application event detector based on subsets and types, and are released by their actions in the running policy. When an action in the running policy releases a specific application event of a subset and type, the detected event of the subset and type is triggered.

- SEM naming counter

  SEM supports a naming counter in the SEM system. Change in the SEM naming counter is detected by the counting event detector of SEM. The value of the SEM naming counter is operated by the counter action in the running policy. The SEM naming counter can be used for policy trigger counting and numerical statistics.

1.1.3 Principle

Figure 1-1 SEM Structure

As shown in Figure 1-1, SEM provides different types of event detectors. These events detectors are embedded in different business to monitor the business in real time. The detectors try to match event triggering conditions in user configurations with business running events. If a match is hit, the event detector notifies the smart management server of the event.

On the basis of the event configuration in the policy, the smart management server determines whether to trigger a policy to run. If the event triggering conditions are met, the smart management server runs the policy in the policy manager.

The policy in the policy manager runs preset actions in order based on user configuration.

1. Event Detectors Supported by SEM

SEM supports a variety of event detectors. These event detectors are embedded in different business. They detect the running business, and decide whether any event occurs. SEM supports the following detector types:

- Counting event detector

  The counting event detector detects the naming counter in SEM. When the naming counter exceeds the specified threshold, a counter event is triggered. After the counter event is triggered, the counting event detector stops working temporarily, and resumes until the counter reaches the threshold. The value of the naming counter is changed by the action of the running counter and can thus be accumulated by other policies. When the counter reaches a threshold, a counter event is triggered, which triggers the policy to run. During the running of this policy, the value of the counter is reset to realize circulation.

- Interface counting event detector

  The interface counting event detector detects interface statistics of a device. By periodic collection and statistics, the detector determines whether the statistics of an interface exceeds a threshold. If yes, an interface counting event is triggered. After the interface counting event is triggered, the interface counting event detector stops working temporarily and resumes until the interface counter reaches the recovery threshold or the suspension time exceeds the recovery cycle.

- Syslog event detector

  The syslog event detector detects log information of a device and uses regular expressions to match the log information. If the log information is matched using the regular expressions, a syslog event is triggered.

- Timer event detector

  The timer event detector detects time-related events. There are four types of timer events as follows:

  - Absolute time timer event: The timer time is set to some time point in the future. When this time point is up, the timer event is triggered.
  - Countdown timer event: The timer time is the number of seconds before which a policy takes effect. When the effective time reaches the number of such seconds, the timer event is triggered.
  - Watchdog timer event: The timer time is the number of seconds set before which a policy takes effect. When the effective time reaches the number of such seconds, the timer event is triggered.
  - Cron timer event: Cron (derived from Greek word chronos, meaning time) is used widely in a Unix-like operating system and used to set a periodically run instruction. SEM supports time detection in cron mode. When the time point described by the cron character string of the cron timer event is up, the timer event is triggered.

- **CLI event detector**

  The CLI event detector detects the CLI input. When the input command matches the detector configuration, the CLI event is triggered. Only the **trigger** command event in the privileged EXCE mode can be detected currently.

- Track event detector

  The track event detector detects tracks. Track refers to status change of a reliable network service (RNS). The track event detector detects change in the status of a tracked entity. When the status of a tracked entity changes, the track event is triggered.

- **Route event detector**

  The route event detector detects the route-unreachable events. When a route is detected unreachable, the route event is triggered.

2. Policy Actions Supported by SEM

SEM supports different actions. An action runs after a policy is triggered by an event. The actions include information collection and device/network troubleshooting. SEM supports the following actions:

- Run CLI commands: Run commands set by users.
- Send syslog: Send specified log messages.
- Operate naming counter: Operate the naming counter in SEM.
- Reset device: Reset devices.
- Wait during policy running: Wait for some time during policy running.
- Configure environmental variables: Configure local policy variables.

3. Environmental Variables Supported by SEM

SEM can use environmental variables in policies. SEM supports the following environmental variables:

- Global variable

Global variables can be used in all policies after they are defined by using the **smart manager env** command. The values of global variables can be read-only in a policy.

- Local variable

  Local variables generated during policy running are divided into local system variables and local user variables. The local system variables are created by detectors and used to describe events. Therefore, they are read-only. Local user variables are created by actions in policies, and can be modified during policy running.

  The priority of local variables in a policy are higher than that of global variables. Reading an inexistent local variable or global variable or modifying a read-only local variable may generate an error. Configuring an inexistent local variable will cause the local variable to automatically generate.

4. Management of the SEM Smart Management Server

The SEM smart management server provides management interfaces to allow users to view SEM running information and perform management. Users can view different types of SEM information, including:

- Supported detector types
- Versions of the smart management server and event detectors
- User configuration and submitted policies
- Policies being run
- Policies to be run
- Event history
- Currently defined counter
- Currently defined SEM global variables

During running of the SEM smart management server, users can manage the running policies and perform the following operations:

- Suspend and restore entire SEM policy scheduling.
- Pause and restore specific policies or specified classes of policies.
- Adjust priority of specified types of policies.
- Forcibly terminate specific policies, specified classes of policies, or all policies.

1.2 Configuration Task Summary

SEM configuration includes the following tasks:

(1) Configuring SEM Policies

(2) (Optional) Configuring Parameters of SEM Policies

1.3 Enabling the SEM Function

1.3.1 Overview

SEM is separately deployed in a device independent from external network management tools. SEM allows customers to customize different types of events and policies so that customers can freely obtain or monitor their desired event information and actions taken for the events.

1.3.2 Restrictions and Guidelines

- The syslog function must be enabled by using the **logging** command before syslog actions are configured.
- The device must be equipped with a normal standby engine before actions are switched to the standby engine.
- Run the **act reload** command with caution. It may cause repeated restart of the system or repeated active/standby switchover.

1.3.3 Configuring SEM Policies

1. Overview

By configuring SEM policies, users can monitor events based on actual needs.

2. Restrictions and Guidelines

- When multiple events are configured for a policy, the events are automatically arranged in the alphabetical order of tags. You are advised to use the naming method based on a sequencing rule, for example, 01_cli, 02_timer, and 03_counter.
- The relationship between events refers to the relationship of the current event with the combination of all other events. Only when the first event is triggered, SEM checks whether to trigger a policy. If users try to configure juxtaposition for other events except the first event, the default juxtaposition is an AND relation. In this case, the juxtaposition of the first event is ignored.
- In either of the following scenarios, the **rollback** command can be used to roll back the policy configuration.
  - A new configured policy has not been submitted.
  - A configured policy has been submitted and registered, but changes to the policy have not been submitted.
- If no action is configured for a submitted policy, the policy can be registered. However, no action is taken when the policy is triggered.
- Generally, multiple actions are configured for a policy. When the policy is triggered, the actions are run in the alphabetical order of the *label* parameter.
- To save the I/O of CLI commands, run the **policy-info record** command.
  The **smart manager policy-info record** command does not save the command I/O as well.
- If the policy is being edited but is submitted, run the **list-config** command to display the configuration not submitted in the currently edited policy. The **commit** command is not included in the displayed content. If the policy is submitted, the configuration of the submitted policy is displayed. The **commit** command is included in the displayed content.
- The submittable policies are divided into new policies and edited and registered policies. When a registered but unedited policy is not submitted, a notification will be displayed. If users want to quit the changes to the policy configuration before submitting the changes, run the **rollback** command to roll back the policy configuration.
- During submission, the validity of the policy configuration is checked. If the checking fails, the policy configuration fails to be submitted. In this case, the policy is not registered and remains in the editing status. For example, if no event is configured for the policy, the policy submission checking fails.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an SEM policy and enter the SEM configuration mode.

smart manager app *app-name* [**class** *class-options*]

No policy is configured by default.

(4) Configure events. Configure at least one of the following tasks.

- Configure a counter monitoring event.

  event tag *event-name* [**correlate** { **andnot** | **and** | **or** }] **counter name** *counter-name* **entry-operation** *operator* **entry-value** *entry-value* **exit-operation** *operator* **exit-value** *exit-value*

  No counter monitoring event is configured by default.

- Configure an interface monitoring event.

  event tag *event-name* [**correlate** { **andnot** | **and** | **or** }] **interface name** *interface-type interface-number* **parameter** { **link_up** | **link_down** }

  No interface monitoring event is configured by default.

- Configure a log monitoring event.

  event tag *event-name* [**correlate** { **andnot** | **and** | **or** }] **syslog pattern** *regular-expression* [**priority-level** *priority-level*] [**occurs** *num-occurrences*] [**period** *period-value*] [**skip** { **yes** | **unset** }]

  No log monitoring event is configured by default.

- Configure a timer monitoring event.

  event tag *event-name* [**correlate** { **andnot** | **and** | **or** }] **timer** { **absolute** { **unix** *time-value* | **date** date-value } | **countdown time** *countdown-timer* | **cron cron-entry** *cron-entry* | **watchdog time** *watchdog-timer* } [**name** *timer-name*]

  No timer monitoring event is configured by default.

- Configure a track monitoring event.

  event tag *event-name* [**correlate** { **andnot** | **and** | **or** }] **track** [**state** { **up** | **down** }] [*track-id*]

  No track monitoring event is configured by default.

- Configure a route monitoring event.

  event tag *event-name* [**correlate** { **andnot** | **and** | **or** }] **route** { **unreachable** | **reachable** } { **ipv4** *ipv4-address* | **ipv6** *ipv6-address* } [**vrf** *vrf-name*]

A complete policy is composed of events and actions. If no event is configured for the policy, an error occurs during policy submission, resulting in submission failure.

(5) Configure actions. Configure one of the following tasks.

- Run CLI commands of a device.

  act *action-label* **cli command** *cli-string* [**pattern** *pattern-string*]

- Operate SEM counters.

act *action-label* **counter name** *counter-name* **op** { **dec** | **inc** | **nop** | **set** } **value** *counter-value*

- Terminate a policy script and set the exiting status.

  act *action-label* **exit** [*result*]

- Restart the device.

  act *action-label* **reload**

- Set local variables.

  act *action- label* **set** *variable-name variable-value*

- Carry out logging.

  act *action-label* **syslog** [**priority-level** *priority-level*] **msg** *syslog-message* [**facility** *mnemonics*]

- Pause a policy script.

  act *action-label* **wait** *wait-time*

- Configure a CLI monitoring event.

  event tag *event-name* [**correlate** { **andnot** | **and** | **or** }] **cli pattern** *regular-expression* [**occurs** *number-occurrences*] [**period** *period-value*]

No action is configured by default.

(6) Enable the function of recording CLI action output.

policy-info record

The recording function is not enabled for CLI command action output by default.

(7) (Optional) Configure description.

description *string*

No description is configured for an SEM policy by default.

(8) (Optional) Display current policy configuration.

list-config

(9) (Optional) Roll back configuration.

rollback

(10) Submit configuration.

commit

1.3.4 Configuring Parameters of SEM Policies

1. Restrictions and Guidelines

- Modification to policy description takes effect immediately without submission.
- A CLI policy can be triggered only after the **trigger** command is configured and the CLI detection event is submitted.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Clear CLI records generated during SEM policy running.

smart manager policy record clean { **all** | **dir** *record-directory* | **no-registed** | **policy-info** *registed-policy-name* }

CLI records generated during SEM policy running are not cleared by default.

(3) Trigger a CLI detection event.

trigger *cmd*

(4) Enter the global configuration mode.

config-system terminal

(5) Configure a thread pool and thread pool size of an SEM policy class.

smart manager schdulr thread-pool class *class-options* **number** *thread-number*

The thread pool size of the default SEM policy is **32** by default, and no thread pool is specified for other classes of SEM policies.

(6) Configure upper limits of SEM parameters. Configure at least one of the following tasks.

- Configure the upper limits of SEM detector parameters.

  smart manager finder { **counter** | **interface** | **timer** } **event-number** *detector-number*

  By default, the maximum number of events for the counting detector, the maximum number of events for the interface detector, and the maximum number of events for the timer detector are **256**, respectively.

- Configure the maximum number of SEM global variables.

  smart manager global-variant number *global-variant-number*

  By default, the maximum number of global variables is **512**.

- Configure the upper limits of SEM policy parameters.

  smart manager policy-info { **act-number** *policy-number* | **config-number** *policy-number* | **event-number** *policy-number* | **register-number** *policy-number* | **trigger-delay-number** *policy-number* }

  By default, the maximum number of actions in a policy is **64**; the maximum numbers of policy detectors and registered policies are **128**, respectively; and the maximum numbers of configured policies and policy delayed triggers are **256**, respectively.

- Configure the upper limits of SEM configuration instance parameters.

  smart manager record { **size-of-instance** *record-number* | **size-of-policy** *record-number* }

  By default, the maximum number of policy instances is **50** and the maximum size of a policy file is **1024** KB.

- Configure the upper limits of SEM scheduler parameters.

  smart manager schdulr { **pending-number** *schdulr-number* | **running-number** *schdulr-number* }

  By default, the maximum number of wait policies of the scheduler and the maximum number of policies run by the scheduler are **128**, respectively.

(7) Configure the maximum number of saved SEM history messages.

smart manager hist-info size events *size*

By default, the maximum number of saved SEM history messages is **50**.

(8) Configure the application delay time of an SEM policy.

smart manager policy-info startup-delay *delay time*

The application delay time of an SEM policy is **60** seconds.

(9) Enter the SEM configuration mode.

smart manager app *app-name* [**class** *class-options*]

(10) Configure the trigger attributes of a policy.

trigger { **correlate-period** *correlate-period-value* | **correlate-start** *period-start-value* | **delay** *delay-value* | **maxrun** *maxruntime-number* | **occurs-period** *occurs-period-value* | **occurs-value** *occurs-value* }*

No trigger attribute is configured for a policy by default.

1.4 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Table 1-1 SEM Monitoring

Command	Purpose
display smart manager finder [**all** | *detector-name*] [**detailed** | **statistics**]	Displays SEM detector information.
display smart manager environment [**all** | *variable-name*]	Displays global variables.
display smart manager hist-info events	Displays SEM history information.
display smart manager policy-info all	Displays all policies and policy submission information.
display smart manager policy-info active [**class** *class-options*] [**detailed**]	Displays active policy instances.
display smart manager policy-info pending [**class** *class-options*] [**detailed**]	Displays policies to be run.
display smart manager policy-info registered [**policy-info** *policy-name*] [**incident-type** *event-name*] [**class** *class-options*] [**time-ordered** | **name-ordered**]	Displays information of registered policies.
display smart manager schdulr thread-pool [**detailed**]	Displays the running status of a SEM scheduler by thread pool.
display smart manager version	Display SEM versions.

1.5 Configuration Examples

1.5.1 Configuring an Interface Monitoring Event

1. Requirements

Device A is directly connected to Device B through GigabitEthernet 0/1. Due to the problem of the line or Device B, Device A often receives many consecutive error frames, which affects communication. After GigabitEthernet 0/1 of Device A is shut down and restarted, the problem is solved.

2. Topology

Figure 1-2 Configuring an Interface Monitoring Event

3. Notes

(1) Create a policy.

(2) Configure an interface monitoring event.

(3) Configure CLI command actions.

(4) Submit the policy configuration.

4. Procedure

(1) Create a policy with the name policy_interface on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA (cfg)# smart manager app policy_interface
```

(2) Configure an event with the name event_1 in the policy_interface policy and set the type to interface. The specific parameter configuration is as follows:

Configure the interface counting type as link_down and set the interface status to down.

Configure the interface name as GigabitEthernet 0/1 to specify the interface to be detected.

```
DeviceA (sem-app)# event tag event_1 interface name GigabitEthernet 0/1 parameter link_down
```

(3) Configure actions of the policy_interface policy.

Configure action_1 to run the **enable** command to enter the privileged EXEC mode.

```
DeviceA (sem-app)#act action_1 cli command “privilege”
```

Configure action_2 to run the **config-system terminal** command to enter the global configuration mode.

```
DeviceA (sem-app)#act action_2 cli command "config-system terminal"
```

Configure action_3 to run the **interface GigabitEthernet 0/1** command to enter the interface configuration mode.

```
DeviceA (sem-app)#act action_3 cli command "interface GigabitEthernet 0/1"
```

Configure action_4 to run the **unset shutdown** command to set the interface status to up.

```
DeviceA (sem-app)#act action_4 cli command "unset shutdown"
```

(4) Submit the policy.

```
DeviceA(sem-app)# commit
```

(5) Exit the policy editing status.

```
DeviceA(sem-app)# exit
```

5. Verification

Run the **display smart manager policy-info registered** command to display a registered SEM policy.

```
DeviceA# display smart manager policy-info registered
 No.   Name                                                    Type      Event Type
   1   policy_interface                                        app   interface
  event_1: interface: parameter link_down name GigabitEthernet 0/1
  act action_1 cli command “privilege”
  act action_2 cli command "config-system terminal"
  act action_3 cli command "interface GigabitEthernet 0/1"
  act action_4 cli command "unset shutdown"
```

Run the **display smart manager policy-info active** command to display an active policy.

```
DeviceA# display smart manager policy-info active
Key: P - Priority              :L - Low, H - High, N - Normal
       S - Scheduling node :A - Active, P - Pending

No.   Job id    P S Status       Time Of Event          Event Type      Policy Name
1     2          N A suspend     2021-03-19 18:05:59    interface       policy_interface
```

Set GigabitEthernet 0/1 to the down status to verify whether the policy takes effect.

```
DeviceA# config-system terminal
DeviceA (cfg)# interfce GigabitEthernet 0/1
DeviceA (cfg-if-GigabitEthernet 0/1)#shutdown
*Mar 19 18:06:19: %SEM-6-PLCY_TRG: Policy policy_1 id 2 is triggered by event 2, and the policy-info instance id is 1.
```

Run the **display smart manager hist-info events detailed** command to display SEM event history.

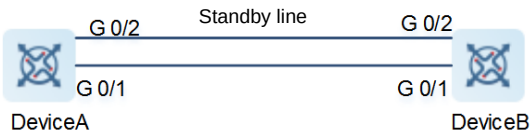
```
DeviceA# display smart manager hist-info events detailed
No.         Job id    Event Type          Time                        Policy name
1           2          interface          2021-03-22 17:19:38         policy_interface
            Class: default, Policy Type: app
```

6. Configuration Files

Device configuration file

```
hostname DeviceA
!
smart manager app policy_interface
 event tag event_1 interface name GigabitEthernet 0/1 parameter link_down
 act action_1 cli command “privilege”
```

```
 act action_2 cli command "config-system terminal"
 act action_3 cli command "interface GigabitEthernet 0/1"
 act action_4 cli command "unset shutdown"
!
end
```



1.5.2 Configuring a Counter Monitoring Event

1. Requirements

Device A is directly connected to Device B through GigabitEthernet 0/1. A low-bandwidth standby line is created between Device A and Device B through GigabitEthernet 0/2. Due to the problem of the line or Device B, Device A often receives many consecutive error frames on GigabitEthernet 0/1, which affects communication. After GigabitEthernet 0/1 of Device A is shut down and restarted, the problem is solved. If the counter monitoring event is triggered more than 50 times, GigabitEthernet 0/1 is shut down permanently and the standby line is used.

2. Topology

Figure 1-3 Configuring a Counter Monitoring Event

3. Notes

(1) Configure an interface monitoring event, including interface counting event, CLI actions, and counter actions.

(2) Configure a counter monitoring event for detecting interface monitoring events.

4. Procedure

(1) Create a policy with the name policy_interface on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# smart manager app policy_interface
```

(2) Configure an event with the name event_1 in the policy_interface policy and set the type to interface. The specific parameter configuration is as follows:

Configure the interface counting type as link_down and set the interface status to down.

Configure the interface name as GigabitEthernet 0/1 to specify the interface to be detected.

```
DeviceA (sem-app)# event tag event_1 interface name GigabitEthernet 0/1 parameter link_down
```

(3) Configure actions of the policy_interface policy.

Configure action_1 to run the **enable** command to enter the privileged EXEC mode.

```
DeviceA (sem-app)#act action_1 cli command “privilege”
```

Configure action_2 to run the **config-system terminal** command to enter the global configuration mode.

```
DeviceA (sem-app)#act action_2 cli command "config-system terminal"
```

Configure action_3 to run the **interface GigabitEthernet 0/1** command to enter the interface configuration mode.

```
DeviceA (sem-app)#act action_3 cli command "interface GigabitEthernet 0/1"
```

Configure action_4 to run the **unset shutdown** command to set the interface status to up.

```
DeviceA (sem-app)#act action_4 cli command "unset shutdown"
```

Configure action_5, and increase the value of the naming counter for the SEM policy name of policy_interface by 1.

```
DeviceA(sem-app)# act action_5 counter name policy_interface op inc value 1
```

(4) Submit the policy.

```
DeviceA(sem-app)# commit
```

(5) Exit the policy editing status.

```
DeviceA(sem-app)# exit
```

(6) Create a policy with the name policy_counter.

```
DeviceA(cfg)# smart manager app policy_counter
```

(7) Configure an event with the name event_counter in the policy_counter policy and set the event type to SEM counter. The specific parameter configuration is as follows:

Set the counter name to policy_interface, which is the policy name in step (1) .

Set the counter trigger parameter **entry-operation ge entry-value** to **6**, indicating that the event is triggered when the value of the SEM counter is equal to or greater than 6.

Set the counter restoration parameter **exit-operation gt exit-value** to **5**, indicating that event monitoring is restored immediately when the value of the SEM counter is greater than 5.

```
DeviceA(sem-app)# event tag event_counter counter name policy_interface entry-operation ge entry-value 6 exit-operation gt exit-value 5
```

(8) Configure actions of the policy_counter policy.

Configure action_counter_1 to set the value of the counter policy_interface to 0.

```
DeviceA(sem-app)# act action_counter_1 counter name policy_interface op set value 0
```

Configure action_counter_2 to run the **enable** command to enter the privileged EXEC mode.

```
DeviceA(sem-app)# act action_counter_2 cli command “privilege”
```

Configure action_counter_3 to run the **config-system terminal** command to enter the global configuration mode.

```
DeviceA(sem-app)# act action_counter_3 cli command "config-system terminal"
```

Configure action_counter_4 to run the **interface GigabitEthernet 0/1** command to enter the interface configuration mode.

```
DeviceA(sem-app)# act action_counter_4 cli command "interface GigabitEthernet 0/1"
```

Configure action_counter_5 to run the **shutdown** command to set the interface status to down permanently.

```
DeviceA(sem-app)# act action_counter_5 cli command "shutdown"
```

(9) Submit the policy.

```
DeviceA(sem-app)# commit
```

(10) Exit the policy editing status.

```
DeviceA(sem-app)# exit
```

5. Verification

Run the **display smart manager policy-info registered** command to display a registered SEM policy.

```
DeviceA# display smart manager policy-info registered
No.    Name                                                                    Type       Event Type
  1    policy_interface                                                        app    interface
 event_1: interface: parameter link_down name GigabitEthernet 0/1
 act action_1 cli command “privilege”
 act action_2 cli command "config-system terminal"
 act action_3 cli command "interface GigabitEthernet 0/1"
 act action_4 cli command "unset shutdown"
   policy-info record per-instance 50 per-policy 1000

  2    policy_counter                                                          app    counter
 event_counter: counter: name policy_interface entry-operation ge entry-value 6 exit-operation gt exit-value 5
 act 1 counter name policy_interface op set value 0
 act action_counter_1 cli command “privilege”
 act action_counter_2 cli command "config-system terminal"
 act action_counter_3 cli command "interface GigabitEthernet 0/1"
 act action_counter_4 cli command "shutdown"
 act action_counter_5 cli command "end"
```

Set GigabitEthernet 0/1 to the down status five times. Run the **display smart manager finder** command to display the monitoring event information.

```
DeviceA# display smart manager finder counter statistics
finder counter events number: 1
    event id: 3, event name: event_counter
      counter name: policy_interface
      counter value: 5
      status: enable
      trigger times: 0
      trigger policy-info times: 0
```

Set GigabitEthernet 0/1 to down status again to trigger the policy_counter policy, and run the **display smart manager finder** command to display the monitoring event information.

```
DeviceA# display smart manager finder counter statistics
finder counter events number: 1
    event id: 3, event name: event_counter
      counter name: policy_interface
      counter value: 1
      status: enable
      trigger times: 1
      trigger policy-info times: 1
```

Run the **display smart manager hist-info events detailed** command to display SEM event history.

```
DeviceA# display smart manager hist-info events detailed
No.       Job id    Event Type        Time                        Policy name
1         65        interface         2021-03-24 11:27:30         policy_interface
          Class: reset, Policy Type: app
2         54        counter           2021-03-24 11:27:29         policy_counter
          Class: reset, Policy Type: app

          Class: reset, Policy Type: app
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
smart manager app policy_interface
 event tag event_1 interface name GigabitEthernet 0/1 parameter link_down
 act action_1 cli command “privilege”
 act action_2 cli command "config-system terminal"
 act action_3 cli command "interface GigabitEthernet 0/1"
 act action_4 cli command "unset shutdown"
 act action_5 counter name policy_interface op inc value 1
!
smart manager app policy_counter
 event tag event_counter counter name policy_interface entry-operation ge entry-value 6 exit-operation gt
exit-value 5
 act 1 counter name policy_interface op set value 0
 act action_counter_1 cli command “privilege”
 act action_counter_2 cli command "config-system terminal"
 act action_counter_3 cli command "interface GigabitEthernet 0/1"
 act action_counter_4 cli command "shutdown"
 act action_counter_5 cli command "end"
 commit
!
end
```

1.5.3 Configuring a Timer Monitoring Event

1. Requirements

Device A is connected to a Trivial File Transfer Protocol (TFTP) server, and Device A archives log files to the TFTP server at 00:00:00 each day and deletes the original log files.

2. Topology

Figure 1-4 Configuring a Timer Monitoring Event

3. Notes

(1) Configure that Device A and the TFTP server are mutually reachable via routes.

(2) Create a policy.

(3) Configure a timer monitoring event.

(4) Configure actions.

(5) Submit the policy configuration.

4. Procedure

(1) Configure that Device A and the TFTP server are mutually reachable via routes.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitEthernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1) ip address 172.16.0.1 255.255.255.0
DeviceA(cfg-if-GigabitEthernet 0/1) exit
```

(2) Create a policy with the name policy_timer on Device A.

```
DeviceA# config-system terminal
DeviceA(cfg)# smart manager app policy_timer
```

(3) Configure an event with the name event_timer in the policy_timer policy, set the type to cron timer, and specify the logging time to 00:00:00 each day.

```
DeviceA(sem-app)# event tag event_timer timer cron cron-entry "0 0 * * *"
```

(4) Configure actions of the policy_timer policy.

Configure action_timer1 to run the **enable** command to enter the privileged EXEC mode.

```
DeviceA(sem-app)# act action_timer1 cli command “privilege”
```

Configure action_timer2 to run the **copy** command to archive the log file named syslog_rfc5424_flag.txt to the server with the IP address 172.16.0.2 through TFTP.

```
DeviceA(sem-app)# act action_timer2 cli command "copy flash:syslog_rfc5424_flag.txt
tftp://172.16.0.2/syslog_rfc5424_flag.txt"
```

(5) Submit the policy.

```
DeviceA(sem-app)# commit
```

(6) Exit the policy editing status.

```
DeviceA(sem-app)# exit
```

5. Verification

Run the **ping** command to verify that Device A and the TFTP server are mutually reachable via routes.

```
DeviceA# ping 172.16.0.2
Sending 5, 100-byte ICMP Echoes to 172.16.0.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/3 ms.
```

Run the **display smart manager policy-info registered** command to display a registered SEM policy.

```
DeviceA# display smart manager policy-info registered
 No.   Name                                                    Type      Event Type
   2   policy_timer                                          app   timer
  event_timer: timer: cron cron-entry 0 0 * * *
  act aciton_timer1 cli command "enble"
  act action_timer2 cli command "copy flash:syslog_rfc5424_flag.txt tftp://172.26.1.33/syslog_rfc5424_flag.txt"
```

Run the **display smart manager policy-info active** command to display an active policy.

```
DeviceA# display smart manager policy-info active
Key: P - Priority              :L - Low, H - High, N - Normal
       S - Scheduling node :A - Active, P - Pending

No.   Job id    P S Status       Time Of Event          Event Type      Policy Name
1     1          N A suspend     2021-03-19 18:05:59   timer           policy_timer
```

Run the **display smart manager hist-info events detailed** command to display SEM event history.

```
DeviceA# display smart manager hist-info events detailed
No.         Job id    Event Type          Time                          Policy name
1           1          timer              2021-03-22 0:0:10          policy_timer
            Class: reset, Policy Type: app
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
smart manager app policy_2
!
smart manager app policy_timer
 event tag event_timer timer cron cron-entry "0 0 * * *"
 act aciton_timer1 cli command "enble"
 act action_timer2 cli command "copy flash:syslog_rfc5424_flag.txt tftp://172.26.1.33/syslog_rfc5424_flag.txt"
 commit
```

```
!
end
```

1.5.4 Configuring a Syslog Monitoring Event

1. Requirements

Though the interface status is down, Device A sends logs. When the logs are detected, the interface status must be restored to up.

2. Topology

Figure 1-5 Configuring a Syslog Monitoring Event

3. Notes

(1) Create a policy.

(2) Configure a syslog monitoring event.

(3) Configure actions.

(4) Configure policy trigger parameters.

(5) Submit the policy configuration.

4. Procedure

(1) Create a policy with the name policy_syslog on Device A.

```
Device> privilege
DeviceA# config-system terminal
DeviceA(cfg)# smart manager app policy_syslog
```

(2) Configure an event with the name event_syslog1 in the policy_syslog policy, set the type to syslog, and put logs with the content "LINEPROTO-5-UPDOWN" within the detection scope.

```
DeviceA(sem-app)# event tag event_1 syslog pattern "LINEPROTO-5-UPDOWN" priority-level critical
```

(3) Configure an event with the name event_syslog2 in the policy_syslog policy, set the type to syslog, and put logs with the content "GigabitEthernet 0/1" within the detection scope.

```
DeviceA(sem-app)# event tag event_syslog2 syslog pattern "GigabitEthernet 0/1"
```

(4) Configure an event with the name event_syslog3 in the policy_syslog policy, set the type to syslog, and put logs with the content "changed state to down" within the detection scope. The conditional relationship between event_syslog3 and event_syslog1/event_syslog2 is an AND relation.

```
DeviceA(sem-app)# event correlate and tag event_syslog3 syslog pattern "changed state to down"
```

(5) Configure actions of the policy_syslog policy.

Configure action_syslog_1 to run the **enable** command to enter the privileged EXEC mode.

```
DeviceA(sem-app)# act action_syslog_1 cli command “privilege”
```

Configure action_syslog_2 to run the **config-system terminal** command to enter the global configuration mode.

```
DeviceA(sem-app)# act action_syslog_2 cli command "config-system terminal"
```

Configure action_syslog_3 to run the **interface GigabitEthernet 0/1** command to enter the interface configuration mode.

```
DeviceA(sem-app)# act action_syslog_3 cli command "interface GigabitEthernet 0/1"
```

Configure action_syslog_4 to wait for five seconds.

```
DeviceA(sem-app)# act action_syslog_4 wait 5
```

Configure action_syslog_5 to run the **unset shutdown** command to set the interface status to up.

```
DeviceA(sem-app)# act action_syslog_5 cli command "unset shutdown"
```

Configure action_syslog_6 to run the **end** command to exit the privileged EXEC mode.

```
DeviceA(sem-app)# act action_syslog_6 cli command "end"
```

Configure action_syslog_7 to run the **display interfaces status | include UP** command to display the interface status.

```
DeviceA(sem-app)# act action_syslog_7 cli command "display interfaces status | include UP"
```

(6) Submit the policy.

```
DeviceA(sem-app)# commit
```

(7) Exit the policy editing status.

```
DeviceA(sem-app)# exit
```

5. Verification

Run the **display smart manager policy-info registered** command to display a registered SEM policy.

```
DeviceA# display smart manager policy-info registered
 No.   Name                                                    Type      Event Type
   1   policy_syslog                                           app   syslog
  event_syslog1: syslog: pattern "LINEPROTO-5-UPDOWN"
  event_syslog2: syslog: pattern "GigabitEthernet 0/1"
  event_syslog3: syslog: pattern "changed state to down"
  act action_syslog_1 cli command “privilege”
  act action_syslog_2 cli command "config-system terminal"
  act action_syslog_3 cli command "interface GigabitEthernet 0/1"
  act action_syslog_4 wait 5
  act action_syslog_5 cli command "unset shutdown"
  act action_syslog_6 cli command "end"
  act action_syslog_7 cli command "display interfaces status | include UP"
```

Run the **display smart manager policy-info active** command to display an active policy.

```
DeviceA# display smart manager policy-info active
Key: P - Priority             :L - Low, H - High, N - Normal
       S - Scheduling node :A - Active, P - Pending

No.   Job id     P S Status       Time Of Event          Event Type      Policy Name
```

```

1.5.5 Configuring a Track Monitoring Event

1. Requirements

To facilitate management, a log is printed when the status of a specified or random tracked entity of Device A changes.

2. Topology

Figure 1-6 Topology of a Track Monitoring Event

3. Notes

(1) Create a policy.

(2) Configure a track monitoring event.

(3) Configure actions.

(4) Submit the policy configuration.

4. Procedure

(1) Create a policy with the name policy_track on Device A.

```
DeviceA> privilege
DeviceA# config-system terminal
DeviceA(cfg)# smart manager app policy_track
```

(2) Configure an event with the name event_track in the policy_track policy, set the type to track, and detect all tracked objects in the down status.

```
DeviceA(sem-app)# event tag event_track track state down
```

(3) Configure actions of the policy_track policy.

Configure action_track1 to print "track obj down".

```
DeviceA(sem-app)# act action_tarck1 syslog msg “track obj down.”
```

Configure action_track2 to run the **enable** command to enter the privileged EXEC mode.

```
DeviceA(sem-app)# act action_track2 cli command “privilege”
```

Configure action_track3 to run the **config-system terminal** command to enter the global configuration mode.

```
DeviceA(sem-app)# act action_track3 cli command "config-system terminal"
```

Configure action_track4 to run the **interface GigabitEthernet 0/1** command to enter the interface configuration mode.

```
DeviceA(sem-app)# act action_track4 cli command "interface GigabitEthernet 0/1"
```

Configure action_track5 to run the **unset shutdown** command to set the interface status to up.

```
DeviceA(sem-app)# act action_track5 cli command "unset shutdown"
```

(4) Submit the policy.

```
DeviceA(sem-app)# commit
```

(5) Exit the policy editing status.

```
DeviceA(sem-app)# exit
```

(6) Configure a track monitoring event.

```
DeviceA(cfg)# track 1 Interface GigabitEthernet 0/1 line-protocol
DeviceA(cfg-track)# delay down 10
```

5. Verification

Run the **display smart manager policy-info registered** command to display a registered SEM policy.

```
DeviceA# display smart manager policy-info registered
No.   Name                                                    Type      Event Type
  1   policy_track                                            app   track
  event_track: track: all state down
  act action_track1 syslog msg "track obj down"
  act action_track2 cli command “privilege”
  act action_track3 cli command "config-system terminal"
  act action_track4 cli command "interface GigabitEthernet 0/1"
  act action_track5 cli command "unset shutdown"
```

Run the **display smart manager policy-info active** command to display an active policy.

```
DeviceA# display smart manager policy-info active
Key: P - Priority          :L - Low, H - High, N - Normal
     S - Scheduling node :A - Active, P - Pending

No.   Job id    P S Status      Time Of Event          Event Type     Policy Name
1     4          N A suspend    2021-03-22 17:21:49   track          policy_track
```

Set GigabitEthernet 0/1 to the down status to verify whether the policy takes effect.

```
DeviceA# config-system terminal
DeviceA(cfg)# interface gigabitEthernet 0/1
DeviceA(cfg-if-GigabitEthernet 0/1)# shutdown
DeviceA(cfg-if-GigabitEthernet 0/1)# end
*Mar 22 17:21:59: %SEM-6-PLCY_TRG: Policy track id 4 is triggered by event 4, and the policy-info instance id is 8.
*Mar 22 17:21:59: %SEM-6-COMM: track: track obj down
*Mar 22 17:22:01: %LINK-3-UPDOWN: Interface GigabitEthernet 0/1, changed state to up.
*Mar 22 17:22:01: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet 0/1, changed state to up.
```

Run the **display smart manager hist-info events detailed** command to display SEM event history.

```
DeviceA# display smart manager hist-info events detailed
No.         Job id    Event Type        Time                      Policy name
1           4          track            2021-03-22 17:21:59       track
            Class: reset, Policy Type: app
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
smart manager app policy_track
```

```
 event tag event_track track state down
act action_track1 syslog msg "track obj down"
 act action_track2 cli command “privilege”
 act action_track3 cli command "config-system terminal"
 act action_track4 cli command "interface GigabitEthernet 0/1"
 act action_track5 cli command "unset shutdown"
commit
!
track 1 Interface GigabitEthernet 0/1 line-protocol
 delay down 10
!
end
```

1.5.6 Configuring a Route Monitoring Event

1. Requirements

A log is printed when a specified route of device A is unreachable.

2. Topology

Figure 1-7 Configuring a Route Monitoring Event

3. Notes

(1) Create a policy.

(2) Configure a route event.

(3) Configure actions.

(4) Configure policy trigger parameters.

(5) Submit the policy configuration.

4. Procedure

(1) Create a policy with the name policy_a on Device A.

(2) Configure an event with the name event_1 for the policy_a policy, set the type to route, and detect the unreachable route destined for 192.168.1.5/32.

(3) Configure log “route 192.168.1.5/32 unreachable.” for policy_a.

(4) Submit the policy.

(5) Exit the policy configuration.

```
Device# config-system terminal
Device(cfg)# smart manager applet policy_a
Device(sem-app)# event tag event_1 route unreachable ipv4 192.168.1.5/32
Device(sem-app)# action action_1 syslog msg “route 192.168.1.5/32 unreachable.”
Device(sem-app)# commit
```

```
Device(sem-app)# exit
Device(cfg)#
```

5. Verification

```
Device# display smart manager policy registered
No.    Name                Type       Event Type
    1    policy_a          applet    route
   event_1: route: unreachable ipv4 192.168.1.5/32
   action action_1 syslog msg "route 192.168.1.5/32 unreachable"
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
smart manager applet policy_a
 event tag event_1 route unreachable ipv4 192.168.1.5/32
 action action_1 syslog msg "route 192.168.1.5/32 unreachable."
 Commit
!
End
```

1.5.7 Configuring a CLI Monitoring Event

1. Requirements

A log is printed when the **trigger test** command is input in the privileged EXEC mode on device A.

2. Topology

Figure 1-8 Configuring a CLI Monitoring Event

3. Notes

(1) Create a policy.

(2) Configure a CLI event.

(3) Configure actions.

(4) Commit the policy configuration.

4. Procedure

(1) Create a policy with the name policy_a on Device A.

(2) Configure an event with the name event_1 for the policy_a policy, set the type to CLI, and detect command **trigger test**.

(3) Configure log “trigger test is running.” for policy_a.

(4) Commit the policy.

(5) Exit the policy configuration.

```
Device# config-system terminal
Device(cfg)# smart manager applet policy_a
Device(sem-app)# event tag event_1 cli pattern "trigger test"
Device(sem-app)# action action_1 syslog msg “trigger test is running.”
Device(sem-app)# commit
Device(sem-app)# exit
Device(cfg)#
```

5. Verification

```
Device# display smart manager policy registered
No.   Name        type      Event Type
1      policy_a applet    cli
  event_1: cli: pattern “trigger test”
  action action_1 syslog msg "track obj down."
```

6. Configuration Files

Device A configuration file

```
hostname Device A
!
smart manager applet policy_a
  event tag event_1 cli pattern "trigger test"
  action action_1 syslog msg “trigger test is running.”
  commit
!
End
```

1 Configuring IDS 1

1.1 Introduction 1

1.1.1 Overview 1

1.1.2 Principles 1

1.2 Configuring IDS 1

1.2.1 Overview 1

1.2.2 Restrictions and Guidelines 1

1.2.3 Procedure 1

1.3 Monitoring 2

1 Configuring IDS

1.1 Introduction

1.1.1 Overview

Intelligent Diagnosis System (IDS) is used for device diagnosis in fault scenarios.

A device may fail to work for various internal and external reasons. When a failure occurs, the O&M personnel needs to identify the fault by collecting related information and generate a rectification plan immediately. To reduce the time for identifying a fault and minimize the impact of faults on services, you can use IDS as the assistant for fault identification.

1.1.2 Principles

IDS extracts typical fault scenarios for diagnosis based on software and hardware issues. The running of IDS includes the following phases:

(1) Failure occurrence: If a fault is detected by a software component associated with a specific fault scenario, the fault is reported to IDS.

(2) Troubleshooting: IDS receives the fault report and asks the software component associated with the fault scenario to start diagnosis.

(3) Information collection: IDS receives a message when the software component finishes diagnosis. If all software components associated with the fault scenario finish diagnosis, the log framework is instructed to collect and package the relevant operational and diagnostic logs. The O&M personnel can locate the fault based on the packaged logs.

1.2 Configuring IDS

1.2.1 Overview

You can specify a specific fault scenario or all fault scenarios that can trigger the IDS function.

1.2.2 Restrictions and Guidelines

- **all**: specifies all fault scenarios. *scenario-name*: specifies a specific fault scenario.
- **enable**: enables the IDS function. **disable**: disables the IDS function.
- Run the **no** { *scenario-name* | **all** } command to restore the default configuration.

1.2.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the IDS configuration mode.

ids

(4) Configure the IDS function.

{ *scenario-name* | **all** } { **enable** | **disable** }

The IDS function is enabled by default.

1.3 Monitoring

Run the **display** command to display the configurations.

Run the **debugging** command to output debugging information.

Caution

The output debugging information of the **debugging** command occupies system resources. Therefore, disable debugging immediately after use.

Table 1-1 Monitoring

Command	Purpose
display ids scenario { *scenario-name* | **all** }	Displays the state of the IDS function.
display base-on-scene debugging { *scenario-name* | **all** }	Displays the state of the IDS debugging function.

1 Configuring Intelligent Monitoring

1.1 Introduction

1.1.1 Overview

Intelligent monitoring is an intelligent hardware management function of devices, including intelligent power management, intelligent fan speed adjustment, and intelligent temperature monitoring. The intelligent monitoring function monitors the power supply of the chassis, processes card power-on/off and monitors its power, automatically adjusts fan speed based on the change of the ambient temperature, and monitors temperature change of the cards in real time in order to give notifications to users. When the card temperature exceeds the maximum temperature of the device, the intelligent monitoring function automatically powers off the cards to protect the device.

By default, the intelligent monitoring function is enabled after the device is powered on. Users can use this function without need of any configuration. Apart from the default configuration, the system provides a variety of configuration methods so that you can change the default configuration of the system as necessary.

1.1.2 Principles

1. Basic Concepts

- Operating mode of power supply

  The power supply can operate in one of the following two modes: non-redundancy mode and N+M redundancy mode.

  - Non-redundancy mode: It is also called the superposition mode. The power supply operates in non-redundancy mode by default. In this mode, the total power of the system is the sum of power of all power modules.
  - N+M redundancy mode: The system has N+M power modules in total, where M indicates the number of configured redundant power modules and N indicates the number of available power modules of the system. The total power of the system is the sum of output power of the N power modules.

- Power supply priority

  The power supply priorities of cards refer to the power-on/off priorities of the cards. A card with a higher power supply priority is powered on earlier, and powered off later. When the system power is insufficient and thus some line cards need to be powered off, a line card with the lowest priority is powered off first. The default power supply priorities of the cards are as follows: supervisor module > FE card > VSL card > line card. If the cards are of the same type, a card with a smaller slot ID has a higher priority. You can change the power supply priorities of the line cards only. The power supply priority of a line card ranges from 1 to 16, where 1 indicates the lowest priority and 16 the highest priority.

Note

When the system power is insufficient and thus some cards need to be automatically powered off, only the line cards will be powered off but the supervisor modules and FE cards will not be automatically powered off.

- Operating modes of fans

  A fan tray on a chassis device normally operates in one of the following three modes:

  - Normal mode: It is the default operating mode. The fans initially run at intermediate speed. As the ambient temperature changes, the rotating speed of the fans automatically decreases or increases to achieve the best heat dissipation effect.
  - Quiet mode: The fans initially run at relatively low speed. As the ambient temperature changes, the rotating speed of the fans automatically decreases or increases. In this mode, the rotating speed of the fans is lower than that of a fan in normal mode. Therefore, in quiet mode, fans' noise is further reduced.
  - User-defined mode: In this mode, users define the rotating speed of the fans and the rotating speed of all the fan trays is the same (user-defined value). The rotating speed of the fans can be set to seven levels.

Note

In Virtual Switching Unit (VSU) mode, the fans in two chassis operate in the same working mode.

- Temperature threshold

  During temperature monitoring, if the temperature reaches a certain threshold, the system takes a corresponding action. For example, if the temperature reaches an alarm threshold, the system generates a Syslog alarm. If the temperature reaches a hazard threshold, the corresponding card is powered off.

2. Power Monitoring

A device supports multiple power modules. However, different types of power modules cannot be mixed. When a power supply is inserted, the system identifies this power supply and checks whether it conflicts with the original power supply type. If yes, a power supply with a lower power is selected. The alarm indicator turns yellow and a log alarm is generated. After the power supply is removed, the abnormality is cleared and the system restores to normal.

3. Configuration of Power Input Mode

A device supports DC or AC power supplies. The two types of power supplies have different input voltage calculation methods. Therefore, the power input mode of the device must be configured manually based on the DC/AC mode of the power supply to ensure that the input voltage value displayed by the **display power** command is correct.

4. Power Redundancy

You can implement redundancy of power supplies in the chassis by configuring power redundancy. As the standby power supply, the redundant power supplies are not involved in system power allocation to avoid in-service power supply failures. When setting the power supply to the redundancy mode, you need to specify the number of redundant power supplies.

After the N+M redundancy mode is configured, the system automatically monitors the redundant power supplies. As the system continuously operates or a card or power supply is removed or inserted, the remaining system power changes. The redundancy mode configured by you may fail to meet the normal power supply needs of the system. In redundancy mode, when the remaining system power is insufficient, the system alarm indicator turns yellow. In this case, you need to modify power redundancy configuration. If you have configured the function of powering off some cards in the case of insufficient power, the specified line cards will be powered off to meet system power allocation needs.

Caution

- When the power modules are mixed, they cannot work in redundancy mode.
- When the specified number of redundant power modules is equal to or greater than the number of available power modules, the redundancy configuration fails.
- The maximum number of redundant power modules is the remaining system power divided by the power of a single power supply. If the system determines that redundancy will result in insufficient remaining system power (exceeding the maximum allowed value), the redundancy configuration fails.

5. Automatic Power-off of Line Cards

After this function is enabled, some line cards are powered off automatically based on the current power supply priorities to meet system power allocation needs in the case of power deficiency.

Meanwhile, the hardware FPGA automatically notifies the CPU of the power deficiency, enabling the software to further process this problem.

The automatic power-off of line cards is disabled by default and can be enabled by running the **power priority card auto-down** command. After this function is enabled, the system automatically monitors the system power and inspects power allocation status of the current system every two minutes. If power deficiency is detected, the system automatically selects a line card with the lowest priority from the line cards in power-on status and powers off this line card.

If this function is not enabled, the active supervisor module prints a Syslog alarm when receiving the power deficiency notification of the field programmable gate array (FPGA) and the alarm indicator turns red.

The power supply priority of a line card can be modified by running the **power priority** command.

6. Manual Power-on/off of Cards

You can manually power off/on a specified card by running a power command.

- When a card is in power-on status, you can run the **power off** command to power off the card.
- When a card is in power-off status, you can run the **power on** command to power on the card.

Caution

- The device hardware boasts the power-on protection function. When the temperature of a card exceeds 50°C, the card cannot be powered on and a notification indicates card power-on failure.
- The active supervisor module of the chassis cannot be manually powered off. If you attempt to specify a card as the active supervisor module of the chassis, a notification is displayed. In VSU mode, the local active supervisor modules in two chassis cannot be manually powered off.
- When the supervisor module of a chassis is reset, the cards that are powered off by running the **power off** command can be powered on again.

7. Intelligent Speed Adjustment of Fans

When the fans work in normal, quiet or energy-saving mode, the rotating speed is automatically adjusted as the temperature changes.

The system automatically specifies a default start rotating speed for the fans based on the current operating mode of the fans. As the ambient temperature rises or drops, the fans automatically raise or reduce their rotating speed to dissipate heat and ensure that the noise is low.

The system provides a user-defined mode to ensure that all the fans operate at a user-specified rotating speed. In user-defined mode, the rotating speed of fans is fixed and not adjusted as the ambient temperature changes. Therefore, the normal mode or quiet mode is recommended so that the rotating speed of fans will automatically change as the temperature changes to best protect the device from a fault due to over-temperature.

8. Intelligent Temperature Monitoring

The active supervisor module monitors the temperature of all cards and notifies users of temperature change when the CA system runs normally.

The system defines three types of temperature, including supervisor module temperature, CPU temperature and media access controller (MAC) temperature, and two temperature thresholds, namely, alarm threshold and hazard threshold. Only hazard thresholds are defined for the CPU temperature and MAC temperature. In intelligent monitoring mode, the system monitors the temperature of all cards every two minutes. When the system discovers that the temperature of a card reaches or exceeds the alarm threshold, the active supervisor module generates a Syslog message and the alarm indicator on the panel turns yellow. If the temperature of a card reaches or exceeds the hazard threshold, the active supervisor module powers off the card and generates a Syslog message. The alarm indicator on the panel turns red.

Warning

The active supervisor module of the chassis or the global active supervisor module in VSU mode generates a Syslog message when discovering that its temperature exceeds the hazard threshold. At the same time, the alarm indicator on the panel turns red. However, the active supervisor module or global active supervisor module will not be automatically powered off. In this case, you need to take effective actions to cool the active supervisor module or manually remove it for cooling.

1.2 Configuration Task Summary

The intelligent monitoring configuration includes the following tasks: All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Energy-saving Mode of Fans
- Configuring Temperature Thresholds

1.3 Notes

This section describes notes for configuring intelligent monitoring functions.

Table 1-1 describes intelligent monitoring functions supported by different products.

Table 1-1 Intelligent Monitoring Functions Supported by Different Products

Function	Product Supporting the Function
Configuring the Energy-saving Mode of Fans	S6980-64QC
Configuring Temperature Thresholds	S6980-64QC, S6580-48CQ8QC, S6580-24DC8QC

1.4 Configuring the Energy-saving Mode of Fans

Note

Only S6980-64QC supports configuration of the energy-saving mode of fans.

1.4.1 Overview

This function can be used to enable or disable the energy-saving mode of fans based on needs.

1.4.2 Restrictions and Guidelines

When a 400G ZR module is inserted into the device, the system automatically disables the energy-saving mode of fans to facilitate heat dissipation of the device.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the operating mode of fans.

fan energy-saving enable

The energy-saving mode of fans is disabled by default.

1.5 Configuring Temperature Thresholds

Note

Only S6980-64QC, S6580-48CQ8QC, and S6580-24DC8QC support configuration of temperature thresholds.

1.5.1 Overview

This function can be used to modify the default alarm thresholds and hazard thresholds of temperature.

1.5.2 Restrictions and Guidelines

- Temperature thresholds are set based on chassis configuration. All line cards of a chassis share the same set of thresholds.
- When the set temperature thresholds exceed the allowed values, the threshold settings are invalid.
- When the set alarm thresholds are excessively low, the system frequently generates alarm logs.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure temperature thresholds of cards.

threshold set temperature [**switch** *device-id*] { **board** *temperature* | **board shutdown** *temperature* } | **cpu shutdown** *temperature* | **mac shutdown** *temperature* }

By default, the alarm threshold of the supervisor module is 56°C and the hazard threshold is 80°C. No alarm thresholds are defined for the CPU and MAC, but the hazard thresholds are 100°C.

1.6 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Figure 1-1 Monitoring

Command	Purpose
display fan [[[*device-id*] *fan-id*] **detail** | **version | speed**]	Displays fan information.
display temperature	Displays line card information such as current temperature and temperature thresholds.
display power [**priority** | **version**]	Displays power information about line cards and respective power supply priorities.

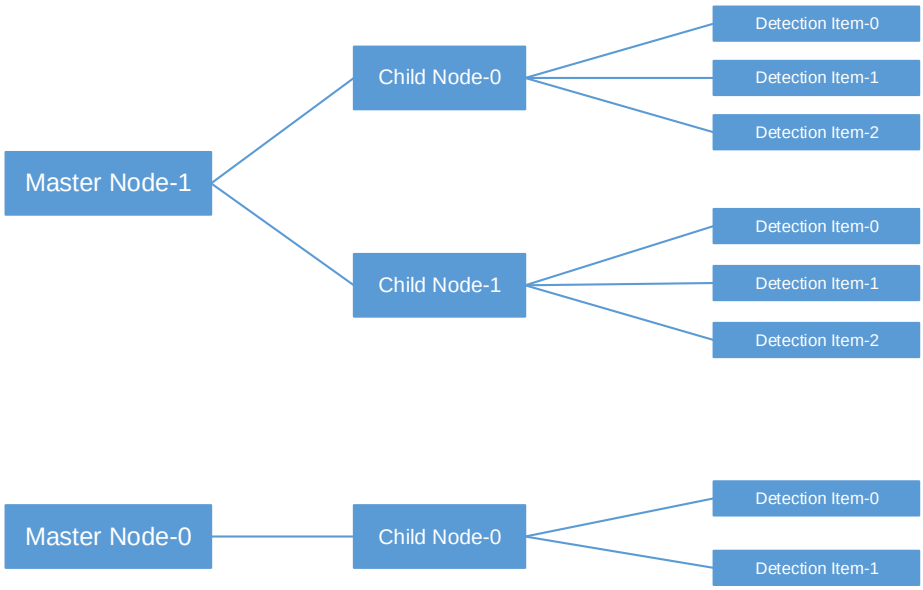
1 Configuring HDF

1.1 Introduction

1.1.1 Overview

Network devices are made up of various semiconductor chips and components. After the devices run for a long period, components may experience functional failures due to factors such as the environment, external forces, and aging, which affects normal services. You can configure Hardware Diagnostics Function (HDF), which allows you to query the status of hardware components on the device in real time and automatically reports faults by using alarm notifications, Trap messages, and Syslog records.

1.1.2 Principles



Based on the idea of logical detection nodes, HDF adopts unified logical detection nodes for anomaly detection on hardware components, implementing various functions such as node management, detection mechanism, diagnostic analysis, self-healing actions, and log alarms.

The master nodes classified based on hardware component types include the CPU, storage, electromechanical module, logic module, Double Data Rate (DDR) Synchronous Dynamic Random Access Memory (SDRAM), interface optical module, and MAC switching chip. As shown in Figure 1-1, HDF supports splitting detection items by using child nodes and provides management capabilities for detection objects in three levels.

HDF manages hardware device detection and shows the status of hardware components of the device. The supported functions are as follows:

- Enabling detection/configuring the detection period
- Displaying the status of detection objects
- Single execution of all detection nodes and items

Figure 1-1 HDF Node Management

1.2 Restrictions and Guidelines

- The running environment of HDF includes a management engine board, a line card, and a switch fabric module. When you configure HDF, ensure that the related components run properly.
- A detection node dynamically registers for a board in the system. In this case, the information of some detection nodes may fail to be queried instantly.

1.3 Configuration Task Summary

HDF configuration includes the following tasks:

(1) Configuring Basic Features

(2) Configuring Single-time Real-time Detection for a Board

(3) (Optional) Configuring Alerting for HDF Detection Items

(4) (Optional) Configuring Alerting for HDF Detection Items

1.4 Configuring Basic Features

1.4.1 Overview

You can manage logical detection nodes using HDF by configuring the detection function on logical detection nodes.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the HDF detection function. All the configuration steps below are optional. Perform the configuration steps as needed.

hdf enable { **all** | **slot** *slot-id* [**main-node** *name* [**child-node** *name* [**item** *item-id*]]] }

The detection function is enabled for a board by default.

1.5 Configuring Single-time Real-time Detection for a Board

1.5.1 Overview

The detection periods of different components of a board vary. In most cases, a round-robin HDF detection is performed for each item periodically. You can configure single-time real-time detection for a board in particular scenarios. For example, you require that the status of a device and all detection items are checked in real-time for troubleshooting the device during initial setup.

1.5.2 Restrictions and Guidelines

After you configure the single-time real-time detection function, real-time detection is performed for all enabled detection nodes and detection items of the board. You must enable detection nodes and detection items by using commands before you perform real-time detection.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Configure single-time real-time detection for a board.

hdf once-run slot *slot-id*

After you configure this function, real-time detection is performed for all enabled detection nodes and detection items of the board. You can run the **display hdf** command to display the detection result.

1.6 Configuring Alerting for HDF Detection Items

1.6.1 Overview

You can configure the fault alerting function for specific detection items of a board in the CLI. You can enable or disable this function as needed.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the fault alerting function for an HDF detection item of a board.

hdf alarm enable slot *slot-id* **main-node** *name* **child-node** *name* **item** *item-id*

By default, the fault alerting function for HDF detection items is automatically configured.

1.7 Configuring the Detection Period for HDF Detection Nodes

1.7.1 Overview

By configuring the detection period of the HDF detection nodes of a hardware component, you can dynamically adjust the detection period of detection child nodes, which helps meet your service requirements.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the detection period for detection nodes.

hdf set cycle slot *slot-id* **main-node** *name* **child-node** *name* **time** *cycle-num*

If you do not configure the detection period, the default detection period is used.

1.8 Monitoring

Run the **display** command to check the configuration.

Table 1-1 Monitoring

Command	Purpose
display hdf all	Displays the status of the hardware components of the device.
display hdf fault	Displays the status of the faulty hardware components of the device.
display hdf slot *slot-id* [**fault**]	Displays the status of the hardware components of a specific slot.
display hdf detail-info slot *slot-id* **main-node name** *child-node name* [**item** *item-id*]	Displays the status information of the child detection nodes or detection items of a slot.

1 Configuring Hotkeys 1

1.1 Introduction 1

1.1.1 Overview 1

1.1.2 Principles 1

1.2 Restrictions and Guidelines 2

1 Configuring Hotkeys

1.1 Introduction

1.1.1 Overview

Hotkeys, also known as magic keys, help you to perform maintenance and debugging on devices. You can view the memory information, interrupt information, lock usage, and process information of a device as the network administrator by using hotkeys when the device is faulty or cannot be controlled properly. You can also perform other actions, including one-click collection and enabling or disabling of the logging function of the console, by using hotkeys. You can use the functions provided by hotkeys to obtain key debugging information of the device, locate the cause of exceptions, and restore the device.

1.1.2 Principles

1. Hotkeys

Hotkeys, also known as magic keys, are input to a device to obtain debugging information of the device in the event of exceptions. You can also restore the services on the device by using hotkeys. Supported hotkeys are 4Esc key combinations (press the **Esc** key on the keyboard four consecutive times) and 4$ key combinations (press and hold the **Shift** key and then press the **$** key on the keyboard four consecutive times).

Note

Hotkeys can be input only on the serial console of the device and are not available on other types of terminals.

2. 4Esc Key Combination

The 4Esc key combinations are supported by the device and provide the following functions:

- Enable and disable the output function of the console.
- Display the information about usage of all locks.
- Perform one-click collection of debugging information.
- Display the help Information about hotkeys.
- Display the CLI debugging information.
- Display the information about interrupts.
- Stop a process by specifying the process identifier (PID).
- Display the information about the running processes.
- Display the memory statistics of the device.
- Enable the timer for periodic output of the information about interrupts.
- Disable the timer for periodic output of the information about interrupts.
- Disable logging of the console.
- Display the information about the context switch and running time for all threads.

- Display the information about the stacks of all CPU cores.
- Display the status information about all threads.
- Display the kernel stack information of all threads.
- Start the task to output periods (.) on the console.
- Stop the task to output periods (.) on the console.

Note

- 4Esc key combinations: Press the **Esc** key on the keyboard four consecutive times and then press a letter key. For more information about letter keys of specific functions, see *Hotkey Commands*.
- You can use the 4@ key combinations (press and hold the **Shift** key, press the @ key on the keyboard four consecutive times, and then press the same letter key as that of the 4Esc key combinations) to replace the 4Esc key combinations. For more information about letter keys of specific functions, see *Hotkey Commands*.

3. 4$ Key Combinations

The 4$ key combinations are supported by the device and provide the following functions:

- Set the kernel log priority level.
- Display the help information about system hotkeys.
- Display the stack information of all active CPUs.
- Display the memory information of the device.
- Display the register information of the device.
- Display the timer information of the device.
- Display the kernel stack information of all threads.
- Display the information about threads that are blocked of the device.

Note

4$ key combinations: Press and hold the **Shift** key, press the **$** key on the keyboard four consecutive times, and then press a letter key. For more information about letter keys of specific functions, see *Hotkey Commands*.

1.2 Restrictions and Guidelines

The hotkeys can be used only on serial consoles rather than other types of remote terminals, such as terminals connected through Telnet and SSH.

1 Configuring Network Packet Loss Detection

Note

Network packet loss detection is not supported by the S6980-64QC, S6920-4C, S6580-24DC8QC, or S6510-48VS8CQ.

1.1 Introduction

1.1.1 Overview

Data transmitted over the network passes through many devices and network links. Packets may be lost at any link. The causes of packet loss between devices are complex and diverse. Even if the device causing packet loss is identified, it is difficult to reproduce the fault in an environment with complex network configurations. The network packet loss detection function can enable the construction of packets containing simulated packet loss issues, facilitating troubleshooting by identifying the causes of packet loss through alternative methods.

1.1.2 Principles

When a device simulates packet loss, the device constructs a probe packet based on the configured profile and simulates the forwarding process of the discarded packet on the device by specifying the source interface of the probe packet.

Users should configure a probe packet profile based on the characteristics of lost packets. The device supports two methods to configure the probe packet profile to simulate lost packets:

- Directly specify the packet content and configure a customized probe packet profile.
- Specify key fields of the packet data link layer, network layer, transport layer, and application layer based on the packet format, and configure a standard parameter-based probe packet profile.

  This method supports IPv4 TCP, IPv4 UDP, IPv6 TCP, and IPv6 UDP packets. For different types of probe packet profiles, the following key fields can be configured:

  - Key fields in IPv4 TCP probe packets: source MAC address, destination MAC address, source IPv4 address, destination IPv4 address, VLAN ID, source port number, destination port number, 802.1p priority, DSCP value, TTL value, transport layer and network layer checksum, and TCP flags.
  - Key fields in IPv4 UDP probe packets: source MAC address, destination MAC address, source IPv4 address, destination IPv4 address, VLAN ID, source port number, destination port number, 802.1p priority, DSCP value, TTL value, transport layer and network layer checksum, and UDP packet length.
  - Key fields in IPv6 TCP probe packets: source MAC address, destination MAC address, source IPv6 address, destination IPv6 address, VLAN ID, source port number, destination port number, 802.1p priority, flow label, hop limit, Traffic Class field, transport layer and network layer checksum, and TCP Flags.
  - Key fields in IPv6 UDP probe packets: source MAC address, destination MAC address, source IPv6 address, destination IPv6 address, VLAN ID, source port number, destination port number, 802.1p priority, flow tag, hop limit, traffic class, transport layer and network layer checksum, and UDP packet length.

1.2 Configuring Network Packet Loss Detection

1.2.1 Overview

The network packet loss detection function is used to locate the causes of packet loss in forwarding. Configure probe packet profiles on network devices. After the devices successfully send probe packets, you can use other methods to locate the causes of packet loss.

1.2.2 Restrictions and Guidelines

- Probe packets are not sent to the network but are only forwarded to the local device.

1.2.3 Configuration Tasks

The probe packet profile can be configured either as a standard parameter-based profile or a customized profile. Select one of the configuration modes.

- Configuring a Standard Parameter-based Probe Packet Profile
- Configuring a Customized Probe Packet Profile
- Sending Probe Packets Based on the Profile

1.2.4 Configuring a Standard Parameter-based Probe Packet Profile

1. Overview

Configure key fields in the packet header and application layer data to create a standard parameter-based probe packet profile to simulate lost packets.

2. Restrictions and Guidelines

- For a standard parameter-based probe packet profile, basic network parameters must be configured. Otherwise, the profile cannot be used to construct a probe packet.
- It is not allowed to create a standard parameter-based probe packet profile with the same name as that of a configured customized probe packet profile. If you need to modify the type of the probe packet profile, you should delete the current profile before you configure it. For a standard parameter-based probe packet profile, if different probe packet profiles use the same profile name, the later configured profile will overwrite the earlier configured profile. For some protocol-specific key fields, such as the DSCP field of IPv4 packets and the flow label field of IPv6 packets, if the value of the field is not changed in the subsequent configuration, the value is still saved in the device and takes effect when the probe packet profile is configured for the corresponding protocol.
- A maximum of 20 probe packet profiles can be configured on a device.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure network parameters for the probe packet profile. Configure one of the following tasks.

- Configure network parameters for the IPv4 TCP probe packet profile.

detector packet-trace profile *profile-name* **source-mac** *src-mac-address* **destination-mac** *dest-mac-address* [**vlan** *vlan-id* [**8021p** *8021p-value*]] **ip source-ip** *src-ipv4-address* **destination-ip** *dest-ipv4-address* **tcp** [**csum** *csum-value*] [**dscp** *dscp-value*] [**network-length** *network-length-value*] [**ttl** *ttl-value*] **source-port** *src-port-number* **destination-port** *dest-port-number* [**csum** *transport-csum*] [**ack** | **cwr** | **ecn** | **fin** | **nonce** | **push** | **reset** | **syn** | **urgent**]

- Configure network parameters of the IPv4 UDP probe packet profile.
  detector packet-trace profile *profile-name* **source-mac** *src-mac-address* **destination-mac** *dest-mac-address* [**vlan** *vlan-id* [**8021p** *8021p-value*]] **ip source-ip** *src-ipv4-address* **destination-ip** *dest-ipv4-address* **udp** [**csum** *csum-value*] [**dscp** *dscp-value*] [**network-length** *network-length-value*] [**ttl** *ttl-value*] **source-port** *src-port-number* **destination-port** *dest-port-number* [**csum** *transport-csum*] [**udp-length** *udp-length-value*]
- Configure network parameters for the IPv6 TCP probe packet profile.

  detector packet-trace profile *profile-name* **source-mac** *src-mac-address* **destination-mac** *dest-mac-address* [**vlan** *vlan-id* [**8021p** *8021p-value*]] **ipv6 source-ip** *src-ipv6-address* **destination-ip** *dest-ipv6-address* **tcp** [**flowlabel** *flowlabel-value*] [**hoplimit** *hoplimit-value*] [**network-length** *network-length-value*] [**tc** *traffic-class*] **source-port** *src-port-number* **destination-port** *dest-port-number* [**csum** *transport-csum*] [**ack** | **cwr** | **ecn** | **fin** | **nonce** | **push** | **reset** | **syn** | **urgent**]
- Configure network parameters for the IPv6 UDP probe packet profile.

  detector packet-trace profile *profile-name* **source-mac** *src-mac-address* **destination-mac** *dest-mac-address* [**vlan** *vlan-id* [**8021p** *8021p-value*]] **ipv6 source-ip** *src-ipv6-address* **destination-ip** *dest-ipv6-address* **udp** [**flowlabel** *flowlabel-value*] [**hoplimit** *hoplimit-value*] [**network-length** *network-length-value*] [**tc** *traffic-class*] **source-port** *src-port-number* **destination-port** *dest-port-number* [**csum** *transport-csum*] [**udp-length** *udp-length-value*]

  No probe packet profile is configured by default.

(4) (Optional) Configure application layer data for the probe packet profile.
detector packet-trace profile *profile-name* { **payload-base** *payload-data* | **payload-extern-1** *payload-data* | **payload-extern-2** *payload-data* | **payload-extern-3** *payload-data* | **payload-extern-4** *payload-data* }

By default, the application layer data of the probe packet profile is not configured. Instead, it is filled with zeros to its minimum length.

1.2.5 Configuring a Customized Probe Packet Profile

1. Overview

You can create a customized probe packet profile by directly configuring the packet content.

2. Restrictions and Guidelines

- It is not allowed to create a customized probe packet profile with the same name as that of a configured standard parameter-based probe packet profile. If you need to modify the type of the probe packet profile, you should delete the current profile before you configure it.
- Different probe packet profiles have different names. If different probe packet profiles use the same name, the later configured profile will overwrite the earlier configured profile.
- A maximum of 20 probe packet profiles can be configured on a device.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a customized probe packet profile.

detector packet-trace profile *profile-name* { **packet-base** *packet-data* | **packet-extern-1** *packet-data* | **packet-extern-2** *packet-data* | **packet-extern-3** *packet-data* | **packet-extern-4** *packet-data* }

No customized probe packet profile is configured by default.

1.2.6 Sending Probe Packets Based on the Profile

1. Overview

After the probe packet profile is configured, the profile is used to send probe packets to simulate the forwarding process of discarded packets within the device.

2. Restrictions and Guidelines

- The source interface of the probe packet must be a physical port.
- The device forwards and processes packets without differentiating whether they are probe packets. Packet statistics are collected for probe packets.
- The number of sent packets is limited to 1 to 1000.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Send probe packets based on a specified profile to locate the cause of packet loss.

send-detector packet-trace profile *profile-name packet-count src-interface*

No probe packet based on a specified profile is sent by default.

1.3 Monitoring

Run the **display** command to display the profile configuration.

Table 1-1 Displaying Profile Configuration

Command	Purpose
display detector packet-trace profile [*profile-name*]	Displays the configuration of a probe packet profile.
display detector packet-trace detail	Displays the sending statistics of the packet profile.

Run the **debugging** command to check the running status of the function configuration.

Table 1-2 Displaying Debugging Information

Caution

The output of debugging information consumes system resources. Therefore, disable the debugging function immediately after use.

Command	Purpose
debugging packet-trace all	Debugging
debugging packet-trace error	Debugs errors.
debugging packet-trace event	Debugs events.
debugging packet-trace packet	Debugs packets.

1.4 Configuration Examples

1.4.1 Configuring Packet Forwarding on the Local Device

1. Networking Requirements

Packets sent from device A to device C are discarded on device B. The cause of packet discard needs to be determined.

2. Networking Diagram

Figure 1-1 Topology of Network Packet Loss Detection

3. Configuration Roadmap

- Based on the packets sent by device A, configure device B to send packets for probing.

4. Procedure

Configure a probe packet profile on device B and send the probe packet.

```
DEVICE-B(cfg)# detector packet-trace profile test payload-base
01234567890123456789012345678901234567890123456789012345678901234567890123456789
DEVICE-B(cfg)# detector packet-trace profile test payload-extern-1 0123
DEVICE-B(cfg)# detector packet-trace profile test payload-extern-2 0123
DEVICE-B(cfg)# detector packet-trace profile test payload-extern-3 0123
DEVICE-B(cfg)# detector packet-trace profile test payload-extern-4 0123
DEVICE-B(cfg)# detector packet-trace profile test source-mac 1111.2222.3333 destination-mac
1111.4444.5555 vlan 1 8021p 5 ip source-ip 1.1.1.3 destination-ip 1.3.4.5 udp dscp 3 ttl 3 network-length 3
source-port 5223 destination-port 6553
```

```
DEVICE-B(cfg)# end
DEVICE-B# send-detector packet-trace profile test GigabitEthernet 1/0/1 100
```

5. Verification

Run the **display detector packet-trace profile test** command to check whether the test profile is configured.

```
DEVICE-B# display detector packet-trace profile test
---------------------------------------
profile name            : test
source-mac              : 1111.2222.3333
destination-mac         : 1111.4444.5555
vlan                    : 1
8021p                   : 5

1 Configuring IFA

Note

IFA is only supported by the S6980-64QC, S6580-48CQ8QC, or S6580-24DC8QC.

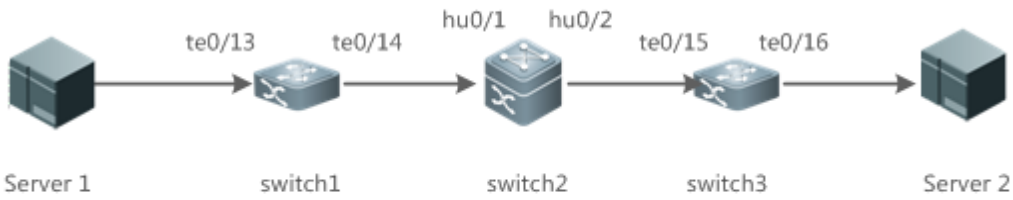
1.1 Introduction

1.1.1 Overview

In-band Flow Analyzer (IFA) can provide sampling for traffic visualization. IFA can be used to accurately determine the traffic forwarding path and latency, encapsulate the data into UDP packets, and send them to the customer's server for analysis.

1.1.2 Principles

1. Basic Concepts



Traffic visualization utilizes network devices as nodes and device interfaces as basic sampling units. It obtains traffic forwarding path through hardware chip-based sampling and sends path information the server for traffic monitoring. This method can monitor traffic conditions in real-time, detect traffic anomalies in a timely manner, and ensure the normal and stable operation of the network. IFA sampling is to encapsulate traffic forwarding path and timestamp into UDP packets and send them to the server for analysis.

The first and last hops of IFA sampling can be selected. There can be more than one intermediate device. On the first -hop device, when a packet reaches the IFA interface and matches the IFA ACL, the device processes the packet according to the IFA configuration on the interface, including adding an INT probe header (containing probe marks, payload length, serial number, and so on) and an MD bit (containing device number, ingress and egress interfaces, and ingress and egress timestamps). By using the loopback interface, IFA enables the packets added with the INT probe header to be forwarded through the default original egress interfaces. The packets passing through the intermediate device and last-hop device are also added with the MD bit. The last-hop device encapsulates the IFA sampling information into UDP packets and send them to the IFA server for traffic analysis. Traffic forwarding path and latency can be identified based on the MD bit in IFA packets.

2. Basic Framework

As shown in Figure 1-1, traffic visualization solution can be used to monitor communication between server 1 and server 2. The devices between them are omitted and only three switches are reserved. The configuration of the omitted intermediate devices is the same as that of switch 2. Enable IFA on switch 1, the IFA first-hop device. The IFA packet is added with the MD bit on switch 1, switch 2, and switch 3 respectively, and sent by the last-hop device to the IFA server for traffic analysis.

Figure 1-1 Traffic Visualization Scheme Monitoring

- Configure an IFA ACL and sampling rate, and enable the interface to add the MD bit to the packet on switch 1.
- Configure the interface to add the MD bit on switch 2.
- Configure the server information and enable the interface to add the MD bit on switch 3.
- Configure MOD sampling on any switch to output packet drop statistics on the sampling interface.

1.2 Restrictions and Guidelines

- The IFA last-hop device can communicate with the server.
- Process the packets passing through the interface according to the sampling rate and send them to the server.

1.3 Configuration Task Summary

IFA configuration includes the following tasks:

(1) Configuring Basic Functions

(2) (Optional) Configuring Optional Features

1.4 Configuring Basic Functions

1.4.1 Overview

Configure the basic functions of IFA.

1.4.2 Restrictions and Guidelines

- The IFA last-hop device can communicate with the server.
- The IFA ACL and sampling rate can be configured on a physical or an aggregate interface. An interface can be configured with up to four sampling policies, each including an ACL and sampling rate.
- Only one sampling rate that is not equal to 1 is supported. For example, if an interface is configured with a sampling rate of 100, the sampling rate for other interfaces can only be 100 if not being 1.
- Run the **ifa set-header md** command in interface configuration command, and the specific interface will add the MD bit to IFA packet header. This command can be configured on a physical or an aggregate interface. After an interface is configured with this command, all interfaces cannot be configured with the **ifa passive md** command.
- Run the **ifa set-header md** command in global configuration command, and all interfaces will add the MD bit to IFA packet header.

- To disable this function on a specific interface, run the **ifa passive md** command on the interface.
- The MD bits added in interface configuration mode and global configuration mode are mutually exclusive. That is, the **ifa set-header md** command be configured in both interface configuration mode and global configuration mode.
- The **ifa set-header md** command must be configured on all non-last-hop devices that the IFA packets pass through included in a Layer 3 route. Otherwise, the IFA packets may not be re-encapsulated and sent to the server. Even if these packets are sent to the server, the packets may have incomplete information. Configure an expert-level ACL before running the **ifa set-header md** [**acl** *acl-id* | **acl** *acl-name*] command. The packets matching the ACL will be added with the MD bit in the header.
- The IFA version includes IFA 1.0 and IFA 2.0. IFA 1.0 are IFA 2.0 are not interchangeable. Running the **show ifa version** command can display IFA 2.0, but not IFA 1.0.
- The IFA 2.0 first-hop device does not need to be configured with the **ifa set-header md** and **ifa passive md** commands.
- Before using IFA, run the **switch-mode ifa** { **global** | **slot** *num* } command to switch the device to the IFA mode.
- The priority of the IFA ACL on each interface is unique.
- The **ifa set-header md** command takes effect on only incoming packets.
- The **ifa set-header md acl** command with the **acl** parameter is supported by only some products (chip-specific). Whether this command is supported is subject to the device.
- Applying both security ACL and IFA ACL on an interface may cause IFA to sample the packets dropped by the security ACL. A packet is dropped if it matches the security ACL, but it is sampled if it matches the IFA ACL. The security ACL and IFA ACL belong to different FP groups. So both of them can match the packet and non-conflicting actions can be implemented simultaneously. In this case, the packet dropped by the security ACL can still be sampled by IFA ACL. This packet is included in the IFA statistics.
- Configure the IFA ACL to allow the packet matching the deny rule to pass through and sample the packet matching the permit rule.
- The packets forwarded within the IFA domain are added with IFA information including IFA header, MD header, or MD bit according to IFA configuration. When the size of a packet exceeds the interface MTU, the packet is dropped. The first-hop device adds IFA information of up to 40 bytes to packets while the intermediate devices add the IFA information of up to 32 bytes to packets. The size of the packet with added IFA information should not exceed the interface MTU.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure the IFA ACL and priority.

ifa acl { *acl-id* | *acl-name* } **rate** *rate* [**priority** *priority*]

(5) Configure the interface to add the MD bit to the IFA packet header.

ifa set-header md [**acl** *acl-id* | **acl** *acl-name*]

1.5 Configuring Optional Features

1.5.1 Overview

- Configure IFA packet filtering.
- Disable the interface to add the MD bit to IFA packet header.
- Configure the IPv4 address of the IFA device.
- Configure IFA statistics.

1.5.2 Restrictions and Guidelines

- This command can be used with the **ifa set-header md** command in global configuration mode to disable this function on a specific interface. This command is mutually exclusive with the **ifa set-header md** command in interface configuration mode.
- This command can be configured on a physical or an aggregate interface.
- The IP address of the IFA device must be authorized.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable IFA statistics.

ifa statistics enable

(4) Enter the interface configuration mode..

interface *interface-type interface-number*

(5) Configure the IP address or ID of the IFA device.

ifa set-device { *ipv4-address* | *id* }

(6) Configure IFA packet filtering.

ifa filter enable

(7) Disable the interface to add the MD bit to the IFA packet header.

ifa passive md

1.6 Monitoring

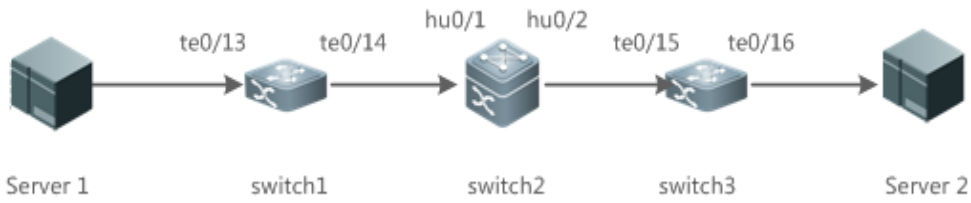
Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** command to clear information.

Caution

Running the **clear** command may lose vital information and thus interrupt services.

Table 1-1 Monitoring



Command	Purpose

1.7 Configuration Examples

1.7.1 Configuring IFA sampling

1. Topology

Figure 1-2 Topology

2. Note

- On switch 1, enable IFA on the interface included in the route, and add the MD bit to the IFA packet header.
- On switch 2, configure the interface included in the route to add the MD bit to the IFA packet header.
- On switch 3, configure the server information and enable the interface included in the route to add the MD bit to the IFA packet header.

3. Procedure

The following example enables IFA on switch 1.

```
Switch1# configure terminal
Switch1(config)# access-list 100 permit ip any any
Switch1(config)# interface TenGigabitEthernet 0/13
Switch1(config-if-TenGigabitEthernet 0/13)# ifa acl 100 rate 100 priority 10
Switch1(config-if-TenGigabitEthernet 0/13)# ifa set-header md
Switch1(config-if-TenGigabitEthernet 0/13)# end
```

The following example enables IFA on switch 2.

```
Switch2# configure terminal
Switch2(config)# interface HundredGigabitEthernet0/1
Switch2(config-if-HundredGigabitEthernet0/1)# ifa set-header md
Switch2(config-if-HundredGigabitEthernet0/1)# end
```

The following example enables IFA on switch 3.

```
 Switch3# configure terminal
Switch3(config)# ifa statistics enable
Switch3(config)# interface TenGigabitEthernet 0/15
Switch3(config-if-TenGigabitEthernet 0/15)# ifa set-header md
Switch3(config-if-TenGigabitEthernet 0/15)# end
```

4. Verification

Run the **show run** command to check whether the command output is consistent with the configuration.

Steer the packet matching the ACL to a path from interface TenGigabitEthernet0/13 on switch 1 toward the proceeding interfaces. Check whether the server receives the IFA packets sent from switch 3 and whether sampling statistics are correct.

Run the **show ifa statistics** command to display statistics.

```
Ruijie# show ifa statistics
Type          Acl    Statistic(pkts)        Applied interface
------------------------------------------------------------------------------
--------------
sample         100    20426                Te0/13-14
sample         101    0                   TF0/2
insert-md       -      20586                Hu0/1-2, Te0/13-16
```

5. Configuration File

- Configuration on switch 1

```
access-list 100 permit ip any any

interface TenGigabitEthernet 0/13
ifa acl 100 rate 100 priority 10
ifa set-header md
```

- Configuration on switch 2

```
interface HundredGigabitEthernet0/1
ifa set-header md
```

- Configuration on switch 3

```
ifa statistics enable

interface TenGigabitEthernet 0/15
ifa set-header md
```

1 Configuring VXLAN

Note

VXLAN is supported by only the S6510-32CQ, S6510-48VS8CQ, S6510-4C, and S6250-48XS8CQ.

1.1 Overview

Virtual extensible local area network (VXLAN) is a virtual Ethernet built over a physical IP network. It is an Layer 2 over User Datagram Protocol (UDP) technology.

The development of network and virtualization technologies brings widespread application of server virtualization in data centers. Deploying virtual machines (VMs) on servers in a data center improves server utilization and reduces hardware costs and operation costs in the data center.

However, the introduction of the virtualization technology poses new challenges to conventional data center networks.

- Layer 2 network boundary limit

  With application of the virtualization technology, many VMs may run on each physical server. The number of VM MAC addresses in an Layer 2 network may increase sharply. To properly forward data packets, an access switch needs to learn the MAC addresses of VMs in each Layer 2 network. Limited by hardware, the capacity of the MAC address table on an access switch is small and cannot meet requirements.

- Inadequate network isolation capability

  In a conventional data center network, the traffic of VMs is isolated using the virtual local area network (VLAN) technology. The VMs of different tenants are classified into different VLANs. The VLAN technology distinguishes VLANs by VLAN ID and the actual number of supported VLAN IDs is 4094, which is insufficient for some large-scale data centers. In addition, conventional VLANs cannot meet the requirement of dynamic network adjustment, and network expansion and adjustment are very difficult.

- VM migration limit

  VMs need to be migrated to other servers because of insufficient server hardware resources (for example, very high CPU usage, insufficient disk space, and insufficient memory) or the relocating of the equipment room. The MAC and IP addresses of the VMs must remain unchanged before and after migration, to ensure that services are not interrupted during VM migration. Therefore, VMs can be migrated only in the current Layer 2 network.

The VXLAN technology effectively solves the problems above.

- Breaking the Layer 2 network boundary limit to solve the MAC address capacity problem

  VXLAN uses UDP to encapsulate data packets sent by VMs. The outer IP or MAC headers of UDP packets use the IP or MAC address of the physical network. Therefore, except edge devices, devices in a VXLAN do not need to identify the MAC addresses of VMs, which reduces the MAC address learning pressure of the devices.

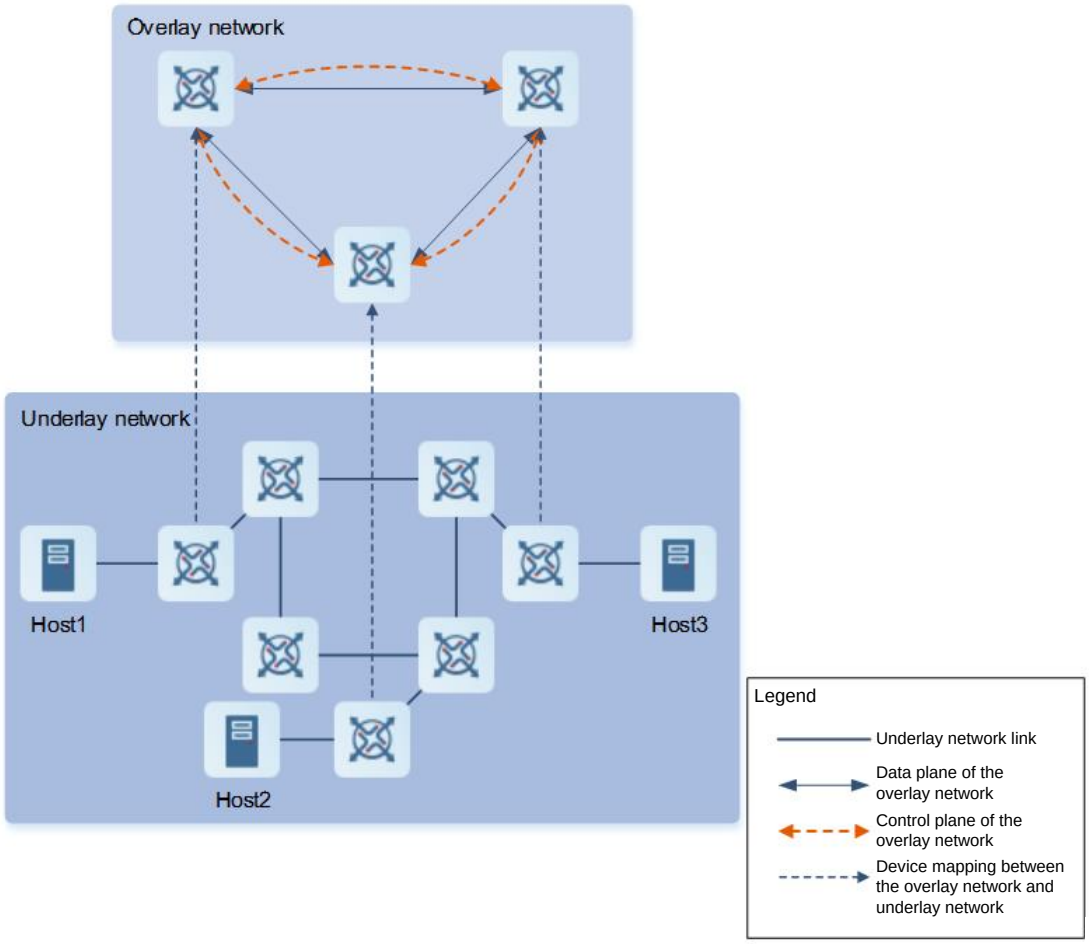
- Solving the VLAN shortage problem

VXLAN uses a 24-bit VXLAN network ID (VNI) akin to a VLAN ID for identification. It can implement isolation of up to 16 million VXLAN segments and accommodate mass tenants. With VXLAN, user isolation and identification are no longer limited.

- Removing the VM migration limit

  VXLAN uses MAC in UDP encapsulation to extend an Layer 2 network and decouple virtual networks from a physical network. VXLAN allows tenants to plan virtual networks without considering restrictions in IP addresses and broadcast domains of physical networks. It reduces network management difficulties. Building a large Layer 2 network through VXLAN can ensure that the IP addresses, MAC addresses, and other parameters of VMs keep unchanged during VM migration.

1.2 Principles



1.2.1 Basic Concepts

1. Overlay Network and Underlay Network

The VXLAN technology can be used to build an overlay logical network on the basis of a physical network (such as an IP network).

- The bearer network (underlay network) and virtual network (overlay network) are completely separated and do not perceive each other.
- The underlay network needs to be simple and easy to manage, and can provide stable and reliable forwarding capability for the overlay network.
- The overlay network needs to provide flexibility and scalability.

Figure 1-1 Overlay Network and Underlay Network

2. VTEP

A VXLAN tunnel end point (VTEP) is used to encapsulate and decapsulate VXLAN packets. At the start point of a VXLAN tunnel, a VTEP encapsulates data generated by VMs into UDP headers and sends out the packets. After encapsulation, the MAC addresses and VLAN information of the VMs are no longer used the basis for data forwarding. At the end point of the VXLAN tunnel, a VTEP decapsulates received VXLAN packets.

3. VNI

VNIs identify different VXLAN segments. Only VMs with the same VNI in the same VXLAN segment can communicate with each other through VXLAN Layer 2 forwarding. Otherwise, VMs communicate with each other through VXLAN Layer 3 forwarding. A VNI is represented by a 24-bit binary number.

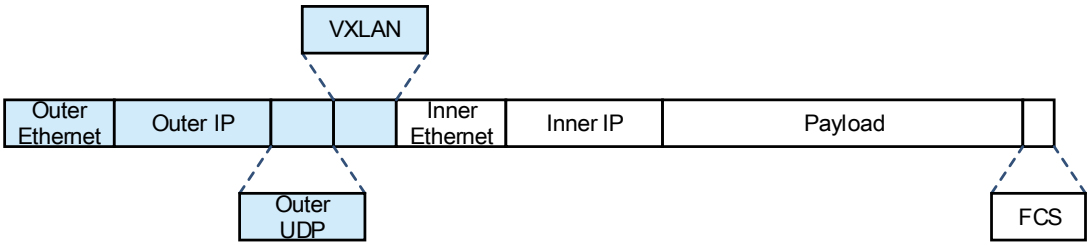
4. VXLAN Tunnel

A VXLAN tunnel is a logical tunnel for transmitting encapsulated VXLAN packets between two VTEPs. When a service packet reaches a VXLAN tunnel, a VXLAN header, UDP header, and IP header are added to the front of the service packet. The encapsulated packet is then transparently transmitted to the remote VTEP by the Layer 3 forwarding function of the underlay network. After receiving the service packet, the remote VTEP decapsulates the packet.

5. VXLAN Gateway

A VXLAN gateway routes VXLAN packets based on IP addresses in the packets. It serves as the gateway of VMs in a VXLAN network. After configuring a VXLAN gateway, you can build an Layer 3 overlay network to implement communication between VXLAN subnets.

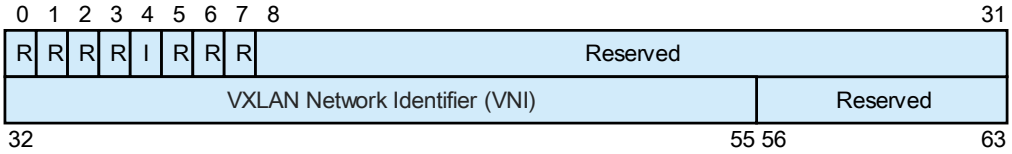
6. VXLAN Instance



A VXLAN instance is a node in a VXLAN-based overlay network. This node can implement conventional Layer 2 switching functions such as MAC address learning and flooding in an overlay network. After being specified as a VXLAN gateway, this node can also perform Layer 3 forwarding. On the same device, VXLAN instances and VNIs are in one-to-one mappings.

1.2.2 Packet Format

After receiving a data frame from a VM, a VTEP encapsulates four elements to form a new frame header. The original destination/source MAC address, inner VLAN tag, and Ethernet type carried in the inner data frame remain unchanged. The four elements from inside out are the VXLAN header, outer UDP header, outer IPv4 header, and outer Ethernet frame header.

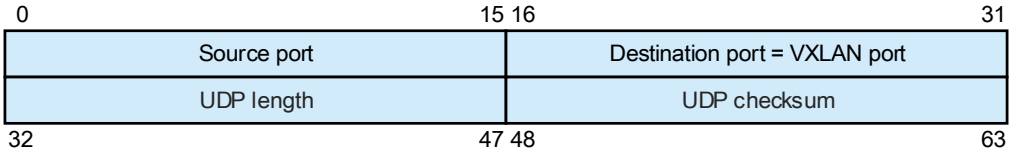


The figure below shows the frame format after VXLAN encapsulation.

Figure 1-2 Frame Format After VXLAN Encapsulation

- VXLAN header

Figure 1-3 VXLAN Header

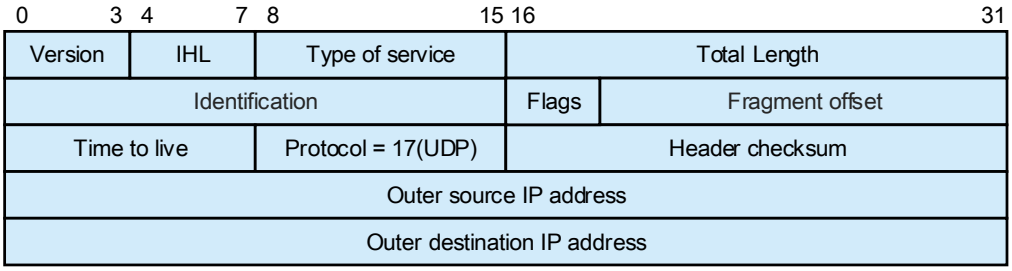


A VXLAN header has 64 bits. In the design of the current protocol version, the sole purpose of a VXLAN header is to carry the 24-bit VNI assigned by a VTEP.

- **Flag** (8 bits): The I bit must be set to 1 to indicate a valid VNI, and the R bits must be set to 0.
- **VXLAN Segment ID/VXLAN Network Identifier (VNI)**: It occupies 24 bits to identify a VXLAN. Only VMs belonging to the same VXLAN can communicate with each other.
- **Reserved**: There are two reserved fields, which occupy 24 bits and 8 bits separately and are filled with zeros.

- Outer UDP header

Figure 1-4 Outer UDP Header

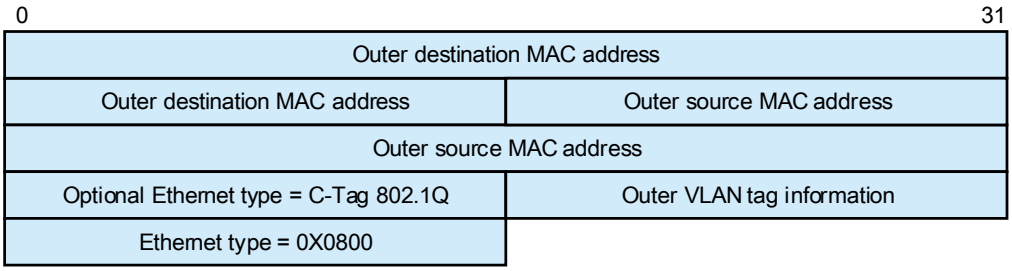


The fields in an outer UDP header are described as follows:

- **Source port**: Indicates the UDP source port ID. Assigned by a VTEP, it is the result of the hash operation performed on the Layer 2 header of a data frame. This hash result can serve as the basis for traffic load balancing.
- **Destination port = VXLAN port**: Indicates a destination port ID. The destination port ID assigned by the Internet Assigned Numbers Authority (IANA) is 4789.
- **UDP length**: Indicates the length of a UDP header.
- **UDP checksum**: Indicates the UDP checksum, which is set to **0** for transmission.

- Outer IP header

Figure 1-5 Outer IP Header



The fields in an outer IP header are described as follows:

- **Outer source IPv4 address**: Indicates the IP address of a VTEP that forwards packets of VMs.
- **Outer destination IPv4 address**: It can be a unicast IP address or multicast IP address. If it is a unicast IP address, the field indicates the IP address of a VTEP corresponding to a VM that needs to make communication.

The IP addresses in an outer IP header are no longer the addresses of VMs that make communication but the IP addresses of VTEPs at both ends of a tunnel. If the hypervisor on a server, on which a VM runs, directly undertakes the work of a VTEP, the IP address here is that of the network interface card (NIC) of the server that runs the VM software. If a VTEP is a switch, the IP address is that of an outbound interface or an Layer 3 switch virtual interface (SVI).

- Outer Ethernet header

Figure 1-6 Outer Ethernet Header

The fields in an outer Ethernet header are described as follows:

- **Outer destination MAC address**: Indicates the next-hop MAC address pointed to the IP address of the destination VTEP.
- **Outer source MAC address**: Indicates the MAC address of the local VTEP.
- **Outer VLAN tag information**: Optional.

1.2.3 Introduction to the VXLAN Operation Mechanism

The VXLAN operation consists of the following parts:

(1) Create a VXLAN instance on a device.

(2) Establish a tunnel between VTEPs and associate the tunnel with the VXLAN instance.

(3) VTEPs learn MAC addresses for data forwarding.

(4) A VTEP determines the VXLAN, to which a received MAC frame belongs, encapsulates the packet into a VXLAN packet, and selects a proper tunnel to forward the packet based on the MAC address learning result. The peer VTEP receives the packet from the tunnel, and decapsulates and forwards the packet.

(5) The VXLAN gateway routes and forwards packets across VXLAN subnets at Layer 3.

1.2.4 Establishment of a VXLAN Tunnel

VXLAN packets are transmitted between two VTEPs through a VXLAN tunnel. Service packets are encapsulated upon entering a tunnel. The Layer 3 forwarding module of the underlay network transmits the encapsulated packets to the remote VTEP, which then decapsulates the packets and sends them out of the tunnel. Therefore, a VXLAN tunnel needs to be established between VTEPs. The established VXLAN tunnel needs to associate with a VXLAN instance so that the tunnel transmits packets of the VXLAN instance. A VXLAN tunnel can be created manually or automatically:

- Manual creation

  Manually configure VXLAN tunnel interfaces and specify the source IP address and destination IP address of the tunnel. A manually created tunnel needs to be manually associated with a VXLAN instance.

- Automatic creation

  An Ethernet virtual private network (EVPN) is used as the control plane of a VXLAN. A VTEP needs to establish a Border Gateway Protocol (BGP) neighbor relationship with another VTEP or an Interior Border Gateway Protocol (IBGP) route reflector first. Then, the VTEP sends an EVPN type-3 route (containing the multicast Ethernet tag) to its neighbor that supports BGP-EVPN. VTEPs send EVPN type-3 routes to each

other to discover VTEPs and establish VXLAN tunnels. The local IP address of a tunnel is IP address of the local VTEP and the peer IP address is the peer VTEP IP address learned from a type-3 route.

VXLAN tunnels automatically established through EVPN are automatically associated with VXLAN instances.

1.2.5 Identifying the VXLAN to Which a Packet Belongs

1. Identifying the VXLAN to Which an Access Packet Belongs

The device can identify the VXLAN, to which an access packet belongs, in two ways:

- Configuring a VLAN to be associated with a VXLAN instance: When the device receives a MAC frame from a VLAN, which is associated with a VXLAN, the device encapsulates the received MAC frame into a VXLAN packet and forwards it through the corresponding VXLAN tunnel. On the same access device, different VXLAN instances cannot be associated with the same VLAN. After a VLAN is associated with a VXLAN, all packets of the VLAN are encapsulated into VXLAN packets. Therefore, no SVI can be created for the VLAN to serve as an IP gateway.
- Configuring a Layer 2 Ethernet sub-interface to access a specified VXLAN: After a Layer 2 Ethernet sub-interface receives a MAC frame, if the sub-interface has been configured to access a VXLAN network, the packet belongs to the VXLAN network. The device encapsulates the MAC frame into a VXLAN packet for forwarding. Layer 2 Ethernet sub-interfaces can access a VXLAN in untagged VLAN encapsulation mode, tagged VLAN encapsulation mode, and QinQ encapsulation mode. After a sub-interface is available, the encapsulation rule of the sub-interface has a higher priority than that of the VLAN associated with a VXLAN instance.

2. Identifying the VXLAN, to Which Packets Received from a VXLAN Tunnel Belongs

The header of a VXLAN packet carries VNI information. After receiving a packet from a VXLAN tunnel, a VTEP can determine the VXLAN network, to which the packet belongs based on the VNI carried in the packet.

1.2.6 MAC Address Learning

A VTEP needs to learn user MAC addresses to forward VXLAN packets. The MAC address learning of a VTEP includes local MAC address learning and remote MAC address learning. You can also manually configure MAC address entries and specify the VLANs, interfaces, and VNIs for the MAC address entries. Binding static MAC address entries and static ARP entries manually is more stable and secure than dynamic MAC address learning.

1. Local MAC Address Learning

Local MAC address learning is triggered by actions on the forwarding plane. After receiving a data frame from a local host, a VTEP determines the VXLAN instance, to which the data frame belongs.. If it is certain that the data frame belongs to a VXLAN instance, the VTEP adds the source MAC address of the data frame to the MAC address table of the VXLAN instance and records the VNI and the interface that receives the data frame.

2. Remote MAC Address Learning

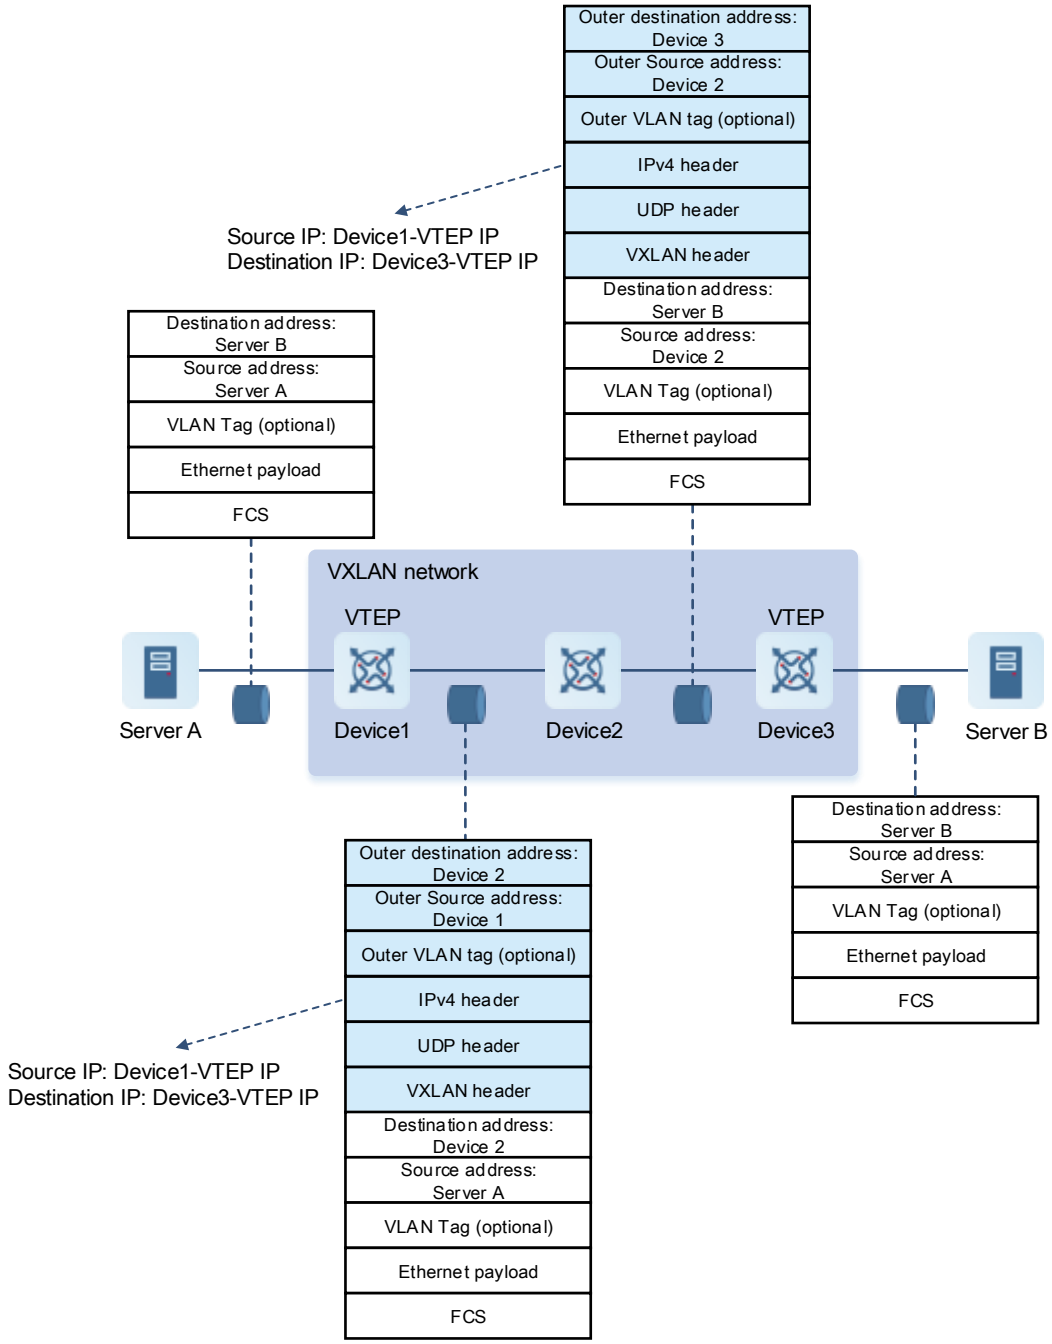
Remote MAC address learning varies with the VXLAN tunnel establishment mode.

A VTEP can learn the MAC address of an Layer 2 broadcast domain where the peer VTEP resides in either of the following ways:

- Source MAC address learning: VXLAN packets are transmitted between VTEPs through a VXLAN tunnel.

After receiving a VXLAN packet from a VXLAN tunnel, a VTEP determines the VXLAN instance, to which the packet belongs, based on the VNI. Then, the VTEP decapsulates the packet, adds the source MAC address in the data frame to the MAC address table of the VXLAN instance, and records the VNI and the VXLAN tunnel interface that receives the packet.

- BGP EVPN type-2 routing packets: After EVPN is imported, a VTEP can transmit hosts' MAC addresses by advertising the type-2 MAC/IP advertisement routes of EVPN, so as to reduce traffic flooding in the VXLAN. After learning a host's MAC address, a VTEP can advertise a MAC-only type-2 route to advertise the MAC entry to other VTEP neighbors. If the VTEP learns a host's ARP entry, it advertises a MAC-IP type-2 route to advertise the host's MAC address to its VTEP neighbors.



1.2.7 Forwarding Model

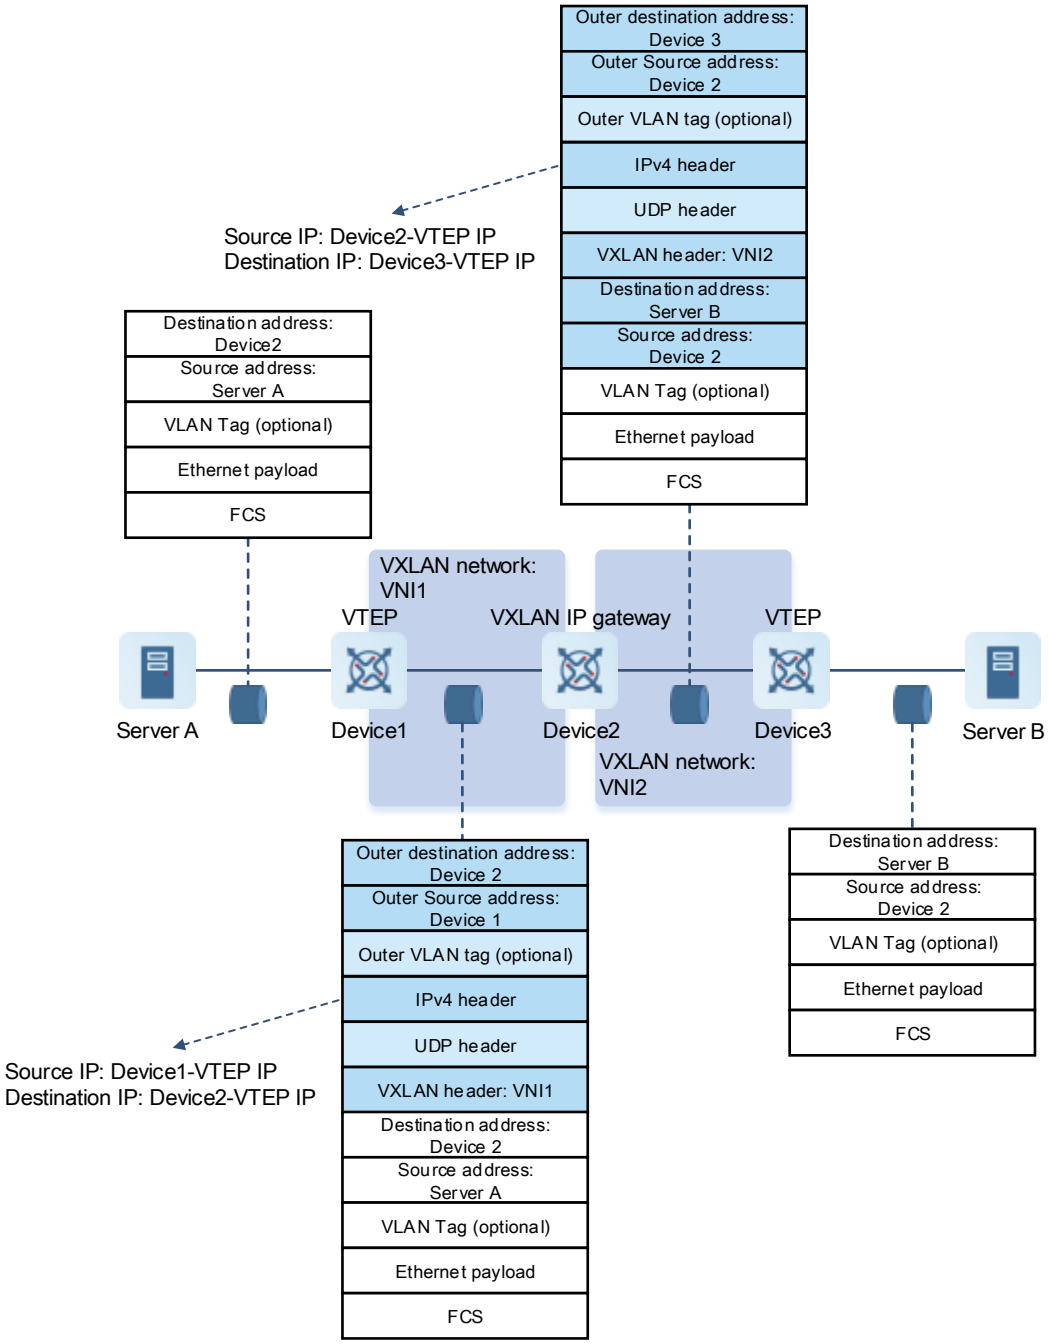
VXLAN forwarding supports bridging mode and routing mode. User communication in the same network segment is forwarded in VXLAN bridging mode, in which hosts using the same VNI communicate with each other through VXLAN Layer 2 forwarding. User communication in different network segments is forwarded in VXLAN routing mode, in which hosts using different VNIs communicate with each other through VXLAN routing and forwarding. A VXLAN gateway is needed for the communication between different VNIs.

1. VXLAN Bridging Principle

After determining the VXLAN, to which a MAC frame belongs, a VTEP encapsulates the MAC frame into a VXLAN packet. VXLAN packets are carried over UDP packets. After IP headers are added, the VXLAN packets are transmitted over the IP network. At the receive end, a VTEP decapsulates VXLAN packets to retrieve MAC frames and then forwards the MAC frames. See the following figures.

Figure 1-7 VXLAN Bridging

(1) Device 1 (switch) receives an Ethernet packet and encapsulates it into a VXLAN packet.



(2) The VXLAN packet is forwarded over the IP core network. As shown in the figure above, device 2 forwards the VXLAN packet.

(3) After receiving the VXLAN packet, device 3 decapsulates the packet, and forwards it at Layer 2 in the LAN.

2. VXLAN Routing Principle

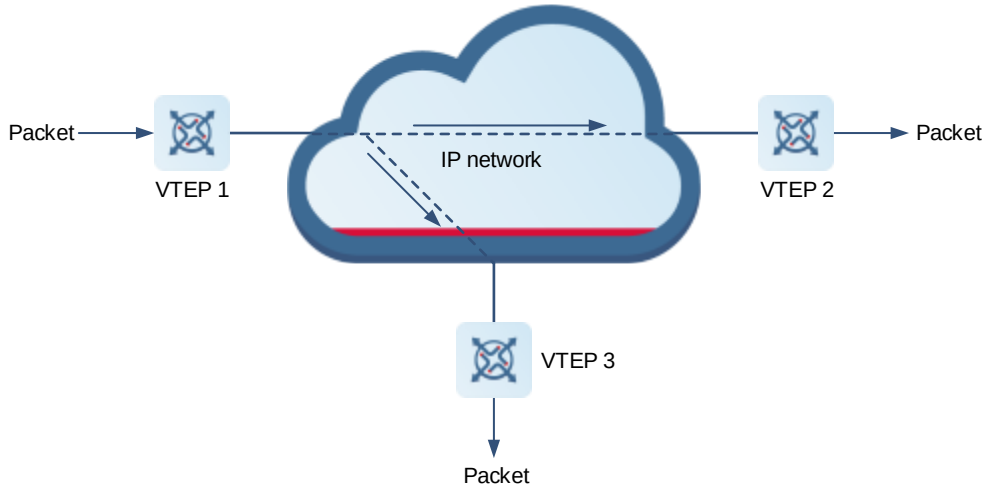
Cross-VXLAN communication is implemented through a VXLAN gateway. See the following figures.

Figure 1-8 VXLAN Routing

(1) To make cross-VXLAN communication, server A first sends a packet to the IP gateway, which is deployed on device 2.

(2) The packet sent by server A is encapsulated by device 1 into a VXLAN packet and then sent to device 2.

(3) After receiving the VXLAN packet, device 2 finds that the inner destination MAC address is not its MAC address and then sends the packet to device 3 after VXLAN routing.



(4) After receiving the packet from device 2, device 3 decapsulates the packet and sends it to server B.

1.2.8 Forwarding Process

1. Packet Flooding Using VXLAN Tunnel Header Replication

A VXLAN uses the tunnel header replication mode to flood broadcast, multicast, and unknown unicast packets. After receiving an Address Resolution Protocol (ARP) request, VTEP 1 encapsulates the ARP request packet into two unicast packets, and forwards the packets to VTEP 2 and VTEP 3, as shown in Figure 1-9.

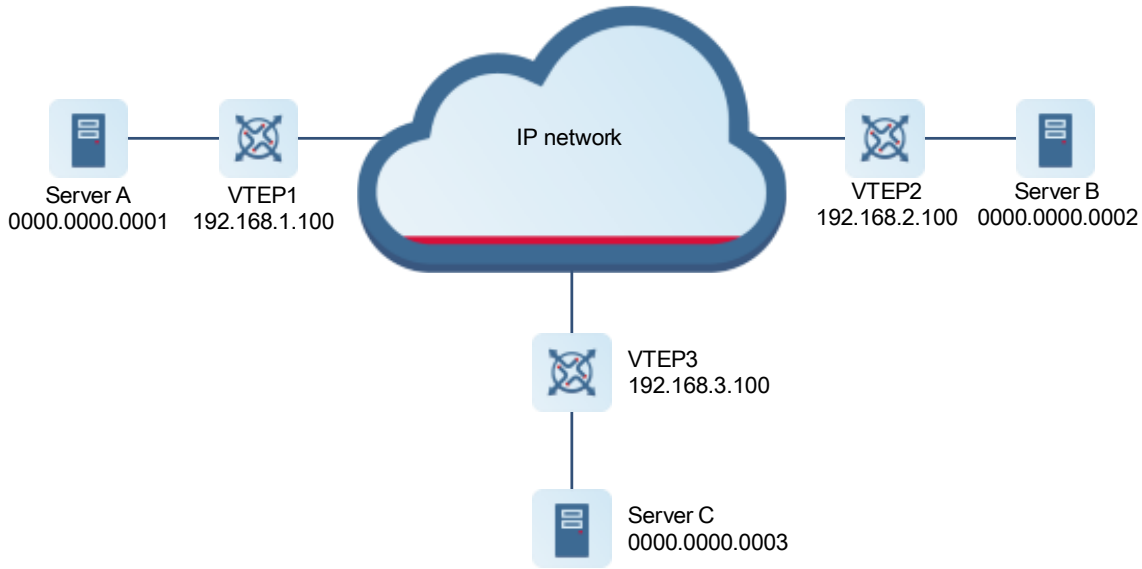


Figure 1-9 Packet Flooding Using VXLAN Tunnel Header Replication

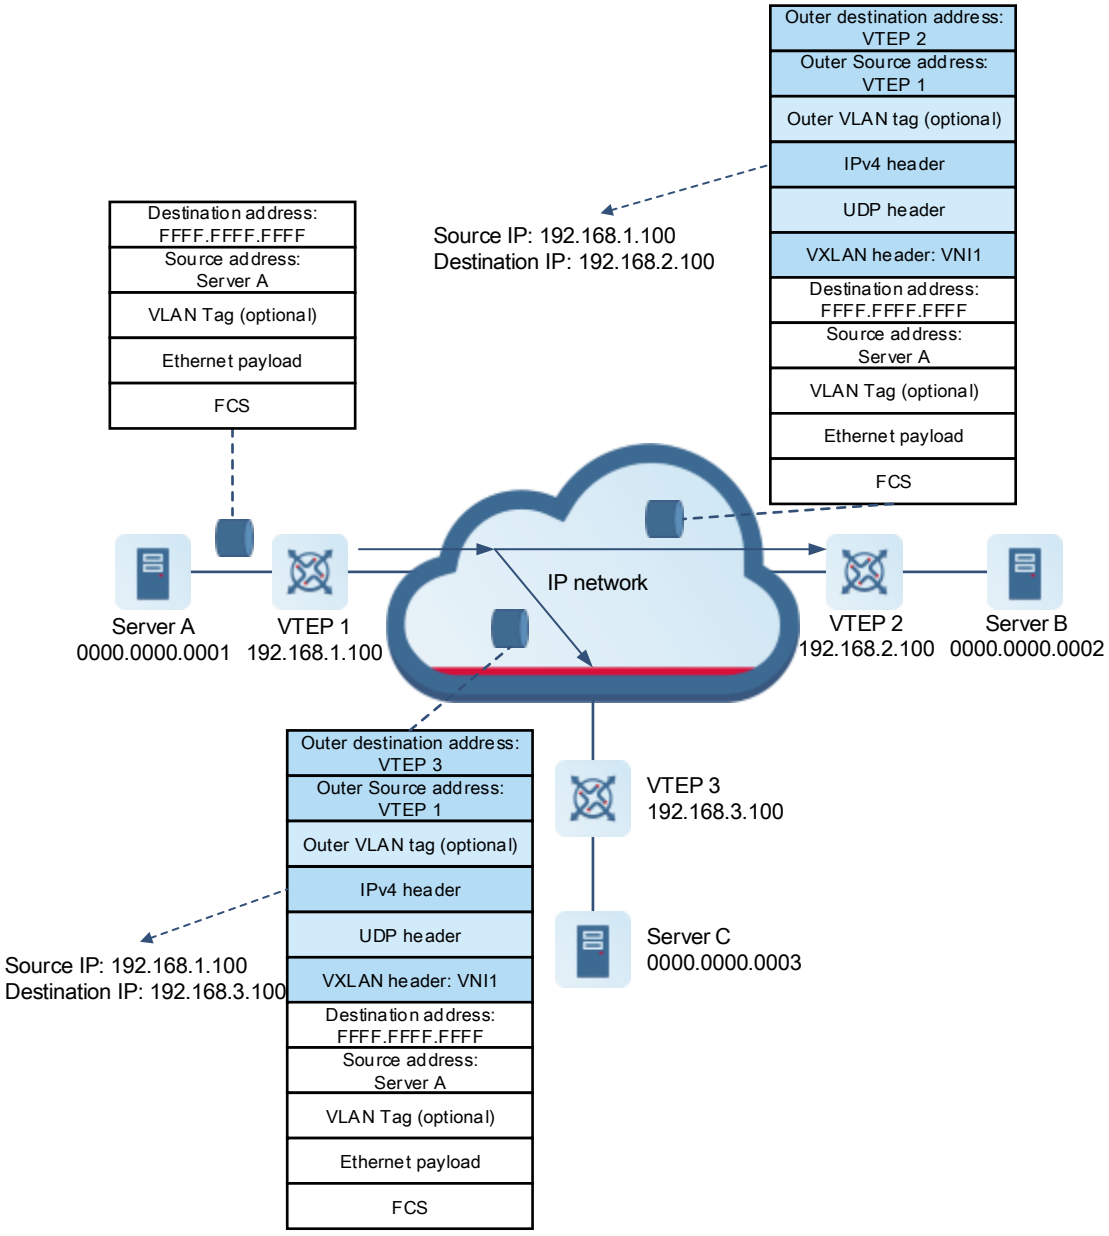
2. VXLAN Layer 2 Forwarding

As shown in Figure 1-10, three servers interconnect to each other at Layer 2 through VXLAN carried over an IP network, and the VXLAN VNI is 100.

Figure 1-10 Topology of VXLAN Layer 2 Forwarding



The following uses the process, in which server A sends an ARP request to server B and server B returns a ARP reply, as an example to illustrate the VXLAN packet forwarding.

Note

The **Next Hop MAC** and **Last Hop MAC** fields mentioned in this chapter refer to the next-hop and last-hop MAC addresses transmitted on the Underlay network. The values of the **Next Hop MAC** and **Last Hop MAC** fields vary with legends.

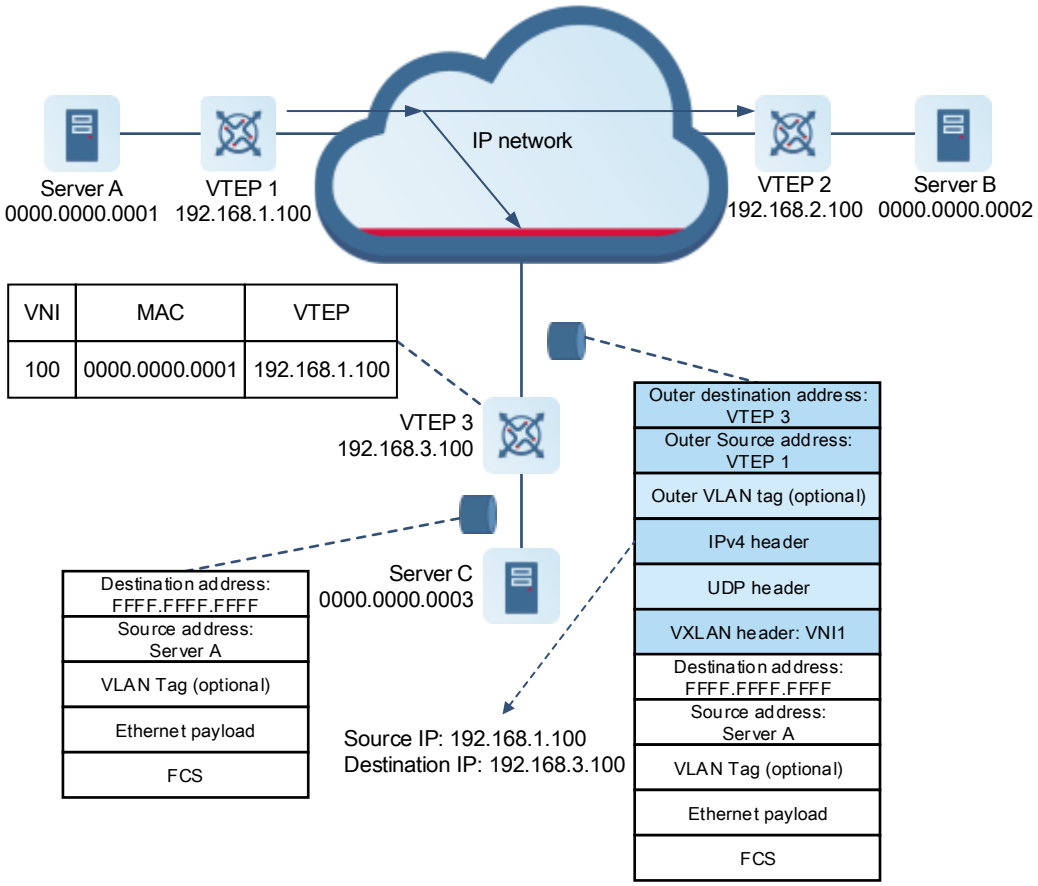


Figure 1-11 Sending an ARP Request from Server A to Server B Through a Static VXLAN Tunnel

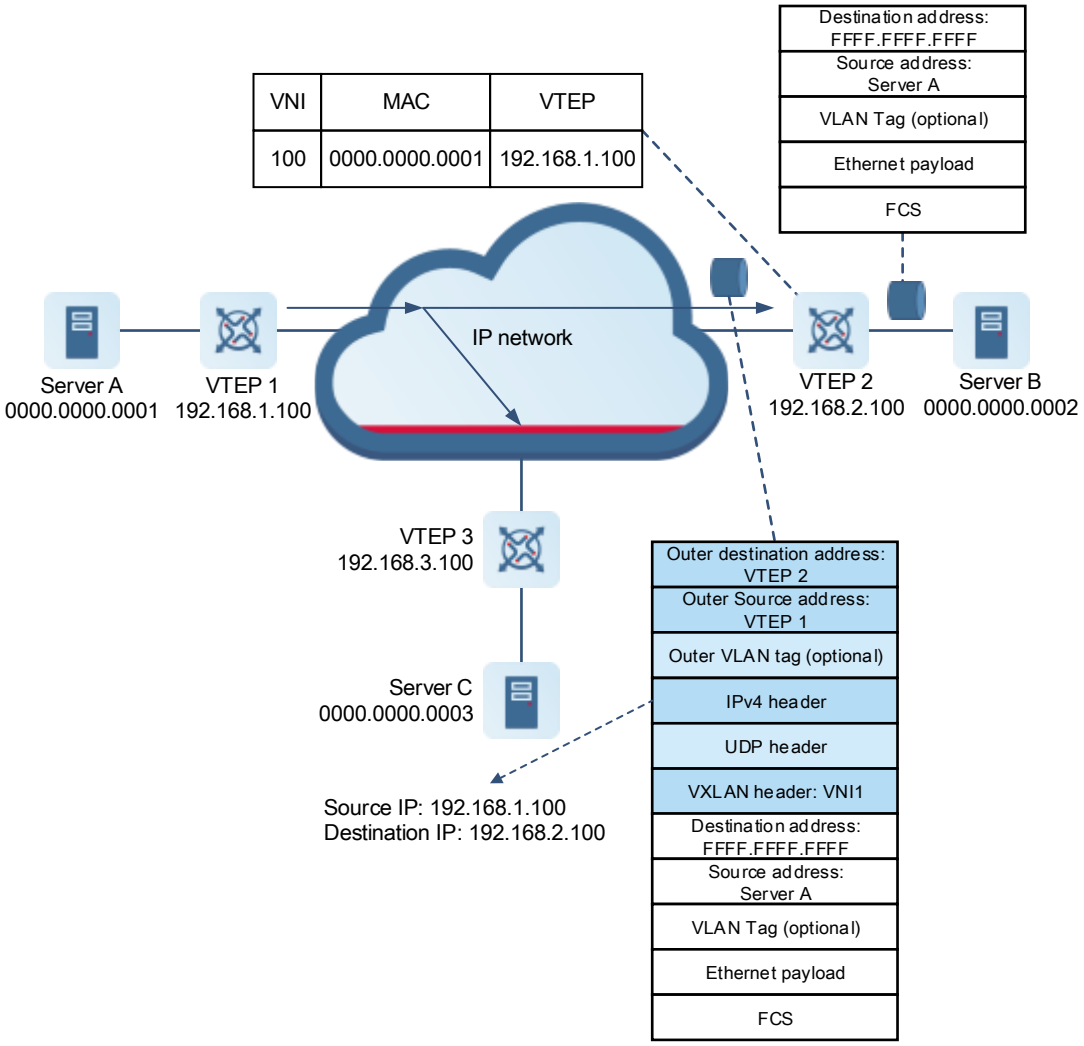
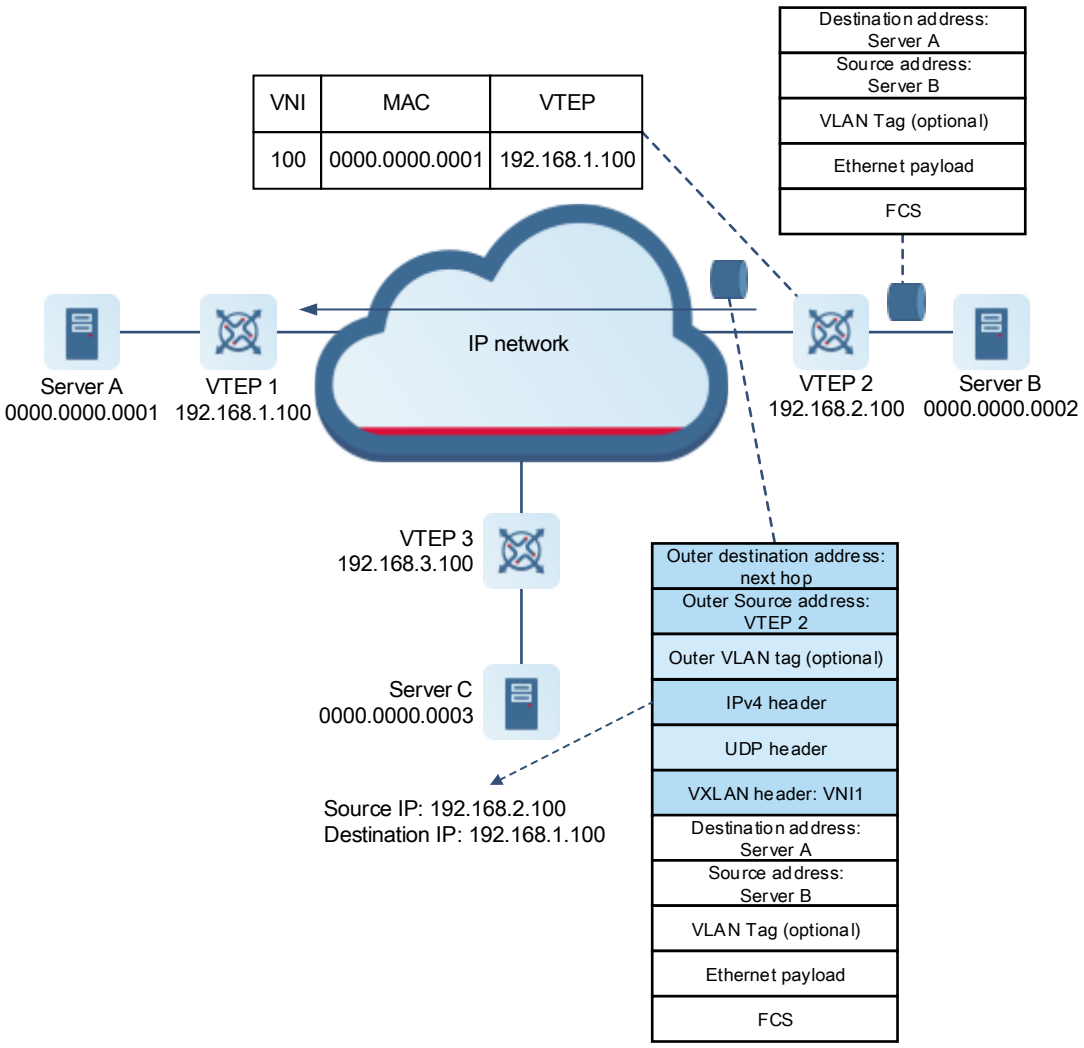
(1) Server A sends an ARP request, which is a broadcast packet. After receiving the ARP request, VTEP 1 (switch) floods the broadcast packet in tunnel header replication mode, encapsulates it into two unicast packets, and sends them to VTEP 2 and VTEP 3 through tunnels.



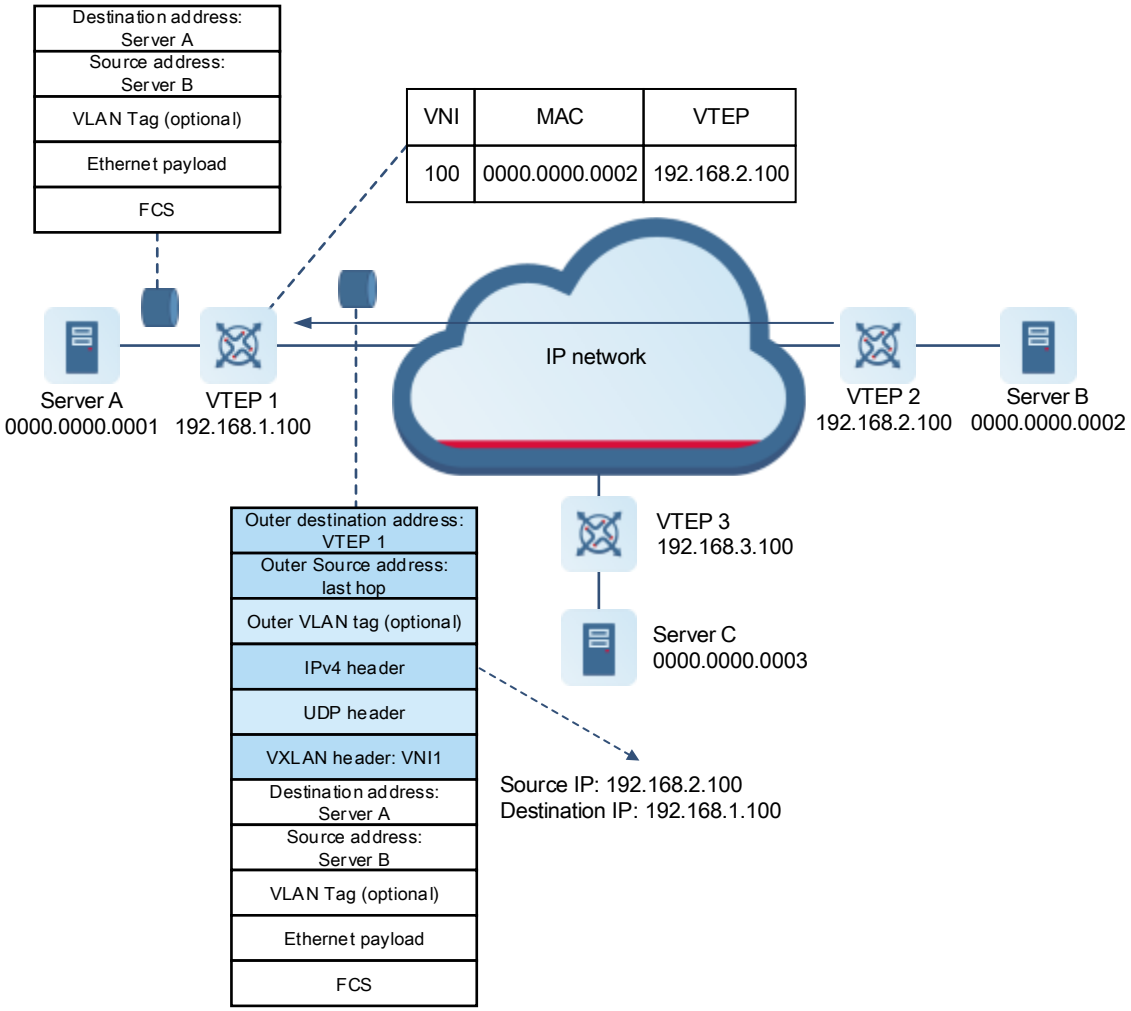
(2) The IP core network forwards the unicast VXLAN packets.

Figure 1-12 VTEP 3 Decapsulating the VXLAN Packet and Performing Address Learning



(3) After receiving the VXLAN packet, VTEP 3 decapsulates it to retrieve the Ethernet packet and performs VXLAN address learning (the VNI is 100, the MAC address is 0000.0000.0001, and the IP address is 192.168.1.100). Then, VTEP 3 floods the decapsulated packet to server C in broadcast mode.

Figure 1-13 VTEP 2 Decapsulating the VXLAN Packet and Performing Address Learning



(4) After receiving the VXLAN packet, VTEP 2 decapsulates it to retrieve the Ethernet packet, learns the address of the Ethernet packet (the VNI is 100, the MAC address is 0000.0000.0001, and the IP address is 192.168.1.100), and forwards the packet. Server B gives a reply after receiving the ARP request.

Figure 1-14 VTEP 2 Searching the Address Table and the Switch Encapsulating the Packet into a Unicast VXLAN Packet

(5) After receiving the ARP reply from server B, VTEP 2 searches the address table and finds that the destination IP address of the outbound interface is 192.168.1.100. Then, the switch encapsulates the packet into a unicast VXLAN packet (the outer source IP address is 192.168.2.100) destined for the switch at 192.168.1.100.

Figure 1-15 VTEP 1 Decapsulating the Received VXLAN Packet and Performing Address Learning

(6) The IP core network forwards the VXLAN packet.

(7) After receiving the VXLAN-encapsulated ARP reply packet from server B, VTEP 1 decapsulates the packet to retrieve an Ethernet packet, performs address learning (VNI is 100, the MAC address is 0000.0000.0002, and the IP address is 192.168.2.100), and forwards the packet. Server A receives the ARP reply.

Note

After obtaining the MAC address of server B, server A interacts with server B in unicast mode. For more information about the interaction process, see the ARP response process of server B.

3. VXLAN Layer 3 Forwarding

To provide Layer 3 services for VMs at a VXLAN site, you are required to deploy a VXLAN gateway in the network so that the VMs at the site can make Layer 3 communication with external networks or VMs in other VXLAN networks through the VXLAN gateway.

Note

The **NH MAC** (**Next Hop MAC**, next-hop MAC address) field mentioned in this chapter refers to the next hop MAC address transmitted on the Underlay network. The value of the **Next Hop MAC** field varies with legends.

- Layer 3 forwarding between users in different VXLANs

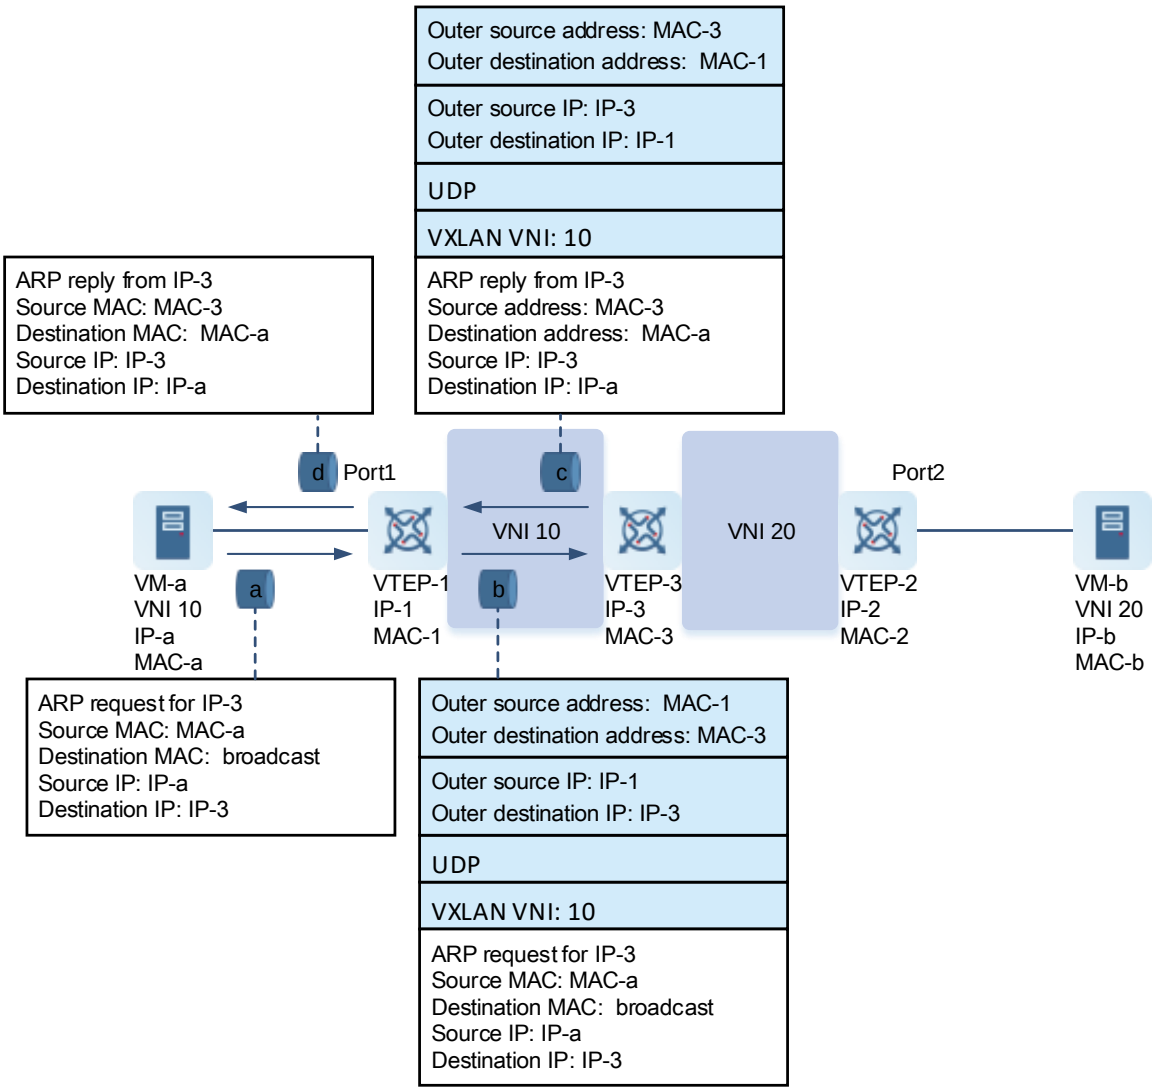
  As shown in Figure 1-16, VTEP-1 and VTEP-2 implement VXLAN Layer 2 forwarding, and VTEP-3 serves as a VXLAN gateway for routing and forwarding. Configure one VNI 10 tunnel on VTEP-1, one VNI 20 tunnel on VTEP-2, and one VNI 10 tunnel and one VNI 20 tunnel on VTEP-3.

  VTEPs completes MAC and ARP information synchronization through EVPN. For existing ARP and MAC entries on each device, see Table 1-1, Table 1-2, and Table 1-3.

Table 1-1 VXLAN Tunnel Information on Devices

Device	VNI	Tunnel	SIP	DIP	Device	VNI	Tunnel	SIP	DIP
VTEP-1	10	Tunnel 3	IP-1	IP-3	VTEP-3	10	Tunnel 1	IP-3	IP-1
VTEP-2	20	Tunnel 3	IP-2	IP-3		20	Tunnel 2	IP-3	IP-2

Table 1-2 VXLAN MAC Entries on Devices



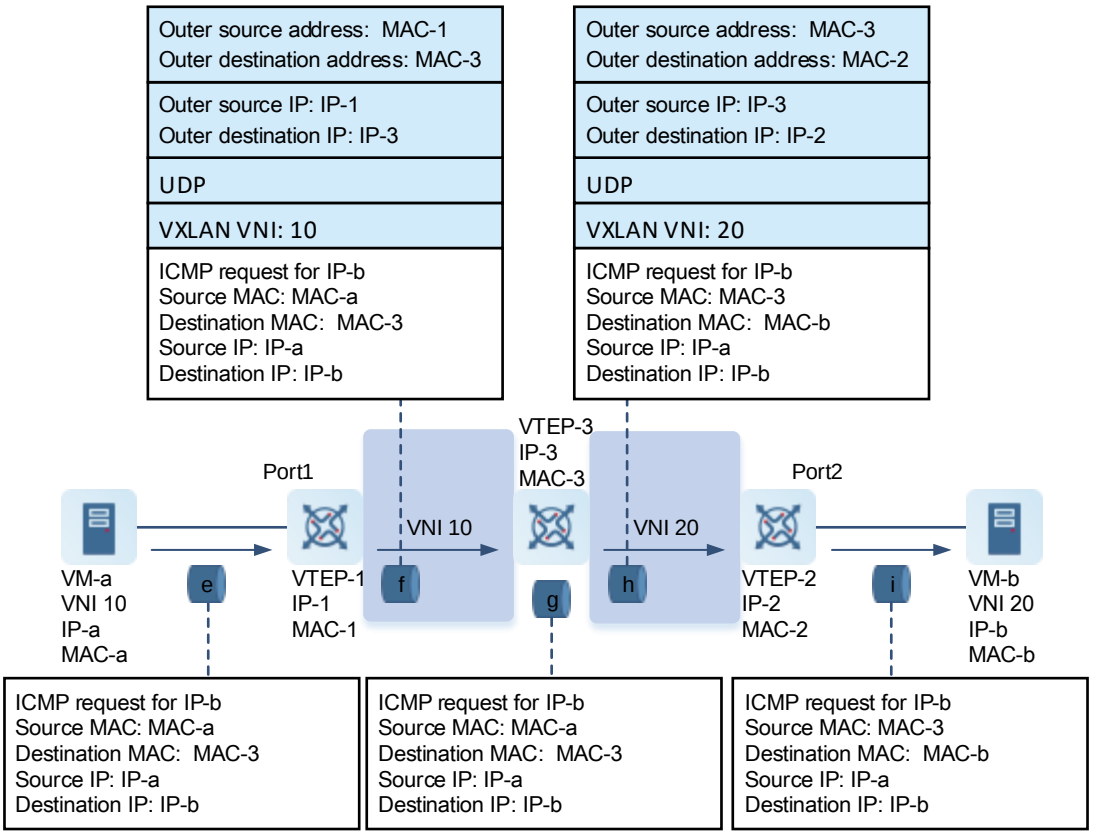
Device	MAC	VNI	Destination	Device	MAC	VNI	Destination
VTEP-1	MAC-a	10	Port1	VTEP-2	MAC-b	20	Port2
	MAC-3	10	Remote IP-3		MAC-3	20	Remote IP-3

Table 1-3 ARP Entries on VTEP-3

IP	VNI	Next Hop	MAC	IP	VNI	Next Hop	MAC
IP-a	10	Remote IP-1	MAC-a	IP-b	20	Remote IP-2	MAC-b

The communication between VM-a and VM-b is illustrated as follows:

Figure 1-16 VM-a Requesting the MAC Address of the Gateway



a VM-a and VM-b belong to different network segments. VM-a broadcasts an ARP packet to request the MAC address of the gateway IP-3.

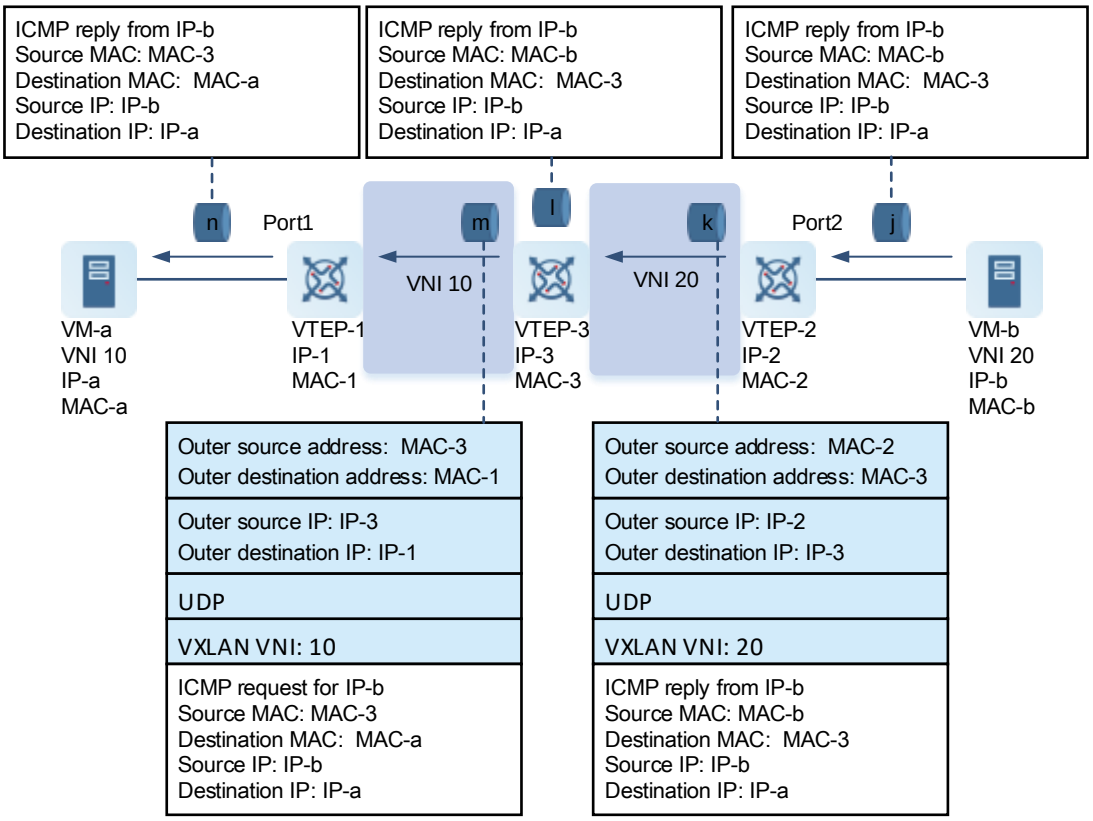
b After receiving the ARP packet from VM-a, VTEP-1 encapsulates the VXLAN header (VNI 10) into the packet and sends the packet to VTEP-3 through a tunnel.

c VTEP-3 decapsulates the packet, finds that VM-a requests the MAC address of IP-3, and returns an ARP reply packet, in which the MAC address (MAC-3) of IP-3 is carried. VTEP-3 also encapsulates the VXLAN header (VNI 10) into the packet before transmitting the packet to VTEP-1.

d After receiving the VXLAN-encapsulated (VNI 10) ARP reply packet, VTEP-1 decapsulates the packet and sends the ARP reply packet to VM-a according to the MAC entry.

Figure 1-17 Forwarding an ICMP Request Between VMs in Different VXLANs

e After learning ARP information, VM-a sends an Internet Control Message Protocol (ICMP) packet to VM-b. Their communication traverses different network segments. Therefore, the destination MAC address of the packet is MAC-3 of the gateway VTEP-3.



f After receiving the ICMP request, VTEP-1 searches the Layer 2 address table and finds that the packet matches an entry of MAC-3 + VNI 10 + egress of remote tunnel IP-3 in the address table. Therefore, VTEP-1 encapsulates the packet into a VXLAN packet and sends it to VTEP-3. The inner packet remains unchanged and the outer destination MAC address refers to the next-hop MAC address that corresponds to the destination IP address IP-3 in the routing table.

g After receiving the encapsulated VXLAN packet, VTEP-3 decapsulates the packet to retrieve the inner packet.

h VTEP-3 is a gateway. The decapsulated inner packet triggers Layer 3 forwarding and matches an entry with the egress of remote tunnel IP-2 in the routing table. VTEP-3 encapsulates the packet into a VXLAN packet and forwards it. The destination MAC address of the inner packet is changed to MAC-b and the outer VNI is VNI 10.

i After receiving the encapsulated VXLAN packet, VTEP-2 decapsulates the packet to retrieve the inner packet, and forwards the packet to VM-b at Layer 2 in unicast mode.

Figure 1-18 Forwarding an ICMP Reply Between VMs in Different VXLANs

j After receiving the ICMP request packet, VM-b judges that the packet is destined for itself and sends an ICMP reply packet.

k After receiving the ICMP reply packet, VTEP-2 encapsulates the packet into a VXLAN packet and forwards it at Layer 2 in unicast mode.

l After receiving the encapsulated VXLAN packet, VTEP-3 decapsulates the packet to retrieve the inner packet.

m VTEP-3 is a gateway. The decapsulated inner packet triggers Layer 3 forwarding and matches an entry with the egress of remote tunnel IP-1 in the routing table. Then, VTEP-3 encapsulates the packet into a VXLAN packet and forwards it. The destination MAC address of the inner packet is changed to MAC-a and the outer VNI is VNI 10.

n After receiving the encapsulated VXLAN packet, VTEP-1 decapsulates the packet to retrieve the inner packet, and forwards the packet to VM-a at Layer 2 in unicast mode. After receiving the packet, VM-a judges that the packet is destined for itself, indicating that the route to VM-b is reachable.

- Communication between a user in a VXLAN and a user outside the VXLAN

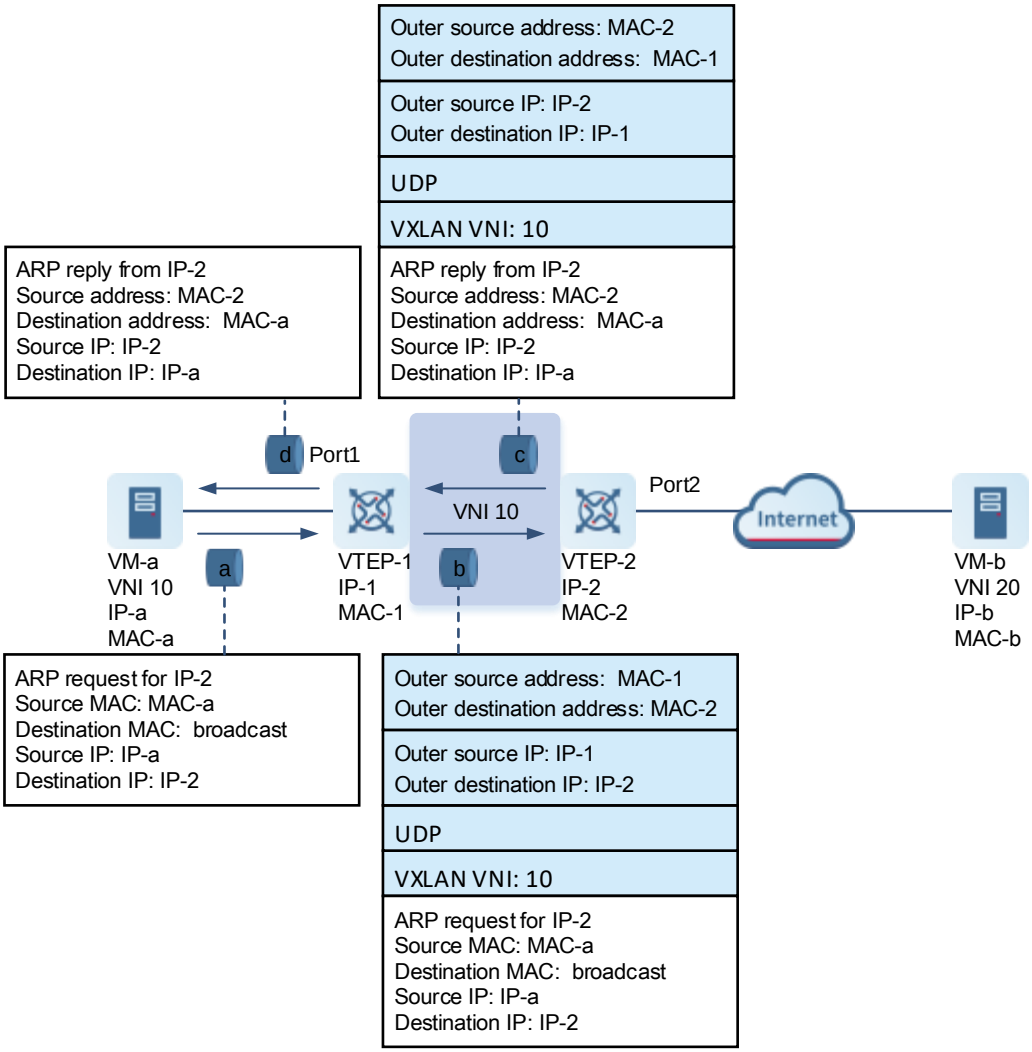
  As shown in Figure 1-19, VTEP-1 implements VXLAN Layer 2 forwarding, VTEP-2 serves as a VXLAN gateway, the external underlay network is connected to the virtualized overlay network through VTEP-2. The overlay network routing table in VTEP-2 is imported into the underlay network routing table so that VTEPs can communicate with each other and forward packets through the overlay network. VTEP-1 establishes one VNI 10 tunnel and VTEP-2 establishes one VNI 10 tunnel.

VTEPs completes MAC and ARP information synchronization through EVPN. For existing ARP and MAC entries on each device, see Table 1-4, Table 1-5, and Table 1-6.

Table 1-4 VXLAN Tunnel Information on Devices

Device	VNI	Tunnel	SIP	DIP	Device	VNI	Tunnel	SIP	DIP
VTEP-1	10	Tunnel 1	IP-1	IP-2	VTEP-2	10	Tunnel 1	IP-2	IP-1

Table 1-5 VXLAN MAC Entries on Devices



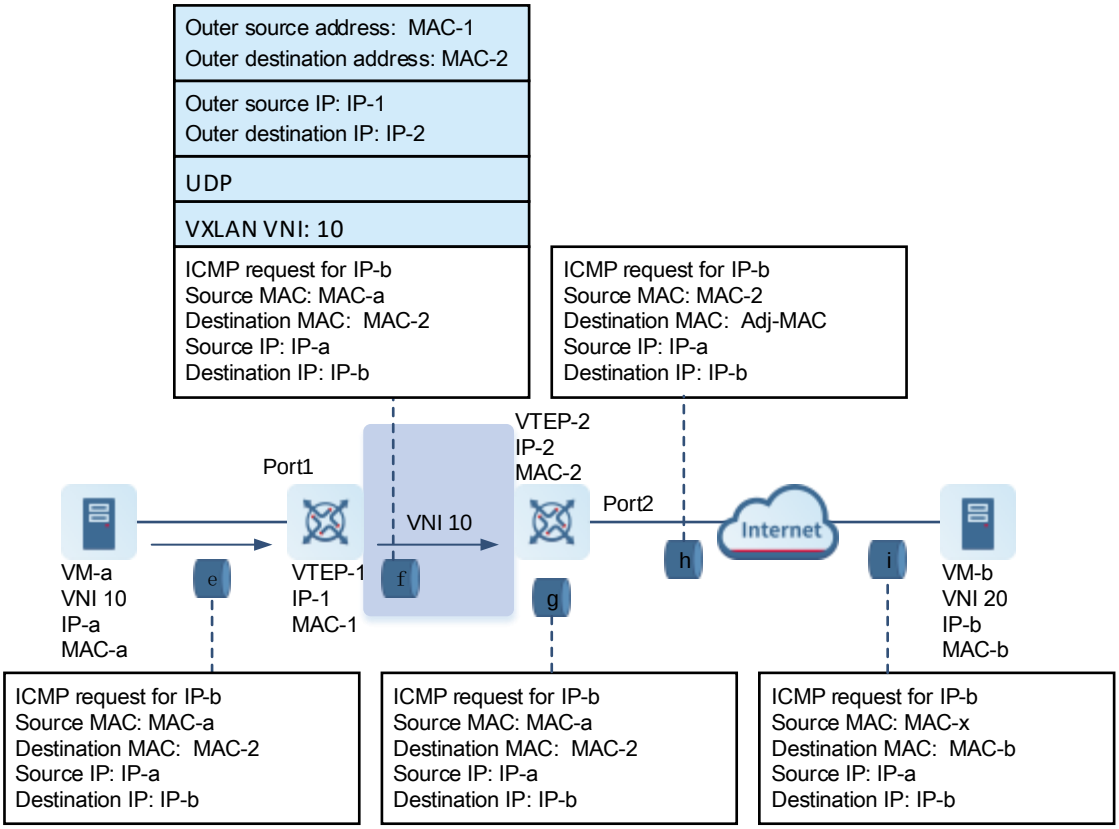
Device	MAC	VNI	Destination	Device	MAC	VNI	Destination
VTEP-1	MAC-a	10	Port1	VTEP-1	MAC-2	10	Remote IP-2

Table 1-6 ARP Entries on VTEP-2

IP	VNI	Next Hop	MAC	IP	VNI	Next Hop	MAC
IP-a	10	Remote IP-1	MAC-a	IP-b	-	Port2	Adj-MAC

The communication between VM-a and VM-b is illustrated as follows:

Figure 1-19 VM-a Requesting the MAC Address of the Gateway (External Network Communication of VXLAN)



a VM-a and VM-b belong to different network segments. VM-a broadcasts an ARP packet to request the MAC address of the gateway IP-2.

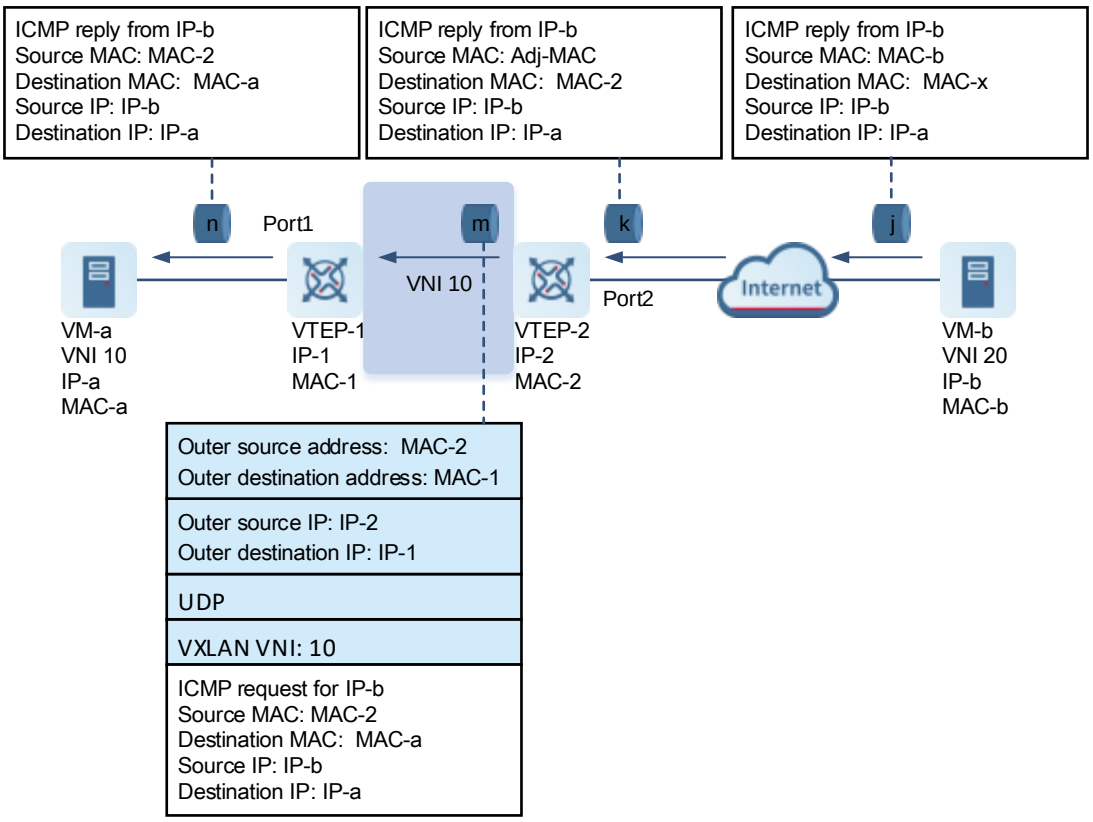
b After receiving the ARP packet from VM-a, VTEP-1 encapsulates the VXLAN header (VNI 10) into the packet and sends the packet to VTEP-2 through a tunnel.

c VTEP-2 decapsulates the packet, finds that VM-a requests the MAC address of IP-2, and returns an ARP reply packet, in which the MAC address (MAC-2) of IP-2 is carried. VTEP-2 also encapsulates the VXLAN header (VNI 10) into the packet before transmitting the packet to VTEP-1.

d After receiving the VXLAN-encapsulated (VNI 10) ARP reply packet, VTEP-1 decapsulates the packet and sends the ARP reply packet to VM-a according to the MAC entry.

Figure 1-20 Forwarding an ICMP Request Between a VM Inside a VXLAN and a VM Outside (External Network Communication of VXLAN)

e After learning ARP information, VM-a sends an ICMP packet to VM-b. Their communication traverses different network segments. Therefore, the destination MAC address of the packet is MAC-2 of the gateway VTEP-2.



f After receiving the ICMP request, VTEP-1 searches the Layer 2 address table and finds that the packet matches an entry of MAC-2 + VNI 10 + egress of remote tunnel IP-2 in the address table. The match triggers the VXLAN packet forwarding mechanism of VTEP-1 to perform Layer 2 unicast forwarding. Therefore, VTEP-1 encapsulates the packet and sends it to VTEP-2. The inner packet remains unchanged and the outer destination MAC address is MAC-2.

g After receiving the VXLAN-encapsulated packet, VTEP-2 decapsulates the packet to retrieve the inner packet.

h VTEP-2 is a gateway. The decapsulated inner packet triggers Layer 3 forwarding and matches an entry with the egress of local port 2 in the routing table. Therefore, VTEP-2 routes and forwards the packet. The destination MAC address of the inner packet is changed to Adj-MAC.

i Then the packet is routed and forwarded as it is in a conventional network. The ICMP request packet reaches VM-b, the source MAC address is MAC-x of the previous-hop device and the destination MAC address is MAC-b.

Figure 1-21 Forwarding an ICMP Reply Between a VM Inside a VXLAN and a VM Outside (External Network Communication of VXLAN)

j After receiving the ICMP request packet, VM-b judges that the packet is destined for itself and sends an ICMP reply packet.

k Then the packet is routed and forwarded as it is in a conventional network. The ICMP reply packet reaches VTEP-2, the source MAC address is Adj-MAC, and the destination MAC address is MAC-2.

l VTEP-2 is a gateway. The received ICMP packet triggers Layer 3 forwarding and the destination IP address matches an entry with the egress of remote tunnel IP-1 in the routing table. Therefore, VTEP-2 encapsulates the packet into a VXLAN packet and forwards it. The destination MAC address of the inner packet is changed to MAC-a and the outer VNI is VNI 10.

m After receiving the encapsulated VXLAN packet, VTEP-1 decapsulates the packet to retrieve the inner packet, and forwards the packet to VM-a at Layer 2 in unicast mode. After receiving the packet, VM-a judges that the packet is destined for itself, indicating that the route to VM-b is reachable.

1.2.9 VXLAN Routing Deployment Model

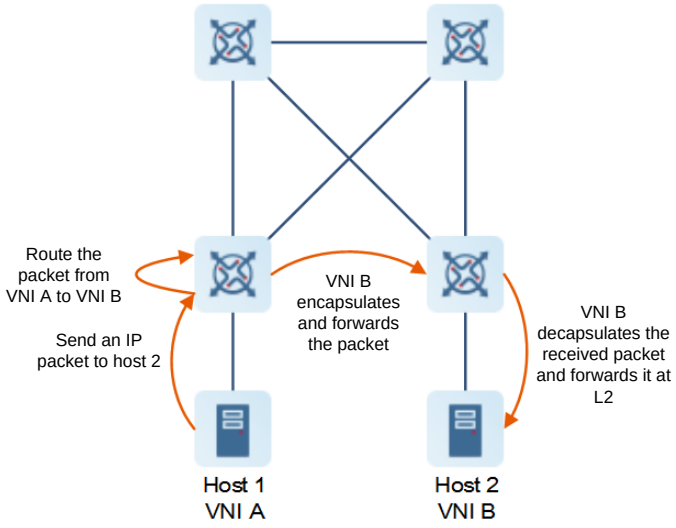
Currently, VXLAN routing can be deployed in two modes: deployed in a centralized VXLAN gateway for small-scale data centers and in distributed VXLAN gateways for large-scale data centers.

1. Centralized Gateway Deployment

All VXLAN gateways in the network are deployed on a core device. Cross-VNI traffic must be forwarded by VXLAN gateways deployed on the core device. The core device needs to learn MAC addresses and ARP

information of all VMs in the topology. All access devices run only the VXLAN bridging function and do not support cross-VNI forwarding of VXLAN traffic.

2. Distributed Gateway Deployment



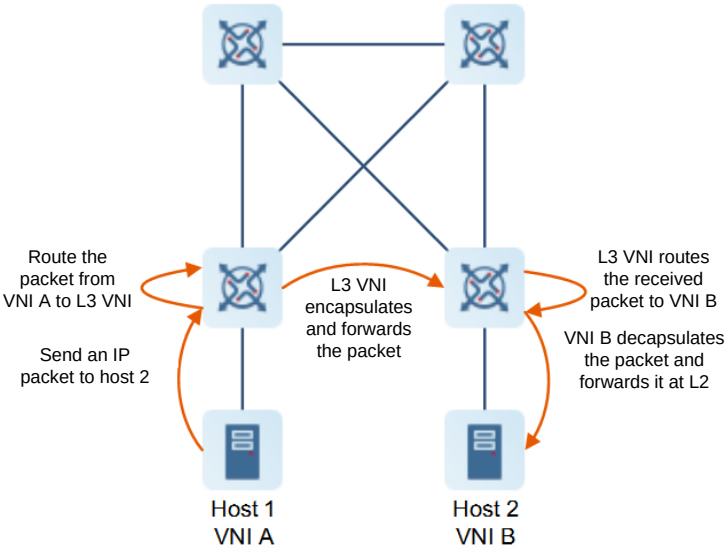
In distributed gateway deployment, each VTEP serves as the gateway of the local VM directly connected to the VTEP. Therefore, cross-VNI traffic does not need to be diverted to the centralized gateway. This deployment mode not only ensures the optimal paths, but also alleviates the traffic forwarding load on the centralized gateway. Distributed gateway deployment can be further classified into distributed asymmetric gateway deployment and distributed symmetric gateway deployment.

- Distributed asymmetric gateway deployment

  During cross-VNI forwarding of data packets, routes are looked up only on the ingress VTEP or egress VTEP. All VNIs must be configured on all VTEPs. Each VTEP can perform both VXLAN bridging and VXLAN routing and forwarding. VTEPs need to learn ARP and address entries of hosts in all VNIs, including non-local hosts. Therefore, the distributed asymmetric gateway deployment has poor scalability.

  The asymmetric gateway deployment provides the optimal path for packet forwarding and supports seamless migration of VMs. However, it is only suitable for small-scale data centers due to poor scalability.

Figure 1-22 Distributed Asymmetric Gateway Deployment



- Distributed symmetric gateway deployment

  The Layer 3 traffic of VMs triggers Layer 3 forwarding on the directly connected VTEPs, which encapsulate packets into VXLAN packets and send the packets to the peer VTEPs. After the peer VTEPs receive and decapsulate the packets, another Layer 3 forwarding is triggered. Compared with asymmetric gateway deployment, this mode is symmetric and called VXLAN symmetric gateway deployment.

  When the distributed symmetric gateway mode is deployed, if intra-VNI forwarding is needed, VXLAN Layer 2 forwarding is performed on the ingress VTEP. If cross-VNI communication is needed, traffic is routed from the ingress VTEP to Layer 3 VNI and then routed by the destination VTEP to the host based on the inner IP address. In this mode, VNI information of the destination host does not need to be configured on the ingress VTEP. Therefore, VTEPs do not need to learn the MAC address and ARP information of the remote hosts, reducing the resource consumption of the MAC address table and ARP adjacency table.

Distributed symmetric gateway deployment reduces the pressure in the capacity of the MAC address table on VTEPs and provides better scalability. However, the seamless VM migration is limited due to the single-side VNI deployment on VTEPs.

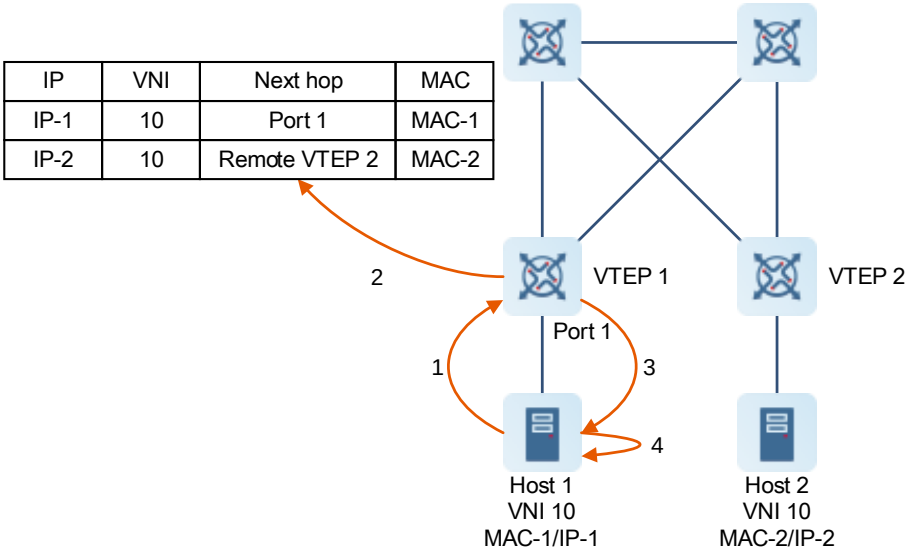
Figure 1-23 Distributed Symmetric Gateway Deployment

1.2.10 Anycast Gateway

Anycast gateway, also called all-active gateway, is a VXLAN gateway deployment mode. In this deployment mode, all gateways are active and any one of them supports cross-VNI routing and forwarding. Generally, the anycast gateway deployment requires two VXLAN gateways. The same virtual MAC address and gateway address must be deployed on the two gateways. Anycast gateway provides different benefits in centralized and distributed gateway deployment scenarios.

In a centralized gateway deployment scenario, the same VXLAN gateway and the same VTEP IP address are configured on multiple core devices to form an all-active anycast gateway based on the equal-cost multi-path routing (ECMP) of the underlay network. When one of the core devices malfunctions, cross-VNI traffic can be balanced to other core devices to prevent service interruption.

In a distributed gateway deployment scenario, if anycast gateway is not deployed, the cross-VNI traffic is forwarded to the only gateway in the network to trigger Layer 3 forwarding even if the VMs are directly connected to VTEPs. As a result, unnecessary detour is caused to most VXLAN packets in the network. After anycast gateway is configured, Layer 3 packets of VMs are directly forwarded by VTEPs directly connected to the VMs according to routes, and traffic forwarding paths in the VXLAN network are optimized. VM migration is also supported in anycast gateway deployment mode.



1.2.11 ARP/ND Flood Suppression

ARP/Neighbor Discovery (ND) flood suppression reduces broadcast traffic in the network by maintaining the ARP/ND cache table in a VNI and enabling VTEPs to respond to ARP/ND requests as a proxy. After ARP/ND flood suppression is enabled, a VTEP maintains the ARP/ND cache table in the VNI. When a host sends an ARP/neighbor solicitation (NS) request, the VTEP directly connected to the host intercepts the ARP/NS request, and responds to the ARP/NS request as a proxy or floods the request to other VTEPs. Dumb terminals (that do

not send any traffic before receiving a request) may exist in a network. If a VTEP does not have ARP/ND information of a dumb terminal (serving as a destination host), the ARP/NS request needs to be flooded to other VTEPs.

Most terminals send a Gratuitous Address Resolution Protocol (GARP), Reverse Address Resolution Protocol (RARP), or NS message upon going online. VTEPs directly connected to the terminals can immediately learn their MAC and IP addresses and spread the information to other VTEPs. Therefore, ARP suppression can reduce flood traffic caused by terminal ARP/ND learning. The following uses ARP suppression as an example to illustrate the flood suppression process.

Figure 1-24 ARP Suppression

(1) Host 1 knows that the IP address of host 2 is IP-2 and sends an ARP request to request the MAC address of host 2.

(2) After receiving the ARP request, VTEP 1 queries the ARP cache table of VNI 10 and finds that the MAC entry of host 2 exists and the MAC address of host 2 is MAC-2.

(3) VTEP 1 sends an ARP reply to host 1, which carries the MAC address (MAC-2) of host 2.

(4) Host 1 receives the ARP reply packet and establishes the mapping between IP-2 and MAC-2.

1.3 Protocols and Standards

- RFC 7348: Virtual eXtensible Local Area Network

2 Configuring VXLAN Basic Features

2.1 Overview

VXLAN supports centralized networking and distributed networking based on the VXLAN routing deployment mode. Centralized networking is classified into static tunnel networking and dynamic tunnel networking,

depending on the tunnel creation mode. Distributed networking is further classified into symmetric networking and asymmetric networking based on whether symmetric routing is adopted. The four networking modes above are the most basic VXLAN networking modes.

2.1.1 Centralized VXLAN Networking Using Static Tunnels

Centralized VXLAN networking using static tunnels is applicable to small- and medium-sized data centers:

- In a centralized networking scenario, all traffic must pass through the centralized gateway, and the core device needs to learn the MAC addresses and ARP information of all VMs in the topology. Therefore, the network size is limited by the core device.
- Tunnels are created statically. Configuration delivery or manual configuration is required for the establishment of each tunnel. Some routes and flow tables also need to be manually delivered. Once the network is oversized, the configuration workload increases sharply, which brings difficulties in network management and planning.

In this networking mode, VXLAN Layer 2 functions need to be configured on access devices to connect VMs to the VXLAN network, and VXLAN Layer 3 functions need to be configured on core devices to provide the VXLAN routing function and implement cross-VXLAN communication. VXLAN tunnels are generated via static configuration. VXLAN configurations can be delivered by the software-defined networking (SDN) controller through communication mechanisms such as NETCONF or manually completed on the command line interface (CLI).

Host routes and VXLAN forwarding flow tables can be delivered by the SDN controller, or routes and entries can be generated via automatic learning. When the SDN controller malfunctions, the automatic learning function ensures that the VXLAN works normally.

2.1.2 Centralized VXLAN Networking Using Dynamic Tunnels

Centralized VXLAN networking using dynamic tunnels is applicable to small- and medium-sized data centers. In a centralized networking scenario, all traffic must pass through the centralized gateway, and the core device needs to learn the MAC addresses and ARP information of all VMs in the topology. Therefore, the network size is limited by the core device.

In this networking mode, VXLAN Layer 2 functions need to be configured on access devices to connect VMs to the VXLAN network, and VXLAN Layer 3 functions need to be configured on core devices to provide the VXLAN routing function and implement cross-VXLAN communication. The EVPN control plane learning function needs to be enabled on access devices and core devices. They accomplish VXLAN tunnel learning, MAC address learning, and route learning via the control plane protocol, as well as VXLAN bridging and VXLAN routing to implement data communication between VXLANs and between a VXLAN and an external network.

2.1.3 Distributed Asymmetric VXLAN Networking

The distributed asymmetric VXLAN networking is applicable to small- and medium-sized data centers. This networking mode is no longer limited by the performance of the core device but it is still inapplicable to large-scale data centers. The reasons are that all VNIs need to be configured on each access device and the devices need to learn ARP and address entries of all hosts.

In this networking mode, VXLAN Layer 2 and Layer 3 functions need to be configured on access devices, to enable VMs to connect to the VXLAN network and provide the VXLAN routing function. The same overlay router gateway must be configured on all access devices. The EVPN control plane learning function needs to

be enabled on access devices. They accomplish VXLAN tunnel learning, MAC address learning, and route learning via the control plane protocol, as well as VXLAN bridging and VXLAN routing to implement data communication between VXLANs and between a VXLAN and an external network.

2.1.4 Distributed Symmetric VXLAN Networking

The distributed symmetric VXLAN networking is applicable to large-sized data centers. In symmetric networking, VNIs do not need to be configured on access devices, and they do not need to learn ARP and address entries of all hosts. Therefore, symmetric VXLAN networking has better scalability.

As in distributed asymmetric networking, VXLAN Layer 2 and Layer 3 functions and EVPN control plane learning need to be configured on access devices. Different overlay router gateways can be configured on access devices, but a unified Layer 3 VNI needs to be configured for Layer 3 traffic forwarding.

2.2 Restrictions and Guidelines

2.2.1 Centralized VXLAN Networking Using Static Tunnels

- VXLAN configurations can be delivered by the SDN controller through communication mechanisms such as NETCONF, or manually completed on the CLI. Only configuration delivery from the SDN controller is recommended in normal cases.
- The VXLAN requires the support from existing unicast routes in the network. Therefore, devices in the network must ensure the connectivity of the IP network through other routing protocols such as the Open Shortest Path First (OSPF).
- On the centralized anycast gateway, you need to add the anycast IP address of gateways to different routing domains to prevent IP address conflict.

2.2.2 Centralized VXLAN Networking Using Dynamic Tunnels

- The VXLAN requires the support from existing unicast routes in the network. Therefore, devices in the network must ensure the connectivity of the IP network through other routing protocols such as OSPF.
- The VXLAN completes VXLAN tunnel learning, MAC address learning, and route learning through the MP-BGP-EVPN protocol. Therefore, BGP configuration must be completed on VTEPs.

2.2.3 Distributed Asymmetric VXLAN Networking

- Layer 3 traffic is routed and forwarded once by the VXLAN gateway only on the ingress VTEP, and the egress VTEP forwards only Layer 2 traffic.
- The gateways of all VXLANs must be configured on each VTEP.
- VTEPs establish a BGP neighbor relationship and synchronize MAC address and ARP information through BGP-EVPN type-2 routes.
- VTEPs do not learn ARP information and MAC addresses from packets received from tunnels by default.

2.2.4 Distributed Symmetric VXLAN Networking

- Layer 3 forwarding is required on both the ingress VTEP and egress VTEP. Therefore, the overlay router interface of the VXLAN distributed gateway and the overlay router interface of the Layer 3 VNI need to be configured on all ingress VTEPs and egress VTEPs.
- Only one symmetric instance is allowed in a virtual routing and forwarding (VRF) instance.

2.3 Configuration Task Summary

2.3.1 Centralized VXLAN Networking Using Static Tunnels

The configuration of the centralized VXLAN networking using static tunnels includes the following tasks:

(1) Configuring a VXLAN Routed

(2) Configuring a Static Tunnel

(3) Configuring a VXLAN

(4) (Optional) Configuring an EVPN

a Configuring a BGP EVPN

b Configuring an EVI

(5) (Optional) Configuring an Anycast Gateway

(6) (Optional) Enabling the Anycast Gateway Synchronization Function

2.3.2 Centralized VXLAN Networking Using Dynamic Tunnels

The configuration of the centralized VXLAN networking using dynamic tunnels includes the following tasks:

(1) Configuring a VXLAN Routed

(2) Configuring a VXLAN

(3) Configuring a VTEP

(4) Configuring an EVPN

a Configuring a BGP EVPN

b Configuring an EVI

(5) Enabling ARP/ND Automatic Learning

(6) (Optional) Configuring an Anycast Gateway

2.3.3 Distributed Asymmetric VXLAN Networking

The configuration of the distributed asymmetric VXLAN networking includes the following tasks:

(1) Configuring a VXLAN Routed

(2) Configuring a VXLAN

(3) Configuring a VTEP

(4) Configuring an EVPN

a Configuring a BGP EVPN

b Configuring an EVI

(5) Configuring an Anycast Gateway

2.3.4 Distributed Symmetric VXLAN Networking

The configuration of the distributed symmetric VXLAN networking includes the following tasks:

(1) Configuring a VXLAN Routed

(2) Configuring a VXLAN

(3) Configuring a VTEP

(4) Configuring an EVPN

a Configuring a BGP EVPN

b Configuring an EVI

(5) Configuring an Anycast Gateway

(6) Configuring a Symmetric VXLAN

2.4 Configuring a VXLAN Routed Interface

2.4.1 Overview

This section describes how to create an overlay router interface and configure the VXLAN gateway IP address.

2.4.2 Restrictions and Guidelines

The configuration is required on the VXLAN gateway. The overlay router interface and gateway IP address are configured on the core device in a centralized scenario, and on access devices in a distributed scenario.

2.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create an overlay router interface and enter the overlay router interface configuration mode.

interface overlayrouter *interface-number*

(4) Configure an IP address for the overlay router interface.

(IPv4 network)

ip address *ipv4-address mask*

No IPv4 address is configured for an interface by default.

(IPv6 network)

ipv6 address *ipv6-address mask*

No IPv6 address is configured for an interface by default.

2.5 Configuring a Static Tunnel

2.5.1 Overview

This section describes how to create a VXLAN tunnel interface and configure the source and destination IP addresses for the interface so that a VXLAN static tunnel is established between devices.

2.5.2 Restrictions and Guidelines

- The source and destination addresses of a VXLAN tunnel interface must belong to the same IP protocol family.

- In scenarios of centralized VXLAN networking using static tunnels, the configuration is required on VXLAN access devices and VXLAN gateways.

2.5.3 Prerequisites

Before configuring a VXLAN tunnel interface, ensure that the route between devices, where the source and destination IP addresses of the VXLAN tunnel interface reside, is reachable. Otherwise, a tunnel cannot be established.

2.5.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a VXLAN tunnel interface and enter the VXLAN tunnel interface configuration mode.

interface overlaytunnel *interface-number*

(4) Configure a source address for the VXLAN tunnel.

overlaytunnel source *ipv4-address*

No source (local) IP address is configured for a VXLAN tunnel by default.

(5) Configure a destination address for the VXLAN tunnel.

overlaytunnel destination *ipv4-address*

No destination IP address is configured for a VXLAN tunnel by default.

2.6 Configuring a VXLAN Instance

2.6.1 Overview

This section describes how to create a VXLAN instance, and configure an overlay router interface, VXLAN static tunnel, and associated VLAN for the VXLAN instance.

2.6.2 Restrictions and Guidelines

- The **tunnel-interface** command must be associated with a created VXLAN tunnel interface.
- The **router-interface** command must be associated with a created overlay router interface.
- One overlay router interface can associate with only one VXLAN.
- Different VXLAN instances cannot be associated with the same VLAN.
- After a VLAN is associated with a VXLAN, all packets of the VLAN will be encapsulated into VXLAN packets. Therefore, an SVI cannot be used as the IP gateway of the VLAN on the device.
- In any VXLAN networking scenarios, the configuration is required on VXLAN access devices and VXLAN gateways.

2.6.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a VLAN and enter the VLAN configuration mode.

vlan *vlan-id*

Only one common static VLAN (VLAN 1) exists by default.

(4) Return to the global configuration mode.

exit

(5) Create a VXLAN instance and enter the VXLAN configuration mode.

vxlan *vni-number*

No VXLAN instance is configured by default.

(6) All the configuration tasks below are optional. Select one of the tasks for configuration based on the VXLAN networking mode and device role.

- Associate the VXLAN instance with an overlay router interface.

  router-interface overlayrouter *interface-number*

  The configuration is required on the VXLAN gateway.

  No VXLAN routing interface is configured by default.

- Associate the VXLAN instance with a VXLAN tunnel.

  tunnel-interface overlaytunnel *interface-number*

  In a scenario, in which a static tunnel is configured, the configuration is required on devices at both ends of the static tunnel.

  No VXLAN instance is configured to associate with a tunnel by default.

- Associate the VXLAN instance with a VLAN.

  extend-vlan *vlan-list*

  The configuration is required on VXLAN access devices.

  The VLAN to be associated with a VXLAN instance is not configured by default.

2.7 Configuring a VTEP

2.7.1 Overview

This section describes how to configure a VTEP.

2.7.2 Restrictions and Guidelines

- In scenarios of centralized VXLAN networking using dynamic tunnels, distributed asymmetric VXLAN networking, and distributed symmetric VXLAN networking, the configuration is required on VXLAN access devices and VXLAN gateways.
- You can specify an IPv4 address for a VTEP in either of the following ways. One VTEP can associate with one IPv4 address in only one way:
  - Associating the VTEP with a loopback interface to use the interface's IPv4 address

- Specifying an IPv4 address directly

- One VTEP can associate with only one IPv4 address.
- If the specified Layer 3 outbound interface is an overlay router interface e during static route configuration, the next-hop IP address cannot be set to the associated IP address of a VTEP.

2.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the VTEP configuration mode.

vtep

(4) Configure an IP address for the VTEP by configuring any of the following tasks:

- Bind a loopback interface to the VTEP.

  source loopback *loopback-port-id*

  No loopback interface is bound to a VTEP by default.

- Bind an IPv4 address to the VTEP.

  source ipv4 *ipv4-address*

  No IPv4 address is configured for a VTEP by default.

2.8 Configuring an EVPN

2.8.1 Overview

The VXLAN implementation involves only the data plane but no control plane. Therefore, when no control plane is available, the establishment of a VXLAN tunnel and remote device address learning can be carried out only through the data plane flooding. This severely affects the normal forwarding of service traffic in the data center network. To solve this problem, VXLAN uses an EVPN as the control plane. After an EVPN is configured, the VXLAN can establish and maintain VXLAN tunnels and synchronize address information of the remote device through the EVPN.

Configuring an EVPN includes two parts:

- Create and configure a BGP EVPN peer relationship.
- Create and configure an EVAN instance (EVI).

2.8.2 Restrictions and Guidelines

- In scenarios of centralized VXLAN networking using SDN static tunnels, if the VXLAN anycast gateway synchronization function needs to be enabled, the configuration is required on VXLAN gateways.
- In scenarios of centralized VXLAN networking using dynamic tunnels, distributed asymmetric VXLAN networking, and distributed symmetric VXLAN networking, the configuration is required on VXLAN access devices and VXLAN gateways.

2.8.3 Configuration Tasks

EVPN configuration includes the following tasks:

(1) Configuring a BGP EVPN

(2) Configuring an EVI

2.8.4 Configuring a BGP EVPN

1. Prerequisites

Ensure that routes between devices are reachable before configuration.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a BGP instance and enter the BGP configuration mode.

router-protocol bgp *as-number*

BGP is disabled by default.

(4) Configure a BGP peer (group).

peer { *neighbor-address* | *peer-group-name* } **remote-as** *as-number*

A BGP peer is disabled by default.

(5) Configure a network interface to be used for establishing a BGP connection between IBGP peers.

peer { *neighbor-address* | *peer-group-name* } **update-source** { *interface-type interface-number* | *address* }

The optimal local interface is used as the output interface by default.

(6) Configure BGP neighbors to exchange L2VPN EVPN information and enter the EVPN address family configuration mode.

address-family-mode l2vpn evpn

The L2VPN address family is disabled by default.

(7) Activate neighbors or peer groups in current address mode.

peer { *neighbor-address* | *peer-group-name* } **activate** { **ipv4** | **ipv6** }

Neighbors or peer groups are activated in address family IPv4 unicast mode by default.

2.8.5 Configuring an EVI

1. Prerequisites

Ensure that routes between devices are reachable before configuration.

2. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the EVPN configuration mode.

evpn

(4) Create an EVI and enter the VNI configuration mode.

vni *vni-id*

No EVI is configured by default.

(5) Define a route distinguisher (RD) for the EVI.

rd { **auto** | *rd-value* }

No RD is configured by default.

(6) Define the route target (RT) attribute for the EVI.

route-target { **import** | **export** | **both** } { **auto** | *rt-value* }

No RT is configured by default.

(7) (Optional) Configure a routing policy rule for the local device to distribute EVPN routes to the remote device.

export map *routemap-name*

No routing policy rule is configured for the local device to distribute EVPN routes to the remote device by default.

(8) (Optional) Configure a routing policy rule of importing remote EVPN routes to the local VNI.

import map *routemap-name*

No routing policy rule is configured for importing remote EVPN routes to the local VNI by default.

2.9 Enabling ARP/ND Automatic Learning

2.9.1 Overview

After remote ARP/ND learning is configured, the switch learns ARP/ND entries from VXLAN-encapsulated ARP/ND packets received from VXLAN tunnels.

2.9.2 Restrictions and Guidelines

- You are advised to enable this function only on gateways in the centralized VXLAN topology. This function is not recommended in other scenarios.
- This function takes effect only on dynamic tunnels and is invalid to static tunnels. The device learns ARP entries from VXLAN packets received from static tunnels by default.

2.9.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the VTEP configuration mode.

vtep

(4) Enable ARP/ND automatic learning.

(IPv4 network)

remote arp learn enable

The global remote ARP packet learning function is disabled by default.

(IPv6 network)

remote nd learn enable

The global remote IPv6 ND entry learning function is disabled by default.

2.10 Configuring an Anycast Gateway

2.10.1 Overview

This section describes how to configure VXLAN gateways as an anycast gateway.

2.10.2 Restrictions and Guidelines

- After the anycast attribute is configured, the device uses the global virtual anycast MAC address as the gateway MAC address.
- When multiple VTEPs are virtualized into one logical VTEP, the virtual anycast MAC address must be the same throughout the network. The anycast MAC address cannot be set to 0000.0000.0000, multicast MAC address, local MAC address, or MAC addresses of other VXLAN devices in the network, to ensure function availability.
- The anycast gateway IP address must be the same in the same VXLAN instance.
- If the device supports a network virtualization edge (NVE) interface, this command will associate with the NVE interface. When the corresponding NVE interface is deleted or configured to work in default state, the configuration of this command will be deleted accordingly.
- In centralized VXLAN networking scenarios, you can configure the settings based on the convergence requirements of the actual network. If a high network convergence requirement is raised, you can configure the settings on the VXLAN gateway.
- In distributed VXLAN networking scenarios, the configuration is required on VXLAN gateways.
- When a VXLAN is configured on the multichassis link aggregation group (M-LAG) system, the VXLAN gateway must be configured as the anycast gateway.

2.10.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure an anycast MAC address.

fabric anycast-gateway-mac *mac-address*

No global anycast virtual MAC address is configured by default.

The configuration is required on the centralized anycast gateway.

(4) Enter the overlay router interface configuration mode.

interface overlayrouter *interface-number*

(5) Configure the anycast attribute for the overlay router interface.

anycast-gateway

No anycast attribute is configured for the overlay router interface by default.

2.11 Enabling the Anycast Gateway Synchronization Function

2.11.1 Restrictions and Guidelines

- If a static tunnel is utilized to deploy the VXLAN centralized anycast gateway, you can use the VXLAN anycast gateway synchronization function to synchronize ARP, IPv6 ND, and MAC entries on all gateways, on which the static tunnel is configured.
- After VXLAN anycast gateway synchronization is enabled, the MAC, ARP, and IPv6 ND entries with the egress of a static tunnel are synchronized outward, and MAC and ARP entries that are synchronized from other devices and have the egress of the static tunnel also take effect.
- The gateway synchronization function can be enabled only on the anycast gateway. It does not need to be enabled on VXLAN access devices.
- To enable the gateway synchronization function on the anycast gateway, ensure that the function is enabled on each physical gateway. Otherwise, entry synchronization may be omitted, affecting the normal operation of the gateway.

2.11.2 Prerequisites

Before configuring synchronization on the anycast gateway, perform the following operations on the anycast gateway:

- Create a BGP instance and configure its peers. Configure the network interface used for establishing BGP connections and configure BGP neighbors to exchange L2VPN EVPN information.
- Create an EVI, and configure the VNI ID, EVI RD and RT attributes.

2.11.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the VTEP configuration mode.

vtep

(4) Enable VXLAN all-active gateway synchronization.

vxlan gateway synchronize

No VXLAN all-active gateway synchronization is configured by default.

The interval for configuring the **vxlan gateway synchronize** command consecutively should be greater than 10s. Otherwise, the configuration will fail.

(5) Return to the global configuration mode.

exit

(6) Enter the VXLAN tunnel interface configuration mode.

interface overlaytunnel *interface-number*

(7) (Optional) Enable the function of synchronizing MAC entries with the egress of static tunnels to the remote VTEP.

evpn mac advertise enable

The function of synchronizing MAC entries with the egress of static tunnels to the remote VTEP is disabled by default.

(8) (Optional) Enable the function of synchronizing ARP/ND entries with the egress of static tunnels to the remote VTEP.

evpn mac-ip advertise enable

The function of synchronizing ARP/ND entries with the egress of static tunnels to the remote VTEP is disabled by default.

2.12 Configuring a Symmetric VXLAN

2.12.1 Overview

This section describes how to configure the symmetric attribute for a VXLAN instance. VXLAN Layer 3 traffic of the VRF instance where a symmetric overlay router interface resides is forwarded by the VXLAN routed interface associated with the instance.

2.12.2 Restrictions and Guidelines

- Symmetric instances need to be configured only in symmetric scenarios. Only one symmetric instance can be configured in each VRF instance. After a symmetric instance is configured in a VRF instance, Layer 3 forwarding in other asymmetric instances is switched to the symmetric instance.
- The symmetric VXLAN and anycast gateway synchronization functions are mutually exclusive and cannot be configured at the same time.
- In distributed symmetric VXLAN networking scenarios, the configuration is required on the VXLAN gateway.

2.12.3 Prerequisites

To configure the symmetric attribute for a VXLAN instance, complete the following operations:

- Create and configure a VRF instance.
- Create and configure an overlay router interface and associate it with a VRF instance.
- Associate the overlay router interface with the VXLAN instance, for which the symmetric attribute is to be configured.

2.12.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the VXLAN configuration mode.

vxlan *vni-number*

No VXLAN instance is configured by default.

(4) Configure the symmetric attribute for the instance.

symmetric

No symmetric attribute is configured for a VXLAN instance by default.

3 Configuring VXLAN Extended Functions

3.1 Overview

This section describes VXLAN extended functions, which are a supplement to VXLAN basic functions. Configure appropriate extended functions as required.

3.2 Restrictions and Guidelines

VXLAN extended functions described in this section are not applicable to all VXLAN networking scenarios. For details, see the restrictions and guidelines of each function.

3.3 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

- Enabling Storm Control
- Configuring the VXLAN UDP Destination Port
- Configuring a Static VXLAN MAC Address Table
- Configuring Multi-Tenant Layer 3 Packet Isolation
- Configuring the EVPN Synchronization Attribute
- Configuring Rate Limits for a Tunnel Interface
- Configuring ARP/ND Suppression
- Configuring ARP/ND Proxy
- Creating VXLAN Instances in Batches
- Configuring a Data Center Interconnection Tunnel
- Configuring VNI Mapping
- Configuring a Layer 2 Ethernet Sub-interface to Access a VXLAN
- Configuring a Delay in the Protocol Status Change of a VXLAN Tunnel
- Configuring the Optimal Minimum Route Length for VXLAN Tunnels

3.4 Enabling Storm Control

3.4.1 Overview

This section describes how to configure storm control for a VXLAN instance. You can limit the rate of broadcast, multicast, or unicast VXLAN packets to implement storm control.

3.4.2 Restrictions and Guidelines

If VNI-based storm control is required, you can configure storm control rate limit for a VXLAN instance.

3.4.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the VXLAN configuration mode.

vxlan *vni-number*

No VXLAN instance is configured by default.

(4) Configure storm control for the VXLAN instance.

storm-control-enable { **broadcast** | **multicast** | **unicast** } [**pps** *limit-value-pps* | **kbps** *limit-value-kbps* | **mbps** *limit-value-mbps*]

No storm control is configured for a VXLAN instance by default.

3.5 Configuring the VXLAN UDP Destination Port

3.5.1 Overview

This section describes how to manually configure the VXLAN UDP destination port ID. The VXLAN UDP destination port used by some devices is not 4789 before the implementation of RFC 7348: Virtual eXtensible Local Area Network. You can run this command to change the VXLAN UDP port ID of the device to ensure compatibility. You can also run this command to define the VXLAN UDP destination port.

3.5.2 Restrictions and Guidelines

After modifying the UDP destination port, save the configuration and restart the device for the configuration to take effect.

3.5.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the VXLAN UDP destination port.

vxlan udp-port *port-number*

The default VXLAN UDP destination port is **4789**.

3.6 Configuring a Static VXLAN MAC Address Table

3.6.1 Overview

Configured static VXLAN MAC forwarding entries are usually used in scenarios of centralized networking using static tunnels. The VXLAN MAC address table delivered by the SDN controller is considered as a static VXLAN MAC address table on the device.

Restrictions and Guidelines

- The next-hop interface must have been created before configuration.
- The next-hop interface cannot be a dynamic tunnel.

3.6.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure a static VXLAN MAC address table.

vxlan mac static *mac-address* **vni** *vni-number* [**interface** *interface-type interface-number* **vlan** *vlan-id* | **interface overlaytunnel** *interface-number*]

No static VXLAN MAC forwarding entry is configured by default.

3.7 Configuring Multi-Tenant Layer 3 Packet Isolation

3.7.1 Overview

The network of a cloud data center can be leased to multiple tenants and tenants cannot access each other to ensure the independence and security of the tenants' networks. Subnets of different VXLANs are Layer 2-isolated and can communicate with each other only through Layer 3 forwarding. Each tenant may have multiple VXLAN subnets with different VNIs. Therefore, it is necessary to ensure that different tenants can perform Layer 3 forwarding only in their own networks and cannot communicate with each other through Layer 3 forwarding.

Multi-tenant Layer 3 packet isolation can be configured to meet the above requirements. The essence of multi-tenant Layer 3 packet isolation is to utilize VRF instances to isolate Layer 3 packet forwarding. You can specify a VRF instance for the overlay router interface of each VXLAN subnet owned by a tenant to define the L3 forwarding range of the VXLAN subnet. This method of isolating multiple tenants by VRF instance not only ensures the independence and security of tenants' networks, but also reserves enough hierarchical space for internal network classification of tenants.

3.7.2 Restrictions and Guidelines

Perform the configuration on VXLAN gateways as required.

3.7.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a single-protocol VRF instance and enter the VRF instance configuration mode.

ip vrf *vrf-name*

No single-protocol VRF instance is configured by default.

(4) Define the RD value for the VRF instance.

rd *rd-value*

No RD value is configured by default.

(5) Configure the RT attribute for the VRF instance.

route-target { **import** | **export** | **both** } *route-target-value*

No RT value is defined by default.

(6) Enter the overlay routed interface configuration mode.

interface overlayrouter *interface-number*

(7) Add the overlay router interface to the single-protocol VRF instance.

ip vrf binding *vrf-name*

No interface is added to any single-protocol VRF by default.

3.8 Configuring the EVPN Synchronization Attribute

3.8.1 Overview

The EVPN standard defines five types of routes. VTEPs mutually synchronize five types of EVPN routes to automatically discover VTEPs, establish VXLAN tunnels, advertise host addresses and routes, and implement multi-homing access. Type-2 routes are used by an EVPN to advertise host information and are classified into MAC-only routes (for advertising host MAC addresses) and MAC/IP routes (for advertising host MAC addresses, host ARP information, host IPv6 ND information, and host routes).

By configuring the EVPN synchronization attribute, you can specify whether a VXLAN instance extracts entry information from type-2 route packets of EVPN.

3.8.2 Restrictions and Guidelines

The following commands can be configured only on Layer 2 VNIs (that is, VXLAN instances with the **symmetric** command not configured). They are unavailable on Layer 3 VNIs.

When you run the following commands on a VXLAN instance, only the EVPN entry resolution of the VXLAN instance is affected, and other VXLAN instances with the commands not configured are not affected.

- **evpn arp mac-learning enable**
  - When this command is configured, the device resolves one ARP entry and one MAC entry from a MAC-IP type-2 route synchronized from a VXLAN-EVPN neighbor.
  - By default, this command is not configured and the device resolves only one ARP entry but no MAC entry from a MAC-IP type-2 route synchronized from a VXLAN-EVPN neighbor.
  - This command can be used together with the **evpn mac advertise disable** command. That is, the network-wide VXLAN-EVPN neighbors synchronize only the MAC-IP type-2 routes but no MAC-only type-2 routes. All devices resolve and extract MAC entries from MAC-IP type-2 routes.
- **evpn nd mac-learning enable**
  - After this command is configured, the device resolves one IPv6 ND entry and one MAC entry from a MAC-IP type-2 route (IPv6 ND) synchronized from a VXLAN-EVPN neighbor.
  - By default, this command is not configured and the device resolves only one IPv6 ND entry but no MAC entry from a MAC-IP type-2 route synchronized from a VXLAN-EVPN neighbor.
  - This command can be used together with the **evpn mac advertise disable** command. That is, the network-wide VXLAN-EVPN neighbors synchronize only the MAC-IP type-2 routes but no MAC-only type-2 routes. All devices resolve and extract MAC entries from MAC-IP type-2 routes.
- **evpn mac advertise disable**
  - This command is not configured on a device by default. The device generates one MAC-only type-2 route based on a locally learned MAC entry according to the VXLAN-EVPN protocol, and synchronizes the type-2 route to an EVPN neighbor (that is, remote VTEP). Then, the remote VTEP learns the MAC entry from the MAC-only type-2 route.
  - After this command is configured, the device does not generate a VXLAN-EVPN MAC-only type-2 route based on the MAC entry. Therefore, the device will not advertise MAC-only type 2 routes to EVPN neighbors.
  - This command can be used together with the **evpn arp mac-learning enable** command. That is, the network-wide VXLAN-EVPN neighbors synchronize only the MAC-IP type-2 routes but no MAC-only type-2 routes. All devices resolve and extract MAC entries from MAC-IP type-2 routes.
- **evpn mac inactive**
  - After this command is configured, the device will not learn MAC entries from VXLAN-EVPN type-2 routes (MAC-IP or MAC-only type-2 routes) synchronized from neighbors.
  - This command is not configured on a device by default. The device learns MAC entries from VXLAN-EVPN type-2 routes synchronized from neighbors.
- **evpn rt-2 advertise disable**
  - This command is not configured on a device by default. The device generates one MAC-only type-2 route based on a locally learned MAC entry according to the VXLAN-EVPN protocol, and synchronizes the type-2 route to an EVPN neighbor (that is, remote VTEP). Then, the remote VTEP learns the MAC entry from the MAC-only type-2 route. In addition, the device generates one MAC-IP type-2 route based on a locally learned ARP entry according to the VXLAN-EVPN protocol and synchronizes the type-2 route to an EVPN neighbor. Then, the remote VTEP learns the ARP entry and host route from the MAC-IP type-2 route.
  - After this command is configured, the device does not generate VXLAN-EVPN type-2 routes (MAC-IP or

MAC-only routes) based on MAC entries and ARP entries and therefore, no type-2 routes are advertised to EVPN neighbors.

3.8.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the VXLAN configuration mode.

vxlan *vni-number*

(4) Configure the EVPN synchronization attribute. Configure at least one of the tasks.

- Configure the function of extracting MAC entries from EVPN MAC-IP type-2 routes (ARP information).

  evpn arp mac-learning enable

  The function of extracting MAC entries from EVPN MAC-IP type-2 routes (ARP information) is not configured by default.

- Configure the function of extracting MAC entries from EVPN MAC-IP type-2 routes (IPv6 ND information).

  evpn nd mac-learning enable

  The function of extracting MAC entries from EVPN MAC-IP type-2 routes (IPv6 ND information) is not configured by default.

- Configure a Layer 2 VNI to disable the synchronization of the local MAC address to the remote VTEP through EVPN messages.

  evpn mac advertise disable

  A Layer 2 VNI is not configured to disable the synchronization of the local MAC address to the remote VTEP through EVPN messages by default.

- Configure a Layer 2 VNI to disable the delivery of MAC addresses remotely synchronized through EVPN messages to the local MAC address table.

  evpn mac inactive

  A Layer 2 VNI is not configured to disable the delivery of MAC addresses remotely synchronized through EVPN messages to the local MAC address table.

- Configure a Layer 2 VNI to stop generating EVPN type-2 routes.

  evpn rt-2 advertise disable

  A Layer 2 VNI is not configured to stop generating EVPN type-2 routes (MAC+ARP entries) by default.

3.9 Configuring Rate Limits for a Tunnel Interface

3.9.1 Overview

This section describes how to configure the input/output rate limits for a dynamic tunnel. If you need to limit the rate of a dynamic tunnel, configure the input/output rate limits.

3.9.2 Restrictions and Guidelines

N/A

3.9.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the VTEP configuration mode.

vtep

(4) Configure the rate limits for a tunnel interface.

vxlan overlaytunnel dip *ipv4-address* **speed-limit** { **input** | **output** } *limit-per-second burst-size*

No rate limit is configured for a dynamic tunnel by default.

3.10 Configuring ARP/ND Suppression

3.10.1 Overview

This section describes how to configure global ARP/ND suppression or VNI-based ARP/ND suppression. ARP/ND suppression is generally enabled on VXLAN access devices in centralized deployment scenarios or on VXLAN gateways in distributed deployment scenarios.

- After ARP suppression is enabled, the VTEP responds to ARP requests from hosts as a proxy, to reduce ARP data flooding in the network.
- After IPv6 ND suppression is enabled, the VTEP responds to NS multicast packets from hosts as a proxy, to reduce NS multicast packet flooding in the network.

3.10.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure ARP/ND suppression. Configure at least one of the tasks.

- Run the following commands in sequence to configure global ARP/ND suppression.

  vtep

  Configure global ARP/ND suppression.

  (IPv4 network)

  arp suppress enable

  No global ARP suppression is configured by default.

  (IPv6 network)

  nd suppress enable

No global IPv6 ND suppression is configured by default.

- Run the following commands in sequence to configure VNI-based ARP/ND suppression.

  vxlan *vni-number*

  No VXLAN instance is configured by default.

  (IPv4 network)

  arp suppress enable

  No VNI-based ARP suppression is configured by default.

  (IPv6 network)

  nd suppress enable

  No VNI-based IPv6 ND suppression is configured by default.

3.11 Configuring ARP/ND Proxy

3.11.1 Overview

The ARP/ND proxy function implements the mutual access between hosts in the same VXLAN through gateway forwarding. After ARP/ND proxy is enabled, a VTEP responds to ARP/NS requests from hosts as a proxy and the MAC address replied by the proxy is that of the gateway on the VTEP. Therefore, the MAC address returned for ARP/NS requests is that of the VTEP, and the access traffic between hosts in the same VNI is implemented through Layer 3 forwarding.

3.11.2 Restrictions and Guidelines

- The **route-in-vni** command configures the ARP proxy and ND proxy functions.
- The ARP/ND proxy function enabled on an overlay router interface takes effect only after the ARP/ND suppression is enabled.
- ARP/ND proxy can be enabled only on VXLAN gateways, and generally on VXLAN gateways in distributed deployment scenarios.

3.11.3 Prerequisites

ARP/ND suppression has been enabled before the **route-in-vni** command is configured.

3.11.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the overlay router interface configuration mode.

interface overlayrouter *interface-number*

(4) Configure ARP/ND proxy.

route-in-vni

No ARP/ND proxy is configured by default.

(5) Return to the global configuration mode.

end

(6) Enter the VXLAN configuration mode.

vxlan *vni-number*

No VXLAN instance is configured by default.

(7) (Optional) Disable VLAN check in the case of ARP/ND proxy.

proxy check vlan disable

VLAN check is enabled in the case of ARP/ND proxy by default.

After VLAN check is enabled and the device serves as an ARP/ND proxy, if the Layer 2 egress and VLAN of a host requested by an ARP/NS packet are the same as those in the ARP/NS packet, the device discards the ARP/NS request and does not respond as a proxy.

3.12 Creating VXLAN Instances in Batches

3.12.1 Overview

This section describes how to create VXLAN instances in batches or enter the batch VXLAN instance configuration mode.

3.12.2 Restrictions and Guidelines

- If the number of VXLAN instances reaches the maximum value, the configuration fails.
- When configuring multiple VIDs, separate the VIDs with commas (,) or connect the first and last VIDs of continuous VIDs with a hyphen (-).

3.12.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create VXLAN instances in batches and enter the batch VXLAN instance configuration mode.

vxlan range *vxlan-list*

No VXLAN instance is configured by default.

3.13 Configuring a Data Center Interconnection Tunnel

3.13.1 Overview

A data center interconnection tunnel controls Layer 2 forwarding of packets between an internal tunnel and an interconnection tunnel of a data center. It does not affect Layer 3 forwarding. The packet processing behavior of the VXLAN gateway is as follows:

- After receiving packets from an internal tunnel of a data center, the gateway forwards them to the interconnection tunnel of the data center at Layer 2.

- After receiving packets from the interconnection tunnel of the data center, the gateway forwards the packets to an internal tunnel of the data center at Layer 2, but will not forward the packets to interconnection tunnels of other data centers.

3.13.2 Restrictions and Guidelines

- This function is usually configured on edge devices that connect data centers.
- Multiple data center interconnection tunnels can be configured on one device.

3.13.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the VTEP configuration mode.

vtep

(4) Configure a data center interconnection tunnel.

vxlan outside center vtep-ip *ipv4-address*

No data center interconnection tunnel is configured by default.

3.14 Configuring VNI Mapping

3.14.1 Overview

In a scenario where multiple data centers are interworked, data centers can be deployed in the following mode: Each data center (hereinafter referred to as a point of delivery (POD)) maintains one independent VNI, and one public VNI is used for interaction across data centers. This deployment mode implements more flexible VNI deployment and maintenance in each center.

In this deployment mode, when an access request packet across data centers is sent out of a center, the VNI of the center is replaced with the cross-center public VNI in the packet. When the request reaches the peer center, the public VNI is replaced with the VNI of a related subnet in the peer center. The VNI replacement across data centers is called VNI mapping.

VNI mapping is classified into Layer 2 VNI mapping and Layer 3 VNI mapping based on the mapping method.

Layer 2 VNI mapping: Used for VNI replacement for cross-center Layer 2 traffic. The Layer 2 VNI of a data center is replaced with the public Layer 2 VNI across data centers.

Layer 3 VNI mapping: Used for VNI replacement for cross-center Layer 3 traffic. The Layer 3 VNI (VNI of a symmetric VXLAN instance) of a data center is replaced with the public Layer 3 VNI (VNI of a symmetric VXLAN instance) across data centers.

3.14.2 Restrictions and Guidelines

The function is explained as follows for your better understanding: If the **mapping vni** VNI-b or **l3mapping vni** VNI-b command is configured in a VNI-a instance, VNI-a is the original VNI and VNI-b is the post-mapping VNI.

- Data center interconnection based on VNI mapping is usually configured on edge devices that connect data

centers.

- After data center interconnection based on VNI mapping is configured, when receiving an internal VXLAN packet from a data center, the device replaces the original VNI in the packet with the post-mapping VNI. When receiving a VXLAN packet from another data center, the device replaces the post-mapping VNI in the packet with the original VNI.
- After data center interconnection based on VNI mapping is configured, the original VNI/Layer 3 VNI carried in the EVPN routes synchronized by the device to other data centers through BGP will be replaced with the post-mapping VNI/Layer 3 VNI.
- Data center interconnection based on VNI mapping takes effect only when both the original VNI and post-mapping VNI exist.
- Mapping cannot be configured on a post-mapping VNI.

3.14.3 Prerequisites

A data center interconnection tunnel has been configured before VNI mapping is configured.

3.14.4 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Create a VXLAN instance and enter the VXLAN configuration mode.

vxlan *vni-number*

No VXLAN instance is configured by default.

(4) Configure VNI mapping. Configure one of the following tasks.

- Configure a Layer 2 VNI mapping.

  mapping vni *vni-number*

  No post-mapping VNI is configured for a VXLAN instance.

  This command can be configured only on Layer 2 VNIs (instances with the **symmetric** command not configured), and post-mapping VNIs can be only Layer 2 VNIs.

  Configuring post-mapping VNIs and configuring associated VLANs are mutually exclusive on VXLANs. That is, a post-mapping VNI cannot be associated with a VLAN, and a VXLAN instance associated with a VLAN cannot be configured as a post-mapping VNI.

  Original VNIs and post-mapping VNIs are in one-to-one mappings.

- Configure an L3VNI mapping.

  l3mapping vni *vni-number*

  No post-mapping VNI is configured for symmetric instances by default.

  This command can be configured only on Layer 3 VNIs (instances configured with the **symmetric** command). That is, the original VNI must be an Layer 3 VNI and the post-mapping VNI can be an Layer 3 VNI or an Layer 2 VNI.

This command supports the mapping from one original VNI to multiple VNIs but one VNI cannot configured as the post-mapping VNI of multiple VNIs.

3.15 Configuring a Layer 2 Ethernet Sub-interface to Access a VXLAN

3.15.1 Overview

This section describes how to configure hosts to access a VXLAN through Layer 2 Ethernet sub-interfaces. Layer 2 Ethernet sub-interfaces can access a VXLAN in untagged VLAN encapsulation mode, tagged VLAN encapsulation mode, and QinQ encapsulation mode.

3.15.2 Restrictions and Guidelines

- The **extend-vlan** command configured for a VXLAN instance uses the same encapsulation rule as that configured for a sub-interface (tagged VLAN or untagged VLAN encapsulation). When a packet matches the encapsulation rule of a sub-interface, the encapsulation rule priority of the sub-interface is higher than that of **extend-vlan** configured for a VXLAN instance.
- Perform the configuration on VXLAN access devices based on actual networking conditions.

3.15.3 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the Layer 2 Ethernet sub-interface configuration mode.

interface *interface-type interface-number.subnumber*

(4) Configure VXLAN encapsulation rules for the sub-interface.

encapsulation vxlan *vni-number*

Configure VXLAN encapsulation rules for the specified sub-interface.

No VXLAN encapsulation rule is configured for a sub-interface by default.

(5) Configure the Layer 2 Ethernet sub-interface to access the VXLAN. Configure either of the following tasks.

- Configure the untagged or VLAN encapsulation rule for the sub-interface.

  encapsulation dot1q { **untag** | **s-vid** *vlan-id* }

  No untagged and VLAN encapsulation rules are configured for a sub-interface by default.

- Configure the QinQ encapsulation rule for the sub-interface.

  encapsulation qinq s-vid *svlan-id* **c-vid** *cvlan-id*

  No QinQ encapsulation rule is configured for a sub-interface by default.

3.16 Configuring a Delay in the Protocol Status Change of a VXLAN Tunnel

3.16.1 Overview

This section describes how to configure a delay in the protocol status change of a VXLAN tunnel from down state to up state.

3.16.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the VTEP configuration mode.

vtep

(4) Configure a delay in the protocol status change of a VXLAN tunnel.

vxlan overlaytunnel carrier-delaytime up *delay-time*

The default delay in the protocol status change of VXLAN tunnels is 2000 ms.

3.17 Configuring the Optimal Minimum Route Length for VXLAN Tunnels

3.17.1 Overview

You can configure the optimal minimum IPv4 route length for tunnels to control the optimal IPv4 DIP routes for the tunnels.

3.17.2 Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enter the VTEP configuration mode.

vtep

(4) Configure the optimal minimum IPv4/IPv6 route length for tunnels.

vxlan overlaytunnel nexthop resolution prefix-length minimum *minimum-length-ipv4*

The default optimal minimum IPv4 route length of tunnels is **0**.

4 Monitoring

Run the **display** command to check the running status of a configured function to verify the configuration effect.

Run the **cleanup** command to clear information.

⚠ Caution

Running the **cleanup** command may interrupt services due to loss of important information.

Table 4-1 VXLAN Monitoring

Command	Purpose
display vxlan *vni-number*	Displays the VXLAN configuration and status of a device.
display vxlan mac-addr-table [**address** *mac-address*] [**vni** *vni-number*] [**remote** | **local**]	Displays the MAC addresses learned by the VXLAN configured on the device.
display vxlan mac-active [**vni** *vni-number*]	Displays active VXLAN MAC entries obtained by the VXLAN protocol module from the local device.
display vxlan mac-bgp [**vni** *vni-number*]	Displays remote VXLAN MAC entries synchronized via BGP.
display vxlan mac-log { **all** | **vni** *vni-number* | **mac** *mac-address* | **vni** *vni-number* **mac** *mac-address* | **status** }	Displays operation logs of VXLAN MAC entries.
display arp vxlan	Displays ARP entries learned by the VXLAN module of the device.
display ipv6 neighbors-table	Displays IPv6 ND entries learned by the VXLAN module of the device.
display vxlan global	Displays the VTEP-IP address and anycast MAC address of the device.
display vxlan route-active [**count** | **vrf** *vrf-name* | **global-vrf** | **vni** *vni-number* | **local** | **remote**]	Displays active VXLAN ARP entries.
display vxlan route-active ipv6 [**count** | **vrf** *vrf-name* | **global-vrf** | **vni** *vni-number* | **local** | **remote**]	Displays active VXLAN IPv6 ND entries.
display vxlan vrf { **all** | **global-vrf** | **vrf-name** *vrf-name* }	Displays VXLAN instances of a VRF instance.

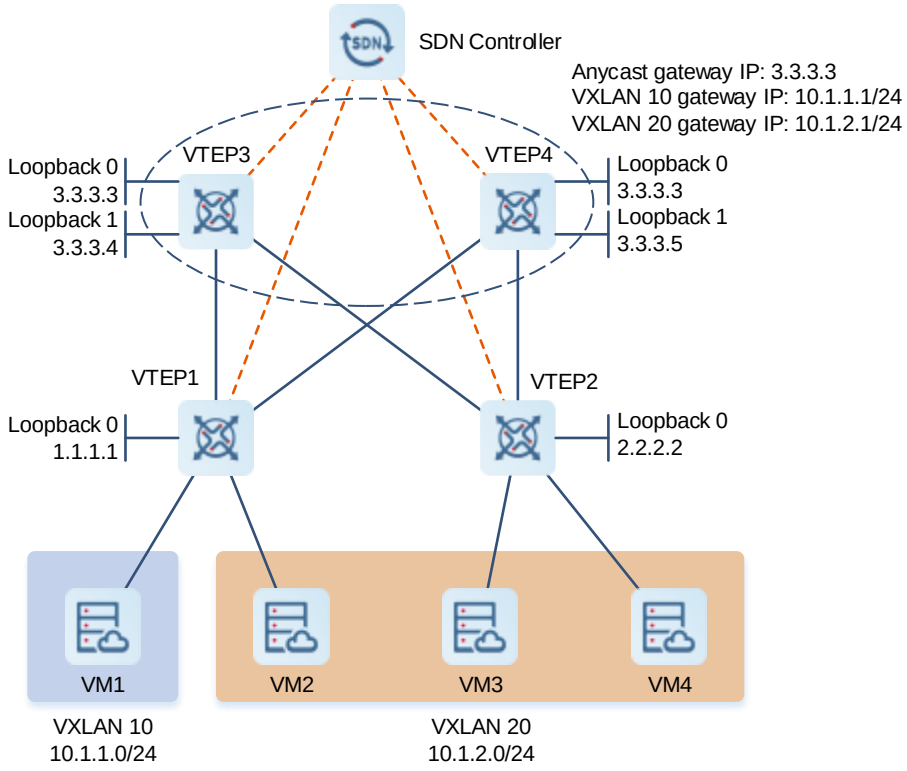
Command	Purpose
display vxlan arp suppress	Displays the enabling status of VXLAN ARP suppression on the device.
display vxlan nd suppress	Displays the enabling status of VXLAN IPv6 ND suppression on the device.
display vxlan udp-port	Displays the VXLAN UDP destination port of the device.
display vxlan vni-statistics { **all** | **vni** *vni-number* }	Displays traffic data of a VNI.
display interface	Displays the traffic statistics of a tunnel interface.
statistics enable	Enables traffic statistics collection on a Layer 2 Ethernet sub-interface in interface configuration mode.
display interface	Displays traffic statistics of a Layer 2 Ethernet sub-interface.
display vxlan debugging detail	Displays specified VXLAN debugging information.
display vxlan ethernet { **interface** | **vlan** [*vlan-id*] | **vni** [*vni-number*] }	Displays VXLAN Ethernet interface information.
display vxlan log	Displays key run logs of the VXLAN process.
display vxlan overlaytunnel route [**interface** *interface-number*] [detail]	Displays routing information of a tunnel.
display vxlan route-bgp [**count** | **vrf** vrf-name | **global-vrf** | **vni** *vni-number*]	Displays VXLAN ARP entries synchronized via BGP.
display vxlan route-bgp ipv6 [**count** | **vrf** vrf-name | **global-vrf** | **vni** *vni-number*]	Displays VXLAN ND entries synchronized via BGP.
display vxlan route-log { **all** | **vni** *vni-number* | **ip** *ipv4-address* | **ipv6** *ipv6-address* | **vni** *vni-number* { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **status** }	Displays operation logs of VXLAN ARP/IPv6 ND entries.
display vxlan server [**database** | **router** | **tunnel** | **client-info** *client-name*]	Displays details about the VXLAN process.
display vxlan storm-control-enable [**vni** *vni-number*]	Displays the configuration of VNI-based storm control.
display vxlan subport { **all** | **vni** *vni-number* | **interface** *interface-type interface-number* }	Displays VXLAN Layer 2 sub-interface information.
display vxlan vtep-log { **all** | **vni** *vni-number* | **ip** *ip-address* | **vni** *vni-number* **ip** *ip-address* | **status** }	Displays operation logs related to a VXLAN tunnel.

Command	Purpose
display vxlan vtep-nbr [**dip** *ipv4-address*]	Displays VTEP neighbor information.
cleanup vxlan config all	Clears all VXLAN-related configuration.
cleanup vxlan mac dynamic [**vni** *vni-number* | **address** *mac-address* **vni** *vni-number*] [**force**]	Clears VXLAN MAC entries.
cleanup vxlan vni-statistics	Clears VNI traffic data.
cleanup vxlan log	Clears key run logs of the VXLAN process.
vni-counting enable	Enables VNI traffic statistics collection (globally or on a VXLAN instance).
vni-counting period sample *sample-time* **load** *load-time*	Configures the sampling period and calculation period of VNI traffic statistics collection.
vxlan overlaytunnel counting enable	Enables tunnel traffic statistics collection globally.
vxlan vtep-log { **disable** | **limit** *limit-num* | **type** { **event** | **nstime** | **timestamp** } }	Configures VXLAN tunnel logging parameters.
vxlan route-log { **disable** | **limit** *limit-num* | **type** { **event** | **nstime** | **timestamp** } }	Configures VXLAN ARP/ND entry logging.
vxlan mac-log { **disable** | **limit** *limit-num* | **type** { **event** | **nstime** | **timestamp** } }	Configures VXLAN MAC entry logging.

5 Configuration Examples

5.1 Configuring a VXLAN SDN

5.1.1 Requirements



In the topology as shown in Figure 5-1, the following requirements need to be met:

- VMs on the network are classified into several VXLAN subnets, which can communicate with each other through Layer 3 forwarding.
- The SDN controller is used to manage and maintain VXLAN configuration.
- Fast convergence can be performed on VXLAN traffic when the gateway is faulty.

Centralized VXLAN networking using static tunnels needs to be configured in this topology.

5.1.2 Topology

Figure 5-1 Configuring a VXLAN SDN

5.1.3 Notes

- On VTEP 1, VTEP 2, VTEP 3, and VTEP 4, configure an IPv4 unicast routing protocol (such as OSPF) to ensure that unicast routes between the devices are reachable (omitted).
- On VTEP 1, VTEP 2, VTEP 3, and VTEP 4, configure a loopback interface and configure an IP address for the loopback interface. The loopback interfaces distribute packets using the unicast routing protocol. The IP addresses of CORE-1 and CORE-2 are the same.
- On VTEP 3 and VTEP 4, configure the anycast gateway, the same VXLAN gateway, and the same VTEP IP address.
- Configure the VXLAN and gateway address on each VM (omitted).
- Create a BGP neighbor relationship between VTEP 3 and VTEP 4 and configure BGP-EVPN.

The following content can be manually configured or delivered by the SDN controller. In this typical configuration example, manual configuration is adopted.

- On VTEP 1, create VXLAN instances VXLAN 10 and VXLAN 20, and associate them with VLAN 10 and VLAN 20 respectively. Disable MAC address auto-learning. Configure two VXLAN tunnels to connect to VTEP 2 and the anycast gateway. Associate VXLAN 10 and VXLAN 20 with the two tunnels respectively.
- On VTEP 2, create a VXLAN instance VXLAN 20 and associate it with VLAN 20. Disable MAC address auto-learning. Configure two VXLAN tunnels to connect to VTEP 1 and anycast gateway. Associate VXLAN 20 with the two tunnels.

- On VTEP 3, create VXLAN instances VXLAN 10 and VXLAN 20. Disable MAC address auto-learning. Configure the anycast MAC address. Configure two overlay router interface and set their IP addresses to 10.1.1.1/24 and 10.1.2.1/24 respectively. Associate VXLAN 10 with the overlay router interface whose IP address is 10.1.1.1/24. Associate VXLAN 20 with the overlay router interface whose IP address is 10.1.2.1/24. Configure two VXLAN tunnels to connect to VTEP 1 and VTEP 2 respectively. Associate VXLAN 10 and VXLAN 20 with the two tunnels respectively.
- The configurations on VTEP 4 are basically the same as those on VTEP 3.
- On VTEP 3 and VTEP 4, configure Loopback 1 and set the IP address to 3.3.3.4 and 3.3.3.5 respectively. Configure the two devices to establish a BGP neighbor relationship through Loopback 1 and activate the BGP neighbor relationship in the L2VPN EVPN address family.

5.1.4 Procedure

(1) Configure VTEP 1.

```
VTEP1> privilege
VTEP1# config-system terminal
VTEP1(cfg)# interface loopback 0
VTEP1(cfg-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
VTEP1(cfg-if-Loopback 0)# exit
VTEP1(cfg)# interface overlaytunnel 1
VTEP1(cfg-if-OverlayTunnel 1)# overlaytunnel source 1.1.1.1
VTEP1(cfg-if-OverlayTunnel 1)# overlaytunnel destination 2.2.2.2
VTEP1(cfg-if-OverlayTunnel 1)# exit
VTEP1(cfg)# interface overlaytunnel 2
VTEP1(cfg-if-OverlayTunnel 2)# overlaytunnel source 1.1.1.1
VTEP1(cfg-if-OverlayTunnel 2)# overlaytunnel destination 3.3.3.3
VTEP1(cfg-if-OverlayTunnel 2)# exit
VTEP1(cfg)# vxlan 10
VTEP1(cfg-vxlan)# tunnel-interface overlaytunnel 1
VTEP1(cfg-vxlan)# tunnel-interface overlaytunnel 2
VTEP1(cfg-vxlan)# extend-vlan 10
VTEP1(cfg-vxlan)# end
VTEP1(cfg)# vxlan 20
VTEP1(cfg-vxlan)# tunnel-interface overlaytunnel 1
VTEP1(cfg-vxlan)# tunnel-interface overlaytunnel 2
VTEP1(cfg-vxlan)# extend-vlan 20
VTEP1(cfg-vxlan)# end
```

(2) Configure VTEP 2.

```
VTEP2> privilege
VTEP2# config-system terminal
VTEP2(cfg)# interface loopback 0
VTEP2(cfg-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
VTEP2(cfg-if-Loopback 0)# exit
VTEP2(cfg)# interface overlaytunnel 1
VTEP2(cfg-if-OverlayTunnel 1)# overlaytunnel source 2.2.2.2
```

```
VTEP2(cfg-if-OverlayTunnel 1)# overlaytunnel destination 1.1.1.1
VTEP2(cfg-if-OverlayTunnel 1)# exit
VTEP2(cfg)# interface overlaytunnel 2
VTEP2(cfg-if-OverlayTunnel 2)# overlaytunnel source 2.2.2.2
VTEP2(cfg-if-OverlayTunnel 2)# overlaytunnel destination 3.3.3.3
VTEP2(cfg-if-OverlayTunnel 2)# exit
VTEP2(cfg)# vxlan 20
VTEP2(cfg-vxlan)# tunnel-interface overlaytunnel 1
VTEP2(cfg-vxlan)# tunnel-interface overlaytunnel 2
VTEP2(cfg-vxlan)# extend-vlan 20
VTEP2(cfg-vxlan)# end
```

(3) Configure VTEP 3.

```
VTEP3> privilege
VTEP3# config-system terminal
VTEP3(cfg)# fabric anycast-gateway-mac 0000.1234.5678
VTEP3(cfg)# vtep
VTEP3(cfg-vtep)# vxlan gateway synchronize
VTEP3(cfg-vtep)# exit
VTEP3(cfg)# interface loopback 0
VTEP3(cfg-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
VTEP3(cfg-if-Loopback 0)# exit
VTEP3(cfg)# interface loopback 1
VTEP3(cfg-if-Loopback 1)# ip address 3.3.3.4 255.255.255.255
VTEP3(cfg-if-Loopback 1)# exit
VTEP3(cfg)# router-protocol bgp 10000
VTEP3(cfg-router)# peer 3.3.3.5 remote-as 10000
VTEP3(cfg-router)# peer 3.3.3.5 update-source loopback 1
VTEP3(cfg-router)# address-family-mode l2vpn evpn
VTEP3(cfg-router-af)# peer 3.3.3.5 activate
VTEP3(cfg-router-af)# peer 3.3.3.5 send-community extended
VTEP3(cfg-router-af)# exit-address-family-mode
VTEP3(cfg-router)# exit
VTEP3(cfg)# interface overlaytunnel 1
VTEP3(cfg-if-OverlayTunnel 1)# overlaytunnel source 3.3.3.3
VTEP3(cfg-if-OverlayTunnel 1)# overlaytunnel destination 2.2.2.2
VTEP3(cfg-if-OverlayTunnel 1)# exit
VTEP3(cfg)# interface overlaytunnel 2
VTEP3(cfg-if-OverlayTunnel 2)# overlaytunnel source 3.3.3.3
VTEP3(cfg-if-OverlayTunnel 2)# overlaytunnel destination 1.1.1.1
VTEP3(cfg-if-OverlayTunnel 2)# exit
VTEP3(cfg)# interface overlayrouter 1
VTEP3(cfg-if-OverlayRouter 1)# ip address 10.1.1.1/24
VTEP3(cfg-if-OverlayRouter 1)# anycast-gateway
VTEP3(cfg-if-OverlayRouter 1)# exit
VTEP3(cfg)# interface overlayrouter 2
VTEP3(cfg-if-OverlayRouter 2)# ip address 10.1.2.1/24
```

```
VTEP3(cfg-if-OverlayRouter 2)# anycast-gateway
VTEP3(cfg-if-OverlayRouter 2)# exit
VTEP3(cfg)# vxlan 10
VTEP3(cfg-vxlan)# tunnel-interface overlaytunnel 1
VTEP3(cfg-vxlan)# tunnel-interface overlaytunnel 2
VTEP3(cfg-vxlan)# router-interface overlayrouter 1
VTEP3(cfg-vxlan)# end
VTEP3(cfg)# vxlan 20
VTEP3(cfg-vxlan)# tunnel-interface overlaytunnel 1
VTEP3(cfg-vxlan)# tunnel-interface overlaytunnel 2
VTEP3(cfg-vxlan)# router-interface overlayrouter 2
VTEP3(cfg-vxlan)# end
```

(4) Configure VTEP 4.

```
VTEP4> privilege
VTEP4# config-system terminal
VTEP4(cfg)# fabric anycast-gateway-mac 0000.1234.5678
VTEP4(cfg)# vtep
VTEP4(cfg-vtep)# vxlan gateway synchronize
VTEP4(cfg-vtep)# exit
VTEP4(cfg)# interface loopback 0
VTEP4(cfg-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
VTEP4(cfg-if-Loopback 0)# exit
VTEP4(cfg)# interface loopback 1
VTEP4(cfg-if-Loopback 1)# ip address 3.3.3.5 255.255.255.255
VTEP4(cfg-if-Loopback 1)# exit
VTEP4(cfg)# router-protocol bgp 10000
VTEP4(cfg-router)# peer 3.3.3.4 remote-as 10000
VTEP4(cfg-router)# peer 3.3.3.4 update-source loopback 1
VTEP4(cfg-router)# address-family-mode l2vpn evpn
VTEP4(cfg-router-af)# peer 3.3.3.4 activate
VTEP4(cfg-router-af)# peer 3.3.3.4 send-community extended
VTEP4(cfg-router-af)# exit-address-family-mode
VTEP4(cfg-router)#exit
VTEP4(cfg)# interface overlaytunnel 1
VTEP4(cfg-if-OverlayTunnel 1)# overlaytunnel source 3.3.3.3
VTEP4(cfg-if-OverlayTunnel 1)# overlaytunnel destination 2.2.2.2
VTEP4(cfg-if-OverlayTunnel 1)# exit
VTEP4(cfg)# interface overlaytunnel 2
VTEP4(cfg-if-OverlayTunnel 2)# overlaytunnel source 3.3.3.3
VTEP4(cfg-if-OverlayTunnel 2)# overlaytunnel destination 1.1.1.1
VTEP4(cfg-if-OverlayTunnel 2)# exit
VTEP4(cfg)# interface overlayrouter 1
VTEP4(cfg-if-OverlayRouter 1)# ip address 10.1.1.1/24
VTEP4(cfg-if-OverlayRouter 1)# anycast-gateway
VTEP4(cfg-if-OverlayRouter 1)# exit
VTEP4(cfg)# interface overlayrouter 2
```

```
VTEP4(cfg-if-OverlayRouter 2)# ip address 10.1.2.1/24
VTEP4(cfg-if-OverlayRouter 2)# anycast-gateway
VTEP4(cfg-if-OverlayRouter 2)# exit
VTEP4(cfg)# vxlan 10
VTEP4(cfg-vxlan)# tunnel-interface overlaytunnel 1
VTEP4(cfg-vxlan)# tunnel-interface overlaytunnel 2
VTEP4(cfg-vxlan)# router-interface overlayrouter 1
VTEP4(cfg-vxlan)# end
VTEP4(cfg)# vxlan 20
VTEP4(cfg-vxlan)# tunnel-interface overlaytunnel 1
VTEP4(cfg-vxlan)# tunnel-interface overlaytunnel 2
VTEP4(cfg-vxlan)# router-interface overlayrouter 2
VTEP4(cfg-vxlan)# end
```

5.1.5 Verification

- After the commands above are run and the centralized VXLAN networking using static tunnels is configured, VM 1, VM 2, VM 3, and VM 4 can mutually ping each other.
- Run the **display vxlan** command to display the VXLAN instance and tunnel configuration on the devices. The following uses VTEP 1 as an example.

```
VTEP1# display vxlan
VXLAN Total Count: 2
VXLAN Capacity     : 8000

VXLAN 10
      Symmetric property    : FALSE
      Routed interface      : -

5.2 Configuring EVPN-based Multi-Tenant Centralized VXLAN Networking

5.2.1 Requirements

In the topology as shown in Figure 5-2, centralized VXLAN networking using dynamic tunnels needs to be configured on VTEPs to support multi-tenant application in the data center, and VRF instances need to be configured to classify VXLANs by tenant. In this way, the VXLANs of the same tenant can communicate with each other through Layer 3 routes, but the VXLANs of different tenants cannot communicate with each other.

5.2.2 Topology

Figure 5-2 Configuring EVPN-based Multi-Tenant Centralized VXLAN Networking

5.2.3 Notes

- On each VTEP, configure an IPv4 unicast routing protocol (such as OSPF) to ensure that the unicast routes are reachable (omitted).
- On each VTEP, configure the BGP-EVPN routing protocol to ensure that the devices establish BGP neighbor relationships and exchange L2VPN EVPN information.
- On each VTEP, configure an EVI for BGP-EVPN.
- On the virtualized servers, configure VXLANs and specify the gateway address for the VMs.
- On each VTEP, configure and associate a loopback interface for the establishment of a VXLAN tunnel.
- On each VTEP, create a VXLAN instance and associate it with a VLAN.
- On VTEP 3, create an overlay router interface and configure the VXLAN gateway IP address. Configure different VRF instances for the overlay router interface and identify tenants by VRF instance.
- On VTEP 3, associate the VXLAN instance with the overlay router interface to implement Layer 3 routing between different VNI networks.
- On VTEP 3, configure remote ARP packet learning so that VXLAN routing entries are dynamically generated.
- (Optional) Configure ARP suppression on VTEP 1 and VTEP 2 to reduce ARP packets flowing to VXLANs.

5.2.4 Procedure

(1) Configure VTEP 1.

```
VTEP1> privilege
VTEP1# config-system terminal
VTEP1(cfg)# interface loopback 1
VTEP1(cfg-if-Loopback 1)# ip address 2.2.2.2/32
VTEP1(cfg-if-Loopback 1)# exit
VTEP1(cfg)# vtep
VTEP1(cfg-vtep)# source loopback 1
VTEP1(cfg-vtep)# arp suppress enable
VTEP1(cfg-vtep)# exit
VTEP1(cfg)# vxlan 10
VTEP1(cfg-vxlan)# extend-vlan 10
VTEP1(cfg-vxlan)# arp suppress enable
VTEP1(cfg-vxlan)# exit
VTEP1(cfg)# vxlan 20
VTEP1(cfg-vxlan)# extend-vlan 20
VTEP1(cfg-vxlan)# arp suppress enable
VTEP1(cfg-vxlan)# exit
VTEP1(cfg)# router-protocol bgp 64512
VTEP1(cfg-router)# peer 1.1.1.1 remote-as 64512
VTEP1(cfg-router)# peer 1.1.1.1 update-source loopback 1
VTEP1(cfg-router)# address-family-mode l2vpn evpn
VTEP1(cfg-router-af)# peer 1.1.1.1 activate
```

```
VTEP1(cfg-router-af)# exit
VTEP1(cfg-router)# exit
VTEP1(cfg)# evpn
VTEP1(cfg-evpn)# vni 10
VTEP1(cfg-evpn-vni)# rd auto
VTEP1(cfg-evpn-vni)# route-target both auto
VTEP1(cfg-evpn-vni)# exit
VTEP1(cfg-evpn)# vni 20
VTEP1(cfg-evpn-vni)# rd auto
VTEP1(cfg-evpn-vni)# route-target both auto
VTEP1(cfg-evpn-vni)# exit
```

(2) Configure VTEP 2.

```
VTEP> privilege
VTEP2# config-system terminal
VTEP2(cfg)# interface loopback 1
VTEP2(cfg-if-Loopback 1)# ip address 3.3.3.3/32
VTEP2(cfg-if-Loopback 1)# exit
VTEP2(cfg)# vtep
VTEP2(cfg-vtep)# source loopback 1
VTEP2(cfg-vtep)# arp suppress enable
VTEP2(cfg-vtep)# exit
VTEP2(cfg)# vxlan 100
VTEP2(cfg-vxlan)# extend-vlan 100
VTEP2(cfg-vxlan)# arp suppress enable
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# vxlan 20
VTEP2(cfg-vxlan)# extend-vlan 20
VTEP2(cfg-vxlan)# arp suppress enable
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# router-protocol bgp 64512
VTEP2(cfg-router)# peer 1.1.1.1 remote-as 64512
VTEP2(cfg-router)# peer 1.1.1.1 update-source loopback 1
VTEP2(cfg-router)# address-family-mode l2vpn evpn
VTEP2(cfg-router)# peer 1.1.1.1 activate
VTEP2(cfg-router-af)# exit
VTEP2(cfg-router)# exit
VTEP2(cfg)# evpn
VTEP2(cfg-evpn)# vni 20
VTEP2(cfg-evpn-vni)# rd auto
VTEP2(cfg-evpn-vni)# route-target both auto
VTEP2(cfg-evpn-vni)# exit
VTEP2(cfg-evpn)# vni 100
VTEP2(cfg-evpn-vni)# rd auto
VTEP2(cfg-evpn-vni)# route-target both auto
VTEP2(cfg-evpn-vni)# exit
```

(3) Configure VTEP 3.

```
VTEP3> privilege
VTEP3# config-system terminal
VTEP3(cfg)# interface loopback 1
VTEP3(cfg-if-Loopback 1)# ip address 1.1.1.1/32
VTEP3(cfg-if-Loopback 1)# exit
VTEP3(cfg)# vtep
VTEP3(cfg-vtep)# source loopback 1
VTEP3(cfg-vtep)# remote arp learn enable
VTEP3(cfg-vtep)# exit
VTEP3(cfg)# ip vrf vrf-10
VTEP3(cfg-vrf)# rd 10:10
VTEP3(cfg-vrf)# route-target both 1000:1000
VTEP3(cfg-vrf)# exit
VTEP3(cfg)# interface overlayrouter 10
VTEP3(cfg-if-OverlayRouter 10)# ip vrf binding vrf-10

VTEP3(cfg-evpn)# vni 100
VTEP3(cfg-evpn-vni)# rd auto
VTEP3(cfg-evpn-vni)# route-target both auto
VTEP3(cfg-evpn-vni)# exit
```

5.2.5 Verification

- After the commands above are run and the centralized VXLAN networking using dynamic tunnels is configured:
  - VMs in VRF-10 can ping each other successfully.
  - VMs in VRF-20 can ping each other successfully.
  - VMs in VRF-10 cannot ping those in VRF-20 and vice versa.
  - VMs can be migrated in the same VXLAN, they can access the Internet service successfully after migration, and the configurations do not need to be modified.
- Run the **display vxlan** command to display VXLAN instances on the devices. The following uses VTEP 1 as an example.

```
VTEP1# display vxlan
VXLAN Total Count: 2
VXLAN Capacity     : 8000

VXLAN 10
     Symmetric property    : FALSE
     Routed interface      : -
     Extend VLAN           : 10
     VTEP Adjacency Count: 1
```

```
    VTEP Adjacency List :
    Interface                Source IP                                    Destination IP
Type
    ---------------------- ---------------------------------------------- ---------------------------------------------- -------
    OverlayTunnel 6145       2.2.2.2                                      1.1.1.1
dynamic

VXLAN 20
    Symmetric property   : FALSE
    Routed interface     : -
    Extend VLAN          : 20
    VTEP Adjacency Count: 2
    VTEP Adjacency List :
    Interface                Source IP                                    Destination IP
Type
    ---------------------- ---------------------------------------------- ---------------------------------------------- -------
    OverlayTunnel 6145       2.2.2.2                                      1.1.1.1
dynamic
    OverlayTunnel 6146       2.2.2.2                                      3.3.3.3
dynamic
```

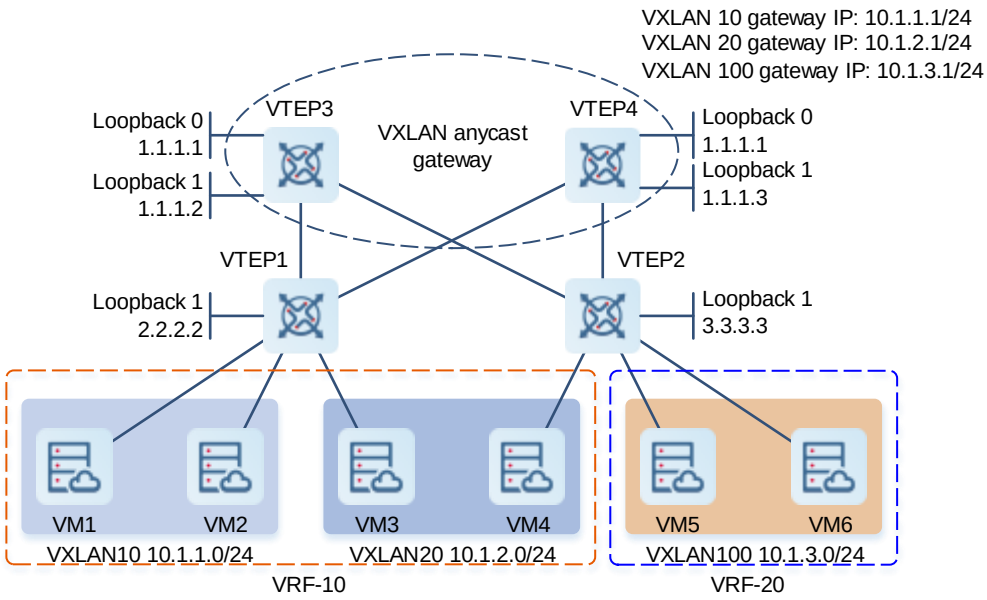
5.3 Configuring EVPN-based Multi-Tenant Centralized Anycast Gateway Deployment



5.3.1 Requirements

In the topology as shown in Figure 5-3, the following configurations are needed to support multi-tenant application in the data center and ensure that fast traffic convergence can be implemented on the deployed VXLANs when the gateway is faulty:

- Configure centralized VXLAN networking using dynamic tunnels on VTEPs, configure VRF instances to configure multiple VXLANs for each tenant so that VXLANs of the same tenant can access each other through Layer 3 routing while VXLANs of different tenants cannot.
- Configure the VXLAN gateways as the anycast gateway so that two VXLAN gateways can be virtualized into one VXLAN gateway. When one VXLAN gateway malfunctions, VXLAN traffic in the topology can be still forwarded normally.

5.3.2 Topology

Figure 5-3 Configuring EVPN-based Multi-Tenant Centralized Anycast All-Alive Gateway Deployment

5.3.3 Notes

- On each VTEP, configure an IPv4 unicast routing protocol (such as OSPF) to ensure that the unicast routes are reachable (omitted).
- On each VTEP, configure the BGP-EVPN routing protocol to ensure that the four VTEPs establish BGP neighbor relationships and exchange L2VPN EVPN information.
- On each VTEP, configure an EVI for BGP-EVPN.
- On the virtualized servers, configure VXLANs and specify the gateway address for the VMs.
- On each VTEP, configure and associate a loopback interface for the establishment of a VXLAN tunnel.

- On VTEP 3, create an overlay router interface and configure the VXLAN gateway IP address. Configure different VRF instances for the overlay router interface and identify tenants by VRF instance.
- On each VTEP, create a VXLAN instance and associate it with a VLAN.
- On VTEP 3 and VTEP 4, create an overlay router interface and configure the VXLAN gateway IP address. Configure different VRF instances for the overlay router interfaces and identify tenants by VRF instance. Associate the VXLAN instance with the overlay router interface to implement VXLAN routing.
- On VTEP 3 and VTEP 4, configure the same anycast gateway MAC address and configure the anycast attribute for all overlay router interfaces.
- On VTEP 3 and VTEP 4, configure remote ARP packet learning so that VXLAN routing entries are dynamically generated.
- (Optional) Configure ARP suppression on VTEP 1 and VTEP 2 to reduce ARP packets flowing to VXLANs.

5.3.4 Procedure

(1) Configure VTEP 1.

```
VTEP1> privilege
VTEP1# config-system terminal
VTEP1(cfg)# interface loopback 1
VTEP1(cfg-if-Loopback 1)# ip address 2.2.2.2/32
VTEP1(cfg-if-Loopback 1)# exit
VTEP1(cfg)# vtep
VTEP1(cfg-vtep)# source loopback 1
VTEP1(cfg-vtep)# arp suppress enable
VTEP1(cfg-vtep)# exit
VTEP1(cfg)# vxlan 10
VTEP1(cfg-vxlan)# extend-vlan 10
VTEP1(cfg-vxlan)# arp suppress enable
VTEP1(cfg-vxlan)# exit
VTEP1(cfg)# vxlan 20
VTEP1(cfg-vxlan)# extend-vlan 20
VTEP1(cfg-vxlan)# arp suppress enable
VTEP1(cfg-vxlan)# exit
VTEP1(cfg)# router-protocol bgp 64512
VTEP1 (cfg-router)# peer 1.1.1.2 remote-as 64512

VTEP1 (cfg-router)# peer 1.1.1.3 remote-as 64512
VTEP1 (cfg-router)# peer 1.1.1.3 update-source loopback 1
VTEP1 (cfg-router)# peer 3.3.3.3 remote-as 64512
VTEP1 (cfg-router)# peer 3.3.3.3 update-source loopback 1
VTEP1(cfg-router)# address-family-mode l2vpn evpn
VTEP1(cfg-router-af)# peer 1.1.1.2 activate
VTEP1(cfg-router-af)# peer 1.1.1.3 activate
VTEP1(cfg-router-af)# peer 3.3.3.3 activate
VTEP1(cfg-router-af)# exit
VTEP1(cfg-router)# exit
```

```
VTEP1(cfg)# evpn
VTEP1(cfg-evpn)# vni 10
VTEP1(cfg-evpn-vni)# rd auto
VTEP1(cfg-evpn-vni)# route-target both auto
VTEP1(cfg-evpn-vni)# exit
VTEP1(cfg-evpn)# vni 20
VTEP1(cfg-evpn-vni)# rd auto
VTEP1(cfg-evpn-vni)# route-target both auto
VTEP1(cfg-evpn-vni)# exit
```

(2) Configure VTEP 2.

```
VTEP2> privilege
VTEP2# config-system terminal
VTEP2(cfg)# interface loopback 1
VTEP2(cfg-if-Loopback 1)# ip address 3.3.3.3/32
VTEP2(cfg-if-Loopback 1)# exit
VTEP2(cfg)# vtep
VTEP2(cfg-vtep)# source loopback 1
VTEP2(cfg-vtep)# arp suppress enable
VTEP2(cfg-vtep)# exit
VTEP2(cfg)# vxlan 100
VTEP2(cfg-vxlan)# extend-vlan 100
VTEP2(cfg-vxlan)# arp suppress enable
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# vxlan 20
VTEP2(cfg-vxlan)# extend-vlan 20
VTEP2(cfg-vxlan)# arp suppress enable
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# router-protocol bgp 64512
VTEP2 (cfg-router)# peer 1.1.1.2 remote-as 64512
VTEP2 (cfg-router)# peer 1.1.1.2 update-source loopback 1
VTEP2 (cfg-router)# peer 1.1.1.3 remote-as 64512
VTEP2 (cfg-router)# peer 1.1.1.3 update-source loopback 1
VTEP2 (cfg-router)# peer 2.2.2.2 remote-as 64512
VTEP2 (cfg-router)# peer 2.2.2.2 update-source loopback 1
VTEP2(cfg-router)# address-family-mode l2vpn evpn
VTEP2(cfg-router-af)# peer 1.1.1.2 activate
VTEP2(cfg-router-af)# peer 1.1.1.3 activate
VTEP2(cfg-router-af)# peer 2.2.2.2 activate
VTEP2(cfg-router-af)# exit
VTEP2(cfg-router)# exit
VTEP2(cfg)# evpn
VTEP2(cfg-evpn)# vni 20
VTEP2(cfg-evpn-vni)# rd auto
VTEP2(cfg-evpn-vni)# route-target both auto
VTEP2(cfg-evpn-vni)# exit
VTEP2(cfg-evpn)# vni 100
```

```
VTEP2(cfg-evpn-vni)# rd auto
VTEP2(cfg-evpn-vni)# route-target both auto
VTEP2(cfg-evpn-vni)# exit
```

(3) Configure VXLANs on VTEP 3 and VTEP 4. The configurations on the two devices are the same. The following uses VTEP 3 as an example.

```
VTEP3> privilege
VTEP3# config-system terminal
VTEP3(cfg)# interface loopback 0
VTEP3(cfg-if- Loopback 0)# ip address 1.1.1.1/32
VTEP3(cfg-if- Loopback 0)# exit
VTEP3(cfg)# interface loopback 1
VTEP3(cfg-if-Loopback 1)# ip address 1.1.1.2/32
VTEP3(cfg-if-Loopback 1)# exit
VTEP3(cfg)# fabric anycast-gateway-mac 0011.2233.2016
VTEP3(cfg)# vtep
VTEP3(cfg-vtep)# source loopback 0
VTEP3(cfg-vtep)# remote arp learn enable
VTEP3(cfg-vtep)# exit
VTEP3(cfg)# ip vrf vrf-10
VTEP3(cfg-vrf)# rd 10:10
VTEP3(cfg-vrf)# route-target both 1000:1000
VTEP3(cfg-vrf)# exit
VTEP3(cfg)# interface overlayrouter 10
VTEP3(cfg-if-OverlayRouter 10)# ip vrf binding vrf-10
VTEP3(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP3(cfg-if-OverlayRouter 10)# anycast-gateway
VTEP3(cfg-if-OverlayRouter 10)# exit
VTEP3(cfg)# vxlan 10
VTEP3(cfg-vxlan)# router-interface overlayrouter 10
VTEP3(cfg-vxlan)# exit
VTEP3(cfg)# interface overlayrouter 20
VTEP3(cfg-if-OverlayRouter 20)# ip vrf binding vrf-10
VTEP3(cfg-if-OverlayRouter 20)# ip address 10.1.2.1/24
VTEP3(cfg-if-OverlayRouter 20)# anycast-gateway
VTEP3(cfg-if-OverlayRouter 20)# exit
VTEP3(cfg)# vxlan 20
VTEP3(cfg-vxlan)# router-interface overlayrouter 20
VTEP3(cfg-vxlan)# exit
VTEP3(cfg)# ip vrf vrf-20

5.3.5 Verification

- After the commands above are run and the centralized VXLAN networking using dynamic tunnels is configured:
  - VMs in VRF-10 can ping each other successfully.
  - VMs in VRF-20 can ping each other successfully.
  - VMs in VRF-10 cannot ping those in VRF-20 and vice versa.
  - VMs can be migrated in the same VXLAN, they can access the Internet service successfully after migration, and the configurations do not need to be modified.
- Run the **display vxlan** command to display VXLAN instances on the devices. The following uses VTEP 1 and VTEP 3 as an example.

  On VTEP 1, run the **display vxlan** command to display VXLAN instances on the device.

```
VTEP1# display vxlan
VXLAN Total Count: 2
VXLAN Capacity     : 8000

VXLAN 10
     Symmetric property    : FALSE
     Routed interface      : -
```

```
    Extend VLAN              : 10
    VTEP Adjacency Count: 1
    VTEP Adjacency List :
    Interface                Source IP                                   Destination IP
Type
    ---------------------- ------------------------------------------- ------------------------------------------- -------
    OverlayTunnel 6145       2.2.2.2                                     1.1.1.1
dynamic

VXLAN 20
    Symmetric property   : FALSE
    Routed interface     : -
    Extend VLAN              : 20
    VTEP Adjacency Count: 2
    VTEP Adjacency List :
    Interface                Source IP                                   Destination IP
Type
    ---------------------- ------------------------------------------- ------------------------------------------- -------
    OverlayTunnel 6145       2.2.2.2                                     1.1.1.1
dynamic
    OverlayTunnel 6146       2.2.2.2                                     3.3.3.3
dynamic
```

On VTEP 3, run the **display vxlan** command to display VXLAN instances on the device.

```
VTEP3# display vxlan
VXLAN Total Count: 3
VXLAN Capacity     : 8000

VXLAN 10
    Symmetric property   : FALSE
    Routed interface     : OverlayRouter 10 (anycast)
    Extend VLAN              : 10
    VTEP Adjacency Count: 1
    VTEP Adjacency List :
    Interface                Source IP                                   Destination IP
Type
    ---------------------- ------------------------------------------- ------------------------------------------- -------
    OverlayTunnel 6147       1.1.1.1                                     2.2.2.2
dynamic

VXLAN 20
    Symmetric property   : FALSE
    Routed interface     : OverlayRouter 20 (anycast)
    Extend VLAN              : 20
    VTEP Adjacency Count: 2
    VTEP Adjacency List :
```

```
      Interface                 Source IP                                 Destination IP
Type
      ----------------------- ---------------------------------------- ---------------------------------------- -------
      OverlayTunnel 6147        1.1.1.1                                   2.2.2.2
dynamic
      OverlayTunnel 6148        1.1.1.1                                   3.3.3.3
dynamic

VXLAN 100
      Symmetric property    : FALSE
      Routed interface      : OverlayRouter 100 (anycast)
      Extend VLAN             : 100
      VTEP Adjacency Count: 1
      VTEP Adjacency List :
      Interface                 Source IP                                 Destination IP

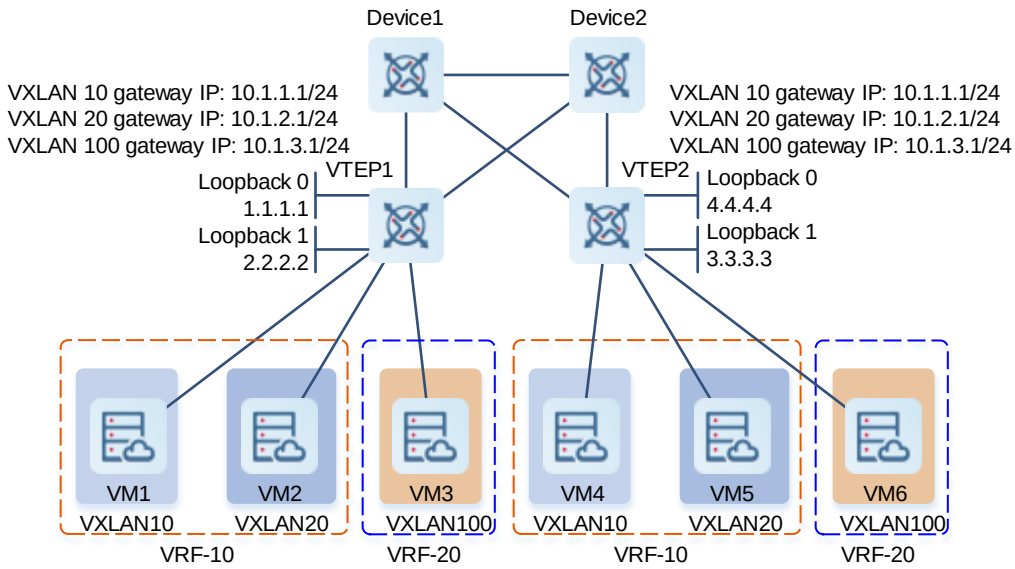
5.4 Configuring EVPN-based Multi-Tenant Distributed VXLAN Networking (Asymmetric Deployment)



5.4.1 Requirements

In the topology as shown in Figure 5-4, the following configurations are needed to support multi-tenant application in the data center and improve the network scalability:

- Configure VTEPs on access devices. Configure distributed VXLAN networking using dynamic tunnels on the VTEPs, configure VRF instances to assign multiple VXLANs to each tenant so that VXLANs of the same tenant can access each other through Layer 3 routing while VXLANs of different tenants cannot.
- Configure VXLAN gateways as the anycast gateway.
- VXLAN configuration is not required on core devices, and the VXLAN access and Layer 3 routing are accomplished on access devices.

5.4.2 Topology

Figure 5-4 Configuring EVPN-based Multi-Tenant Distributed VXLAN Networking (Asymmetric Deployment)

5.4.3 Notes

- On device 1, device 2, and VTEPs, configure an IPv4 unicast routing protocol (such as OSPF) to ensure that

the unicast routes are reachable (omitted).

- On device 1, device 2, and VTEPs, configure the BGP-EVPN routing protocol to ensure that the four devices establish BGP neighbor relationships and exchange L2VPN EVPN information.
- On each VTEP, configure an EVI for BGP-EVPN.
- On the virtualized servers, configure VXLANs and specify the gateway address for the VMs.
- On each VTEP, configure and associate a loopback interface for the establishment of a tunnel.
- On each VTEP, configure the anycast gateway MAC address.
- On each VTEP, create a VXLAN instance and associate it with a VLAN.
- On each VTEP, create an overlay router interface and configure the VXLAN gateway IP address. Configure different VRF instances for the overlay router interfaces and identify tenants by VRF instance. Configure the anycast attribute for the overlay router interface so that all VXLAN gateways in the network use the same IP address/MAC address.
- On each VTEP, associate the VXLAN instance with the overlay router interface to implement VXLAN routing.
- (Optional) Configure ARP suppression on each VTEP to reduce ARP packets flowing into the VXLANs.
- (Optional) Configure ARP proxy on the overlay router interface of each VTEP. The VXLAN gateway responds with the gateway MAC address as a proxy and VXLANs perform only Layer 3 forwarding.

5.4.4 Procedure

(1) Configure VTEP 1.

```
VTEP1> privilege
VTEP1# config-system terminal
VTEP1(cfg)# interface loopback 0
VTEP1(cfg-if-Loopback 0)# ip address 1.1.1.1/32
VTEP1(cfg-if-Loopback 0)# exit
VTEP1(cfg)# interface loopback 1
VTEP1(cfg-if-Loopback 1)# ip address 2.2.2.2/32
VTEP1(cfg-if-Loopback 1)# exit
VTEP1(cfg)# fabric anycast-gateway-mac 0011.2233.2016
VTEP1(cfg)# vtep
VTEP1(cfg-vtep)# source loopback 0
VTEP1(cfg-vtep)# arp suppress enable
VTEP1(cfg-vtep)# exit
VTEP1(cfg)# ip vrf vrf-10
VTEP1(cfg-vrf)# rd 10:10
VTEP1(cfg-vrf)# route-target both 1000:1000
VTEP1(cfg-vrf)# exit
VTEP1(cfg)# interface overlayrouter 10
VTEP1(cfg-if-OverlayRouter 10)# ip vrf binding vrf-10
VTEP1(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP1(cfg-if-OverlayRouter 10)# anycast-gateway
VTEP1(cfg-if-OverlayRouter 10)# route-in-vni    //Optional. The arp suppress enable command needs to be used together.
VTEP1(cfg-if-OverlayRouter 10)# exit
```

```
VTEP1(cfg)# vxlan 10
VTEP1(cfg-vxlan)# extend-vlan 10
VTEP1(cfg-vxlan)# router-interface overlayrouter 10
VTEP1(cfg-vxlan)# arp suppress enable
VTEP1(cfg-vxlan)# exit
VTEP1(cfg)# interface overlayrouter 20
VTEP1(cfg-if-OverlayRouter 20)# ip vrf binding vrf-10
VTEP1(cfg-if-OverlayRouter 20)# ip address 10.1.2.1/24
VTEP1(cfg-if-OverlayRouter 20)# anycast-gateway
VTEP1(cfg-if-OverlayRouter 20)# route-in-vni    //Optional. The arp suppress enable command needs to be used together.
VTEP1(cfg-if-OverlayRouter 20)# exit
VTEP1(cfg)# vxlan 20

```

5.4.5 Verification

- After the commands above are run and the distributed asymmetric VXLAN networking is configured:
  - VMs in VRF-10 can ping each other successfully.
  - VMs in VRF-20 can ping each other successfully.

- VMs in VRF-10 cannot ping those in VRF-20 and vice versa.
- VMs can be migrated in the same VXLAN, they can access the Internet service successfully after migration, and the configurations do not need to be modified.

- Run the **display vxlan** command to display VXLAN instances on the devices. The following uses VTEP 1 as an example.

```
VTEP1# display vxlan
VXLAN Total Count: 3
VXLAN Capacity     : 8000

VXLAN 10
      Symmetric property    : FALSE
      Routed interface      : overlayrouter 10 (anycast)
      Extend VLAN           : 10
      VTEP Adjacency Count: 1
      VTEP Adjacency List :
      Interface                 Source IP                                   Destination IP
Type
      ----------------------- ------------------------------------------- ------------------------------------------- -------
      OverlayTunnel 6145        1.1.1.1                                     4.4.4.4
dynamic

VXLAN 20
      Symmetric property    : FALSE
      Routed interface      : overlayrouter 20 (anycast)
      Extend VLAN           : 20
      VTEP Adjacency Count: 1
      VTEP Adjacency List :
      Interface                 Source IP                                   Destination IP
Type
      ----------------------- ------------------------------------------- ------------------------------------------- -------
      OverlayTunnel 6145        1.1.1.1                                     4.4.4.4
dynamic

VXLAN 100
      Symmetric property    : FALSE
      Routed interface      : overlayrouter 100 (anycast)
      Extend VLAN           : 100
      VTEP Adjacency Count: 1
      VTEP Adjacency List :
      Interface                 Source IP                                   Destination IP
Type
      ----------------------- ------------------------------------------- ------------------------------------------- -------
      OverlayTunnel 6145        1.1.1.1                                     4.4.4.4
dynamic
```

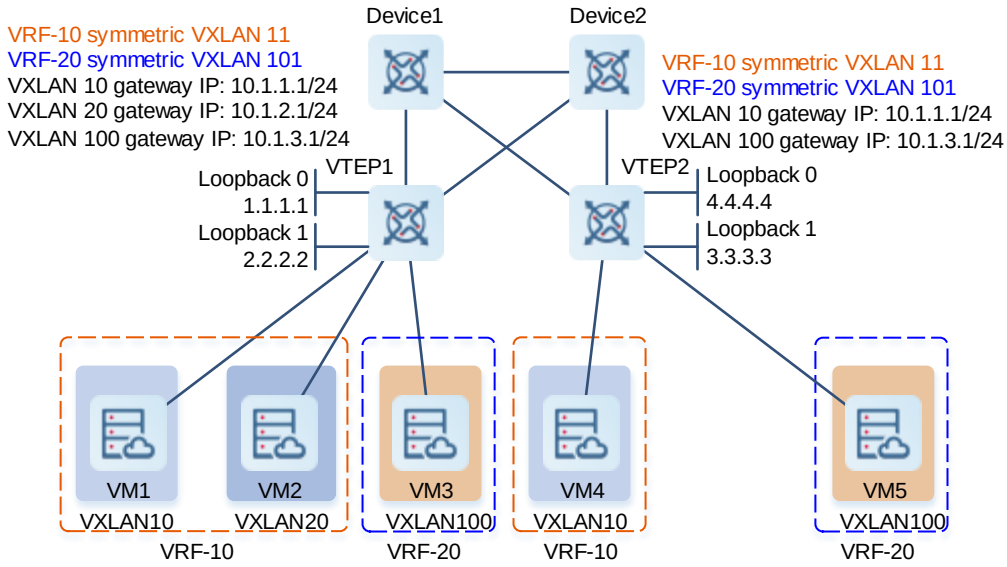
5.4.7 Common Errors

- In an asymmetric deployment scenario, a VRF instance is configured on a VTEP but no gateway is configured for all VXLANs in the VRF instance. As a result, the VXLANs with the gateway not configured cannot perform Layer 3 forwarding with other VXLANs.
- The anycast gateway MAC address conflicts with the MAC address of a device in VXLANs, resulting in a forwarding abnormality.

5.5 Configuring EVPN-based Multi-Tenant Distributed VXLAN Networking (Symmetric Deployment)

5.5.1 Requirements

In the topology as shown in Figure 5-5, the following configurations are needed to support multi-tenant application in the data center, improve the network scalability, and meet networking requirements of large data centers:



- Configure VTEPs on access devices. Configure distributed VXLAN networking using dynamic tunnels on the

VTEPs, configure VRF instances to assign multiple VXLANs to each tenant so that VXLANs of the same tenant can access each other through Layer 3 routing while VXLANs of different tenants cannot.

- Configure VXLAN gateways as the anycast gateway.
- VXLAN configuration is not required on core devices, and the VXLAN access and Layer 3 routing are accomplished on access devices.
- Deploy symmetric VXLANs on VTEPs.

5.5.2 Topology

Figure 5-5 Configuring EVPN-based Multi-Tenant Distributed VXLAN Networking (Symmetric Deployment)

5.5.3 Notes

- On device 1, device 2, and VTEPs, configure an IPv4 unicast routing protocol (such as OSPF) to ensure that the unicast routes are reachable (omitted).
- On device 1, device 2, and VTEPs, configure the BGP-EVPN routing protocol to ensure that the four devices establish BGP neighbor relationships and exchange L2VPN EVPN information.
- On each VTEP, configure an EVI for BGP-EVPN.
- On the virtualized servers, configure VXLANs and specify the gateway address for the VMs.
- On each VTEP, configure and associate a loopback interface for the establishment of a tunnel.
- On each VTEP, configure the anycast gateway MAC address.
- On VTEP 1, create VXLAN instances 10, 20, and 100 and associate them with VLANs.
- On VTEP 2, create VXLAN instances 10 and 100, and associate them with VLANs.
- On each VTEP, create an overlay router interface and configure the VXLAN gateway IP address. Configure different VRF instances for the overlay router interfaces and identify tenants by VRF instance. Configure the anycast attribute for the overlay router interface so that all VXLAN gateways in the network use the same IP address/MAC address.

- On VTEP 1 and VTEP 2, create both VXLAN instances 11 and 101, configure the symmetric attribute, and configure the symmetric VXLANs as Layer 3 routing VXLANs in the VRF instances.
- On VTEP 1 and VTEP 2, create overlay router interfaces for VXLAN instances 11 and 101, configure different VRF instances for the overlay router interfaces, and configure VXLAN 11 and VXLAN 101 as the symmetric VXLANs of the VRF instances.
- On each VTEP, associate a VXLAN instance with the VXLAN routed interface to implement VXLAN routing.
- (Optional) Configure ARP suppression on VTEP 1 and VTEP 2 to reduce ARP packets flowing to VXLANs.
- (Optional) Configure ARP proxy on the overlay router interfaces associated with VXLAN instances 10, 20, and 100 on VTEP 1 and VTEP 2 so that the traffic of hosts in the same VXLAN is forwarded at Layer 3. This function needs to be enabled together with ARP suppression.
- (Optional) In ARP proxy deployment scenarios, configure the reduction of EVPN entry synchronization. On VXLAN instances 10, 20, and 100 on VTEP 1 and VTEP 2, configure the devices not to advertise or receive MAC-only EVPN type-2 routes.
  - Configure the devices not to advertise EVPN MAC-only type-2 routes to reduce EVPN route synchronization between devices.
  - Configure the devices not to deliver MAC entries synchronized by EVPNs to reduce the occupancy of hardware entry resources.

  There is no dependency between the two configurations. You can perform the configuration separately as required.
- (Optional) In scenarios in which ARP proxy is not deployed, configure the reduction of EVPN entry synchronization. On Layer 2 VNI VXLAN instances 10, 20, and 100 on VTEP 1 and VTEP 2, configure the devices not to advertise EVPN MAC-only type-2 routes and configure devices to extract MAC addresses from MAC-IP type-2 routes:
  - Configure the devices not to advertise EVPN MAC-only type-2 routes to reduce EVPN route synchronization between devices.
  - Configure the devices to extract MAC addresses from MAC-IP type-2 routes so that MAC entries can be learned even if the neighbor does not advertise MAC-only type-2 routes.

  The two configurations above must be used in combination. Otherwise, the devices cannot learn MAC entries from neighbors and Layer 2 forwarding cannot be implemented in VXLANs.

5.5.4 Procedure

(1) Configure VTEP 1.

```
VTEP1> privilege
VTEP1# config-system terminal
VTEP1(cfg)# interface loopback 0
VTEP1(cfg-if-Loopback 1)# ip address 1.1.1.1/32
VTEP1(cfg-if-Loopback 1)# exit
VTEP1(cfg)# interface loopback 1
VTEP1(cfg-if-Loopback 1)# ip address 2.2.2.2/32
VTEP1(cfg-if-Loopback 1)# exit
VTEP1(cfg)# fabric anycast-gateway-mac 0011.2233.2016
VTEP1(cfg)# vtep
```

```
VTEP1(cfg-vtep)# source loopback 0
VTEP1(cfg-vtep)# arp suppress enable
VTEP1(cfg-vtep)# exit
VTEP1(cfg)# ip vrf vrf-10
VTEP1(cfg-vrf)# rd 10:10
VTEP1(cfg-vrf)# route-target both 1000:1000
VTEP1(cfg-vrf)# exit
VTEP1(cfg)# interface overlayrouter 10
VTEP1(cfg-if-OverlayRouter 10)# ip vrf binding vrf-10
VTEP1(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP1(cfg-if-OverlayRouter 10)# anycast-gateway
VTEP1(cfg-if-OverlayRouter 10)# route-in-vni    //Optional. It is used to enable ARP proxy and needs to be used together with the arp suppress enable command.
VTEP1(cfg-if-OverlayRouter 10)# exit
VTEP1(cfg)# vxlan 10
VTEP1(cfg-vxlan)# extend-vlan 10
VTEP1(cfg-vxlan)# router-interface overlayrouter 10
VTEP1(cfg-vxlan)# arp suppress enable

5.5.5 Verification

- After the commands above are run and the distributed symmetric VXLAN networking using dynamic tunnels is configured:
  - VMs in VRF-10 can ping each other successfully.
  - VMs in VRF-20 can ping each other successfully.
  - VMs in VRF-10 cannot ping those in VRF-20 and vice versa.
  - VMs can be migrated in the same VXLAN, they can access the Internet service successfully after migration, and the configurations do not need to be modified.
- Run the **display vxlan** command to display VXLAN instances on the devices. The following uses VTEP 1 as an example.

```
VTEP1#display vxlan
VXLAN Total Count: 5
VXLAN Capacity     : 8000

VXLAN 10
      Symmetric property    : FALSE
      Routed interface      : overlayrouter 10 (anycast)

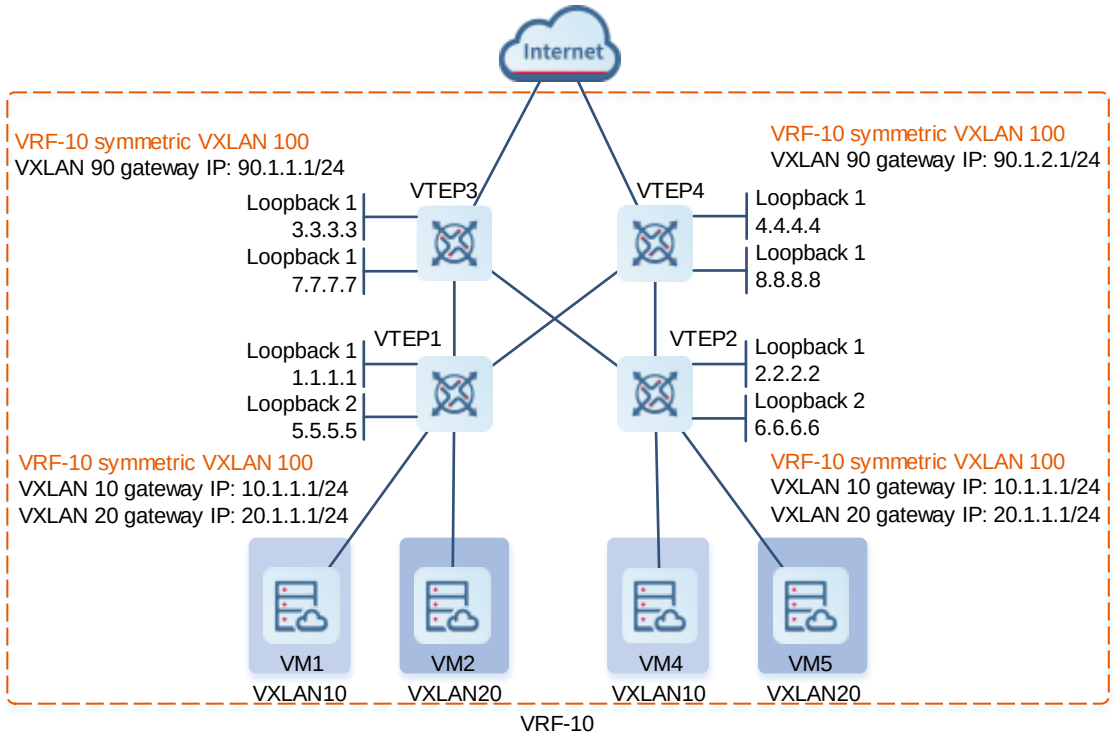
5.5.7 Common Errors

The anycast gateway MAC address conflicts with the MAC address of a device in VXLANs, resulting in a forwarding abnormality.

5.6 Configuring EVPN-based Single-Tenant VXLAN Routing

5.6.1 Requirements

In the topology as shown in Figure 5-6, VMs, access devices, and edge switches form a simple data center network:



- VMs connect to the VXLAN through access devices VTEP 1 and VTEP 2.
- The data center network connects to the Internet through VTEP 3 and VTEP 4.

The following configurations are needed to support single-tenant application in the data center, improve the network scalability, and meet the networking requirements of large data centers:

- Configure distributed VXLAN networking using dynamic tunnels on VTEP 1 and VTEP 2, and configure VRF instances to allocate the VXLANs to tenants.
- Configure the anycast gateway on VTEP 1 and VTEP 2.
- Configure gateways on VTEP 3 and VTEP 4 for Layer 3 forwarding between VXLAN networks and non-VXLAN networks.
- Configure symmetric VXLAN networking on each VTEP, and configure VTEP 3 and VTEP 4 to import network routes to the VTEPs through the symmetric VXLAN.

5.6.2 Topology

Figure 5-6 Configuring EVPN-based Single-Tenant VXLAN Routing

5.6.3 Notes

- On each VTEP, configure an IPv4 unicast routing protocol (such as OSPF) to ensure that the unicast routes are reachable (omitted).
- On each VTEP, configure the BGP-EVPN routing protocol to ensure that the devices establish BGP neighbor relationships (not between VTEP 3 and VTEP 4) and exchange L2VPN EVPN information.
- On each VTEP, configure an EVI for BGP-EVPN.
- On the virtualized servers, configure VXLANs and specify the gateway address for the VMs.
- On each VTEP, configure and associate a loopback interface for the establishment of a tunnel.
- On VTEP 1 and VTEP 2, configure the anycast gateway MAC address.

- On VTEP 1 and VTEP 2, create VXLAN instances 10 and 20 and associate them with VLANs.
- On VTEP 3 and VTEP 4, create VXLAN instance 90 and associate it with a VLAN.
- On VTEP 1 and VTEP 2, create overlay router interfaces for VXLAN instances 10 and 20 and configure the VXLAN gateway IP address. Configure the same VRF instance for the overlay router interfaces and configure the anycast attribute.
- On each VTEP, create VXLAN instance 100, configure the symmetric attribute, and configure the VXLAN instance as the Layer 3 routing VXLAN of the VRF instance.
- On each VTEP, create an overlay router interface for VXLAN instance 100, configure the same VRF instance for the overlay router interfaces, and configure VXLAN instance 100 as the symmetric VXLAN of the VRF instance.
- On each VTEP, associate a VXLAN instance with the overlay router interface to implement VXLAN routing.
- (Optional) Configure ARP suppression on VTEP 1 and VTEP 2 to reduce ARP packets flowing to VXLANs.

5.6.4 Procedure

(1) Configure VTEP 1.

```
VTEP> privilege
VTEP1# config-system terminal
VTEP1(cfg)# interface loopback 1
VTEP1(cfg-if-Loopback 1)# ip address 1.1.1.1/32
VTEP1(cfg-if-Loopback 1)# exit
VTEP1(cfg)# interface loopback 2
VTEP1(cfg-if-Loopback 2)# ip address 5.5.5.5/32
VTEP1(cfg-if-Loopback 2)# exit
VTEP1(cfg)# fabric anycast-gateway-mac 0011.2233.2016
VTEP1(cfg)# vtep
VTEP1(cfg-vtep)# source loopback 2
VTEP1(cfg-vtep)# arp suppress enable
VTEP1(cfg-vtep)# exit
VTEP1(cfg)# ip vrf vrf-10
VTEP1(cfg-vrf)# rd 10:10
VTEP1(cfg-vrf)# route-target export 1000:1000
VTEP1(cfg-vrf)# exit
VTEP1(cfg)# interface overlayrouter 10
VTEP1(cfg-if-OverlayRouter 10)# ip vrf binding vrf-10
VTEP1(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP1(cfg-if-OverlayRouter 10)# anycast-gateway

```

5.6.5 Verification

- VM 1, VM 2, VM 3, and VM 4 can ping each other.
- VMs can be migrated in the same VXLAN, they can access the Internet service successfully after migration, and the configurations do not need to be modified.
- Run the **display vxlan** command to display VXLAN instances on the devices. The following uses VTEP 3 as an example.

```
VTEP3# display vxlan
VXLAN Total Count: 2
VXLAN Capacity     : 8000

VXLAN 90
      Symmetric property    : FALSE
      Routed interface      : overlayrouter 90 (anycast)
      Extend VLAN           : 90
      VTEP Adjacency Count: 0

VXLAN 100
      Symmetric property    : TRUE
      Routed interface      : overlayrouter 100 (non-anycast)
      Extend VLAN           : -
      VTEP Adjacency Count: 2
      VTEP Adjacency List :
      Interface                Source IP                                    Destination IP
Type
      ---------------------- ------------------------------------------- ------------------------------------------- -------
      OverlayTunnel 6145       7.7.7.7                                      5.5.5.5
dynamic
      OverlayTunnel 6146       7.7.7.7                                      6.6.6.6
dynamic
```

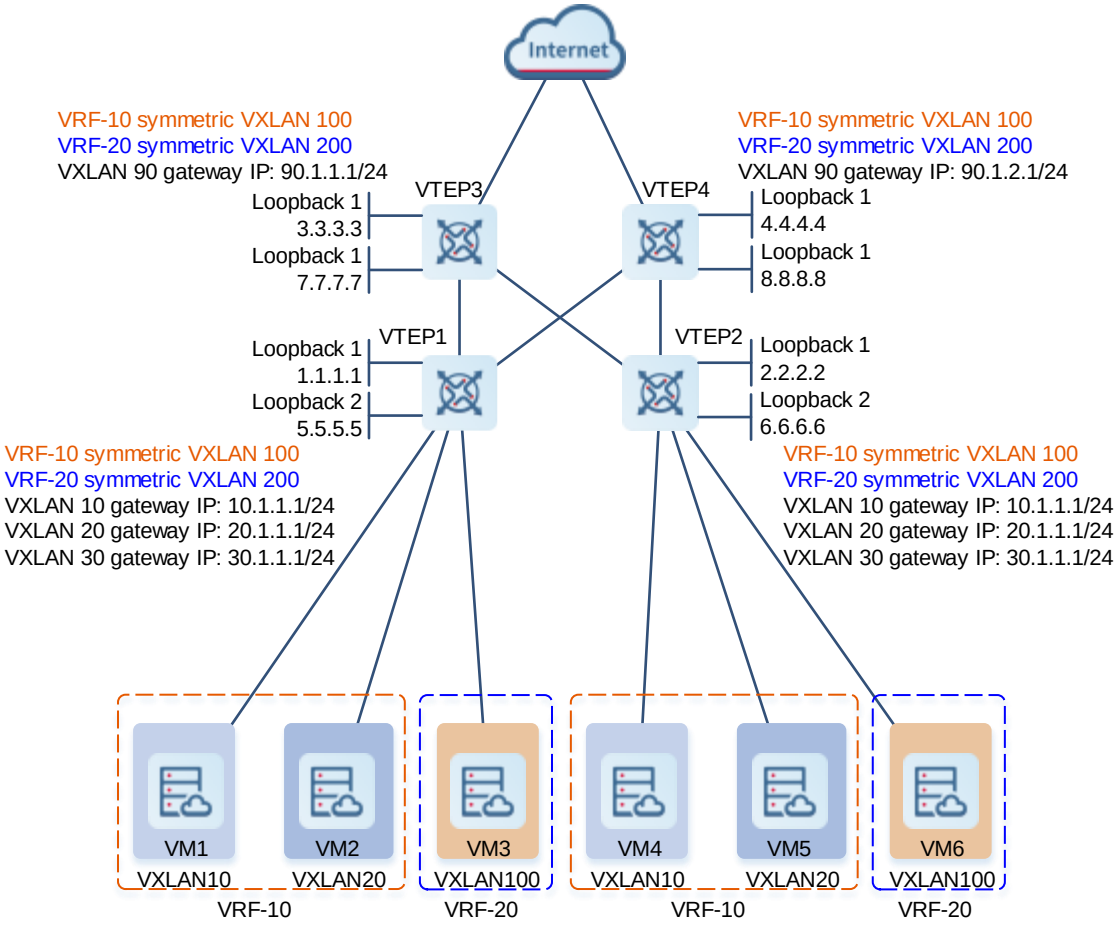
5.7 Configuring EVPN-based Multi-Tenant VXLAN Routing

5.7.1 Requirements

In the topology as shown in Figure 5-7, VMs, access devices, and edge switches form a simple data center network:

- VMs connect to the VXLAN through access devices VTEP 1 and VTEP 2.
- The data center network connects to the Internet through VTEP 3 and VTEP 4.

The following configurations are needed to support multi-tenant application in the data center, improve the network scalability, and meet the networking requirements of large data centers:



- Configure distributed VXLAN networking using dynamic tunnels on VTEP 1 and VTEP 2, and configure VRF instances to allocate the VXLANs to tenants.
- Configure the anycast gateway on VTEP 1 and VTEP 2.
- Configure gateways on VTEP 3 and VTEP 4 for Layer 3 forwarding between VXLAN networks and

non-VXLAN networks.

- Configure symmetric VXLAN networking on each VTEP, and configure VTEP 3 and VTEP 4 to import network routes to the VTEPs through the symmetric VXLAN.

5.7.2 Topology

Figure 5-7 Configuring EVPN-based Multi-Tenant VXLAN Routing

5.7.3 Notes

- On each VTEP, configure an IPv4 unicast routing protocol (such as OSPF) to ensure that the unicast routes are reachable (omitted).
- On each VTEP, configure the BGP-EVPN routing protocol to ensure that the devices establish BGP neighbor relationships (not between VTEP 3 and VTEP 4) and exchange L2VPN EVPN information.
- On each VTEP, configure an EVI for BGP-EVPN.
- On the virtualized servers, configure VXLANs and specify the gateway address for the VMs.
- On each VTEP, configure and associate a loopback interface for the establishment of a tunnel.
- On VTEP 1 and VTEP 2, configure the anycast gateway MAC address.
- On VTEP 1 and VTEP 2, create VXLAN instances 10, 20, and 30 and associate them with VXLANs.
- On VTEP 3 and VTEP 4, create VXLAN instance 90 and associate it with a VLAN.

- On VTEP 1 and VTEP 2, create overlay router interfaces for VXLAN instances 10, 20, and 30 and configure the VXLAN gateway IP address. Configure different VRF instances for the overlay router interfaces and configure the anycast attribute.
- On each VTEP, create VXLAN instances100 and 200, configure the symmetric attribute, and configure the VXLAN instances as the Layer 3 routing VXLANs of VRF instances.
- On each VTEP, create overlay router interfaces for VXLAN instances 100 and 200, configure VRF instances for the overlay router interfaces, and configure the VXLAN instances as the symmetric VXLANs of the VRF instances.
- On each VTEP, associate a VXLAN instance with the overlay router interface to implement VXLAN routing.
- (Optional) Configure ARP suppression on VTEP 1 and VTEP 2 to reduce ARP packets flowing to VXLANs.

5.7.4 Procedure

(1) Configure VTEP 1.

```
VTEP1> privilege
VTEP1# config-system terminal
VTEP1(cfg)# interface loopback 1
VTEP1(cfg-if-Loopback 1)# ip address 1.1.1.1/32
VTEP1(cfg-if-Loopback 1)# exit
VTEP1(cfg)# interface loopback 2
VTEP1(cfg-if-Loopback 2)# ip address 5.5.5.5/32
VTEP1(cfg-if-Loopback 2)# exit
VTEP1(cfg)# fabric anycast-gateway-mac 0011.2233.2016
VTEP1(cfg)# vtep
VTEP1(cfg-vtep)# source loopback 2

```

5.7.5 Verification

- VM 1, VM 2, VM 4, and VM 5 can ping each other.
- VM 3 and VM 6 can ping each other.
- VMs belonging to different VRF instances cannot ping each other.
- VMs can be migrated in the same VXLAN, they can access the Internet service successfully after migration, and the configurations do not need to be modified.

- Run the **display vxlan** command to display VXLAN instances on the devices. The following uses VTEP 3 as an example.

```
VTEP3# display vxlan
VXLAN Total Count: 3
VXLAN Capacity     : 8000

VXLAN 90
      Symmetric property    : FALSE
      Routed interface      : overlayrouter 90 (anycast)
      Extend VLAN           : 90
      VTEP Adjacency Count: 0

VXLAN 100
      Symmetric property    : TRUE
      Routed interface      : overlayrouter 100 (non-anycast)
      Extend VLAN           : -
      VTEP Adjacency Count: 2
      VTEP Adjacency List :
      Interface                Source IP                                   Destination IP
Type
      ---------------------- ------------------------------------------- ------------------------------------------- -------
      OverlayTunnel 6145       7.7.7.7                                     5.5.5.5
dynamic
      OverlayTunnel 6146       7.7.7.7                                     6.6.6.6
dynamic

VXLAN 200
      Symmetric property    : TRUE
      Routed interface      : overlayrouter 200 (non-anycast)
      Extend VLAN           : -
      VTEP Adjacency Count: 2
      VTEP Adjacency List :
      Interface                Source IP                                   Destination IP
Type
      ---------------------- ------------------------------------------- ------------------------------------------- -------
      OverlayTunnel 6145       7.7.7.7                                     5.5.5.5
dynamic
      OverlayTunnel 6146       7.7.7.7                                     6.6.6.6
dynamic

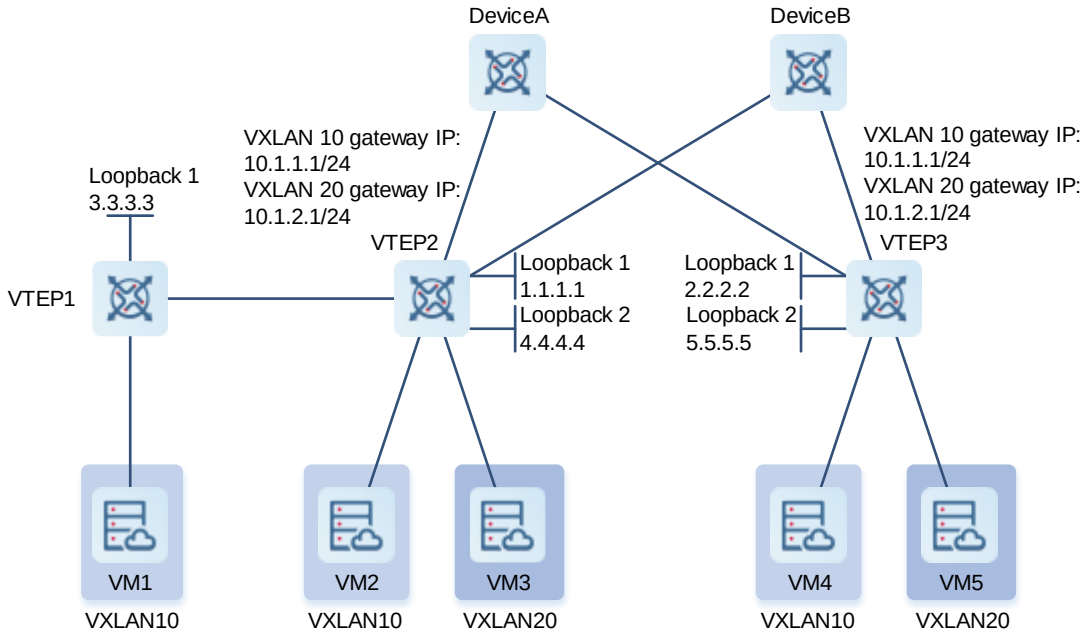
5.8 Configuring an EVPN Distributed Network to Support Non-EVPN VTEPs



5.8.1 Requirements

In the topology as shown in Figure 5-8, VMs, access devices, and edge switches form a simple data center network. VTEP 1 does not support the EVPN function but VTEP 2 and VTEP 3 support the EVPN function. VTEP 2 and VTEP 3 form an EVPN distributed network. The following configurations are needed to connect VTEP 1 to the EVPN distributed network:

- On VTEP 2 and VTEP 3, configure distributed VXLAN networking using dynamic tunnels.
- On VTEP 2 and VTEP 3, configure the anycast gateway.
- On VTEP 2 and VTEP 3, configure the gateway to perform Layer 3 forwarding on traffic from the VXLAN network and non-VXLAN network.
- On VTEP 1 and VTEP 2, configure VXLAN networking using static tunnels and specify the tunnel.

5.8.2 Topology

Figure 5-8 Configuring an EVPN Distributed Network to Support Non-EVPN VTEPs

5.8.3 Notes

- On each device, configure an IPv4 unicast routing protocol (such as OSPF) to ensure that the unicast routes are reachable (omitted).
- On VTEP 2, VTEP 3, device A, and device B, configure the BGP-EVPN routing protocol to ensure that the devices establish BGP neighbor relationships and exchange L2VPN EVPN information.
- On VTEP 2 and VTEP 3, configure an EVI for BGP-EVPN.
- On the virtualized servers, configure VXLANs and specify the gateway address for the VMs.
- On VTEP 2 and VTEP 3, configure and associate a loopback interface for the establishment of a tunnel.
- On VTEP 2 and VTEP 3, configure the anycast gateway MAC address.
- On each VTEP, create a VXLAN instance.
- On VTEP 2 and VTEP 3, create an overlay router interface for the VXLAN instance and configure the VXLAN gateway IP address. Configure the anycast attribute for the overlay router interface.
- On VTEP 2 and VTEP 3, associate the VXLAN instance with the overlay router interface to implement VXLAN routing.
- On VTEP 1 and VTEP 2, create a VXLAN tunnel and configure the source and destination IP addresses.
- On VTEP 1 and VTEP 2, associate the VXLAN instance with the VXLAN tunnel, and configure the tunnel as the data center interconnection tunnel.
- On VTEP 2, configure a route map and apply it to the EVPN protocol family so that the next hop of all EVPN type-2 routes advertised by VTEP 2 is changed to the IP address of VTEP 2.
- (Optional) Configure ARP suppression on VTEP 2 and VTEP 3 to reduce ARP packets flowing to the

VXLANs.

5.8.4 Procedure

(1) Configure VTEP 1.

```
VTEP1> privilege
VTEP1# config-system terminal
VTEP1(cfg)# interface loopback 1
VTEP1(cfg-if-Loopback 1)# ip address 3.3.3.3/32
VTEP1(cfg-if-Loopback 1)# exit
VTEP1(cfg)# interface overlaytunnel 1
VTEP1(cfg-if-OverlayTunnel 1)# overlaytunnel source 3.3.3.3
VTEP1(cfg-if-OverlayTunnel 1)# overlaytunnel destination 1.1.1.1
VTEP1(cfg-if-OverlayTunnel 1)# exit
VTEP1(cfg)# vxlan 10
VTEP1(cfg-vxlan)# extend-vlan 10
VTEP1(cfg-vxlan)# tunnel-interface overlaytunnel 1
```

(2) Configure VTEP 2.

```
VTEP2> privilege
VTEP2# config-system terminal
VTEP2(cfg)# route-map dc
VTEP2(cfg-routemap)# match-rule route-type evpn-type-2
VTEP2(cfg-routemap)# set-rule next-hop 4.4.4.4
VTEP2(cfg-routemap)# exit
VTEP2(cfg)# interface loopback 1
VTEP2(cfg-if-Loopback 1)# ip address 1.1.1.1/32
VTEP2(cfg-if-Loopback 1)# exit
VTEP2(cfg)# interface loopback 2
VTEP2(cfg-if-Loopback 2)# ip address 4.4.4.4/32
VTEP2(cfg-if-Loopback 2)# exit
VTEP2(cfg)# fabric anycast-gateway-mac 0000.1234.5678
VTEP2(cfg)# vtep
VTEP2(cfg-vtep)# source loopback 1
VTEP2(cfg-vtep)# arp suppress enable
VTEP2(cfg-vtep)# vxlan outside center vtep-ip 3.3.3.3
VTEP2(cfg-vtep)# exit
VTEP2(cfg)# interface overlayrouter 10
VTEP2(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP2(cfg-if-OverlayRouter 10)# anycast-gateway
VTEP2(cfg-if-OverlayRouter 10)# route-in-vni    //Optional. The arp suppress enable command needs to be used together.
VTEP2(cfg-if-OverlayRouter 10)# exit
VTEP2(cfg)# interface overlaytunnel 1
VTEP2(cfg-if-OverlayTunnel 1)# overlaytunnel source 1.1.1.1
VTEP2(cfg-if-OverlayTunnel 1)# overlaytunnel destination 3.3.3.3
VTEP2(cfg-if-OverlayTunnel 1)# evpn mac advertise enable
```

```
VTEP2(cfg-if-OverlayTunnel 1)# evpn mac-ip advertise enable
VTEP2(cfg-if-OverlayTunnel 1)# exit
VTEP2(cfg)# vxlan 10
VTEP2(cfg-vxlan)# extend-vlan 10
VTEP2(cfg-vxlan)# router-interface overlayrouter 10
VTEP2(cfg-vxlan)# tunnel-interface overlaytunnel 1
VTEP2(cfg-vxlan)# arp suppress enable
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# interface overlayrouter 20
VTEP2(cfg-if-OverlayRouter 20)# ip address 10.1.2.1/24
VTEP2(cfg-if-OverlayRouter 20)# anycast-gateway
VTEP2(cfg-if-OverlayRouter 20)# route-in-vni    //Optional. The arp suppress enable command needs to be used together.
VTEP2(cfg-if-OverlayRouter 20)# exit
VTEP2(cfg)# vxlan 20
VTEP2(cfg-vxlan)# extend-vlan 20
VTEP2(cfg-vxlan)# router-interface overlayrouter 20
VTEP2(cfg-vxlan)# arp suppress enable
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# router-protocol bgp 100
VTEP2(cfg-router)# peer 5.5.5.5 remote-as 100
VTEP2(cfg-router)# peer 5.5.5.5 update-source loopback 2
VTEP2(cfg-router)# address-family-mode l2vpn evpn
VTEP2(cfg-router-af)# peer 5.5.5.5 activate
VTEP2(cfg-router-af)# peer 5.5.5.5 route-map dc out
VTEP2(cfg-router-af)# exit
VTEP2(cfg-router)# exit

VTEP2(cfg-evpn-vni)# rd auto
VTEP2(cfg-evpn-vni)# route-target both auto
VTEP2(cfg-evpn-vni)# exit
```

(3) Configure VTEP 3.

```
VTEP3# config-system terminal
VTEP3(cfg)# interface loopback 1
VTEP3(cfg-if-Loopback 1)# ip address 2.2.2.2/32
VTEP3(cfg-if-Loopback 1)# exit
VTEP3(cfg)# interface loopback 2
VTEP3(cfg-if-Loopback 2)# ip address 5.5.5.5/32
VTEP3(cfg-if-Loopback 2)# exit
VTEP3(cfg)# fabric anycast-gateway-mac 0000.1234.5678
VTEP3(cfg)# vtep
```

```
VTEP3(cfg-vtep)# source loopback 1
VTEP3(cfg-vtep)# arp suppress enable
VTEP3(cfg-vtep)# exit
VTEP3(cfg)# interface overlayrouter 10
VTEP3(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP3(cfg-if-OverlayRouter 10)# anycast-gateway
VTEP3(cfg-if-OverlayRouter 10)# route-in-vni    //Optional. The arp suppress enable command needs to be used together.
VTEP3(cfg-if-OverlayRouter 10)# exit
VTEP3(cfg)# vxlan 10
VTEP3(cfg-vxlan)# extend-vlan 10
VTEP3(cfg-vxlan)# router-interface overlayrouter 10
VTEP3(cfg-vxlan)# arp suppress enable
VTEP3(cfg-vxlan)# exit
VTEP3(cfg)# interface overlayrouter 20
VTEP3(cfg-if-OverlayRouter 20)# ip address 10.1.2.1/24
VTEP3(cfg-if-OverlayRouter 20)# anycast-gateway
VTEP3(cfg-if-OverlayRouter 20)# route-in-vni    //Optional. The arp suppress enable command needs to be used together.
VTEP3(cfg-if-OverlayRouter 20)# exit
VTEP3(cfg)# vxlan 20
VTEP3(cfg-vxlan)# extend-vlan 20
VTEP3(cfg-vxlan)# router-interface overlayrouter 20
VTEP3(cfg-vxlan)# arp suppress enable
VTEP3(cfg-vxlan)# exit
VTEP3(cfg)# router-protocol bgp 100
VTEP3(cfg-router)# peer 4.4.4.4 remote-as 100
VTEP3(cfg-router)# peer 4.4.4.4 update-source loopback 2
VTEP3(cfg-router)# address-family-mode l2vpn evpn
VTEP3(cfg-router-af)# peer 4.4.4.4 activate
VTEP3(cfg-router-af)# exit
VTEP3(cfg-router)# exit

```

5.8.5 Verification

- VMs can ping each other.
- VMs can be migrated in the same VXLAN, they can access the Internet service successfully after migration, and the configurations do not need to be modified.

- Run the **display vxlan** command to display VXLAN instances on the devices. The following uses VTEP 2 as an example.

```
VTEP2# display vxlan
VXLAN Total Count: 2
VXLAN Capacity     : 8000

VXLAN 10
      Symmetric property    : FALSE
      Routed interface      : overlayrouter 10 (anycast)
      Extend VLAN           : 10
      VTEP Adjacency Count: 2
      VTEP Adjacency List :
      Interface                Source IP                                    Destination IP
Type
      ---------------------- ---------------------------------------------- ---------------------------------------------- -------
      OverlayTunnel 1          1.1.1.1                                      3.3.3.3
static
      OverlayTunnel 6145       1.1.1.1                                      2.2.2.2
dynamic

VXLAN 20
      Symmetric property    : FALSE
      Routed interface      : overlayrouter 20 (anycast)
      Extend VLAN           : 20
      VTEP Adjacency Count: 1
      VTEP Adjacency List :
      Interface                Source IP                                    Destination IP
Type
      ---------------------- ---------------------------------------------- ---------------------------------------------- -------
      OverlayTunnel 6145       1.1.1.1                                      2.2.2.2
dynamic
```

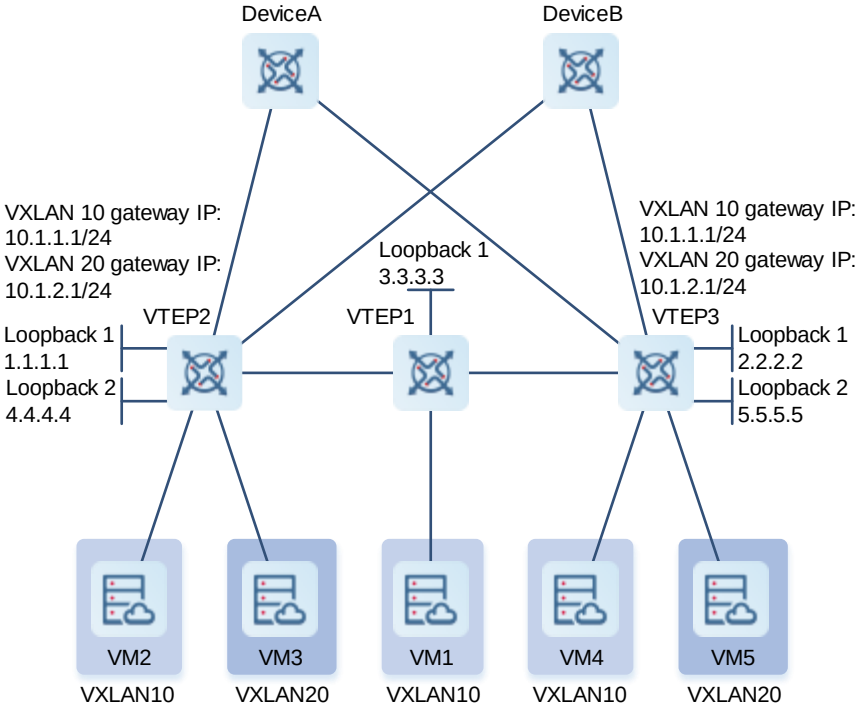
5.9 Configuring Non-EVPN VTEPs to Connect to an EVPN Distributed Network in Full-Mesh Pattern



5.9.1 Requirements

In the topology as shown in Figure 5-9, VMs, access devices, and edge switches form a simple data center network. VTEP 1 does not support the EVPN function but VTEP 2 and VTEP 3 support the EVPN function. VTEP 2 and VTEP 3 form an EVPN distributed network. The following configurations are needed to connect VTEP 1 to the EVPN distributed network in full-mesh pattern:

- On VTEP 2 and VTEP 3, configure distributed VXLAN networking using dynamic tunnels.
- On VTEP 2 and VTEP 3, configure the anycast gateway.
- On VTEP 2 and VTEP 3, configure the gateway to perform Layer 3 forwarding on traffic from the VXLAN network and non-VXLAN network.
- On VTEP 1 and VTEP 2, configure VXLAN networking using static tunnels and specify the tunnel.

5.9.2 Topology

Figure 5-9 Configuring Non-EVPN VTEPs to Connect to an EVPN Distributed Network in Full-Mesh Pattern

5.9.3 Notes

- On each device, configure an IPv4 unicast routing protocol (such as OSPF) to ensure that the unicast routes are reachable (omitted).
- On VTEP 2, VTEP 3, device A, and device B, configure the BGP-EVPN routing protocol to ensure that the devices establish BGP neighbor relationships and exchange L2VPN EVPN information.
- On VTEP 2 and VTEP 3, configure an EVI for BGP-EVPN.
- On the virtualized servers, configure VXLANs and specify the gateway address for the VMs.
- On VTEP 2 and VTEP 3, configure and associate a loopback interface for the establishment of a tunnel.
- On VTEP 2 and VTEP 3, configure the anycast gateway MAC address.
- On each VTEP, create a VXLAN instance.
- On VTEP 2 and VTEP 3, create an overlay router interface for the VXLAN instance and configure the VXLAN gateway IP address. Configure the anycast attribute for the overlay router interface.

- On VTEP 2 and VTEP 3, associate the VXLAN instance with the overlay router interface to implement VXLAN routing.
- On VTEP 1, VTEP 2, and VTEP 3, create a VXLAN tunnel and configure the source and destination IP addresses for the tunnel.
- On VTEP 1, VTEP 2, and VTEP 3, configure a VXLAN instance to associate with the VXLAN tunnel.
- (Optional) Configure ARP suppression on VTEP 2 and VTEP 3 to reduce ARP packets flowing to the VXLANs.

5.9.4 Procedure

(1) Configure VTEP 1.

```
VTEP1> privilege
VTEP1# config-system terminal
VTEP1(cfg)# interface loopback 1
VTEP1(cfg-if-Loopback 1)# ip address 3.3.3.3/32
VTEP1(cfg-if-Loopback 1)# exit
VTEP1(cfg)# interface overlaytunnel 1
VTEP1(cfg-if-OverlayTunnel 1)# overlaytunnel source 3.3.3.3
VTEP1(cfg-if-OverlayTunnel 1)# overlaytunnel destination 1.1.1.1
VTEP1(cfg-if-OverlayTunnel 1)# exit
VTEP1(cfg)# interface overlaytunnel 2
VTEP1(cfg-if-OverlayTunnel 2)# overlaytunnel source 3.3.3.3
VTEP1(cfg-if-OverlayTunnel 2)# overlaytunnel destination 2.2.2.2
VTEP1(cfg-if-OverlayTunnel 2)# exit
VTEP1(cfg)# vxlan 10
VTEP1(cfg-vxlan)# extend-vlan 10
VTEP1(cfg-vxlan)# tunnel-interface overlaytunnel 1
VTEP1(cfg-vxlan)# tunnel-interface overlaytunnel 2
```

(2) Configure VTEP 2.

```
VTEP2> privilege
VTEP2# config-system terminal
VTEP2(cfg)# interface loopback 1
VTEP2(cfg-if-Loopback 1)# ip address 1.1.1.1/32
VTEP2(cfg-if-Loopback 1)# exit
VTEP2(cfg)# interface loopback 2
VTEP2(cfg-if-Loopback 2)# ip address 4.4.4.4/32
VTEP2(cfg-if-Loopback 2)# exit
VTEP2(cfg)# fabric anycast-gateway-mac 0000.1234.5678
VTEP2(cfg)# vtep
VTEP2(cfg-vtep)# source loopback 1
VTEP2(cfg-vtep)# arp suppress enable
VTEP2(cfg-vtep)# exit
VTEP2(cfg)# interface overlayrouter 10
VTEP2(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP2(cfg-if-OverlayRouter 10)# anycast-gateway
```

```
VTEP2(cfg-if-OverlayRouter 10)# route-in-vni    //Optional. The arp suppress enable command needs to be used together.
VTEP2(cfg-if-OverlayRouter 10)# exit
VTEP2(cfg)# interface overlaytunnel 1
VTEP2(cfg-if-OverlayTunnel 1)# overlaytunnel source 1.1.1.1
VTEP2(cfg-if-OverlayTunnel 1)# overlaytunnel destination 3.3.3.3
VTEP2(cfg-if-OverlayTunnel 1)# exit
VTEP2(cfg)# vxlan 10
VTEP2(cfg-vxlan)# extend-vlan 10
VTEP2(cfg-vxlan)# router-interface overlayrouter 10
VTEP2(cfg-vxlan)# tunnel-interface overlaytunnel 1
VTEP2(cfg-vxlan)# arp suppress enable
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# interface overlayrouter 20
VTEP2(cfg-if-OverlayRouter 20)# ip address 10.1.2.1/24
VTEP2(cfg-if-OverlayRouter 20)# anycast-gateway
VTEP2(cfg-if-OverlayRouter 20)# route-in-vni    //Optional. The arp suppress enable command needs to be used together.
VTEP2(cfg-if-OverlayRouter 20)# exit
VTEP2(cfg)# vxlan 20
VTEP2(cfg-vxlan)# extend-vlan 20
VTEP2(cfg-vxlan)# router-interface OverlayRouter 20
VTEP2(cfg-vxlan)# arp suppress enable
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# router-protocol bgp 100
VTEP2(cfg-router)# peer 5.5.5.5 remote-as 100
VTEP2(cfg-router)# peer 5.5.5.5 update-source loopback 2
VTEP2(cfg-router)# address-family-mode l2vpn evpn
VTEP2(cfg-router-af)# peer 5.5.5.5 activate
VTEP2(cfg-router-af)# exit
VTEP2(cfg-router)# exit
VTEP2(cfg)# evpn
VTEP2(cfg-evpn)# vni 10
VTEP2(cfg-evpn-vni)# rd auto
VTEP2(cfg-evpn-vni)# route-target both auto

VTEP2(cfg-evpn)# vni 20
VTEP2(cfg-evpn-vni)# rd auto
VTEP2(cfg-evpn-vni)# route-target both auto
VTEP2(cfg-evpn-vni)# exit
```

(3) Configure VTEP 3.

```
VTEP3> privilege
VTEP3# config-system terminal
VTEP3(cfg)# interface loopback 1
VTEP3(cfg-if-Loopback 1)# ip address 2.2.2.2/32
VTEP3(cfg-if-Loopback 1)# exit
```

```
VTEP3(cfg)# interface loopback 2
VTEP3(cfg-if-Loopback 2)# ip address 5.5.5.5/32
VTEP3(cfg-if-Loopback 2)# exit
VTEP3(cfg)# fabric anycast-gateway-mac 0000.1234.5678
VTEP3(cfg)# vtep
VTEP3(cfg-vtep)# source loopback 1
VTEP3(cfg-vtep)# arp suppress enable
VTEP3(cfg-vtep)# exit
VTEP3(cfg)# interface overlayrouter 10
VTEP3(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP3(cfg-if-OverlayRouter 10)# anycast-gateway
VTEP3(cfg-if-OverlayRouter 10)# route-in-vni    //Optional. The arp suppress enable command needs to be used together.
VTEP3(cfg-if-OverlayRouter 10)# exit
VTEP3(cfg)# interface overlaytunnel 1
VTEP3(cfg-if-OverlayTunnel 1)# overlaytunnel source 2.2.2.2
VTEP3(cfg-if-OverlayTunnel 1)# overlaytunnel destination 3.3.3.3
VTEP3(cfg-if-OverlayTunnel 1)# exit
VTEP3(cfg)# vxlan 10
VTEP3(cfg-vxlan)# extend-vlan 10
VTEP3(cfg-vxlan)# router-interface overlayrouter 10
VTEP3(cfg-vxlan)# tunnel-interface overlaytunnel 1
VTEP3(cfg-vxlan)# arp suppress enable
VTEP3(cfg-vxlan)# exit
VTEP3(cfg)# interface overlayrouter 20
VTEP3(cfg-if-OverlayRouter 20)# ip address 10.1.2.1/24
VTEP3(cfg-if-OverlayRouter 20)# anycast-gateway
VTEP3(cfg-if-OverlayRouter 20)# route-in-vni    //Optional. The arp suppress enable command needs to be used together.
VTEP3(cfg-if-OverlayRouter 20)# exit
VTEP3(cfg)# vxlan 20
VTEP3(cfg-vxlan)# extend-vlan 20
VTEP3(cfg-vxlan)# router-interface overlayrouter 20
VTEP3(cfg-vxlan)# arp suppress enable
VTEP3(cfg-vxlan)# exit
VTEP3(cfg)# router-protocol bgp 100
VTEP3(cfg-router)# peer 4.4.4.4 remote-as 100

```

```
VTEP3(cfg-evpn-vni)# exit
VTEP3(cfg-evpn)# vni 20
VTEP3(cfg-evpn-vni)# rd auto
VTEP3(cfg-evpn-vni)# route-target both auto
VTEP3(cfg-evpn-vni)# exit
```

5.9.5 Verification

- VMs can ping each other.
- VMs can be migrated in the same VXLAN, they can access the Internet service successfully after migration, and the configurations do not need to be modified.
- Run the **display vxlan** command to display VXLAN instances on the devices. The following uses VTEP 2 as an example.

```
VTEP2# display vxlan
VXLAN Total Count: 2
VXLAN Capacity     : 8000

VXLAN 10
      Symmetric property    : FALSE
      Routed interface      : overlayrouter 10 (anycast)
      Extend VLAN           : 10
      VTEP Adjacency Count: 2
      VTEP Adjacency List :
Interface                   Source IP                                       Destination IP
Type
      ---------------------- ---------------------------------------------- ---------------------------------------------- -------
OverlayTunnel 1             1.1.1.1                                         3.3.3.3
static
OverlayTunnel 6145          1.1.1.1                                         2.2.2.2
dynamic

VXLAN 20
      Symmetric property    : FALSE
      Routed interface      : overlayrouter 20 (anycast)
      Extend VLAN           : 20
      VTEP Adjacency Count: 1
      VTEP Adjacency List :
      Interface                   Source IP                                       Destination IP
Type
      ---------------------- ---------------------------------------------- ---------------------------------------------- -------
      OverlayTunnel 6145          1.1.1.1                                         2.2.2.2
dynamic
```

5.10 Configuring Data Center Interconnection Based on VNI Mappings

5.10.1 Requirements

In the topology as shown in Figure 5-10, PODs (data centers) connected through an IP network. VNI mappings need to be configured on Layer 3 routing devices in PODs so that an independent VNI is maintained inside each POD and a public VNI is maintained for the interaction of PODs.

5.10.2 Topology

Figure 5-10 Configuring Data Center Interconnection Based on VNI Mappings

5.10.3 Notes

- On each VTEP, configure an IPv4 unicast routing protocol (such as OSPF) to ensure that the unicast routes are reachable (omitted).
- On each VTEP, configure the BGP-EVPN routing protocol to ensure that the devices establish BGP neighbor relationships and exchange L2VPN EVPN information.
- On each VTEP, configure an EVI for BGP-EVPN.
- On each VTEP, configure and associate a loopback interface for the establishment of a tunnel.
- On each VTEP, create a VXLAN instance.
- On each VTEP, create an overlay router interface for the VXLAN instance and configure the VXLAN gateway IP address.
- On each VTEP, associate the VXLAN instance with the overlay router interface to implement VXLAN routing.
- On VTEP 1 and VTEP 2, configure a data center interconnection tunnel.
- On each VTEP, configure a VNI mapping.
- On each VTEP, create a symmetric instance and configure the VXLAN gateway. No IP address needs to be configured for the gateway associated with the symmetric instance.
- On each VTEP, configure Layer 3 VNI mappings.

5.10.4 Procedure

For the network topology and device configuration of each POD, see 5.4 Configuring EVPN-based Multi-Tenant Distributed VXLAN Networking (Asymmetric Deployment). This section focuses on VXLAN configuration on core devices in PODs.

(1) Configure VTEP 1.

```
VTEP1> privilege
VTEP1# config-system terminal
VTEP1(cfg)# interface loopback 1
VTEP1(cfg-if-Loopback 1)# ip address 1.1.1.1/32
VTEP1(cfg-if-Loopback 1)# exit
VTEP1(cfg)# interface loopback 2
VTEP1(cfg-if-Loopback 2)# ip address 3.3.3.3/32
VTEP1(cfg-if-Loopback 2)# exit
VTEP1(cfg)# fabric anycast-gateway-mac 0011.2233.2016
VTEP1(cfg)# vtep
VTEP1(cfg-vtep)# source loopback 1
VTEP1(cfg-vtep)# vxlan outside center vtep-ip 2.2.2.2
VTEP1(cfg-vtep)# exit
VTEP1(cfg)# ip vrf vrf-10
VTEP1(cfg-vrf)# rd 10:10
VTEP1(cfg-vrf)# route-target export 1000:1000
VTEP1(cfg-vrf)# exit
VTEP1(cfg)# interface overlayrouter 10
VTEP1(cfg-if-OverlayRouter 10)# ip vrf binding vrf-10
VTEP1(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP1(cfg-if-OverlayRouter 10)# anycast-gateway
VTEP1(cfg-if-OverlayRouter 10)# exit
VTEP1(cfg)# vxlan 10
VTEP1(cfg-vxlan)# router-interface overlayrouter 10
VTEP1(cfg-vxlan)# mapping vni 30
VTEP1(cfg-vxlan)# arp suppress enable
VTEP1(cfg-vxlan)# exit
VTEP1(cfg)# interface overlayrouter 30
VTEP1(cfg-if-OverlayRouter 30)# ip vrf binding vrf-10
VTEP1(cfg-if-OverlayRouter 30)# ip address 30.1.1.1/24
VTEP1(cfg-if-OverlayRouter 30)# anycast-gateway
VTEP1(cfg-if-OverlayRouter 30)# exit
VTEP1(cfg)# vxlan 30
VTEP1(cfg-vxlan)# router-interface overlayrouter 30
VTEP1(cfg-vxlan)# arp suppress enable
VTEP1(cfg-vxlan)# exit
VTEP1(cfg)# interface overlayrouter 100
VTEP1(cfg-if-OverlayRouter 100)# ip vrf binding vrf-10
VTEP1(cfg-if-OverlayRouter 100)# exit
VTEP1(cfg)# vxlan 100
```

```
VTEP1(cfg-vxlan)# symmetric
VTEP1(cfg-vxlan)# router-interface overlayrouter 100

VTEP1(cfg-evpn)# vni 300
VTEP1(cfg-evpn-vni)# rd auto
VTEP1(cfg-evpn-vni)# route-target both auto
VTEP1(cfg-evpn-vni)# exit
```

(2) Configure VTEP 2.

```
VTEP2> privilege
VTEP2# config-system terminal
VTEP2(cfg)# interface loopback 1
VTEP2(cfg-if-Loopback 1)# ip address 2.2.2.2/32
VTEP2(cfg-if-Loopback 1)# exit
VTEP2(cfg)# interface loopback 2
VTEP2(cfg-if-Loopback 2)# ip address 4.4.4.4/32
VTEP2(cfg-if-Loopback 2)# exit
```

```
VTEP2(cfg)# fabric anycast-gateway-mac 0000.1111.2222
VTEP2(cfg)# vtep
VTEP2(cfg-vtep)# source loopback 1
VTEP2(cfg-vtep)# vxlan outside center vtep-ip 1.1.1.1
VTEP2(cfg-vtep)# exit
VTEP2(cfg)# ip vrf vrf-20
VTEP2(cfg-vrf)# rd 20:20
VTEP2(cfg-vrf)# route-target export 2000:2000
VTEP2(cfg-vrf)# exit
VTEP2(cfg)# interface overlayrouter 20
VTEP2(cfg-if-OverlayRouter 20)# ip vrf binding vrf-20
VTEP2(cfg-if-OverlayRouter 20)# ip address 20.1.1.1/24
VTEP2(cfg-if-OverlayRouter 20)# anycast-gateway
VTEP2(cfg-if-OverlayRouter 20)# exit
VTEP2(cfg)# vxlan 20
VTEP2(cfg-vxlan)# router-interface overlayrouter 20
VTEP2(cfg-vxlan)# mapping vni 30
VTEP2(cfg-vxlan)# arp suppress enable
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# interface overlayrouter 30
VTEP2(cfg-if-OverlayRouter 30)# ip vrf binding vrf-20
VTEP2(cfg-if-OverlayRouter 30)# ip address 30.1.1.1/24
VTEP2(cfg-if-OverlayRouter 30)# anycast-gateway
VTEP2(cfg-if-OverlayRouter 30)# exit
VTEP2(cfg)# vxlan 30
VTEP2(cfg-vxlan)# router-interface overlayrouter 30
VTEP2(cfg-vxlan)# arp suppress enable
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# interface overlayrouter 200
VTEP2(cfg-if-OverlayRouter 200)# ip vrf binding vrf-20
VTEP2(cfg-if-OverlayRouter 200)# exit
VTEP2(cfg)# vxlan 200

5.11 Configuring a Layer 2 Ethernet Sub-interface to Access a VXLAN

5.11.1 Requirements

In the topology as shown in Figure 5-11, different Layer 2 Ethernet sub-interface access modes can be configured to enable VMs to connect to a VXLAN.

5.11.2 Topology

Figure 5-11 Configuring a Layer 2 Ethernet Sub-interface to Access a VXLAN

5.11.3 Notes

- Configure virtual servers, VMs, and physical servers (omitted).
- On the VTEP, create a Layer 2 Ethernet sub-interface, configure a VXLAN, and the untagged, VLAN, or QinQ encapsulation rule.
- On the VTEP, create an overlay router interface and configure the VXLAN gateway IP address.
- On the VTEP, associate the VXLAN instance with the overlay router interface to implement VXLAN routing.

5.11.4 Procedure

This section focuses only on VTEP-related configuration.

Configure the VTEP.

```
VTEP> privilege
VTEP# config-system terminal
VTEP(cfg)# vlan 10
VTEP(cfg-vlan)# exit
VTEP(cfg)# vlan 20
VTEP(cfg-vlan)# exit
VTEP(cfg)# interface gigabitethernet 0/1
VTEP(cfg-if-GigabitEthernet 0/1)# switch-port mode trunk
VTEP(cfg-if-GigabitEthernet 0/1)# exit
VTEP(cfg)# interface gigabitethernet 0/1.1
VTEP(cfg-subif-GigabitEthernet 0/1.1)# subinf-traffic-encapsulation dot1q s-vid 10
VTEP(cfg-subif-GigabitEthernet 0/1.1)# subinf-traffic-encapsulation vxlan 10
VTEP(cfg-subif-GigabitEthernet 0/1.1)# exit
```

```
VTEP(cfg)#interface gigabitethernet 0/1.2
VTEP(cfg-subif-GigabitEthernet 0/1.2)# subinf-traffic-encapsulation dot1q s-vid 20
VTEP(cfg-subif-GigabitEthernet 0/1.2)# subinf-traffic-encapsulation vxlan 20
VTEP(cfg-subif-GigabitEthernet 0/1.2)# exit
VTEP(cfg)#interface gigabitethernet 0/2
VTEP(cfg-if-GigabitEthernet 0/2)# switch-port mode access
VTEP(cfg-if-GigabitEthernet 0/2)# switch-port access vlan 10
VTEP(cfg-if-GigabitEthernet 0/2)# exit
VTEP(cfg)#interface gigabitethernet 0/2.1
VTEP(cfg-subif-GigabitEthernet 0/2.1)# subinf-traffic-encapsulation dot1q untag
VTEP(cfg-subif-GigabitEthernet 0/2.1)# subinf-traffic-encapsulation vxlan 10
VTEP(cfg-subif-GigabitEthernet 0/2.1)# exit
VTEP(cfg)#interface gigabitethernet 0/3
VTEP(cfg-if-GigabitEthernet 0/3)# switch-port mode trunk
VTEP(cfg-if-GigabitEthernet 0/3)# exit
VTEP(cfg)#interface gigabitethernet 0/3.1
VTEP(cfg-subif-GigabitEthernet 0/3.1)# subinf-traffic-encapsulation qinq s-vid 100 c-vid 10
VTEP(cfg-subif-GigabitEthernet 0/3.1)# subinf-traffic-encapsulation vxlan 10
VTEP(cfg-subif-GigabitEthernet 0/3.1)# exit
VTEP(cfg)#interface gigabitethernet 0/3.2
VTEP(cfg-subif-GigabitEthernet 0/3.2)# subinf-traffic-encapsulation s-vid 100 c-vid 20
VTEP(cfg-subif-GigabitEthernet 0/3.2)# subinf-traffic-encapsulation vxlan 20
VTEP(cfg-subif-GigabitEthernet 0/3.2)# exit
VTEP(cfg)# interface overlayrouter 10
VTEP(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP(cfg-if-OverlayRouter 10)# exit
VTEP(cfg)# vxlan 10
VTEP(cfg-vxlan)# router-interface overlayrouter 10
VTEP(cfg-vxlan)# exit
VTEP(cfg)# interface overlayrouter 20
VTEP(cfg-if-OverlayRouter 20)# ip address 20.1.1.1/24
VTEP(cfg-if-OverlayRouter 20)# exit
VTEP(cfg)# vxlan 20
VTEP(cfg-vxlan)# router-interface overlayrouter 20
VTEP1(cfg-vxlan)# exit
```

5.11.5 Verification

Run the **display vxlan** command to display VXLAN instances on the devices.

```
VTEP# display vxlan
VXLAN Total Count: 2
VXLAN Capacity     : 8000

VXLAN 10
      Symmetric property    : FALSE
      Routed interface      : overlayrouter 10 (non-anycast)
      Extend VLAN             : -
```

```
    VTEP Adjacency Count: 0

VXLAN 20
    Symmetric property   : FALSE
    Routed interface     : overlayrouter 20 (non-anycast)
    Extend VLAN          : -
    VTEP Adjacency Count: 0
```

5.11.6 Configuration Files

VTEP configuration file

```

5.12 Configuring a VXLAN in an M-LAG Scenario

5.12.1 Requirements

In the topology as shown in Figure 5-12, all VTEPs form an EVPN-based VXLAN network. VTEP 1 and VTEP 2 compose an M-LAG system to enhance the network reliability. VMs connect to the VXLAN network through VTEP 1 and VTEP 2.

5.12.2 Topology

Figure 5-12 Configuring a VXLAN in an M-LAG Scenario

5.12.3 Notes

- Configure VTEP 1 and VTEP 2 to form an M-LAG system and configure the server to connect to the M-LAG system at Layer 2 through a VAP. For details about the M-LAG configuration, see *Configuring M-LAG*.
- On each VTEP, configure an IPv4 unicast routing protocol (such as OSPF) to ensure that the unicast routes are reachable (omitted).
- On each VTEP, configure the BGP-EVPN routing protocol to ensure that three VTEPs establish BGP neighbor relationships and exchange L2VPN EVPN information.

- On each VTEP, configure an EVI for BGP-EVPN.
- On the virtualized server, configure VMs and VXLAN and specify the VLAN, IP address, and gateway address for the VMs (omitted).
- On each VTEP, configure and associate a loopback interface for the establishment of a VXLAN tunnel.
- On each VTEP, create an overlay router interface and configure the VXLAN gateway IP address.
- On each VTEP, create a VXLAN instance and associate it with a VLAN.
- On each VTEP, create an overlay router interface and configure the VXLAN gateway IP address. Configure different VRF instances for the overlay router interfaces and identify tenants by VRF instance. Associate the VXLAN instance with the overlay router interface to implement VXLAN routing.
- On each VTEP, configure the same anycast gateway MAC address and configure the anycast attribute for all overlay router interfaces.

5.12.4 Procedure

This section focuses on VXLAN configuration on VTEP 1 and VTEP 2 that compose an M-LAG system.

(1) Configure VTEP 1.

```
VTEP1> privilege
VTEP1# config-system terminal
VTEP1(cfg)# interface loopback 1
VTEP1(cfg-if-Loopback 1)# ip address 1.1.1.1/32
VTEP1(cfg-if-Loopback 1)# exit
VTEP1(cfg)# interface loopback 2
VTEP1(cfg-if-Loopback 2)# ip address 3.3.3.3/32
VTEP1(cfg-if-Loopback 2)# exit
VTEP1(cfg)# fabric anycast-gateway-mac 0000.1122.3344
VTEP1(cfg)# vtep
VTEP1(cfg-vtep)# source loopback 1
VTEP1(cfg-vtep)# exit
VTEP1(cfg)# interface overlayrouter 10
VTEP1(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP1(cfg-if-OverlayRouter 10)# anycast-gateway
VTEP1(cfg-if-OverlayRouter 10)# exit
VTEP1(cfg)# vxlan 10
VTEP1(cfg-vxlan)# extend-vlan 10
VTEP1(cfg-vxlan)# router-interface overlayrouter 10
VTEP1(cfg-vxlan)# exit
VTEP1(cfg)# interface overlayrouter 20
VTEP1(cfg-if-OverlayRouter 20)# ip address 20.1.1.1/24
VTEP1(cfg-if-OverlayRouter 20)# anycast-gateway
VTEP1(cfg-if-OverlayRouter 20)# exit
VTEP1(cfg)# vxlan 20
VTEP1(cfg-vxlan)# extend-vlan 20
VTEP1(cfg-vxlan)# router-interface overlayrouter 20
VTEP1(cfg-vxlan)# exit
VTEP1(cfg)# interface overlayrouter 100
```

```
VTEP1(cfg-if-OverlayRouter 100)# anycast-gateway
VTEP1(cfg-if-OverlayRouter 100)# exit
VTEP1(cfg)# vxlan 100
VTEP1(cfg-vxlan)# symmetric
VTEP1(cfg-vxlan)# router-interface overlayrouter 100
VTEP1(cfg-vxlan)# exit
VTEP1(cfg)# router-protocol bgp 100
VTEP1 (cfg-router)# peer 4.4.4.4 remote-as 100
VTEP1 (cfg-router)# peer 4.4.4.4 update-source loopback 2
VTEP1 (cfg-router)# peer 5.5.5.5 remote-as 100
VTEP1 (cfg-router)# peer 5.5.5.5 update-source loopback 2
VTEP1(cfg-router)# address-family-mode l2vpn evpn
VTEP1(cfg-router-af)# peer 4.4.4.4 activate
VTEP1(cfg-router-af)# peer 5.5.5.5 activate
VTEP1(cfg-router-af)# exit
VTEP1(cfg-router)# exit
VTEP1(cfg)# evpn
VTEP1(cfg-evpn)# vni 10
VTEP1(cfg-evpn-vni)# rd auto
VTEP1(cfg-evpn-vni)# route-target both auto
VTEP1(cfg-evpn-vni)# exit
VTEP1(cfg-evpn)# vni 20
VTEP1(cfg-evpn-vni)# rd auto
VTEP1(cfg-evpn-vni)# route-target both auto

VTEP1(cfg-evpn)# vni 100
VTEP1(cfg-evpn-vni)# rd auto
VTEP1(cfg-evpn-vni)# route-target both auto
VTEP1(cfg-evpn-vni)# exit
```

(2) Configure VTEP 2.

```
VTEP2> privilege
VTEP2# config-system terminal
VTEP2(cfg)# interface loopback 1
VTEP2(cfg-if-Loopback 1)# ip address 1.1.1.1/32
VTEP2(cfg-if-Loopback 1)# exit
VTEP2(cfg)# interface loopback 2
VTEP2(cfg-if-Loopback 2)# ip address 4.4.4.4/32
VTEP2(cfg-if-Loopback 2)# exit
VTEP2(cfg)# fabric anycast-gateway-mac 0000.1122.3344
VTEP2(cfg)# vtep
VTEP2(cfg-vtep)# source loopback 1
VTEP2(cfg-vtep)# exit
VTEP2(cfg)# interface overlayrouter 10
VTEP2(cfg-if-OverlayRouter 10)# ip address 10.1.1.1/24
VTEP2(cfg-if-OverlayRouter 10)# anycast-gateway
VTEP2(cfg-if-OverlayRouter 10)# exit
```

```
VTEP2(cfg)# vxlan 10
VTEP2(cfg-vxlan)# extend-vlan 10
VTEP2(cfg-vxlan)# router-interface overlayrouter 10
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# interface overlayrouter 20
VTEP2(cfg-if-OverlayRouter 20)# ip address 20.1.1.1/24
VTEP2(cfg-if-OverlayRouter 20)# anycast-gateway
VTEP2(cfg-if-OverlayRouter 20)# exit
VTEP2(cfg)# vxlan 20
VTEP2(cfg-vxlan)# extend-vlan 20
VTEP2(cfg-vxlan)# router-interface overlayrouter 20
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# interface overlayrouter 100
VTEP2(cfg-if-OverlayRouter 100)# anycast-gateway
VTEP2(cfg-if-OverlayRouter 100)# exit
VTEP2(cfg)# vxlan 100
VTEP2(cfg-vxlan)# symmetric
VTEP2(cfg-vxlan)# router-interface overlayrouter 100
VTEP2(cfg-vxlan)# exit
VTEP2(cfg)# router-protocol bgp 100
VTEP2 (cfg-router)# peer 3.3.3.3 remote-as 100
VTEP2 (cfg-router)# peer 3.3.3.3 update-source loopback 2
VTEP2 (cfg-router)# peer 5.5.5.5 remote-as 100
VTEP2 (cfg-router)# peer 5.5.5.5 update-source loopback 2
VTEP2(cfg-router)# address-family-mode l2vpn evpn
VTEP2(cfg-router-af)# peer 3.3.3.3 activate

5.12.7 Common Errors

- Two devices composing an M-LAG system serve as VTEPs but the VXLAN configurations on the two devices are different, resulting in traffic interruption during forwarding.
- Two devices composing an M-LAG system serve as VTEPs but no anycast attribute is configured for the overlay router interfaces on the devices, resulting in traffic interruption during forwarding.

1 Configuring PFC

1.1 Overview

In a converged data center, SAN traffic needs to be transmitted on the Ethernet network with no packet loss.

The Ethernet Pause mechanism can ensure no packet loss. For the Ethernet Pause mechanism, when the transmit rate of a sender is higher than the receive rate of a receiver, the receiver sends a Pause frame to the sender, requesting that the traffic be paused for a given period of time. The Ethernet Pause mechanism operates on the entire link. In other words, all traffic on an interface is paused. Actually, link sharing is critical. Link sharing has the following requirements:

- One type of burst traffic does not affect forwarding of other types of traffic.
- A large backlog of one type of traffic in a queue does not preempt cache resources of other types of traffic.

PFC is introduced to resolve conflicts between the Ethernet Pause mechanism and link sharing.

1.2 Introduction

When SAN traffic, Inter Process Communication (IPC) traffic, and LAN traffic coexist on a physical link, PFC ensures that no packet loss occurs for SAN traffic and that SAN traffic does not affect the other types of traffic. (One 802.1p priority level is assigned to SAN traffic, and PFC is enabled for this priority level. Different 802.1p priority levels are assigned to IPC traffic and LAN traffic, and PFC is disabled for these priority levels).

1.2.1 Basic Concepts

- 802.1p priority /Class of Service (CoS)

  The 802.1p standard specifies eight priority levels (from 0 to 7) in the Layer 2 Virtual Local Area Network (VLAN) Tag field.

16 bits	3 bits	1 bit	12 bits
Tag Protocol Identifier (TPID) (Value: 0x8100)	Priority	Canonical Format Indicator (CFI)	VLAN ID

1.2.2 Packet Format

A backpressure signal is an Ethernet frame. The PFC frame format is as follows.

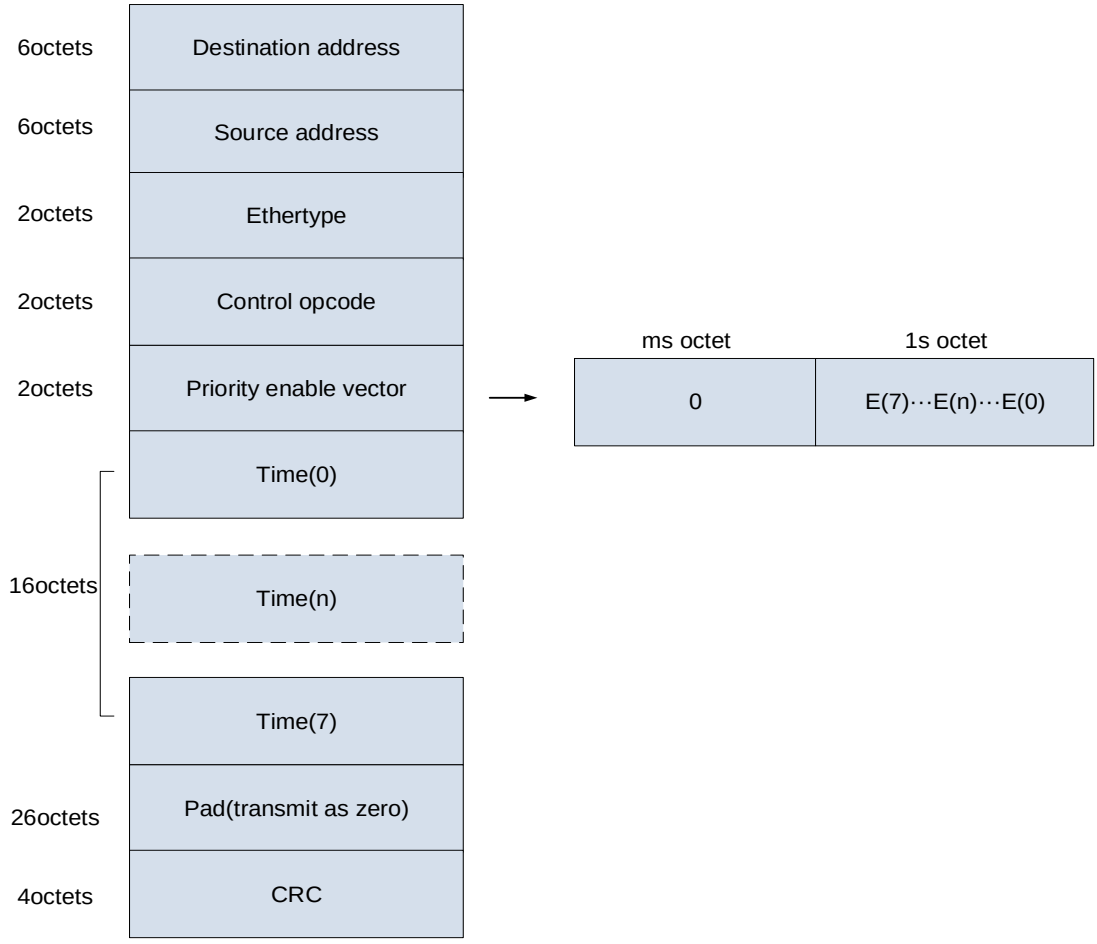

Table 1-1 Fields in a PFC Frame

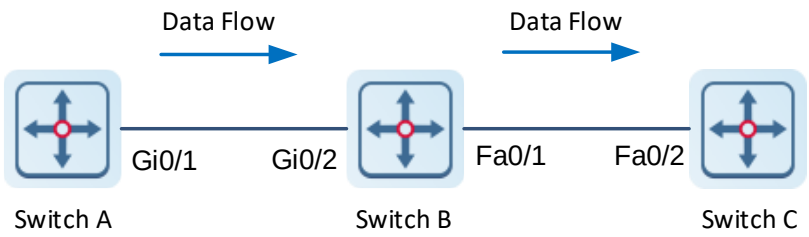


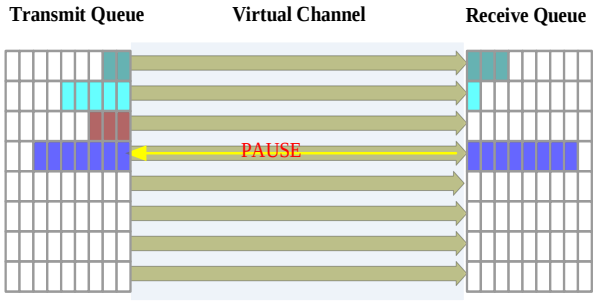
Field	Description
Destination address	Destination MAC address, which has a fixed value of 01-80-c2-00-00-01.
Source address	Source MAC address.
Ethertype	Ethernet frame type. The value is 88-08.
Control opcode	Control code. The value is 01-01.
Priority enable vector	E(*n*) corresponds to queue *n* and determines whether backpressure is enabled for queue *n*. If E(*n*) is 1, backpressure is enabled for queue *n*, and the backpressure time is Time(*n*). If E(*n*) is 0, backpressure is disabled for queue *n*.
Time(0) to Time(7)	The backpressure timer. If Time(*n*) is 0, backpressure is canceled.
Pad (transmit as zero)	Reserved. The value is 0 during PFC frame transmission.
CRC	Cyclic Redundancy Check (CRC).

1.2.3 Principles

1. Principles of PFC

PFC is an enhancement to flow control. Flow control is implemented as follows: When the receiver cannot process the received packets, it notifies the sender to temporarily stop sending packets. This prevents the packets from being dropped. Normal flow control is implemented by sending and receiving Pause frames on an interface.

Figure 1-1 Flow Control



As shown in Figure 1-1, Fa0/1 is congested when Gi0/1 and Gi0/2 forward packets at 1 Gbps. To avoid packet loss, enable flow control for Gi0/1 and Gi0/2.

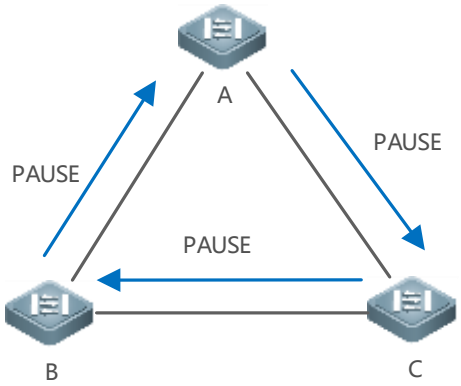
- When port Fa0/1 is congested during packet forwarding, Switch B handles the packets in the buffer and discards packets when the traffic exceeds the forwarding capability. In this case, Switch B sends a normal Pause frame through Gi0/2 to port Gi0/1 of Switch A, requesting Switch A to temporarily stop sending packets.
- Upon receiving the Pause frame, Switch A stops sending packets to Gi0/2 of Switch B in a specified period. The pause duration is carried by the Pause frame. When congestion persists, repeat the preceding steps until congestion is resolved.

Flow control can prevent packets from being dropped. However, all traffic is blocked on the entire link. With PFC, eight virtual channels can be created on an Ethernet link, with an 802.1p priority level specified for each virtual channel. Any of the virtual channels can be separately suspended or restarted without interrupting traffic on the other virtual channels.

Figure 1-2 PFC

In the preceding figure, PFC is enabled for packets with the priority of 3 for ports Gi0/1 and Gi0/2.

- When port Fa0/1 is congested during packet forwarding, Switch B handles the packets in the buffer and discards packets if the traffic exceeds the forwarding capability. To prevent packet loss, Switch B sends a PFC Pause frame through Gi0/2 to Gi0/1, requesting Switch A stop sending packets with the priority of 3.
- Upon receiving the PFC Pause frame, Switch A stops sending packets to Gi0/2 of Switch B in a specified



period. The pause duration is carried by the PFC Pause frame. When congestion persists, repeat the preceding steps until congestion is resolved. As shown in Figure 1-2, the sender stops sending packets with the priority level of 3, and other packets sent through ports Gi0/1 and Gi0/2 are not affected.

2. Principles of PFC Deadlock

After you configure the PFC function for switches, a PFC deadlock may occur when a link is congested.

The following figure shows a typical scenario where a cyclic buffer dependency exists among a group of devices in a data center. In a ring topology, any device affects the buffer of the upstream device while waiting for the downstream device to release part of the buffer to resume packet transmission. When the PFC-XOFF thresholds of A, B, and C switches are reached and the three switches send PFC Pause frames to the peer device simultaneously, all switches in the topology stop sending traffic. In this case, a PFC deadlock occurs. In addition, due to the backpressure effect of PFC Pause frames, the throughput of the entire or part of the network becomes zero. Deadlocks may easily occur on such networks. Deadlocks may also occur when a temporary loop is formed on a closed-loop network. In a data center, a temporary loop may occur when Border Gateway Protocol (BGP) route reselection is performed in the case of link failures. During upgrade of a data center based on Software-defined Networking (SDN), a temporary loop may also occur. Although temporary loops disappear quickly, the resulting deadlocks persist. Deadlocks cannot be eliminated automatically even after the error causing the issue (misconfiguration, link failure, or update) is fixed.

Figure 1-3 Figure 1-1 Principles of Deadlock

- Switch A, Switch B, and Switch C are on a network.
- To eliminate the deadlock, set a buffer period for the priority queues of an interface. This way, when the queue is congested and a PFC Pause frame is received, a few time slices are provided to process packets. This helps remove the deadlock.
- When deadlocks occur for a specific PFC priority frequently, disable the PFC function for this priority to prevent normal packet forwarding from being affected.

1.3 Restrictions and Guidelines

- You can adopt UTF-8/GBK to perform configuration in Chinese. When you use the cursor to process words or delete words by using the **Backspace** key in the CLI, the interface may display errors or garbled characters. You are advised to delete all current characters and then configure a unified character set

encoding format. Upon word processing or Backspace deletion, you can run the **display current-config** command to check whether the configurations are correct. (To delete a Chinese character, you must press the **Backspace** key twice in the case of GBK, and press the **Backspace** key three times in the case of UTF-8.)

1.4 Configuration Task Summary

Configuration in the CLI includes the following tasks: All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Basic Features
- Configuring the PFC Deadlock Detection and Threshold Functions

1.5 Configuring Basic Features

1. Overview

You can control the traffic of an interface based on the 802.1p priority levels.

2. Restrictions and Guidelines

- PFC only applies to point-to-point full-duplex links, not to half-duplex or shared links.
- PFC and the normal flow control function are mutually exclusive.
- If a PFC-enabled priority level and a PFC-disabled priority level map to the same queue, the packets with a PFC-disabled priority level are blocked. Therefore, it is not recommended to map a PFC-enabled priority level and a PFC-disabled priority level to the same queue.
- PFC is not valid for packets sent by the CPU.
- PFC takes effect only if CoS is trusted on the interface.
- The devices that support globally enabled ETS can be used. PFC-enabled priority cannot be mapped to the same TC or queue as any other PFC-enabled priority; PFC feature cannot be enabled with any other priority mapping of the same TC or queue priority as any other priority.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Enable the PFC function.

priority-flow-control nodrop *cos-value-list* { **off** | **on** }

The PFC function is disabled by default.

(4) Disable PFC in both the send (Tx) and receive (Rx) directions.

priority-flow-control { rx | tx } disable

PFC is enabled in both the send (Tx) and receive (Rx) directions by default.

(5) Configure the pause quanta of the PFC Pause frame. A quanta is the time that is required for transmitting 512 bits at the speed of the chip.

priority-flow-control xoff-time *number*

The pause quanta is 65535 by default.

(6) Configuring the global PFC counting interval.

priority-flow-control counting-interval *number*

The global PFC counting interval is 5s by default.

(7) Configure the packet per second (PPS) rate limit for an interface (interface configuration mode).

priority-flow-control early-warning *cos-value-list* **{ output pps** *rate-num*] **| input pps** *rate-num* **}**

The PPS rate limit function is disabled by default.

1.6 Configuring the PFC Deadlock Detection and Threshold Functions

1. Overview

You can control the traffic of an interface based on the 802.1p priority levels.

2. Restrictions and Guidelines

- The PFC deadlock detection function is valid only if PFC is enabled for the priority level.
- The PFC deadlock threshold function takes effect only if the PFC deadlock detection function is enabled for the priority level.
- If you modify the time precision of the PFC deadlock functions, the configured PFC deadlock detection period and the packet processing time are affected.
- When PFC deadlock detection is disabled for a priority level, the configuration of the PFC deadlock threshold function is also removed for this priority level.
- If you disable the globally configured PFC deadlock detection function or the PFC function of a priority level, the command used to enable the PFC deadlock detection function for this priority level is removed from all interfaces.

3. Procedure

(1) Enter the privileged EXEC mode.

privilege

(2) Enter the global configuration mode.

config-system terminal

(3) Configure the PFC deadlock detection function for the priority levels.

priority-flow-control deadlock cos-value *cos-value-list* [**detect** *detect-time* **recover** *recover-time* [**continue** | **backoff** *most-times*]]

The deadlock detection period is 15 time slices and the deadlock recovery time is 150 ms by default.

(4) Configure the deadlock detection function for the priority levels of an interface (interface configuration mode).

priority-flow-control deadlock cos-value *cos-value-list* **enable**

The deadlock detection function is disabled for all priority levels of an interface by default.

(5) Configure the action to drop packets when the PFC deadlock occurs.

priority-flow-control deadlock drop

Packets are forwarded by the interface by default.

(6) Configure a low time precision for the PFC deadlock detection.

priority-flow-control deadlock precision low

The time precision for the deadlock detection is 10ms by default, which is of a high precision.

(7) Configure the PFC deadlock threshold function for the priority levels.

priority-flow-control deadlock limit cos-value *cos-value-list* **enable** [**rx**]

The deadlock threshold function is disabled for all priority levels by default.

(8) Configure the PFC deadlock threshold and the deadlock detection duration.

priority-flow-control deadlock limit frequency *number* { **period | period-second** } *time*

The deadlock detection duration is 60 seconds, and the deadlock threshold is 10 by default.

1.7 Monitoring

Run the **display** command to display the configurations.

Run the **cleanup** command to clear information.

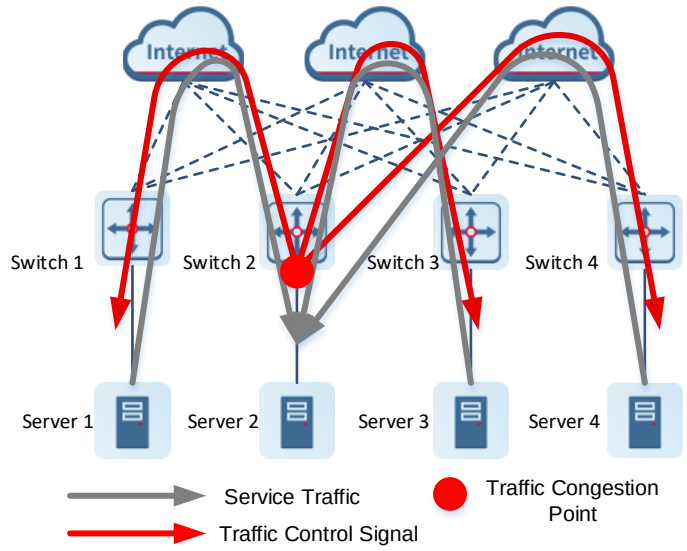
Run the **debugging** commands to output debugging information.

Table 1-2 Monitoring of the CLI

Command	Purpose
cleanup priority-flow-control statistics [**interface** *type interface-number*]	Clears PFC statistics.
cleanup priority-flow-control deadlock statistics [interface *type interface-number* **]**	Clears the deadlock statistics of a specified interface.
display priority-flow-control statistics [**interface** *type interface-number*]	Displays PFC statistics.
display priority-flow-control status	Displays the global configuration of PFC.
display priority-flow-control status [**interface** *type interface-number*]	Displays the PFC configuration and status of a specified interface.
display priority-flow-control deadlock statistics [**interface** *type interface-number*]	Displays PFC deadlock statistics of priority levels of an interface.

Command	Purpose
display priority-flow-control deadlock status	Displays the configuration of the PFC deadlock detection and threshold functions and the enabling status.
debugging pfc cap	Debugs the PFC capability of a device.
debugging pfc deadlock	Debugs the PFC deadlock detection and threshold functions.
debugging pfc detail	Debugs the PFC details.
debugging pfc error	Debugs the PFC errors.
debugging pfc event	Debugs the PFC events.
debugging pfc mom	Debugs the message-oriented middleware of PFC.
debugging pfc statistics	Debugs the PFC statistics.

1.8 Configuration Examples



1.8.1 Configuring PFC

1. Requirements

A typical data center topology is shown in Figure 1-4. A distributed storage service is deployed on the servers. When the application on Server 2 needs to read data from Server 1, Server 3, and Server 4 at the same time, the traffic converges on Switch 2. At this point, the cache space in the egress direction of Switch 2 toward Server 2 becomes the bottleneck. To ensure that packets are not dropped due to buffer overflows, the PFC function is deployed on Switch 2. This way, once the cache space usage of the traffic reaches the PFC Pause frame threshold, Switch 2 sends the PFC Pause frame to the upstream switch, requesting the sender to stop transmitting packets of the specified priority level temporarily. This reduces congestion and ensures no packet loss.

2. Topology

Figure 1-4 Topology of a PFC-configured Data Center

3. Note

- Configure PFC priority levels on Switch 1/2/3/4 to ensure that PFC Pause frames are sent and received during traffic congestion.
- (Optional) Disable the PFC Pause frame in the egress or ingress direction of Switch 1/2/3/4.
- (Optional) Configure the PFC pause quanta on Switch 1/2/3/4.
- (Optional) Configure the PFC traffic warning threshold on Switch 1/2/3/4.
- (Optional) Configure the interval of PFC traffic statistics on Switch 1/2/3/4.
- (Optional) Configure the PFC deadlock detection and threshold functions on Switch 1/2/3/4.

4. Procedure

Configure the PFC function on Switch 2.

```
Switch2> privilege
Switch2# config-system terminal
Switch2(cfg)# priority-flow-control nodrop 3 on
Switch2(cfg)# priority-flow-control counting-interval 10
```

Configure the PFC function on Switch 1, Switch 3, and Switch 4.

```
Switch1> privilege
Switch1# config-system terminal
Switch1(cfg)# priority-flow-control nodrop 3 on
```

5. Verification

Display the PFC configuration of Switch 2.

```
Switch2# display priority-flow-control status
```

```
PFC Global PriorityEnablePFC: 3
