1 Configuring IPv6 Multicast Route Management

1.1 Introduction

Multicast route management covers how to create and modify multicast routes to control multicast packet forwarding and how to detect and maintain correctness of multicast forwarding paths. Multicast route management mainly includes the static multicast routing and reverse path forwarding (RPF) check features. Static multicast routing is used to modify or connect RPF routes, and RPF check is used to ensure that multicast data is forwarded on correct paths.

1.1.1 IPv6 Multicast Routing and Forwarding

An IPv6 multicast routing table includes MLD group entries, multicast protocol routing entries, multicast routing entries, and multicast hardware routing entries. These entries are maintained by different multicast routing protocols in the multicast network. The optimal IPv6 multicast routes are delivered to the hardware routing table and used to guide IPv6 multicast data forwarding. The RPF mechanism ensures that multicast data is forwarded on correct paths.

- MLD group entries: They are created when a host sends MLD join packets and used to maintain group member information and ask the multicast routing protocol to create (S, G) or (*, G) entries.
- Multicast protocol routing entries: They function as basis of multicast routing and forwarding and are maintained by different multicast routing protocols (the most widely applied protocol is PIM).
- Multicast routing entries: They are generated by the multicast routing management module and delivered to a multicast hardware routing table. Different multicast routing protocols can be summarized based on the multicast routing entries to select an optimal route.
- Hardware routing entries: They are generated based on routing tables and used to guide multicast data forwarding.

1.1.2 RPF Check

1. Basic Principles

In unicast routing and forwarding, a device gets to know the outbound interface of packets based on the destination address. In multicast routing and forwarding, the destination address in multicast packets is a multicast address, based on which, a receiver address cannot be determined. However, the source address in multicast packets is determined and based on this source address, multicast packets can be forwarded on correct paths.

When receiving a multicast packet, a multicast device queries the unicast route of the multicast source based on the source address in the multicast packet and checks whether the outbound interface of this unicast route is consistent with the inbound interface of the multicast packet. If yes, it is considered that this multicast packet is forwarded on a correct path. The inbound interface of the multicast packet is referred to as an RPF interface.

2. RPF Check Procedure

Unicast route, MBGP route, and static multicast route are the basis of RPF check. If these three types of routing entries exist on a multicast device, the multicast device performs the following checks in order after receiving a multicast packet:

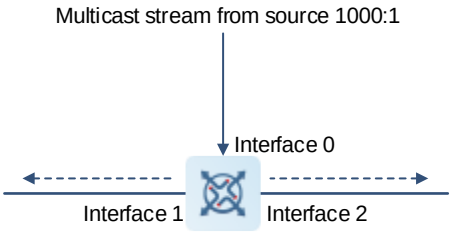
(1) Select an optimal route from each of the three types of routing entries, respectively, based on the source address in the packet.

- The outbound interface of a unicast route is an RPF interface and the next hop is an RPF neighbor.
- The outbound interface of an MBGP route is an RPF interface and the next hop is an RPF neighbor.
- The static multicast route is manually configured and an RPF interface and neighbor are specified.

(2) Select one route out of the three optimal routes as the RPF route. The selection rule is as follows:

- If the longest match rule is not configured for selecting an RPF route, the one with the highest priority is selected as the RPF route. If the three routes have the same priority, the RPF route is selected in the order of static multicast route, MBGP route, and unicast route.
- If the longest match rule is configured for selecting an RPF route, the one with the longest match is selected as the RPF route. If the three routes have the same mask, the one with the highest priority is selected as the RPF route. If they have the same priority, the RPF route is selected in the order of static multicast route, MBGP route, and unicast route.

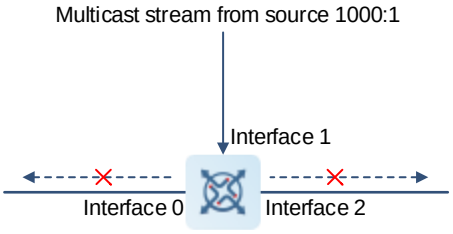
(3) Compare the RPF interface of the RPF route with the inbound interface of the multicast packet.



- If they are consistent, the route passes the RPF check and the multicast packet is forwarded to the downlink devices.
- If they are inconsistent, the route fails the RPF check and the received multicast packet is discarded.

Table 1-1 Routing Table on a Multicast Device

IP Routing Table	
Network	**Interface**
1000::/64	Interface 0
2000::/64	Interface 1
3000::/64	Interface 2



As shown in Figure 1-1, the multicast device receives a multicast packet from the source 1000::1 through interface 0 and as listed in Table 1-1, the outbound interface of the route to the source 1000::1 is also interface 0. The outbound interface of the route is consistent with the inbound interface of the multicast packet. The route passes the RPF check and the multicast packet is forwarded on the correct path.

Figure 1-1 Topology of RPF Check Success

As shown in Figure 1-2, the multicast device receives a multicast packet from the source 1000::1 through interface 1 and the outbound interface of the route to the source 1000::1 is Interface 0. The outbound interface of the route is inconsistent with the inbound interface of the multicast packet. The route fails the RPF check and the multicast packet is discarded.

Figure 1-2 Topology of RPF Check Failure

3. Application Scenarios of RPF Check in Multicast Forwarding

A multicast device ensures that multicast packets are forwarded on correct paths and avoids loops on the forwarding paths based on the RPF check mechanism. In actual applications, if the multicast device performs RPF check each time it receives a multicast packet, the multicast device is overloaded. Therefore, upon receiving a multicast packet, the multicast device checks for corresponding (S, G) hardware routing entry, rather than performs RPF check. The checking process is as follows:

- If no (S, G) hardware routing entry exists, the multicast device performs RPF check, uses the RPF interface as an inbound interface, creates a multicast routing entry, and delivers the entry to the multicast forwarding table.
  - If the route passes the RPF check, the inbound interface of the multicast packet is consistent with the RPF interface. The multicast packet is forwarded to all the outbound interfaces in the forwarding table.
  - If the route fails the RPF check, the inbound interface of the multicast packet is inconsistent with the RPF interface. The multicast packet is discarded.
- If (S, G) hardware routing entries exist, the multicast device checks whether the inbound interface in the forwarding entry is consistent with the inbound interface of the multicast packet.
  - If they are consistent, the multicast packet is forwarded to all the outbound interfaces.
  - If they are inconsistent, the multicast device performs RPF check. If the RPF interface is consistent with the inbound interface in the hardware routing entry, the source path of the packet is incorrect but the (S, G) entry is correct. The multicast packet is discarded. If the RPF interface is inconsistent with the inbound interface in the hardware routing entry, the (S, G) entry expired. The inbound interface in the

entry is updated as an RPF interface. Then, the multicast device checks whether the RPF interface is consistent with the inbound interface of the packet. If they are consistent, this multicast packet is forwarded to all outbound interfaces in the forwarding table. Otherwise, this multicast packet is discarded.

1.1.3 Protocols and Standards

- RFC 2710: Multicast Listener Discovery (MLDv1) for IPv6
- RFC 3810: Multicast Listener Discovery Version 2 (MLDv2) for IPv6
- RFC 4601: Protocol Independent Multicast-Sparse Mode (PIM-SM)
- RFC 5059: Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- RFC 4607: Source-Specific Multicast for IP

1.2 Configuration Task Summary

The IPv6 multicast route management configuration includes the following tasks:

(1) Configuring Basic Functions of IPv6 Multicast

(2) (Optional) Configuring the Maximum Number of Entries in an IPv6 Multicast Routing Table

(3) (Optional) Configuring an IPv6 Multicast Border

(4) (Optional) Configuring an IPv6 Static Multicast Route

(5) (Optional) Enabling Forced Forwarding of Multicast Packets by Software

(6) (Optional) Enabling L2 Direction Control for Multicast Streams

(7) (Optional) Configuring RPF Route Selection Based on the Longest Match Rule

1.3 Prerequisites

- In the multicast network, all nodes are reachable via IPv6 unicast routes.
- Configuring Basic Functions of IPv6 Multicast.

1.4 Configuring Basic Functions of IPv6 Multicast

1.4.1 Overview

The multicast routing function is enabled in the local network and a PIM network is created to provide data sources and user hosts in the network with the IPv6 multicast service.

A device maintains the routing table used for multicast packet forwarding over an IPv6 multicast routing protocol (for example, PIM-SMv6), and learns information about the status of group members in the directly-connected network segments over the MLDv1/v2 protocol. A host joins a specific IPv6 multicast group by sending an MLD REPORT message.

1.4.2 Restrictions and Guidelines

- The IPv6 multicast routing function should be enabled on each multicast device.
- The IPv6 multicast routing function is enabled prior to different IPv6 multicast protocols.
- The IPv6 multicast routing function and the MLD Snooping function are mutually exclusive.

- The IPv6 multicast protocol function must be enabled on each interface in the multicast network.
- After L3 multicast is enabled in the private VLAN and super VLAN and a multicast source exists in a sub VLAN, an extra entry whose ingress is the sub VLAN into which the multicast stream enters must be copied due to the validity check during multicast forwarding. This increases a multicast hardware entry and decreases the multicast capacity by one.

1.4.3 Prerequisites

In the multicast network, all nodes are reachable via IPv6 unicast routes.

1.4.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the IPv6 multicast routing function.

ipv6 multicast-routing

The IPv6 multicast routing function is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(5) Configure an IPv6 multicast protocol.

ipv6 pim sparse-mode

No IPv6 multicast protocol is enabled by default.

1.5 Configuring the Maximum Number of Entries in an IPv6 Multicast Routing Table

1.5.1 Overview

Every multicast data packet received by a device is used to maintain relevant IPv6 multicast routing entries. However, excessive multicast routing entries may exhaust device memory and cause device performance to decrease. Users can restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements.

1.5.2 Restrictions and Guidelines

Due to limitations by hardware resources, routing entries that exceed the range permitted by hardware can be forwarded only by software, which causes performance to decrease.

1.5.3 Prerequisites

Configuring Basic Functions of IPv6 Multicast.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the maximum number of entries in an IPv6 multicast routing table.

ipv6 multicast route-limit *limit* [*threshold*]

By default, a maximum of 4000 entries can be added to an IPv6 multicast routing table.

The configured value of *threshold* must be smaller than or equal to the configured value of *limit*.

1.6 Configuring an IPv6 Multicast Border

1.6.1 Overview

An IPv6 multicast border is configured to define the transmission range of multicast packets. When a multicast border is configured on an interface, this interface cannot forward or receive multicast packets, including those sent from the local host.

1.6.2 Restrictions and Guidelines

- The ACL referenced in this command can be a standard ACL or an extended ACL. If an extended ACL is used, only destination addresses need to be matched.
- This command can be used to filter MLD and PIM-SMv6 protocol packets relevant to the IPv6 multicast group range. Multicast data streams are not sent or received by this multicast border interface.

1.6.3 Prerequisites

- Configuring Basic Functions of IPv6 Multicast.
- Before an IPv6 multicast border is configured, ensure that the corresponding ACL is created and a multicast group range is specified. For details about ACL configuration, see *Configuring ACL*.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Enable the IPv6 multicast routing function.

ipv6 multicast boundary *acl-name* [**in** | **out**]

No IPv6 multicast border is configured by default.

1.7 Configuring an IPv6 Static Multicast Route

1.7.1 Overview

An IPv6 static multicast route is configured to specify an RPF interface or RPF neighbor for multicast packets from a specific multicast source. This function is used to modify and connect RPF routes.

- Modify an RPF route. A device expects to receive multicast packets from a source through a specified interface. However, the RPF check result indicates that the RPF interface is not this specified interface. In this case, you need to configure an IPv6 static multicast route to specify this interface as an RPF interface. Upon receiving multicast packets from the source, the device performs RPF check. If the RPF check result indicates that the RPF interface is not this specified interface, the route fails the RPF check.
- Connect an RPF route. If the unicast route is interrupted, the RPF routing fails. In this case, you can configure a static multicast route to specify the RPF interface to complete the RPF check and implement multicast packet forwarding.

1.7.2 Restrictions and Guidelines

To specify an outbound interface rather than a next-hop IP address for the IPv6 static multicast route, ensure that the outbound interface is of the point-to-point type.

1.7.3 Prerequisites

Configuring Basic Functions of IPv6 Multicast.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an IPv6 static multicast route.

ipv6 mroute *ipv6-address/prefix-length* [*protocol*] { *ipv6-rpf-addrress* | *interface-type interface-number* } [*distance*]

No IPv6 static multicast route is configured by default.

1.8 Enabling Forced Forwarding of Multicast Packets by Software

1.8.1 Overview

After this function is enabled, all IPv6 multicast data packets destined for the CPU are forcedly forwarded by software.

1.8.2 Restrictions and Guidelines

The cache mechanism and forwarding performance problem may cause packet disorder if the multicast streams are heavy. You are not advised to run this command generally.

1.8.3 Prerequisites

Configuring Basic Functions of IPv6 Multicast.

1.8.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of forced forwarding of multicast packets by software.

msf6 force-forwarding

The function of forced forwarding of IPv6 multicast packets (destined for the CPU) by software is disabled by default.

1.9 Enabling L2 Direction Control for Multicast Streams

1.9.1 Overview

L2 direction control is enabled for multicast streams to control the forwarding of multicast streams on an interface. Multiple commands can be configured for a specified multicast stream so that the stream can be forwarded by multiple interfaces. After direction control is enabled for a multicast stream, the stream can be forwarded only by these configured interfaces. Other interfaces are not permitted to forward the stream.

1.9.2 Restrictions and Guidelines

This function controls only the forwarding of multicast streams on interfaces, but does not directly affect the processing of multicast protocols on the protocol packets. Some features (for example, establishment of L3 hardware routing entry) of multicast protocols (such as PIM-SMv6) are driven by multicast data streams, and therefore, the behavior of the multicast routing protocols may still be affected.

1.9.3 Prerequisites

Configuring Basic Functions of IPv6 Multicast.

1.9.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable L2 direction control for multicast streams.

ipv6 multicast static *ipv6-source-address ipv6-group-address interface-type interface-number*

L2 direction control is disabled for multicast streams by default.

1.10 Configuring RPF Route Selection Based on the Longest Match Rule

1.10.1 Overview

In multicast routing, various routing entries, such as static multicast routing entry, MBGP routing entry and unicast routing entry, may exist. If RPF route selection based on the longest match rule is configured, the route with the longest match mask is selected from the optimal routes of multiple routing entries as the RPF route. If the routes have the same mask length, the route with the highest priority is selected from the optimal routes. If they have the same priority, the RPF route is selected in the order of static multicast route, MBGP route, and unicast route.

1.10.2 Restrictions and Guidelines

It is recommended that RPF route selection based on the longest match rule be configured on each device unless otherwise specified.

1.10.3 Prerequisites

Configuring Basic Functions of IPv6 Multicast.

1.10.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure RPF route selection based on the longest match rule.

ipv6 multicast rpf longest-match

By default, the route with the highest priority is selected as the RPF route. If the routes have the same priority, the RPF route is selected in the order of IPv6 static multicast route, IPv6 MBGP route and IPv6 unicast route.

1.11 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **clear** commands to clear information.

Caution

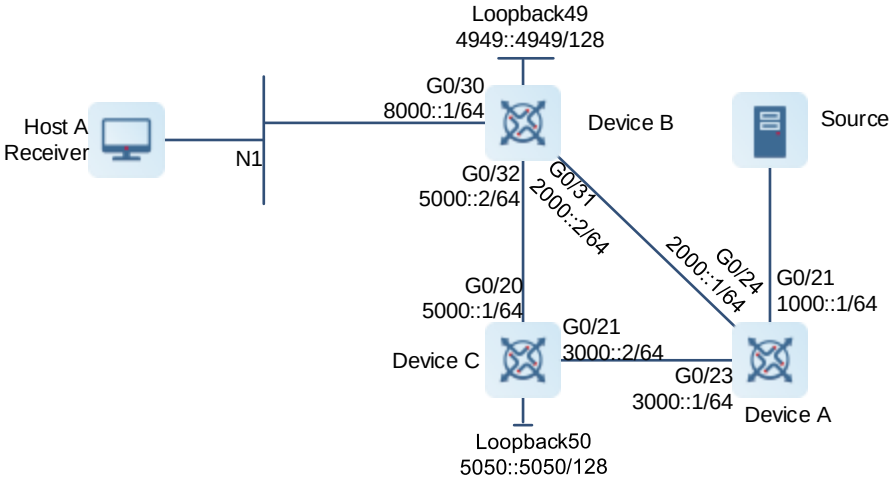
Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-2 Monitoring

Command	Purpose
clear ipv6 mroute { ***** | *ipv6-group-address* [*ipv6-source –address*] }	Clears IPv6 multicast forwarding table.
clear ipv6 mroute statistics { ***** | *ipv6-group-address* [*ipv6-source-address*] }	Resets statistics in the IPv6 multicast forwarding table.
show ipv6 mroute [*ipv6-group-or-source-address* [*ipv6-group-or-source-address*]] [**sparse**] [**summary** | **count**]	Displays the IPv6 hardware routing entry.
show ipv6 rpf *ipv6-source-address*	Displays the RPF information of a specified IPv6 source address.
show ipv6 mroute static	Displays the IPv6 static multicast route information.
show ipv6 mvif [*interface-type interface-number*]	Displays information about the configured IPv6 multicast interface that takes effect.
show ipv6 mrf6 gr	Displays information about restart of the IPv6 multicast routing process.
show ipv6 mrf mfc	Displays the IPv6 L3 hardware routing entry.
show ipv6 mrf6 sync-info	Displays statistics on delivered data of the IPv6 multicast routing forwarding table.
show msf6 global	Displays global information about an MSF6 process.
show msf6 msc	Displays the IPv6 L2 and L3 hardware routing entry.
debug nsm mcast6 all	Displays the running procedure of the multicast core.

Command	Purpose
debug nsm mcast6 fib-msg	Displays the communication procedure between the IPv6 multicast core and protocol module.
debug nsm mcast6 mif	Displays the interface running procedure of the IPv6 multicast core.
debug nsm mcast6 stats	Displays the procedure for processing interfaces and behavior statistics of the IPv6 multicast core.
debug ipv6 mrf forwarding	Displays the procedure for IPv6 L3 multicast forwarding.
debug ipv6 mrf mfc	Displays the procedure for operating IPv6 L3 hardware routing entries.
debug ipv6 mrf event	Displays the procedure for processing IPv6 L3 multicast forwarding events.
debug msf6 forwarding	Displays the procedure for IPv6 L2 and L3 multicast packet forwarding.
debug msf6 mfc	Displays the procedure for operating IPv6 L2 and L3 hardware routing entries.
debug msf6 ssp	Displays the bottom-layer hardware processing procedure of IPv6 L2 and L3 multicast forwarding.
debug msf6 api	Displays the procedure for invoking API interfaces for IPv6 L2 and L3 multicast forwarding.
debug msf6 event	Displays the procedure for processing IPv6 L2 and L3 multicast forwarding events.

1.12 Configuration Examples



1.12.1 Configuring an IPv6 Static Multicast Route to Modify the RPF Route

1. Requirements

As shown in Figure 1-3, Device A, Device B, and Device C run the OSPF protocol and the PIM-SMv6 function is enabled on each interface. Originally, multicast data sent by the multicast source to Host A is forwarded through the path Device A> Device B. To reduce the load of the link from Device A to Device B, multicast data stream is separated from the unicast data stream. Therefore, the multicast data from the multicast source is sent through the path Device A > Device C > Device B.

2. Topology

Figure 1-3 Topology of IPv6 Static Multicast Route Configuration for Modifying the RPF Route

3. Notes

As shown in Figure 1-3, separate multicast data from unicast data by configuring a static multicast route on Device B to modify the RPF interface of the multicast data. Unicast data is forwarded through the path Device A > Device B, and multicast data is forwarded through the path Device A > Device C > Device B. The specific configuration method is as follows:

- Configure an IPv6 address and a unicast routing protocol on the multicast devices. A reachable unicast route is a basis of multicast protocol running.
- Enable the IPv6 multicast routing function on all multicast devices. Enable the PIM-SMv6 function on the interfaces connecting multicast devices, the interfaces connecting user hosts, and the multicast source interfaces. Configure C-BSR and C-RP on Device C.
- Configure an RPF static multicast route on Device B, specify Device C as an RPF neighbor, and modify the forwarding path of the multicast data packets.

4. Procedure

(1) Configure an IPv6 address and a unicast routing protocol on the multicast devices.

Configure an IPv6 address and a unicast routing protocol on Device A.

```
DeviceA> enable
DeviceA# config terminal
DeviceA(config)# interface GigabitEthernet 0/21
DeviceA(config-if-GigabitEthernet 0/21)# no switchport
DeviceA(config-if-GigabitEthernet 0/21)# ipv6 address 1000::1/64
DeviceA(config-if-GigabitEthernet 0/21)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/21)# exit
DeviceA(config)# interface GigabitEthernet 0/23
DeviceA(config-if-GigabitEthernet 0/23)# no switchport
DeviceA(config-if-GigabitEthernet 0/23)# ipv6 address 3000::1/64
```

```
DeviceA(config-if-GigabitEthernet 0/23)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/23)# exit
DeviceA(config)# interface GigabitEthernet 0/24
DeviceA(config-if-GigabitEthernet 0/24)# no switchport
DeviceA(config-if-GigabitEthernet 0/24)# ipv6 address 2000::1/64
DeviceA(config-if-GigabitEthernet 0/24)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/24)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/24)# exit
DeviceA(config)# ipv6 router ospf 4949
```

Configure an IPv6 address and a unicast routing protocol on Device B.

```
DeviceB> enable
DeviceB# config terminal
DeviceB(config)# interface GigabitEthernet 0/30
DeviceB(config-if-GigabitEthernet 0/30)# no switchport
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 address 8000::1/64
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 ospf 4949 area 0
DeviceB(config-if-GigabitEthernet 0/30)# exit
DeviceB(config)# interface GigabitEthernet 0/31
DeviceB(config-if-GigabitEthernet 0/31)# no switchport
DeviceB(config-if-GigabitEthernet 0/31)# ipv6 address 2000::2/64
DeviceB(config-if-GigabitEthernet 0/31)# ipv6 ospf 4949 area 0
DeviceB(config-if-GigabitEthernet 0/31)# exit
DeviceB(config)# interface GigabitEthernet 0/32
DeviceB(config-if-GigabitEthernet 0/32)# no switchport
DeviceB(config-if-GigabitEthernet 0/32)# ipv6 address 5000::2/64
DeviceB(config-if-GigabitEthernet 0/32)# exit
DeviceB(config)# interface Loopback 49
DeviceB(config-if-Loopback 49)# ipv6 address 4949::4949/128
DeviceB(config-if-Loopback 49)# ipv6 ospf 4949 area 0
DeviceB(config-if-Loopback 49)# exit
DeviceB(config)# ipv6 router ospf 4949
```

Configure an IPv6 address and a unicast routing protocol on Device C.

```
DeviceC> enable
DeviceC# config terminal
DeviceC(config)# interface GigabitEthernet 0/20
DeviceC(config-if-GigabitEthernet 0/20)# no switchport
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 address 5000::1/64
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/20)# exit
DeviceC(config)# interface GigabitEthernet 0/21
DeviceC(config-if-GigabitEthernet 0/21)# no switchport
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 address 3000::2/64
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/21)# exit
DeviceC(config)# interface Loopback 50
```

```
DeviceC(config-if-Loopback 50)# ipv6 address 5050::5050/128
DeviceC(config-if-Loopback 50)# ipv6 ospf 4949 area 0
DeviceC(config-if-Loopback 50)# exit
DeviceC(config)# ipv6 router ospf 4949
```

(2) Enable the IPv6 multicast routing function on all multicast devices. Enable the PIM-SMv6 function on the interfaces connecting multicast devices, the interfaces connecting user hosts, and the multicast source interfaces. Configure C-BSR and C-RP on Device C.

Enable the multicast routing and PIM-SMv6 related functions on Device A.

```
DeviceA> enable
DeviceA# config terminal
DeviceA(config)# ipv6 multicast-routing
DeviceA(config)# interface GigabitEthernet 0/21
DeviceA(config-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/21)# exit
DeviceA(config)# interface GigabitEthernet 0/23
DeviceA(config-if-GigabitEthernet 0/23)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/23)# exit
DeviceA(config)# interface GigabitEthernet 0/24
DeviceA(config-if-GigabitEthernet 0/24)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/24)# exit
```

Enable the multicast routing and PIM-SMv6 related functions on Device B.

```
DeviceB> enable
DeviceB# config terminal
DeviceB(config)# ipv6 multicast-routing
DeviceB(config)# interface GigabitEthernet 0/30
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 pim sparse-mode
DeviceB(config-if-GigabitEthernet 0/30)# exit
DeviceB(config)# interface GigabitEthernet 0/31
DeviceB(config-if-GigabitEthernet 0/31)# ipv6 pim sparse-mode
DeviceB(config-if-GigabitEthernet 0/31)# exit
DeviceB(config)# interface GigabitEthernet 0/32
DeviceB(config-if-GigabitEthernet 0/32)# ipv6 pim sparse-mode
DeviceB(config-if-GigabitEthernet 0/32)# exit
DeviceB(config)# interface Loopback 49
DeviceB(config-if-Loopback 49)# ipv6 pim sparse-mode
DeviceB(config-if-Loopback 49)# exit
```

Enable the multicast routing and PIM-SMv6 related functions on Device C.

```
DeviceC> enable
DeviceC# config terminal
DeviceC(config)# ipv6 multicast-routing
DeviceC(config)# ipv6 multicast-routing
DeviceC(config)# interface GigabitEthernet 0/20
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/20)# exit
```

```
DeviceC(config)# interface GigabitEthernet 0/21
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/21)# exit
DeviceC(config)# interface Loopback 50
DeviceC(config-if-Loopback 50)# ipv6 pim sparse-mode
DeviceC(config-if-Loopback 50)# exit
```

Configure C-BSR and C-RP on Device A.

```
DeviceA> enable
DeviceA# config terminal
DeviceA(config)# ipv6 pim bsr-candidate GigabitEthernet 0/21
DeviceA(config)# ipv6 pim rp-candidate GigabitEthernet 0/21
```

(3) Configure an RPF static multicast route on Device B, specify Device C as an RPF neighbor, and modify the forwarding path of the multicast data packets.

```
DeviceB> enable
DeviceB# config terminal
DeviceB(config)# ipv6  mroute 1000::/64 5000::1
```

5. Verification

(1) Run the **show ipv6 mld groups** command on Device B to check whether Host A joins the group FF15::11 and the multicast source 1000::2 sends packets to the group FF15::11.

```
DeviceB# show ipv6 mld groups
MLD Connected Group Membership
Group Address                    Interface                      Uptime
Expires   Last Reporter
ff15::11                        GigabitEthernet 0/30            00:12:17
00:03:00  fe80::8205:88ff:fe22:b468
DeviceB#
```

(2) Run the **show ipv6 mroute** command on Device A to display the hardware routing entry and check whether the next hop is Device C and the outbound interface is GigabitEthernet 0/23.

```
DeviceA# show ipv6 mroute

IPv6 Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed,
      R - RPT, S - SPT, s - SSM Group
Timers: Uptime/Stat Expiry
Interface State: Interface

(1000::2, ff15::11), uptime 00:08:53, stat expires 00:03:12
Owner PIMSMV6, Flags: TFS
  Incoming interface: GigabitEthernet 0/21
  Outgoing interface list:
    GigabitEthernet 0/23

DeviceA#
```

(3) Run the **show ipv6 rpf** command on Device B to check whether the next hop of the multicast source is Device C and the RPF interface is GigabitEthernet 0/32.

```
DeviceB# show ipv6 rpf 1000::
RPF information for 1000::
RPF interface: GigabitEthernet 0/32
  RPF neighbor: 5000::1
  RPF route: 1000::/64
  RPF type: static
  RPF recursion count: 0
  Doing distance-preferred lookups across tables
Distance: 0
  Metric: 0
DeviceB#
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ipv6 multicast-routing
!
interface GigabitEthernet 0/21
 no switchport
 ipv6 address 1000::1/64
 ipv6 ospf 4949 area 0
 ipv6 pim sparse-mode
!
interface GigabitEthernet 0/23
 no switchport
 ipv6 address 3000::1/64
 ipv6 ospf 4949 area 0
 ipv6 pim sparse-mode
!
interface GigabitEthernet 0/24
 no switchport
 ipv6 address 2000::1/64
 ipv6 ospf 4949 area 0
 ipv6 pim sparse-mode
!
ipv6 router ospf 4949
 graceful-restart
!
ipv6 pim bsr-candidate GigabitEthernet 0/21
ipv6 pim rp-candidate GigabitEthernet 0/21
!
```

- Device B configuration file

```
hostname DeviceB
!
ipv6 multicast-routing
!
ipv6 mroute 1000::/64 5000::1
!
interface GigabitEthernet 0/30
 no switchport
 ipv6 address 8000::1/64
 ipv6 ospf 4949 area 0
 ipv6 pim sparse-mode
!
interface GigabitEthernet 0/31
 no switchport
 ipv6 address 2000::2/64
 ipv6 ospf 4949 area 0
 ipv6 pim sparse-mode
!
interface GigabitEthernet 0/32
 no switchport
 ipv6 address 5000::2/64
 ipv6 pim sparse-mode
!
interface Loopback 49
 ipv6 address 4949::4949/128
 ipv6 ospf 4949 area 0
 ipv6 pim sparse-mode

 graceful-restart
!
```

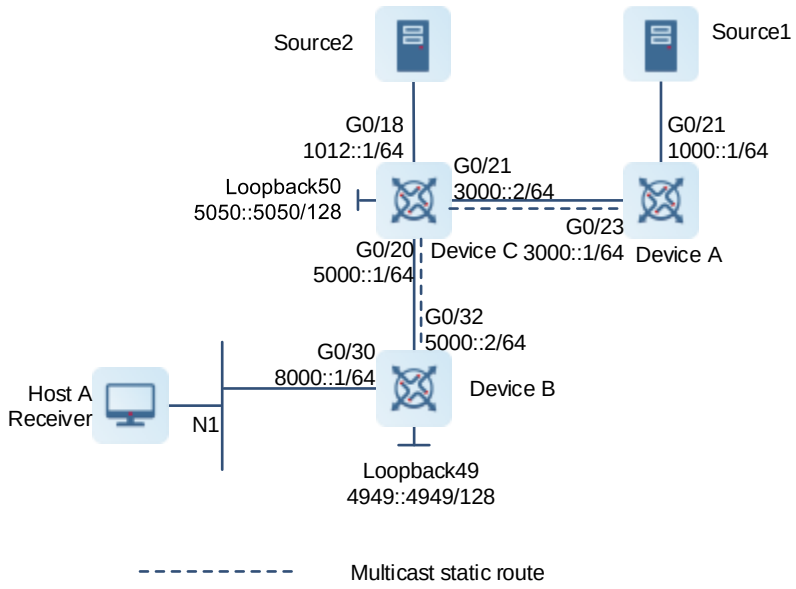
- Device C configuration file

```
hostname DeviceC
!
ipv6 multicast-routing
!
interface GigabitEthernet 0/20
 no switchport
 ipv6 address 5000::1/64
 ipv6 ospf 4949 area 0
 ipv6 pim sparse-mode
!
interface GigabitEthernet 0/21
 no switchport
 ipv6 address 3000::2/64
 ipv6 ospf 4949 area 0
```

```
 ipv6 pim sparse-mode
!
interface Loopback 50
 ipv6 address 5050::5050/128
 ipv6 ospf 4949 area 0
 ipv6 pim sparse-mode
!
ipv6 router ospf 4949
 graceful-restart
!
```

7. Common Errors

- IPv6 unicast routing is incorrectly configured.
- The IPv6 multicast routing function is not enabled on a multicast device.
- No IPv6 multicast protocol is enabled on an interface.



1.12.2 Configuring a Static Multicast Route to Connect the RPF Route

1. Requirements

As shown in Figure 1-4, Device B and Device C run the OSPF protocol, and the unicast route to Device A is isolated. The PIM-SMv6 function is enabled on the interfaces of Device A, Device B and Device C. Host A can normally receive multicast data packets from Source 2, and it is required to receive multicast data packets from Source 1 as well.

2. Topology

Figure 1-4 Topology of IPv6 Static Multicast Route Configuration for Connecting the RPF Route

3. Notes

Configure a static multicast route to establish an RPF route that is destined to source 1 based on the path Device B > Device C > Device A. The specific configuration method is as follows:

- Configure an IPv6 address for each interface of the devices, and configure the OSPF protocol on Device B and Device C to separate multicast routes from unicast routes on Device A.
- Enable the IPv6 multicast routing function, configure the PIM-SMv6 protocol on each L3 interface of the devices and configure the C-BSR and C-RP in the global configuration, and enable the MLD function on the interface connected to hosts.
- Configure static multicast routes to source 1 on Device B and Device C.

4. Procedure

(1) Configure an IPv6 address for each interface of the devices, and configure the OSPF protocol on Device B and Device C to separate multicast routes from unicast routes on Device A.

Configure an IPv6 address for the interface on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface GigabitEthernet 0/21
DeviceA(config-if-GigabitEthernet 0/21)# no switchport
DeviceA(config-if-GigabitEthernet 0/21)# ipv6 address 1000::1/64
DeviceA(config-if-GigabitEthernet 0/21)# exit
DeviceA(config)# interface GigabitEthernet 0/23
DeviceA(config-if-GigabitEthernet 0/23)# no switchport
DeviceA(config-if-GigabitEthernet 0/23)# ipv6 address 3000::1/64
DeviceA(config-if-GigabitEthernet 0/23)# exit
DeviceA(config)# ipv6 route 5050::5050/128 3000::2
```

Configure an IPv6 address and the OSPF protocol for the interface on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# interface GigabitEthernet 0/30
DeviceB(config-if-GigabitEthernet 0/30)# no switchport
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 address 8000::1/64
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 ospf 4949 area 0
DeviceB(config-if-GigabitEthernet 0/30)# exit
DeviceB(config)# interface GigabitEthernet 0/32
DeviceB(config-if-GigabitEthernet 0/32)# no switchport
DeviceB(config-if-GigabitEthernet 0/32)# ipv6 address 5000::2/64
DeviceB(config-if-GigabitEthernet 0/32)# ipv6 ospf 4949 area 0
DeviceB(config-if-GigabitEthernet 0/32)# exit
DeviceB(config)# interface Loopback 49
DeviceB(config-if-Loopback 49)# ipv6 address 4949::4949/128
DeviceB(config-if-Loopback 49)# ipv6 ospf 4949 area 0
DeviceB(config-if-Loopback 49)# exit
DeviceB(config)# ipv6 router ospf 4949
DeviceB(config-router)# exit
```

Configure an IPv6 address and the OSPF protocol for the interface on Device C.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# interface GigabitEthernet 0/18
DeviceC(config-if-GigabitEthernet 0/18)# no switchport
DeviceC(config-if-GigabitEthernet 0/18)# ipv6 address 1012::1/64
DeviceC(config-if-GigabitEthernet 0/18)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/18)# exit
DeviceC(config)# interface GigabitEthernet 0/20
DeviceC(config-if-GigabitEthernet 0/20)# no switchport
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 address 5000::1/64
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/20)# exit
DeviceC(config)# interface GigabitEthernet 0/21
DeviceC(config-if-GigabitEthernet 0/21)# no switchport
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 address 3000::2/64
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/21)# exit
DeviceC(config)# interface Loopback 50
DeviceC(config-if-Loopback 50)# ipv6 address 5050::5050/128
DeviceC(config-if-Loopback 50)# ipv6 ospf 4949 area 0
DeviceC(config-if-Loopback 50)# exit
DeviceC(config)# ipv6 router ospf 4949
DeviceC(config-router)# exit
```

(2) Enable the IPv6 multicast routing function, configure the PIM-SMv6 protocol on each L3 interface of the devices and configure the C-BSR and C-RP in the global configuration, and enable the MLD function on the interface connected to hosts.

Enable the IPv6 multicast routing function and configure the PIM-SMv6 protocol on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# ipv6 multicast-routing
DeviceA(config)# interface GigabitEthernet 0/21
DeviceA(config-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/21)# exit
DeviceA(config)# interface GigabitEthernet 0/23
DeviceA(config-if-GigabitEthernet 0/23)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/23)# exit
```

Enable the IPv6 multicast routing function and configure the PIM-SMv6 protocol on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ipv6 multicast-routing
DeviceB(config)# interface GigabitEthernet 0/30
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 pim sparse-mode
DeviceB(config-if-GigabitEthernet 0/30)# exit
DeviceB(config)# interface GigabitEthernet 0/32
```

```
DeviceB(config-if-GigabitEthernet 0/32)# ipv6 pim sparse-mode
DeviceB(config-if-GigabitEthernet 0/32)# exit
DeviceB(config)# interface Loopback 49
DeviceB(config-if-Loopback 49)# ipv6 pim sparse-mode
DeviceB(config-if-Loopback 49)# exit
```

Enable the IPv6 multicast routing function and functions related to the PIM-SMv6 protocol on Device C.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# ipv6 multicast-routing
DeviceC(config)# interface GigabitEthernet 0/18
DeviceC(config-if-GigabitEthernet 0/18)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/18)# exit
DeviceC(config)# interface GigabitEthernet 0/20
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/20)# exit
DeviceC(config)# interface GigabitEthernet 0/21
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/21)# exit
DeviceC(config)# interface Loopback 50
DeviceC(config-if-Loopback 50)# ipv6 pim sparse-mode
DeviceC(config-if-Loopback 50)# exit
DeviceC(config)# ipv6 pim bsr-candidate Loopback 50
DeviceC(config)# ipv6 pim rp-candidate Loopback 50
```

Enable Source 1 (1000::2/64) and Source 2 (1012::2/64) to send multicast data packets to the multicast group (FF14::10). Add Host A to the multicast group (FF14::10) so that Host A can receive multicast data packets from Source 2 but cannot receive multicast data packets from Source 1.

Run the **show ipv6 rpf** 1000::2 command on Device C. No route exists. No RPF route to Source 1 exists on Device C.

(3) Configure static multicast routes to source 1 on Device B and Device C.

On Device B, configure an RPF static multicast route and configure Device C as an RPF neighbor to Source 1.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ipv6 mroute 1000::/64 5000::1
```

On Device C, configure an RPF static multicast route and configure Device A as an RPF neighbor to Source 1.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# ipv6 mroute 1000::/64 3000::1
```

5. Verification

Run the **show ipv6 rpf** 1000::2 command on Device B to display the RPF information of Source 1. The RPF information is displayed as follows:

```
DeviceB# show ipv6 rpf 1000::2
RPF information for 1000::2
RPF interface: GigabitEthernet 0/32
  RPF neighbor: 5000::1
  RPF route: 1000::/64
  RPF type: static
  RPF recursion count: 0
  Doing distance-preferred lookups across tables
Distance: 0
  Metric: 0
DeviceB#
```

Run the **show ipv6 rpf** 1000::2 command on Device C to display the RPF information of Source 1. The RPF information is displayed as follows:

```
DeviceC# show ipv6 rpf 1000::2
RPF information for 1000::2
RPF interface: GigabitEthernet 0/21
  RPF neighbor: 3000::1
  RPF route: 1000::/64
  RPF type: static
  RPF recursion count: 0
  Doing distance-preferred lookups across tables
Distance: 0
  Metric: 0
DeviceC#
```

Enable Source 1 and Source 2 to send multicast data packets to the multicast group (FF14::10), and add Host A to the multicast group.

Run the **show ipv6 pim sparse-mode mroute** command on Device B and Device C to display routing entry information. The multicast entries of Source 1 exist on Device B and Device C. Host A normally receives multicast data packets from Source 1.

```
DeviceC# show ipv6 pim sparse-mode mroute

1 Configuring PIM-SMv6

1.1 Introduction

The Protocol Independent Multicast (PIM) is an intra-domain multicast routing protocol that is independent from unicast routing protocols. Any unicast routing protocol, for example, static route, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF), can provide routing information for IP multicast. Multicast routing is independent of unicast routing, and simply uses unicast routing tables to generate multicast routing information. The Protocol Independent Multicast-Sparse Mode version 6 (PIM-SMv6) is used most widely, and applies to networks of any form, especially large networks where group members are scattered in a wide area. Compared with other intra-domain multicast routing protocols, PIM-SMv6 has irreplaceable advantages.

1.2 Principles

Suppose that not all hosts need to receive multicast data, PIM-SMv6 sends multicast data to hosts that require the multicast data.

A PIM multicast device provides multicast service in any-source multicast (ASM) and source-specific multicast (SSM) models. For groups in the SSM address range, the SSM model is used. For other groups, the ASM model is used. In the ASM model, a host joins a specified multicast group G without the multicast source S specified. In the SSM model, a host can join a specified multicast group G to receive multicast data from a specified source S.

1.2.1 ASM Model

1. Basic Principles

PIM-SMv6 in the ASM model is implemented as follows:

- A rendezvous point (RP) is used as a root of a rendezvous point tree (RPT) for transition. The designated router (DR) connected to a host sends a join message to the RP of a multicast group, and the multicast devices on the route create (*, G) entries hop by hop. Based on the entries, an RPT is created with the RP as the root.
- To send data to a multicast group, the source DR sends a register message to the RP to create an (S, G) entry on the RP. After the registration succeeds, the multicast source sends multicast data to the RP. After the multicast data arrives at the RP, it is copied and sent to the host via the RPT.

In the ASM model, the key mechanisms of PIM-SMv6 include PIM neighbor creation, DR election, RP, bootstrap router (BSR), multicast source registration, shortest path tree (SPT) switchover, and assertion.

2. PIMv6 Neighbor Creation

Neighbor relationship must be created between PIM multicast devices to form a PIM network, so that PIM control messages and multicast packets can be transmitted on the network. A Hello message is sent from a PIM interface. In the multicast packet with the Hello message encapsulated, the destination address is FF02::D (indicating all PIM multicast devices in the same network segment), the source address is the IP address of the PIM interface, and the time to live (TTL) value is 1. The Hello message is used to:

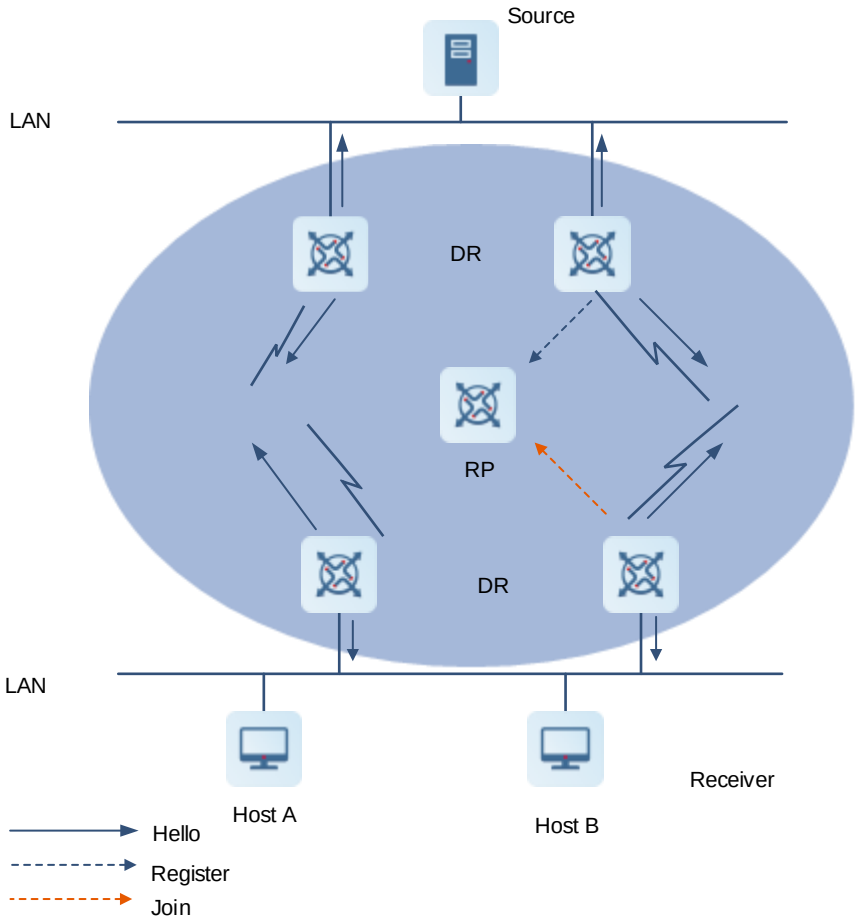
- Discover PIM neighbors.

  PIM multicast devices in the same network segment receive the multicast packet with the destination address as FF02::D, obtain neighbor information, and create neighbor relationship. After the neighbor relationship is created, the PIM interfaces can receive and process other PIM packets and create multicast routing entries.

  When a PIM interface is enabled or detects a new neighbor, a Triggered-Hello-Delay message is used to generate a random time. Within the time, the interface sends Hello messages.

- Negotiate protocol parameters. The Hello message contains the following key parameters:
  - **DR Priority**: The priority of a multicast device for DR election. The device with a higher priority is selected.
  - **Holdtime**: The neighbor is considered reachable before timeout.
  - **Propagation Delay**: Duration between the time when a PIM device receives a prune packet and the time when the PIM device sends the prune packet to the uplink devices.
  - **Override-Interval**: The interval to override the prune.
- Maintain neighbor relationship.

  A Hello message is sent periodically between PIM multicast devices. If no new Hello message is received from a PIM neighbor within the hold time, this neighbor is considered unreachable and then removed from the neighbor list. Any change of PIM neighbors will cause change of the multicast topology in the network. If an uplink or downlink neighbor in a multicast distribution tree (MDT) is unreachable, multicast routes converge again and the MDT is reshaped.



3. DR Election

As shown in Figure 1-1, the source DR sends a register message to the RP. Member DRs send join messages to the RP and forward multicast data to members in a multicast group. In the network segment to which members and multicast source are connected, multiple PIM devices obtain IP addresses and DR priorities of neighbors based on the Hello messages sent between the PIM devices during PIM neighbor creation. The PIM device that is elected becomes a member DR or source DR. The election rules are as follows:

(1) The DR priorities are compared. The device with a higher priority is selected.

(2) If the DR priorities are the same or there is any neighbor in the shared network segment that does not support DR priority, the IP addresses of the devices are compared. The device with a larger IP address is selected.

Figure 1-1 Schematic Diagram of DR Election

4. BSR Election

In the PIM network, the BSR periodically generates bootstrap messages (BSMs) that include a series of candidate-RPs (C-RPs) and corresponding group addresses. The BSMs are sent in the entire domain hop by hop. All PIM multicast devices in the network receive the BSMs and record the C-RPs and corresponding group addresses.

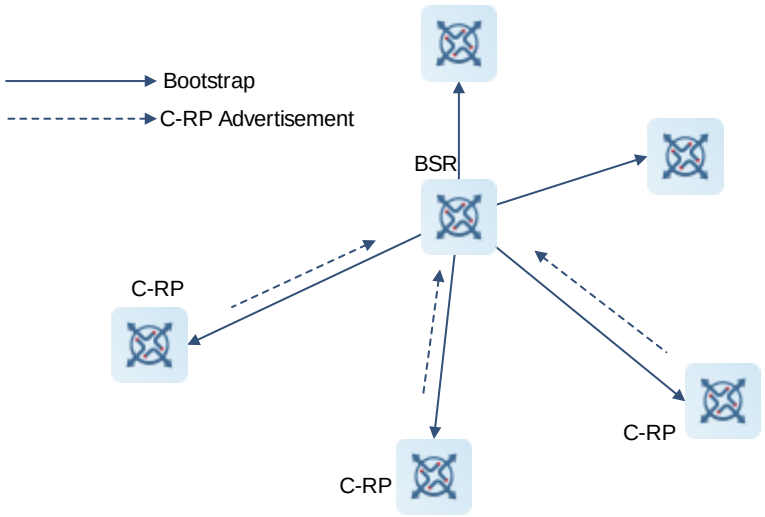
In the PIM-SMv6 domain, one or multiple candidate-BSRs (C-BSRs) are configured and the BSR is elected based on rules.

5. RP Election

In the PIMv6 network, the RP processes register messages of the source DR and join packets of group members. The process from the multicast source to members of the multicast group is divided into two sections: The SPT that uses the source DR as the root and the RP as the leaf, and the RPT that uses the RP as the root and member DRs as leaves. In the PIM-SMv6 network with the ASM model, the RP must act as a transition to create or forward data.

In the PIM network, an RP can serve one or more groups, and a group can be served by only one RP. In the PIM network, the RP can be configured as static or dynamic.

- Static RP



A static RP sets the RP address on each PIM multicast device to enable the entire PIMv6 network to know the RP address.

- Dynamic RP

  Multiple C-RPs can be configured in a PIM-SMv6 domain to elect an RP dynamically. These C-RPs add their own addresses and served multicast groups to advertisement packets and sent the packets to the BSR periodically in unicast mode. The BSR is elected from the configured C-BSRs based on rules. The BSR periodically generates BSMs that include a series of C-RPs and corresponding group addresses. The BSMs are sent in the entire domain. Each PIM device in the domain receives and saves these BSMs, and applies the same hash algorithms to compute and elect an RP for each group.

  - BSR election process: Initially, each C-BSR considers itself a BSR and sends a BSM throughout the network. The BSMs carry the C-BSR addresses and priorities. Upon receiving the BSMs, each PIM device compares the C-BSR addresses and priorities to elect the BSR.
  - RP election process: The C-RPs periodically send advertisement packets to the BSR in unicast mode to advertise the C-RP addresses, priorities, and addresses of the served groups. The BSR collects the information as RP-Set, encapsulates the information in a BSM, and sends the messages to each PIM device in the network. Upon receiving the RP-Set, the PIM devices in the network use the same algorithms for computation to obtain the RP that serves each group. Each PIM device obtains the RP position of each group. Figure 1-2 shows the schematic diagram of dynamic RP election.

Figure 1-2 Schematic Diagram of Dynamic RP Election

6. Multicast Source Registration

Figure 1-3 Schematic Diagram of Multicast Source Registration

As shown in Figure 1-3, when a multicast source sends data to a group, the source DR sends a register message to the RP so that the RP obtains the source information and a multicast packet and forwards the multicast packet to the members in the group. The forwarding process is described as follows:

(1) The multicast source sends a multicast packet to the source DR.

(2) The source DR encapsulates the multicast packet in a register message and sends the message to the RP in unicast mode.

(3) Upon receiving the register message, the RP decapsulates the message and forwards the multicast packet to the members in a group via the RPT. Meanwhile, the RP sends an (S, G) join packet to the source. The PIM devices on the route create (S, G) entries, and finally create an SPT from the source to the RP.

(4) The source DR S forwards multicast packets based on this SPT. The multicast data is sent to the RP in the form of multicast packets.

(5) Upon receiving multicast packets from the source, the RP discards the register message and sends a register-stop message to the source.

(6) Upon receiving the register-stop message, the source DR stops encapsulating the register message, forwards multicast packets via the SPT, and periodically sends a register-probe message to the RP.

(7) Upon receiving the register-probe message, the RP sends a register-stop message to the source DR and updates the (S, G) entries.

(8) Upon receiving the register-stop message, the source DR continues forwarding multicast packets via the SPT without encapsulating the register message.

7. RPT Construction

When a group member joins the network, the DR connecting to the group member sends a join packet to the RP. If a multicast source has sent a multicast packet to the RP, the multicast packet will be sent to the group member via the RPT.

The RPT construction procedure is as follows:

- When a member DR receives an MLD (*, G) INCLUDE Report packet, if the member DR is not an RP of the group G, the member DR sends a (*, G) join packet to the RP and the multicast devices on the route create the (*, G) entries hop by hop to generate an RPT that uses the RP as the root.
- During RPT construction, each PIM device checks the reverse path forwarding (RPF) when sending a join packet to the RP to find the unicast route to the RP. The outbound interface of the unicast route is an uplink interface, and the next hop of the unicast route is the RPF neighbor. The join packet is sent from the member DR to the RP.

8. SPT Switchover

In the PIM-SMv6 network of the ASM model, one or multiple multicast groups correspond to one RP. Before SPT switchover, all packets of multicast groups sent to the RP service must be transitioned by the RP. When the sending rate of multicast packets grows, the RP load is increased. To solve this problem, the PIM-SMv6 relieves the RP load by SPT switchover. SPT switchover can be triggered by the RP or a member DR.

- SPT switchover triggered by the RP

  After receiving a register message from the source DR, the RP decapsulates the register message, forwards the multicast packets in the message to the group members via the RPT, and sends an (S, G) join packet to the source DR. The PIM multicast devices on the route create (S, G) entries hop by hop to create an SPT from the RP to the source.

- SPT switchover triggered by a member DR

  a When receiving the first multicast packet from the RP, the member DR obtains the source address.

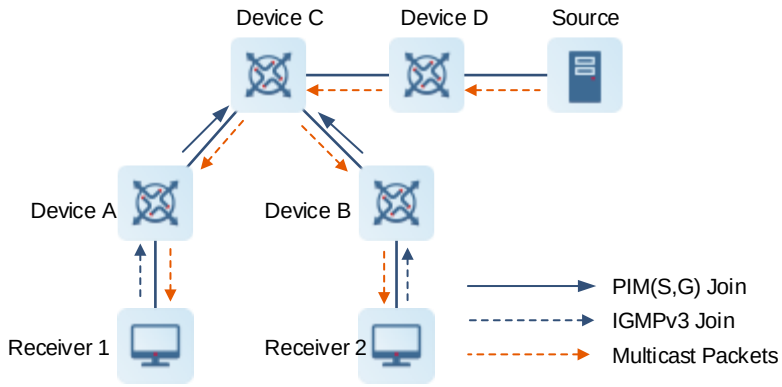
  b The member DR sends an (S, G) join packet to the source. The PIM devices on the route create (S, G) entries and create an SPT from the member DR to the source DR.

  c After the SPT is created, the member DR sends a prune packet to the RP hop by hop and removes the downlink interface from the (*, G) entries. After the pruning, the RP does not forward multicast packets to the member DR via the RPT.

  d The SPT from the member DR to the source DR does not pass the RP. The RP sends a prune packet to the source DR to remove the downlink interface from the (S, G) entries. After the pruning, the source DR does not forward packets to the RP via the original "RP-source DR" SPT.

1.2.2 SSM Model

1. Basic Principles



In the SSM model, members in a multicast group can specify to receive or reject data from a multicast source. The group members get to know the (S, G) entries of sources through access to the server or receiving advertisements. After understanding requirement of group members, the member DR sends a join packet to the source DR. This join packet is transmitted to the multicast source hop by hop to create an SPT from the source to the group members.

Note

- To implement the SSM model on IPv6, complete multicast interconnection through the PIM-SMv6 and configure MLDv2 to manage relationship between the hosts and devices.
- SSM model requirements: The hosts must know the addresses of multicast sources in advance using other network services so that the hosts can select multicast sources.

- On the devices that reside on the route from the hosts to the multicast source, the PIM-SMv6 and SSM functions must be enabled.

Figure 1-4 SSM Model

Caution

After the SSM function is enabled, the default group range of the SSM is FF3x::/32 (x cannot be 1 or 2). You can modify the group range of the SSM using commands.

In the SSM model, the key mechanisms of PIM-SMv6 include neighbor creation, DR election, and SPT creation.

2. PIMv6 Neighbor Creation

For more information about the PIMv6 neighbor creation mechanism in the SSM model, see the PIMv6 neighbor creation mechanism in the ASM model in 1.2.1 2. PIMv6 Neighbor Creation.

3. DR Election

For more information about the DR election mechanism in the SSM model, see the DR election mechanism in the ASM model in 1.2.1 3. DR Election.

4. SPT Construction

The SPT construction mechanism is as follows:

(1) The member DR learns through MLDv2 that a group member wants to receive data of a multicast source and sends an (S, G) join packet to the source hop by hop.

(2) The PIMv6 multicast devices on the route receive the (S, G) join packet and create the (S, G) entries, creating an SPT from the group member to the source.

(3) After the SPT is created, the multicast source distributes the multicast packets to the group member via the SPT.

1.2.3 Protocols and Standards

- RFC 4601: Protocol Independent Multicast-Sparse Mode (PIM-SM)
- RFC 5059: Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- RFC 3962: Protocol Independent Multicast-Dense Mode protocol

- RFC 4607: Source-Specific Multicast for IP

1.3 Restrictions and Guidelines

- Before PIM-SMv6 is enabled, enable the multicast routing and forwarding function in global configuration mode. Otherwise, multicast packets cannot be sent even if PIM-SMv6 is enabled.
- In the IPv6 multicast network, the PIM (IPv6) protocol must be run on all L3 devices. Otherwise, a forwarding route cannot be created.

1.4 Configuration Task Summary

The PIM-SMv6 configuration includes the following tasks:

(1) Enabling the PIM-SMv6 Function

(2) Configuring a model for PIM-SMv6. Select one of the following to configure:

- Configuring PIM-SMv6 in the ASM Model
- Configuring PIM-SMv6 in the SSM Model

(3) Configuring PIM-SMv6 Neighbor Parameters. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Neighbor Message Time Parameters
- Configuring Neighbor Tracking
- Configuring Neighbor Filtering

(4) (Optional) Configuring DR Priority

(5) Configuring Parameters of the Join/Prune Packets. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Join/Prune Packet Sending Interval
- Configuring the Prune Delay

(6) (Optional) Enabling PIM-SMv6 BFD Correlation

(7) (Optional) Configuring the Device to Ignore RPF Check

1.5 Enabling the PIM-SMv6 Function

1.5.1 Overview

Neighbor relationship must be created between PIM multicast devices to form a PIM-SMv6 network, so that PIM control messages and multicast packets can be transmitted on the network. The PIM-SMv6 function must be configured on all interfaces so that PIM neighbor creation, multicast entry creation, and multicast packet forwarding can be successful.

In a PIMv6 network, if you want an interface, for example, a stub network device interface connecting to hosts, to receive multicast packets without involving the PIMv6 network topology construction, you can set the interface to the PIM-SMv6 passive mode. After the PIM-SMv6 passive mode is configured, the interface does not process PIM packets. This improves device performance.

1.5.2 Restrictions and Guidelines

- The IPv6 multicast routing function must be enabled on each multicast device.
- The PIM-SMv6 function should be enabled on the following interfaces: interfaces interconnecting multicast devices, interfaces connecting the static RP, C-RP and C-BSRs, and interfaces connecting multicast sources or hosts.

1.5.3 Prerequisites

All PIM interfaces can be reached via IPv6 unicast routes.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable IPv6 multicast routing.

ipv6 multicast-routing

The IPv6 multicast routing function is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(5) Enable the PIM-SMv6 function.

ipv6 pim sparse-mode

The PIM-SMv6 function is disabled by default.

(6) (Optional) Enable the PIM-SMv6 passive mode.

ipv6 pim sparse-mode passive

The PIM-SMv6 passive mode is disabled by default.

1.6 Configuring PIM-SMv6 in the ASM Model

1.6.1 Overview

The PIM-SMv6 network supports the multicast service in the ASM and SSM models. Either one model or two models can be configured.

PIM-SMv6 in the ASM model can provide hosts with multicast services of any source. A host joining a multicast group can receive multicast packets destined to this multicast group from any source.

If you require a PIMv6 network to support the multicast service in the ASM model, an RP must be configured. There are three methods to configure an RP:

- Configure a static RP.
- Configure a dynamic RP.
- Configure static and dynamic RPs. If static and dynamic RPs are available at the same time, dynamic RPs prevail.

1.6.2 Configuration Tasks

The PIM-SMv6 configuration in the ASM model includes the following tasks. Configure at least one RP, either dynamic or static. You can also configure both a static RP and a dynamic RP.

- Configuring a Static RP
- Configuring a Dynamic RP
  - Configuring C-BSRs and Related Parameters
  - Configuring C-RPs and Related Parameters
  - (Optional) Configuring Registration Parameters
- (Optional) Configuring the Last Hop Device to Switch over from the RPT to SPT

1.6.3 Prerequisites

In the PIM-SMv6 multicast network, all nodes are reachable via IPv6 unicast routes.

1.6.4 Configuring a Static RP

1. Overview

You can manually configure a static RP to prevent frequent packet interaction between the BSR and C-RPs or between the BSR and PIM multicast devices and avoid bandwidth occupation. If the multicast network is simple and small, you can configure a static RP.

2. Restrictions and Guidelines

- Static RPs must be configured on every multicast device.
- The multicast device selected as a static RP must boast high performance.
- You are advised to use the loopback interface as a static RP address.
- Static RPs configured on multicast devices should be consistent, including RP address and address range of the served groups.
- If multiple static RPs are configured to correspond to different addresses of groups, the RPs can implement load balancing.
- If multiple static RPs serve the same group, the static RP with a larger IPv6 address is selected first.
- You can use the control list to configure an RP to serve multiple (referencing an ACL) or all (not referencing an ACL) multicast groups. However, an RP can adopt only one configuration.

3. Prerequisites

Before an address range of a group is configured for an RP, ensure that the corresponding ACL is created and specify a multicast group range for the static RP to serve. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a static RP.

ipv6 pim rp-address *ipv6-rp-address* [*acl-name*]

No static RP is configured by default.

1.6.5 Configuring C-BSRs and Related Parameters

1. Overview

In the PIM-SMv6 domain of the ASM model, a unique BSR must be available. The BSR collects and releases RP information.

- The BSR is elected from C-BSRs based on rules. The election rules are as follows:
  a The priorities of the C-BSRs are compared. The device with a higher priority is selected.
  b If the priorities are the same, the IP addresses are compared. The device with a larger IP address is selected.

  The winner is elected as the BSR in the domain and periodically sends BSMs in the domain. A BSM contains the BSR IP address, RP-Set and hash mask information. The hash mask is used for hash calculation during C-RP election. In the hold time of a BSM, if other C-BSRs do not receive the BSM from the BSR, the BSR is considered unreachable and a new round of BSR election is initiated.
- To avoid fraud by an illegitimate BSR, a BSR range can be specified on all PIM devices in the domain so that the PIM devices ignore a BSM that is sent from an illegitimate BSR.
- To limit BSM flooding, you can configure a BSR border on an interface. Upon receiving BSMs, this interface discards the BSMs without forwarding them. This limits the BSM flooding.

2. Restrictions and Guidelines

- C-BSRs must be configured on one or multiple multicast devices.
- The multicast devices selected as C-BSRs must boast high performance. The C-RPs and C-BSRs can reside on the same or different multicast devices.
- You are advised to use the loopback interface as a C-BSR address.
- If multiple C-BSRs are configured, they can implement redundancy backup.
- You are advised to configure a valid BSR address range on all PIM devices in the domain.
- A BSR border must be configured on the interface between domains.

3. Prerequisites

- Enabling the PIM-SMv6 Function.
- Before a valid BSR address range is configured on PIM devices, ensure that the corresponding ACL is created and specify a valid BSR range. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure C-BSRs and related parameters.

ipv6 pim bsr-candidate *interface-type interface-number* [*hash-mask-length* [*priority-value*]]

No C-BSR is configured by default.

(4) (Optional) Configure a valid BSR address range on all PIM devices.

ipv6 pim accept-bsr list *acl-name*

All BSMs are received by default.

(5) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(6) (Optional) Configure a BSR border on the interface between PIM-SMv6 domains.

Ipv6 pim bsr-border

No BSR border is configured by default.

If multiple domains exist, the BSR border must be configured on the interface between two domains.

1.6.6 Configuring C-RPs and Related Parameters

1. Overview

- After a multicast device is configured as a C-RP, the C-RP periodically sends an advertisement packet to the BSR in unicast mode. The packet includes the RP priority, advertisement packet hold time (greater than the interval of sending the advertisement packet), RP address, address of the served group, and prefix of the multicast address. Upon receiving the advertisement packet, the BSR collects the information in the packet as RP-Set in the advertisement packet hold time, encapsulates the information in a BSM, and sends the message to all PIM devices. Upon receiving the BSM from the BSR, the PIM devices in the domain apply the same algorithms for hash calculation to calculate the C-RP serving each multicast group. After the

advertisement packet hold time expires, if the BSR does not receive a next advertisement packet from the C-RP, this C-RP is considered unreachable.

- To prevent fraud by an illegitimate C-RP, a C-RP range can be specified on the BSR. If an advertisement packet comes from an illegitimate C-RP, the packet is ignored.
- The BSR can determine whether to receive an advertisement packet with the prefix of the multicast address being 0 from a C-RP. When the prefix of the multicast address is 0, this C-RP serves all multicast groups.
- When receiving the BSM from the BSR, each PIM multicast device in the domain applies rules to select the RP. The RP election rules are as follows:
  a The address of the multicast group that a host joins is compared with the mask length of the group address range that the C-RP serves. The device with the longest mask is selected.
  b If the addresses are consistent with the mask length, the priorities of the C-RPs are compared. The device with the smallest priority value is selected.
  c If the priorities are consistent, hash values are calculated and compared. The device with the largest hash value is selected.
  d If the hash values are the same, the IP addresses of the C-RPs are compared. The device with the largest IP address is selected.

2. Restrictions and Guidelines

- C-RPs must be configured on one or multiple multicast devices.
- The multicast devices selected as C-RPs must boast high performance. The C-RPs and C-BSRs can reside on the same or different multicast devices.
- You are advised to use the loopback interface as a C-RP address.
- If multiple C-RPs are configured to serve the same group, they can implement redundancy backup.
- If multiple C-RPs are configured to serve different groups, they can implement load balancing.
- A valid C-RP range can be configured on the BSR.
- To specify a group range for C-RPs to serve, you can add the ACL option to the **ip pim rp-candidate** command. The group range is calculated based on the permit access control entry (ACE), rather than the deny ACE.

3. Prerequisites

- Enabling the PIM-SMv6 Function.
- If the **group-list** parameter is used to limit the range of groups served by the RP, ensure that the corresponding ACL is created and specify a multicast group range for the RP to serve. For more information about ACL configuration, see *Configuring ACL*
- Before a valid C-RP address range is configured on PIM BSRs, ensure that the corresponding ACL is created and specify a multicast group range for the static RP to serve. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

- Configure a C-RP and related parameters.
  a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Configure a C-RP.

ipv6 pim rp-candidate *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval-seconds*] [**group-list** *acl-name*]

No C-RP is configured by default.

- (Optional) Configure the BSR to receive C-RP advertisement packets with the prefix of the multicast address being 0. This C-RP serves all the multicast groups.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Configure the BSR to receive advertisement packets from the C-RP that serves all multicast groups.

ipv6 pim accept-crp-with-null-group

The function for the BSR to receive advertisement packets from the C-RP that serves all multicast groups is disabled by default.

You are advised to enable this function on all C-BSRs.

- (Optional) Configure a valid C-RP range on the BSR.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Configure a valid C-RP range.

ipv6 pim accept-crp list *acl-name*

The C-BSRs receive all external C-RP advertisement packets by default.

You are advised to enable this function on all C-BSRs.

- (Optional) Configure all PIM multicast devices to ignore RP priority and reselect an RP.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Configure all PIM multicast devices to ignore the RP priority for RP election.

ipv6 pim ignore-rp-set-priority

If the address of the multicast group that a host joins is consistent with the mask length of the group address range that the C-RPs serve, the RP with the highest priority is selected by default.

You can configure each multicast device to ignore C-RP priority.

- (Optional) Configure static RP priority to be higher than dynamic RP priority on all PIM multicast devices.
  a Enter the privileged EXEC mode.

  enable

  b Enter the global configuration mode.

  configure terminal

  c Configure the static RP priority.

  ipv6 pim static-rp-preferred

  The dynamic RP priority is higher than the static RP priority by default.

  You can configure each multicast device to ignore dynamic RP priority.

1.6.7 Configuring Registration Parameters

1. Overview

When a multicast source sends multicast data, the data arrives at the source DR first. Upon receiving the multicast data, the source DR encapsulates the multicast data as a register message and sends the message to the RP. Related parameters of the register message are configured on the source DR and RP.

- You can configure the following parameters on the source DR:
  - RP reachability checking: Before sending a register message, the source DR determines whether the RP is reachable. If the RP is reachable, the message is sent. Otherwise, the message is not sent.
  - Limit on the rate of sending the register message: The rate of sending each register message in (S, G) status is limited. If multiple register messages in (S, G) status are sent from the same source, the rate of the register messages is limited to the product of *N* x Limit value.
  - Source address in the register message: The source address in the register message is the address of the DR interface connected to the multicast source by default. If a security policy is configured on the RP to filter out this address, the RP does not receive register messages from this source DR. In this case, you can specify a reachable source address as the source address of the register message.
  - Register suppression time: When the RP receives multicast packets sent by the multicast source via the SPT, the RP sends a register-stop message to the source DR. Within the register suppression time, the source DR stops encapsulating the register message and sends multicast packets to the RP via the SPT. After the register suppression time expires, if the source DR does not receive another register-stop message from the RP, the source DR continues to encapsulate the register message and send the message to the RP.
  - Null message detection time: Before the register suppression time expires, the RP receives a null message from the source DR, refreshes the local (S, G) entries, and sends a register-stop message to the source DR so that the source DR refreshes the register suppression timer. Otherwise, the source DR continues to encapsulate the register message and send multicast packets to the RP in the form of the register message.
- You can configure the following parameters on the RP:
  - (S, G) address range of source: Provide multicast services for hosts in the permitted multicast group in the ASM model. After this parameter is configured, the RP replies a register-stop message upon receiving data from an unauthorized source.

- Length of register message checksum: Adjust the calculation method of the register message checksum and calculate the checksum of the entire PIM protocol packets (including encapsulated multicast packets) or the checksum of PIM headers of separate register messages.
- Register message decapsulation and delivery to downlink interface: Configure this parameter on the RP to decapsulate the received register message and forward the multicast packets in the register message.
- Register message (S, G) entry timeout period: Configure this parameter to configure the timeout period of (S, G) entries. The (S, G) entries age if no packet is received within the register message timeout period.

2. Restrictions and Guidelines

- The source address in the specified register message must be reachable in unicast mode. You are advised to use the loopback interface of the source DR as the source address of the register message.
- If the **ip pim rp-register-kat** command is not configured, modifying the register suppression time on the RP changes the (S, G) entry timeout period.
- Configuring a limit to the register message rate reduces the load of the source DR and RP. Only register messages under the limit are sent.
- The register-probe time cannot be greater than a half of the register suppression time. Otherwise, the configuration failed and an alarm is generated.
- The sum of the three times of register suppression time and the register-probe time does not exceed 65,535. Otherwise, the configuration failed and an alarm is generated.

3. Prerequisites

- Enabling the PIM-SMv6 Function.
- Before an (S, G) address range is configured for the source, if the **list** parameter is specified, ensure that the corresponding ACL is created and specify an (S, G) address range for the source. For more information about ACL configuration, see *Configuring ACL*
- Before an (S, G) address range is configured for the source, if the **route-map** parameter is specified, ensure that the corresponding route map is created and specify an (S, G) address range for the source. For more information about route map configuration, see *Configuring Routing Policies*.
- Before the register message checksum calculation is applied to entire packets, if the **group-list** parameter is specified, ensure that the corresponding ACL is created and specify the register message checksum calculation to apply to the entire packets in a multicast group address range. For more information about ACL configuration, see *Configuring ACL*.

4. Procedure

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configure registration parameters on the source DR.

  a Enter the privileged EXEC mode.

  enable

  b Enter the global configuration mode.

  configure terminal

c Enable RP reachability checking on the source DR.

ipv6 pim register-rp-reachability

The RP reachability checking function is disabled by default.

d Limit the rate of sending register messages on the source DR.

ipv6 pim register-rate-limit *rate*

The sending rate of register messages is not limited by default.

e Configure a source address in the register messages on the source DR.

ipv6 pim register-source { *ipv6-local-address* | *interface-type interface-number* }

The source IP address in the register messages is the address of the DR interface connected to the source by default.

f Configure the register suppression time on the source DR.

ipv6 pim register-suppression *suppression-time*

The default register suppression time is **60** seconds.

g Configure the null message detection time on the source DR.

ipv6 pim probe-interval *interval*

The default register-probe time is **5** seconds.

- Configure registration parameters on the RP.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Configure the (S, G) address range for the source on the RP.

ipv6 pim accept-register { **list** *acl-name* | **route-map** *route-map-name* }*

The (S, G) address range of register messages is not limited by default. The RP receives register messages with any (S, G) address.

You can configure to filter the source register message information on all C-RP or static RP multicast devices.

d Enable register message checksum calculation to be applied to the entire packets on the RP.

ipv6 pim register-checksum-wholepkt [**group-list** *acl-name*]

By default, the register message checksum of headers of only PIM packets and register messages, rather than the entire packets, is calculated.

If the **group-list** parameter is not specified, this configuration applies to all group addresses.

e Configure the timeout period for the (S, G) entries created upon receiving the register message on the RP.

ipv6 pim rp-register-kat *interval*

By default, the timeout period for the (S, G) entries is the sum of three times of the register suppression time and the register-probe time.

You can configure the (S, G) entry timeout period on all C-RP or static RP multicast devices.

1.6.8 Configuring the Last Hop Device to Switch over from the RPT to SPT

1. Overview

If the multicast traffic in a network is heavy, the RP easily gets overloaded and then faulty. To relieve the RP load, you can initiate SPT switchover through the member DR. You can specify multicast groups to perform SPT switchover.

2. Prerequisites

- Enabling the PIM-SMv6 Function.
- Before an address range of a group is configured for SPT switchover, ensure that the corresponding ACL is created and specify a multicast group range for SPT switchover. For more information about ACL configuration, see *Configuring ACL*.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the SPT switchover function.

ipv6 pim spt-threshold [**group-list** *acl-name*]

The SPT switchover function is disabled by default.

If the **group-list** parameter is not specified, all groups support SPT switchover.

1.7 Configuring PIM-SMv6 in the SSM Model

1.7.1 Overview

The PIM-SMv6 function in the SSM model can provide specified source services for hosts so that the hosts can determine to receive or reject multicast data of specified sources based on needs.

1.7.2 Restrictions and Guidelines

- If you require a PIM network to support the multicast service in the SSM model, the SSM function must be enabled.
- The SSM function must be enabled on each multicast device.
- The address range of SSM groups configured on all multicast devices must be consistent.
- MLDv2 or SSM mapping must be enabled.

1.7.3 Prerequisites

- In the multicast network, all nodes are reachable via IPv6 unicast routes.
- Enabling the PIM-SMv6 Function.
- Before an SSM group range is configured using an ACL, ensure that the corresponding ACL is created and specify an SSM multicast group range. For more information about ACL configuration, see *Configuring ACL*.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the SSM function.

ipv6 pim ssm { **default** | **range** *acl-name* }

By default, the SSM function is enabled, and the SSM group address range is FF3X::/32.

1.8 Configuring PIM-SMv6 Neighbor Parameters

1.8.1 Overview

PIM multicast devices transmit Hello messages to discover neighbors, coordinate protocol parameters and maintain neighbor relationships.

1.8.2 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Neighbor Message Time Parameters
- Configuring Neighbor Tracking
- Configuring Neighbor Filtering

1.8.3 Prerequisites

- In the multicast network, all nodes are reachable via IPv6 unicast routes.
- Enabling the PIM-SMv6 Function.

1.8.4 Configuring the Neighbor Message Time Parameters

1. Overview

The neighbor message time parameters include hello message sending interval and hello message sending delay.

- The hello message sending interval can be configured, and the hello message hold time is 3.5 times the hello message sending interval. If no new hello message is received within the hello message hold time, the neighbor is considered unreachable.
- When the PIM interface is enabled or detects a new neighbor, random time is generated and it is referred to as hello message sending delay. Within the delay time, the interface sends hello messages out.

2. Restrictions and Guidelines

If the hello message hold time is greater than 65,535 seconds, the hello message sending interval is automatically set to 18,725 seconds.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure the neighbor message time parameters. Configure at least one of the tasks.

- Configure the hello message sending interval.

  ipv6 pim query-interval *interval*

  The hello message is sent at an interval of **30** seconds by default.

- Configure the hello message sending delay.

  ipv6 pim triggered-hello-delay *delay*

  The default hello message sending delay is **5** seconds.

1.8.5 Configuring Neighbor Tracking

1. Overview

After the suppression capability of an interface is enabled, when a multicast device plans to send a join packet to an uplink multicast device but it receives a join packet sent from the neighbor to the uplink multicast device, this local multicast device suppresses its own join packet. If the suppression capability of the interface is disabled, the join packet can be sent. When the suppression capability of downlink hosts is disabled, an uplink device can determine the number of the downlink hosts based on the quantity of received join packets. This is neighbor tracking.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Enable the neighbor tracking function.

ipv6 pim neighbor-tracking

The neighbor tracking function is disabled by default.

1.8.6 Configuring Neighbor Filtering

1. Overview

The neighbor filtering function can protect neighborhood. Controlling neighbors can strengthen PIM network security and limit the valid address range of neighbors. If a neighbor is filtered out based on an access filtering list, PIM-SMv6 does not create peer relationship with the neighbor or stops the peer relationship with this neighbor.

2. Prerequisites

Before an access filtering list is configured, ensure that the corresponding ACL is created and specify a valid neighbor address range. For more information about ACL configuration, see *Configuring ACL*.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Enable the neighbor filtering function.

ip pim neighbor-filter *acl-name*

The neighbor filtering function is disabled by default.

1.9 Configuring DR Priority

1.9.1 Overview

In a network segment shared by multicast sources and group members, multiple PIM multicast devices exist. The PIM multicast devices elect a DR based on neighbor messages. A device with the highest priority is selected. If the priorities are the same or some PIM devices do not support the DR priority function, the IP addresses are compared and the PIM multicast device with the largest IP address is selected. The selected PIM device functions as a DR, transmits protocol packets between the sources and members, and forwards multicast packets.

1.9.2 Prerequisites

- In the multicast network, all nodes are reachable via IPv6 unicast routes.
- Enabling the PIM-SMv6 Function.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure a DR priority in hello messages.

ipv6 pim dr-priority *priority-value*

The default DR priority in hello messages is **1**.

1.10 Configuring Parameters of the Join/Prune Packets

1.10.1 Overview

A device sends a join packet to request an uplink device to forward multicast packets and sends a prune packet to request the uplink device to stop forwarding multicast packets. The request route is referred to as an RPT or SPT.

1.10.2 Restrictions and Guidelines

- The network administrator must ensure that the prune override interval is smaller than the join-prune packet hold time. Otherwise, a short interrupt may occur.
- When the PIM multicast device receives a prune message from an uplink interface, there are other downlink devices existent in the shared network segment. If this PIM multicast device still needs to receive multicast data, the PIM multicast device must send a prune override message to the uplink device within the override interval.

1.10.3 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Join/Prune Packet Sending Interval
- Configuring the Prune Delay

1.10.4 Prerequisites

Enabling the PIM-SMv6 Function.

1.10.5 Configuring Join/Prune Packet Sending Interval

1. Overview

A PIM device periodically sends the join/prune packet to an uplink device to update the forwarding status. The join packet is used to request data forwarding and the prune packet is used to stop data forwarding. Upon receiving the join/prune packet, the uplink device starts the join/prune packet hold time timer.

- If a join packet hold time timer expires, the PIM device is suppressed to forward multicast packets of the corresponding multicast group through the downlink interface.
- If a prune packet hold time timer expires, the PIM device is restored to forward the multicast packets of the corresponding multicast group through the downlink interface.

2. Restrictions and Guidelines

The join/prune packet sending interval must be smaller than the join/prune packet hold time. Generally, the join/prune packet hold time is 3.5 times the join/prune packet sending interval.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the join/prune packet sending interval.

ipv6 pim jp-timer *interval*

The join/prune packet is sent at an interval of **60** seconds by default.

1.10.6 Configuring the Prune Delay

1. Overview

Upon receiving a prune packet from a downlink device, the multicast device does not perform prune immediately and it waits for a period of time. This period of time is divided into two parts: The part from the time when the multicast device receives a prune message to the time when the multicast device sends the prune message to the uplink device is referred to as the propagation delay; the part from the time when the PIM device receives a prune packet to the time when the device continues to forward the multicast packets to a downlink device is referred to as the override interval. The period from the time when the multicast device receives a prune message to the time when the prune action is performed is the sum of the propagation delay and the override interval.

2. Restrictions and Guidelines

In the period from the time when the multicast device receives a prune message to the time when the prune action is performed, if the PIM device receives a prune override message from the downlink interface, the PIM device cancels pruning.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure the prune message propagation delay.

ipv6 pim propagation-delay *propagation-delay*

The default propagation delay of an interface is **500** ms.

(5) Configure the prune override interval.

ipv6 pim override-interval *override-interval*

The default prune override interval is **2500** ms.

1.11 Enabling PIM-SMv6 BFD Correlation

1. Overview

In some shared multicast network, PIM neighbor status change triggers re-initiation of some mechanisms, for example, DR election mechanism. Generally, a PIM neighbor triggers a new round of election after the neighborhood times out, causing multicast data interruption. PIM bidirectional forwarding detection (BFD) correlation can quickly detect link status and neighbor faults in a shared network segment and trigger a new round of DR election. This reduces multicast data transmission interrupt time and ensures reliability of the multicast network.

2. Restrictions and Guidelines

- If DR or assertion election is required in a multicast network, you are advised to enable PIM-SMv6 BFD correlation.
- The PIM BFD function must be enabled on the interconnection interface of the multicast devices.

3. Prerequisites

- In the network, all nodes are reachable via IPv6 unicast routes.
- Enabling the PIM-SMv6 Function.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Enable PIM-SMv6 BFD correlation.

ipv6 pim bfd

PIM-SMv6 BFD correlation is disabled by default.

1.12 Configuring the Device to Ignore RPF Check

1. Overview

In some special scenarios, when this command is used, the device can establish a multicast forwarding table for the multicast data packets that are not originated from the directly connected source address and are not from the RPF neighbor.

2. Restrictions and Guidelines

- This command is only used in the preceding scenario.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the device to ignore RPF check.

ipv6 pim ignore-rpf-neighbor-check

By default, RPF check is required when the device generates multicast entries.

1.13 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

Caution

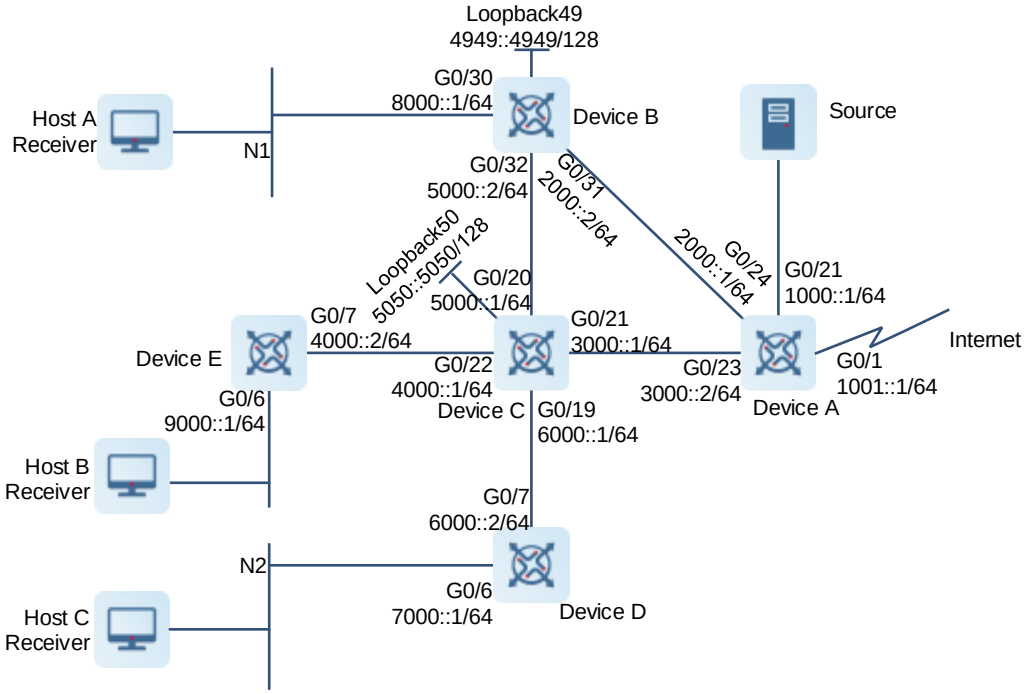
Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
clear ipv6 pim sparse-mode bsr rp-set *	Clears dynamic RP information.
clear ipv6 pim sparse-mode track	Resets the statistic start time and clears the counter of the PIMv6 packets.
show ipv6 pim sparse-mode bsr-router	Displays details about the BSR.
show ipv6 pim sparse-mode gr	Displays information about restart of a PIM-SMv6 process.
show ipv6 pim sparse-mode interface [*interface-type interface-number*] [**detail**]	Displays PIM-SMv6 information of an interface.

Command	Purpose
show ipv6 pim sparse-mode local-members [*interface-type interface-number*]	Displays local MLD information of a PIM-SMv6 interface.
show ipv6 pim sparse-mode mroute [*ipv6-group-or-source-address* [*ipv6-group-or-source-address*]]	Displays PIM-SMv6 routing information.
show ipv6 pim sparse-mode neighbor [**detail**]	Displays PIM-SMv6 neighbor information.
show ipv6 pim sparse-mode nexthop	Displays next hop information, including interface number, address, and metric value of a next hop.
show ipv6 pim sparse-mode rp mapping	Displays all RPs and the groups served by the RPs on the local device.
show ipv6 pim sparse-mode rp-hash *ipv6-group-address*	Displays RP information corresponding to a group address.
show ipv6 pim sparse-mode sync-info	Displays statistics about data delivered by PIM-SM v6.
show ipv6 pim sparse-mode track	Displays the number of PIM packets sent and received since the statistic start time.

1.14 Configuration Examples



1.14.1 Configuring Basic Functions of PIM-SMv6 in the ASM Model

1. Requirements

As shown in Figure 1-5, the internal network is connected to the Internet. The PIM-SMv6 protocol is configured on each multicast device to provide ASM multicast services for hosts in networks N1 and N2 so that hosts joining a multicast group can receive multicast data destined to this multicast group from any multicast source, including video-on-demand information.

2. Topology

Figure 1-5 PIM-SMv6 Multicast Network Topology in the ASM Model

3. Notes

- Configure IPv6 addresses and unicast routing protocols for multicast devices. The PIMv6 protocol in a multicast domain depends on unicast routing protocols. Normal communication of unicast routing lays a foundation of multicast routing. Ensure that each PIM node is reachable via unicast routes.
- Enable the IPv6 multicast function on all multicast devices. Enabling the multicast function is a prerequisite of PIM-SMv6 configuration.
- Enable the basic functions of PIM-SMv6 on all interfaces of the multicast devices. The other functions of PIM-SMv6 can be enabled only after the basic functions of PIM-SMv6 are enabled.
- Enable the MLD function on the interface connected to hosts so that the hosts can join or leave a multicast group by sending MLD messages. The multicast devices acting as leaf nodes maintain group membership based on the MLD protocol.
- Configure RPs. In the PIM-SMv6 network in the ASM model, the RP is a transitional station for forwarding multicast data. It is recommended that the multicast device with many traffic flows be configured as an RP, for example, device C in Figure 1-5.
- Configure a BSR border on the interface connected to the Internet. BSMs must be transmitted in the PIM-SMv6 domain within the border to improve the multicast controllability.

4. Procedure

(1) Configure IP addresses and enable unicast routing protocols on interfaces of different devices.

Configure an IPv6 address for the interface of Device A and configure the OSPFv3 protocol to implement internetworking.

```
DeviceA> enable
DeviceA# config terminal
DeviceA(config)# ipv6 router ospf 4949
DeviceA(config-router)# exit
DeviceA(config)# interface gigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no switchport
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 address 1001::1/64
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface gigabitEthernet 0/21
DeviceA(config-if-GigabitEthernet 0/21)# no switchport
DeviceA(config-if-GigabitEthernet 0/21)# ipv6 address 1000::1/64
DeviceA(config-if-GigabitEthernet 0/21)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/21)# exit
DeviceA(config)#interface gigabitEthernet 0/23
DeviceA(config-if-GigabitEthernet 0/23)# no switchport
DeviceA(config-if-GigabitEthernet 0/23)# ipv6 address 3000::2/64
DeviceA(config-if-GigabitEthernet 0/23)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/23)# exit
DeviceA(config)# interface gigabitEthernet 0/24
DeviceA(config-if-GigabitEthernet 0/24)# no switchport
DeviceA(config-if-GigabitEthernet 0/24)# ipv6 address 2000::1/64
DeviceA(config-if-GigabitEthernet 0/24)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/24)# exit
```

Configure IPv6 addresses on interfaces of device B, and configure the OSPFv3 protocol to implement internetworking.

```
DeviceB> enable
DeviceB# config terminal
DeviceB(config)# ipv6 router ospf 4949
DeviceB(config-router)# exit
DeviceB(config)# interface GigabitEthernet 0/30
DeviceB(config-if-GigabitEthernet 0/30)# no switchport
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 address 8000::1/64
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 ospf 4949 area 0
DeviceB(config-if-GigabitEthernet 0/30)# exit
DeviceB(config)# interface GigabitEthernet 0/31
DeviceB(config-if-GigabitEthernet 0/31)# no switchport
DeviceB(config-if-GigabitEthernet 0/31)# ipv6 address 2000::2/64
DeviceB(config-if-GigabitEthernet 0/31)# ipv6 ospf 4949 area 0
DeviceB(config-if-GigabitEthernet 0/31)# exit
DeviceB(config)# interface GigabitEthernet 0/32
DeviceB(config-if-GigabitEthernet 0/32)# no switchport
DeviceB(config-if-GigabitEthernet 0/32)# ipv6 address 5000::2/64
DeviceB(config-if-GigabitEthernet 0/32)# ipv6 ospf 4949 area 0
DeviceB(config-if-GigabitEthernet 0/32)# exit
DeviceB(config)# interface loopback 49
```

```
DeviceB(config-if-Loopback 49)# ipv6 address 4949::4949/128
DeviceB(config-if-Loopback 49)# ipv6 ospf 4949 area 0
DeviceB(config-if-Loopback 49)# exit
```

Configure IPv6 addresses on interfaces of device C, and configure the OSPFv3 protocol to implement internetworking.

```
DeviceC> enable
DeviceC# config terminal
DeviceC(config)# ipv6 router ospf 4949
DeviceC(config-router)# exit
DeviceC(config)# interface GigabitEthernet 0/19
DeviceC(config-if-GigabitEthernet 0/19)# no switchport
DeviceC(config-if-GigabitEthernet 0/19)# ipv6  address 6000::1/64
DeviceC(config-if-GigabitEthernet 0/19)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/19)# exit
DeviceC(config)#interface GigabitEthernet 0/20
DeviceC(config-if-GigabitEthernet 0/20)# no switchport
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 address 5000::1/64
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/20)# exit
DeviceC(config)# interface GigabitEthernet 0/21
DeviceC(config-if-GigabitEthernet 0/21)# no switchport
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 address 3000::1/64
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/21)# exit
DeviceC(config)# interface GigabitEthernet 0/22
DeviceC(config-if-GigabitEthernet 0/22)# no switchport
DeviceC(config-if-GigabitEthernet 0/22)# ipv6 address 4000::1/64
DeviceC(config-if-GigabitEthernet 0/22)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/22)# exit
DeviceC(config)# interface loopback 50
DeviceC(config-if-Loopback 50)# ipv6 address 5050::5050/128
DeviceC(config-if-Loopback 50)# ipv6 ospf 4949 area 0
DeviceC(config-if-Loopback 50)# exit
```

Configure IPv6 addresses on interfaces of device D, and configure the OSPFv3 protocol to implement internetworking.

```
DeviceD> enable
DeviceD# config terminal
DeviceD(config)# ipv6 router ospf 4949
DeviceD(config-router)# exit
DeviceD(config)# interface GigabitEthernet 0/6
DeviceD(config-if-GigabitEthernet 0/6)# no switchport
DeviceD(config-if-GigabitEthernet 0/6)# ipv6 address 7000::1/64
DeviceD(config-if-GigabitEthernet 0/6)# ipv6 ospf 4949 area 0
DeviceD(config-if-GigabitEthernet 0/6)# exit
DeviceD(config)# interface GigabitEthernet 0/7
```

```
DeviceD(config-if-GigabitEthernet 0/7)# no switchport
DeviceD(config-if-GigabitEthernet 0/7)# ipv6 address 6000::2/64
DeviceD(config-if-GigabitEthernet 0/7)# ipv6 ospf 4949 area 0
DeviceD(config-if-GigabitEthernet 0/7)# exit
```

Configure IPv6 addresses on interfaces of device E, and configure the OSPFv3 protocol to implement internetworking.

```
DeviceE> enable
DeviceE# config terminal
DeviceE(config)# ipv6 router ospf 4949
DeviceE(config-router)# exit
DeviceE(config)# interface GigabitEthernet 0/6
DeviceE(config-if-GigabitEthernet 0/6)# no switchport
DeviceE(config-if-GigabitEthernet 0/6)# ipv6 address 9000::1/64
DeviceE(config-if-GigabitEthernet 0/6)# ipv6 ospf 4949 area 0
DeviceE(config-if-GigabitEthernet 0/6)# interface GigabitEthernet 0/7
DeviceE(config-if-GigabitEthernet 0/7)# no switchport
DeviceE(config-if-GigabitEthernet 0/7)# ipv6 address 4000::2/64
DeviceE(config-if-GigabitEthernet 0/7)# ipv6 ospf 4949 area 0
DeviceE(config-if-GigabitEthernet 0/7)# exit
```

(2) Enable the multicast and PIM-SMv6 functions on all multicast devices, and enable the MLD function on all multicast devices connected to hosts.

Enable the multicast and PIM-SMv6 functions on device A.

```
DeviceA(config)# ipv6 multicast-routing
DeviceA(config)# interface gigabitEthernet 0/21
DeviceA(config-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/21)# exit
DeviceA(config)# interface gigabitEthernet 0/23
DeviceA(config-if-GigabitEthernet 0/23)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/23)# exit
DeviceA(config)# interface gigabitEthernet 0/24
DeviceA(config-if-GigabitEthernet 0/24)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/24)# exit
```

Enable the IPv6 multicast, IPv6-SMv6, and MLD functions on device B.

```
DeviceB(config)# ipv6 multicast-routing
DeviceB(config)# interface gigabitEthernet 0/30
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 pim sparse-mode
DeviceB(config-if-GigabitEthernet 0/30)# exit
DeviceB(config)# interface gigabitEthernet 0/31
DeviceB(config-if-GigabitEthernet 0/31)# ipv6 pim sparse-mode
DeviceB(config-if-GigabitEthernet 0/31)# exit
DeviceB(config)# interface gigabitEthernet 0/32
DeviceB(config-if-GigabitEthernet 0/32)# ipv6 pim sparse-mode
DeviceB(config-if-GigabitEthernet 0/32)# exit
DeviceB(config)# interface loopback 49
```

```
DeviceB(config-if-Loopback 49)# ipv6 pim sparse-mode
DeviceB(config-if-Loopback 49)# exit
```

Enable the IPv6 multicast and PIM-SMv6 functions on device C.

```
DeviceC(config)# ipv6 multicast-routing
DeviceC(config)# interface gigabitEthernet 0/19
DeviceC(config-if-GigabitEthernet 0/19)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/19)# exit
DeviceC(config)# interface gigabitEthernet 0/20
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/20)# exit
DeviceC(config)# interface gigabitEthernet 0/21
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/21)# exit
DeviceC(config)# interface gigabitEthernet 0/22
DeviceC(config-if-GigabitEthernet 0/22)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/22)# exit
DeviceC(config)# interface loopback 50
DeviceC(config-if-Loopback 50)# ipv6 pim sparse-mode
DeviceC(config-if-Loopback 50)# exit
```

Enable the IPv6 multicast, IPv6-SMv6, and MLD functions on device D.

```
DeviceD(config)# ipv6 multicast-routing
DeviceD(config)# interface gigabitEthernet 0/6
DeviceD(config-if-GigabitEthernet 0/6)# ipv6 pim sparse-mode
DeviceD(config-if-GigabitEthernet 0/6)# exit
DeviceD(config)# interface gigabitEthernet 0/7
DeviceD(config-if-GigabitEthernet 0/7)# ipv6 pim sparse-mode
DeviceD(config-if-GigabitEthernet 0/7)# exit
```

Enable the IPv6 multicast, IPv6-SMv6, and MLD functions on device E.

```
DeviceE(config)# ipv6 multicast-routing
DeviceE(config)# interface gigabitEthernet 0/6
DeviceE(config-if-GigabitEthernet 0/6)# ipv6 pim sparse-mode
DeviceE(config-if-GigabitEthernet 0/6)# exit
DeviceE(config)# interface gigabitEthernet 0/7
DeviceE(config-if-GigabitEthernet 0/7)# ipv6 pim sparse-mode
DeviceE(config-if-GigabitEthernet 0/7)# exit
```

(3) Configure RPs.

Note

There are two methods to configure RPs: dynamic RPs and static RPs. You can configure either or both types of RPs. If static and dynamic RPs are available at the same time, the dynamic RPs are preferred by default.

Configure dynamic RPs. One or multiple multicast devices in the PIM-SMv6 domain must be configured as C-RPs and C-BSRs. In this example, device B and device C are configured as C-RP and C-BSR. The address range of the served groups of the RP, as well as the interfaces of the C-RP and C-BSR are

configured on device B and device C. The loopback interface is configured as the interface of the C-RP and C-BSR.

Configure C-RP and C-BSR and address range of the served groups of the RP on device B.

```
DeviceB(config)# ipv6 pim bsr-candidate loopback 49
DeviceB(config)# ipv6 access-list mcast-ipv6-list
DeviceB(config-ipv6-acl)# permit ipv6 any ff13::/64
DeviceB(config)# ipv6 pim rp-candidate loopback 49 group-list mcast-ipv6-list
```

Configure C-RP and C-BSR and address range of the served groups of the RP on device C.

```
DeviceC(config)# ipv6 pim bsr-candidate loopback 50
DeviceC(config)# ipv6 access-list mcast-ipv6-list
DeviceC(config-ipv6-acl)# permit ipv6 any ff14::/64
DeviceC(config-std-nacl)# exit
DeviceC(config)# ipv6 pim rp-candidate loopback 50 group-list mcast-ipv6-list
```

Configure static RPs. The addresses of static RPs must be specified on all multicast devices.

Configure a static RP on device A.

```
DeviceA(config)# ipv6 pim rp-address 5050::5050
```

Configure a static RP on device B.

```
DeviceB(config)# ipv6 pim rp-address 5050::5050
```

Configure a static RP on device C.

```
DeviceC(config)# ipv6 pim rp-address 5050::5050
```

Configure a static RP on device D.

```
DeviceD(config)# ipv6 pim rp-address 5050::5050
```

Configure a static RP on device E.

```
DeviceE(config)# ipv6 pim rp-address 5050::5050
```

(4) Configure a BSR border on the device A interface connected to the Internet.

```
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 pim bsr-border
```

5. Verification

(1) Run the **show ipv6 pim sparse-mode interface** command to display the PIM-SMv6 running information on the interfaces.

The PIM-SMv6 running information on the interface of device A is as follows:

```
DeviceA# show ipv6 pim sparse-mode interface
Interface                          VIFindex Ver/   Nbr    DR
                                            Mode   Count  Prior
GigabitEthernet 0/24                  3       v2/S   1      1
   Address      : fe80::2d0:f8ff:fe22:358d
   Global Address: 2000::1
   DR           : fe80::2d0:f8ff:feee:8c1f
GigabitEthernet 0/23                  2       v2/S   1      1
   Address      : fe80::2d0:f8ff:fe22:358d
   Global Address: 3000::2
```

```
   DR          : this system
GigabitEthernet 0/21                1       v2/S   0     1
   Address      : fe80::2d0:f8ff:fe22:358d
   Global Address: 1000::1
   DR          : this system
DeviceA#
```

The PIM-SMv6 running information on the interface of device B is as follows:

```
DeviceB# show ipv6 pim sparse-mode interface
Interface                          VIFindex Ver/   Nbr    DR
                                            Mode   Count  Prior
GigabitEthernet 0/31                2       v2/S   1     1
   Address      : fe80::2d0:f8ff:feee:8c1f
   Global Address: 2000::2
   DR          : this system
GigabitEthernet 0/32                3       v2/S   1     1
   Address      : fe80::2d0:f8ff:feee:8c1f
   Global Address: 5000::2
   DR          : this system
GigabitEthernet 0/30                1       v2/S   0     1
   Address      : fe80::2d0:f8ff:feee:8c1f
   Global Address: 8000::1
   DR          : this system
Loopback 49                         4       v2/S   0     1
   Address      : fe80::2d0:f8ff:feee:8c1f
   Global Address: 4949::4949
   DR          : this system
DeviceB#
```

The PIM-SMv6 running information on the interface of device C is as follows:

```
DeviceC# show ipv6 pim sparse-mode interface
Interface                          VIFindex Ver/   Nbr    DR
                                            Mode   Count  Prior
GigabitEthernet 0/21                3       v2/S   1     1

DeviceE#
```

(2) Run the **show ipv6 pim sparse-mode bsr-router** command to display the election information of the BSRs.

The BSR election information on device A is as follows:

```
DeviceA# show ipv6 pim sparse-mode bsr-router
BSR address: 5050::5050
  Uptime:     00:05:28, BSR Priority: 64, Hash mask length: 126
  Expires:    00:01:54
  Role: Non-candidate BSR  Priority: 0, Hash mask length: 126
  State: Accept Preferred
DeviceA#
```

The BSR election information on device B is as follows:

```
DeviceB# show ipv6 pim sparse-mode bsr-router
PIMv2 Bootstrap information
  BSR address: 5050::5050
  Uptime:     00:04:13, BSR Priority: 64, Hash mask length: 126
  Expires:    00:02:09
  Role: Candidate BSR  Priority: 64, Hash mask length: 126
  State: Candidate BSR

  Candidate RP: 4949::4949(Loopback 49)
    Advertisement interval 60 seconds
    Next Cand_RP_advertisement in 00:00:53
DeviceB#
```

The BSR election information on device C is as follows:

```
DeviceC# show ipv6 pim sparse-mode bsr-router
PIMv2 Bootstrap information
This system is the Bootstrap Router (BSR)
  BSR address: 5050::5050
  Uptime:     00:04:25, BSR Priority: 64, Hash mask length: 126
  Next bootstrap message in 00:00:52
  Role: Candidate BSR  Priority: 64, Hash mask length: 126
  State: Elected BSR

  Candidate RP: 5050::5050(Loopback 50)
    Advertisement interval 60 seconds
    Next Cand_RP_advertisement in 00:00:44
```

The BSR election information on device D is as follows:

```
DeviceD# show ipv6 pim sparse-mode bsr-router
PIMv2 Bootstrap information
  BSR address: 5050::5050
  Uptime:     00:06:00, BSR Priority: 64, Hash mask length: 126
  Expires:    00:01:21
  Role: Non-candidate BSR  Priority: 0, Hash mask length: 126
  State: Accept Preferred
DeviceD#
```

The BSR election information on device E is as follows:

```
DeviceE# show ipv6 pim sparse-mode bsr-router
PIMv2 Bootstrap information
  BSR address: 5050::5050
  Uptime:     00:06:23, BSR Priority: 64, Hash mask length: 126
  Expires:    00:01:58
  Role: Non-candidate BSR  Priority: 0, Hash mask length: 126
  State: Accept Preferred
DeviceE#
```

(3) Run the **show ipv6 pim sparse-mode rp mapping** command to display the RP information on the multicast devices.

The RP information on device A is as follows:

```
DeviceA# show ipv6 pim sparse-mode rp mapping
PIM Group-to-RP Mappings
Group(s): ff13::/64
  RP: 4949::4949(Not self)
    Info source: 5050::5050, via bootstrap, priority 192
         Uptime: 03:10:58, expires: 00:01:32
Group(s): ff14::/64
  RP: 5050::5050(Not self)
    Info source: 5050::5050, via bootstrap, priority 192
         Uptime: 03:08:58, expires: 00:01:32
Group(s): ff00::/8, Static
    RP: 5050::5050(Not self), Static
         Uptime: 03:08:15
DeviceA#
```

The RP information on device B is as follows:

```
DeviceB# show ipv6 pim sparse-mode rp mapping
PIM Group-to-RP Mappings
Group(s): ff13::/64
  RP: 4949::4949(Self)
    Info source: 5050::5050, via bootstrap, priority 192
         Uptime: 03:12:31, expires: 00:02:08
Group(s): ff14::/64
  RP: 5050::5050(Not self)
    Info source: 5050::5050, via bootstrap, priority 192
         Uptime: 03:10:26, expires: 00:02:08
Group(s): ff00::/8, Static
    RP: 5050::5050(Not self), Static
         Uptime: 03:09:35
DeviceB#
```

The RP information on device C is as follows:

```
DeviceC# show ipv6 pim sparse-mode rp mapping
PIM Group-to-RP Mappings
Group(s): ff13::/64
  RP: 4949::4949(Not self)
    Info source: 4949::4949, via bootstrap, priority 192
         Uptime: 00:21:40, expires: 00:01:49
Group(s): ff14::/64
  RP: 5050::5050(Self)
    Info source: 4949::4949, via bootstrap, priority 192
         Uptime: 00:19:40, expires: 00:01:49
Group(s): ff00::/8, Static
    RP: 5050::5050(Self), Static
         Uptime: 00:18:52
DeviceC#
```

The RP information on device D is as follows:

```
DeviceD# show ipv6 pim sparse-mode rp mapping
PIM Group-to-RP Mappings
Group(s): ff13::/64
  RP: 4949::4949(Not self)
    Info source: 4949::4949, via bootstrap, priority 192
         Uptime: 00:21:59, expires: 00:01:31
Group(s): ff14::/64
  RP: 5050::5050(Not self)
    Info source: 4949::4949, via bootstrap, priority 192
         Uptime: 00:19:59, expires: 00:01:31
Group(s): ff00::/8, Static
    RP: 5050::5050(Not self), Static
         Uptime: 00:19:09
DeviceD#
```

The RP information on device E is as follows:

```
DeviceE# show ipv6 pim sparse-mode rp mapping
PIM Group-to-RP Mappings
Group(s): ff13::/64
  RP: 4949::4949(Not self)
    Info source: 4949::4949, via bootstrap, priority 192
         Uptime: 00:22:24, expires: 00:02:06
Group(s): ff14::/64
  RP: 5050::5050(Not self)
    Info source: 4949::4949, via bootstrap, priority 192
         Uptime: 00:20:24, expires: 00:02:06
Group(s): ff00::/8, Static
    RP: 5050::5050(Not self), Static
         Uptime: 00:19:31
DeviceE#
```

(4) Run the **show ipv6 pim sparse-mode mroute** command to display the multicast routing tables of PIM-SMv6. The multicast source (1001:: 2/64) sends traffic to the multicast groups (FF14::1/64) and (FF13::1/64). Host A joins the multicast group (FF14::1/64), and host B joins the multicast group (FF13::1/64).

The routing table information on device A is as follows:

```
DeviceA# show ipv6 pim sparse-mode mroute
IPv6 Multicast Routing Table
(*,*,RP) Entries: 0
(*,G) Entries: 0
(S,G) Entries: 3
(S,G,rpt) Entries: 3
FCR Entries: 0
REG Entries: 3
```

```

!
```

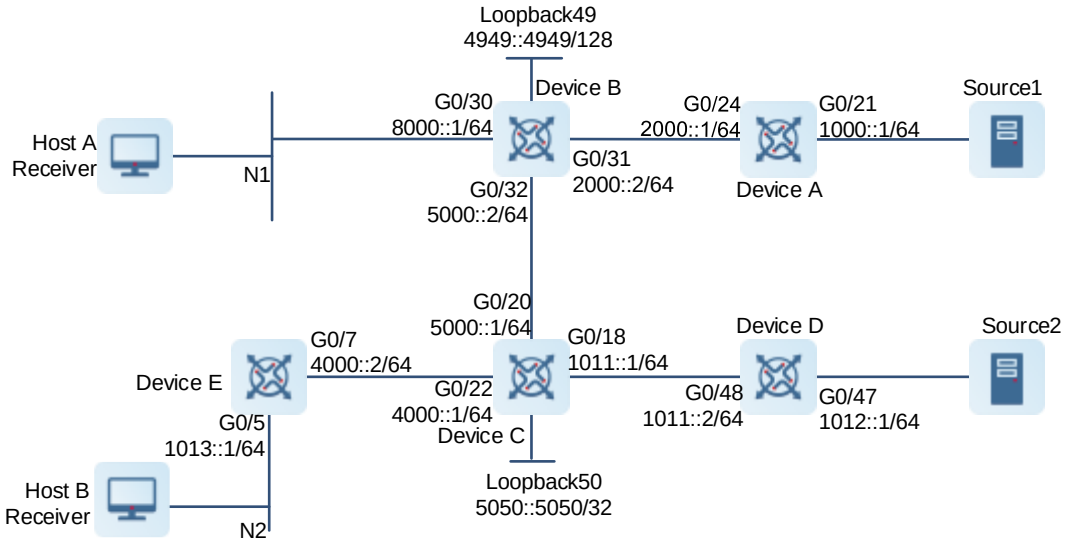
7. Common Errors

- The multicast routing function is not enabled on multicast devices.
- The multicast function is not enabled on any interface.
- No BSR border is configured between PIM-SMv6 domains.
- No RP is configured.
- No static RP is configured on a multicast device, or the configured static RP on this multicast device is not consistent with the configuration on other multicast devices.
- C-RPs are configured, but no C-BSR is configured.
- Static RP, C-RP or C-BSR is unreachable via unicast routes.



1.14.2 Configuring Basic Functions of PIM-SMv6 in the SSM Model

1. Requirements

As shown in Figure 1-6, the PIM-SMv6 protocol is enabled on multicast devices to provide SSM services for hosts in N1 and N2 so that the hosts can receive multicast data from specified multicast sources to the multicast group that the hosts join, for example, video-on-demand.

2. Topology

Figure 1-6 PIM-SMv6 Multicast Network Topology in the SSM Model

3. Notes

- Configure IPv6 addresses and unicast routing protocols for multicast devices. The PIMv6 protocol in a multicast domain depends on unicast routing protocols. Normal communication of unicast routing lays a foundation of multicast routing. Ensure that each PIMv6 node is reachable via unicast routes.
- Enable the multicast function on all multicast devices. Enabling the multicast function is a prerequisite of PIM-SMv6 configuration.
- Enable the basic functions of PIM-SMv6 on all interfaces of the multicast devices. The other functions of PIM-SMv6 can be enabled only after the basic functions of PIM-SMv6 are enabled.
- Enable the MLD function on the interface connected to hosts and set the MLD version to 2 so that the hosts can join or leave a multicast group by sending MLD messages based on the specified source. The multicast devices acting as leaf nodes maintain group membership based on the MLD protocol.
- Configure the same address range of SSM on all multicast devices. The SSM services provided by the multicast devices in the PIM-SMv6 domain are dedicated to specified groups, which realizes multicast controllability.

4. Procedure

(1) Configure IP addresses and enable unicast routing protocols on interfaces of different devices.

Configure IPv6 addresses and enable the OSPFv6 unicast routing protocol on interfaces of device A.

```
DeviceA> enable
DeviceA# config terminal
DeviceA(config)# interface GigabitEthernet 0/21
DeviceA(config-if-GigabitEthernet 0/21)# no switchport
DeviceA(config-if-GigabitEthernet 0/21)# ipv6 address 1000::1/64
DeviceA(config-if-GigabitEthernet 0/21)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/21)# exit
DeviceA(config)# interface GigabitEthernet 0/24
DeviceA(config-if-GigabitEthernet 0/24)# no switchport
DeviceA(config-if-GigabitEthernet 0/24)# ipv6 address 2000::1/64
DeviceA(config-if-GigabitEthernet 0/24)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/24)# exit
```

Configure IPv6 addresses and enable the OSPFv6 unicast routing protocol on interfaces of device B.

```
DeviceB> enable
DeviceB# config terminal
DeviceB(config)# interface GigabitEthernet 0/30
DeviceB(config-if-GigabitEthernet 0/30)# no switchport
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 address 8000::1/64
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 ospf 4949 area 0
DeviceB(config-if-GigabitEthernet 0/30)# exit
DeviceB(config)# interface GigabitEthernet 0/31
DeviceB(config-if-GigabitEthernet 0/31)# no switchport
DeviceB(config-if-GigabitEthernet 0/31)# ipv6 address 2000::2/64
DeviceB(config-if-GigabitEthernet 0/31)# ipv6 ospf 4949 area 0
DeviceB(config-if-GigabitEthernet 0/31)# exit
```

```
DeviceB(config)# interface GigabitEthernet 0/32
DeviceB(config-if-GigabitEthernet 0/32)# no switchport
DeviceB(config-if-GigabitEthernet 0/32)# ipv6 address 5000::2/64
DeviceB(config-if-GigabitEthernet 0/32)# ipv6 ospf 4949 area 0
DeviceB(config-if-GigabitEthernet 0/32)# exit
DeviceB(config)# interface Loopback 49
DeviceB(config-if-Loopback 49)# ipv6 address 4949::4949/128
DeviceB(config-if-Loopback 49)# ipv6 ospf 4949 area 0
DeviceB(config-if-Loopback 49)# exit
```

Configure IPv6 addresses and enable the OSPFv6 unicast routing protocol on interfaces of device C.

```
DeviceC> enable
DeviceC# config terminal
DeviceC(config)# interface GigabitEthernet 0/18
DeviceC(config-if-GigabitEthernet 0/18)# no switchport
DeviceC(config-if-GigabitEthernet 0/18)# ipv6 address 1011::1/64
DeviceC(config-if-GigabitEthernet 0/18)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/18)# exit
DeviceC(config)# interface GigabitEthernet 0/20
DeviceC(config-if-GigabitEthernet 0/20)# no switchport
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 address 5000::1/64
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/20)# exit
DeviceC(config)# interface GigabitEthernet 0/22
DeviceC(config-if-GigabitEthernet 0/22)# no switchport
DeviceC(config-if-GigabitEthernet 0/22)# ipv6 address 4000::1/64
DeviceC(config-if-GigabitEthernet 0/22)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/22)# exit
DeviceC(config)# interface Loopback 50
DeviceC(config-if-Loopback 50)# ipv6 address 5050::5050/128
DeviceC(config-if-Loopback 50)# ipv6 ospf 4949 area 0
DeviceC(config-if-Loopback 50)# exit
```

Configure IPv6 addresses and enable the OSPFv6 unicast routing protocol on interfaces of device D.

```
DeviceD> enable
DeviceD# config terminal
DeviceD(config)# interface GigabitEthernet 0/47
DeviceD(config-if-GigabitEthernet 0/47)# no switchport
DeviceD(config-if-GigabitEthernet 0/47)# ipv6 address 1012::1/64
DeviceD(config-if-GigabitEthernet 0/47)#  ipv6 ospf 4949 area 0
DeviceD(config-if-GigabitEthernet 0/47)# exit
DeviceD(config)# interface GigabitEthernet 0/48
DeviceD(config-if-GigabitEthernet 0/48)# no switchport
DeviceD(config-if-GigabitEthernet 0/48)# ipv6 address 1011::2/64
DeviceD(config-if-GigabitEthernet 0/48)# ipv6 ospf 4949 area 0
DeviceD(config-if-GigabitEthernet 0/48)# exit
```

Configure IPv6 addresses and enable the OSPFv6 unicast routing protocol on interfaces of device E.

```
DeviceE> enable
DeviceE# config terminal
DeviceE(config)# interface GigabitEthernet 0/7
DeviceE(config-if-GigabitEthernet 0/7)# no switchport
DeviceE(config-if-GigabitEthernet 0/7)# ipv6 address 4000::2/64
DeviceE(config-if-GigabitEthernet 0/7)# ipv6 ospf 4949 area 0
DeviceE(config-if-GigabitEthernet 0/7)# exit
DeviceE(config)# interface GigabitEthernet 0/5
DeviceE(config-if-GigabitEthernet 0/5)# no switchport
DeviceE(config-if-GigabitEthernet 0/5)# ipv6 address 1013::1/64
DeviceE(config-if-GigabitEthernet 0/5)# ipv6 ospf 4949 area 0
DeviceE(config-if-GigabitEthernet 0/5)# exit
```

(2) Enable the multicast and PIM-SMv6 functions on all multicast devices, and enable the MLD function on all multicast devices connected to hosts.

Enable the IPv6 multicast and PIM-SMv6 functions on device A.

```
DeviceA(config)# ipv6 multicast-routing
DeviceA(config)# interface GigabitEthernet 0/21
DeviceA(config-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/21)# exit
DeviceA(config)# interface GigabitEthernet 0/24
DeviceA(config-if-GigabitEthernet 0/24)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/24)# exit
```

Enable the IPv6 multicast, PIM-SMv6, and MLD functions on device B, and set the MLD version to 3.

```
DeviceB(config)# ipv6 multicast-routing
DeviceB(config)# interface GigabitEthernet 0/30
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 pim sparse-mode
DeviceB(config-if-GigabitEthernet 0/30)# ipv6 mld version 2
DeviceB(config-if-GigabitEthernet 0/30)# exit
DeviceB(config)# interface GigabitEthernet 0/31
DeviceB(config-if-GigabitEthernet 0/31)# ipv6 pim sparse-mode
DeviceB(config-if-GigabitEthernet 0/31)# exit
DeviceB(config)# interface GigabitEthernet 0/32
DeviceB(config-if-GigabitEthernet 0/32)# ipv6 pim sparse-mode
DeviceB(config-if-GigabitEthernet 0/32)# exit
DeviceB(config)# interface Loopback 49
DeviceB(config-if-Loopback 49)# ipv6 pim sparse-mode
DeviceB(config-if-Loopback 49)# exit
```

Enable the IPv6 multicast and PIM-SMv6 functions on device C.

```
DeviceC(config)# ipv6 multicast-routing
DeviceC(config)# interface GigabitEthernet 0/18
DeviceC(config-if-GigabitEthernet 0/18)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/18)# exit
DeviceC(config)# interface GigabitEthernet 0/20
DeviceC(config-if-GigabitEthernet 0/20)# ipv6 pim sparse-mode
```

```
DeviceC(config-if-GigabitEthernet 0/20)# exit
DeviceC(config)# interface GigabitEthernet 0/22
DeviceC(config-if-GigabitEthernet 0/22)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/22)# exit
DeviceC(config)# interface Loopback 50
DeviceC(config-if-Loopback 50)# ipv6 pim sparse-mode
DeviceC(config-if-Loopback 50)# exit
DeviceC(config)#
```

Enable the IPv6 multicast and PIM-SMv6 functions on device D.

```
DeviceD(config)# ipv6 multicast-routing
DeviceD(config)# interface GigabitEthernet 0/47
DeviceD(config-if-GigabitEthernet 0/47)# ipv6 pim sparse-mode
DeviceD(config-if-GigabitEthernet 0/47)# exit
DeviceD(config)# interface GigabitEthernet 0/48
DeviceD(config-if-GigabitEthernet 0/48)# ipv6 pim sparse-mode
DeviceD(config-if-GigabitEthernet 0/48)# exit
```

Enable the IPv6 multicast, PIM-SMv6, and MLD functions on Device E, and set the MLD version to 3.

```
DeviceE(config)# ipv6 multicast-routing
DeviceE(config)# interface GigabitEthernet 0/7
DeviceE(config-if-GigabitEthernet 0/7)# ipv6 pim sparse-mode
DeviceE(config-if-GigabitEthernet 0/7)# exit
DeviceE(config)# interface GigabitEthernet 0/5
DeviceE(config-if-GigabitEthernet 0/5)# ipv6 mld version 2
DeviceE(config-if-GigabitEthernet 0/5)# ipv6 pim sparse-mode
DeviceE(config-if-GigabitEthernet 0/5)# exit
```

(3) Enable the SSM function and configure an address range of multicast groups on all multicast devices.

Set the address range of an SSM multicast group to FF33::/64 on device A.

```
DeviceA(config)# ipv6 access-list ipv6-ssm-list
DeviceA(config-ipv6-acl)# permit ipv6 any FF33::/64
DeviceA(config-ipv6-acl)#exit
DeviceA(config)# ipv6 pim ssm range ipv6-ssm-list
```

Set the address range of an SSM multicast group to FF33::/64 on device B.

```
DeviceB(config)# ipv6 access-list ipv6-ssm-list
DeviceB(config-ipv6-acl)# permit ipv6 any FF33::/64
DeviceB(config-ipv6-acl)#exit
DeviceB(config)# ipv6 pim ssm range ipv6-ssm-list
```

Set the address range of an SSM multicast group to FF33::/64 on device C.

```
DeviceC(config)# ipv6 access-list ipv6-ssm-list
DeviceC(config-ipv6-acl)# permit ipv6 any FF33::/64
DeviceC(config-ipv6-acl)#exit
DeviceC(config)# ipv6 pim ssm range ipv6-ssm-list
```

Set the address range of an SSM multicast group to FF33::/64 on device D.

```
DeviceD(config)# ipv6 access-list ipv6-ssm-list
```

```
DeviceD(config-ipv6-acl)# permit ipv6 any FF33::/64
DeviceD(config-ipv6-acl)#exit
DeviceD(config)# ipv6 pim ssm range ipv6-ssm-list
```

Set the address range of an SSM multicast group to FF33::/64 on device E.

```
DeviceE(config)# ipv6 access-list ipv6-ssm-list
DeviceE(config-ipv6-acl)# permit ipv6 any FF33::/64
DeviceE(config-ipv6-acl)#exit
DeviceE(config)# ipv6 pim ssm range ipv6-ssm-list
```

5. Verification

(1) Run the **show ipv6 pim sparse-mode interface** command to display the PIM-SMv6 running information on the interfaces of each device.

The PIM-SMv6 running information on the interfaces of device A is as follows. The PIM-SM running information on the interfaces of devices B, C, D, and E is the same.

```
DeviceA> enable
DeviceA# show ipv6 pim sparse-mode interface
Interface                          VIFindex Ver/   Nbr    DR
                                            Mode   Count  Prior
GigabitEthernet 0/21                 2       v2/S   0      1
   Address      : fe80::2d0:f8ff:fe22:358d
   Global Address: 1000::1
   DR           : this system
GigabitEthernet 0/24                 3       v2/S   1      1
   Address      : fe80::2d0:f8ff:fe22:358d
   Global Address: 2000::1
   DR           : fe80::2d0:f8ff:feee:8c1f
DeviceA#
```

(2) Run the **show ipv6 pim sparse-mode mroute** command to display the multicast routing tables of PIMv6. Host A needs to receive packets sent from the source (1000::2/64) and the source (1012::2/64) to the multicast group (FF33::100). Host B needs to receive packets sent from the source (1000::2/64) to the multicast group (FF33::100). The information output is as follows:

Run the **show ipv6 pim sparse-mode mroute** command to display the multicast routing tables of device A.

```
DeviceA> enable
DeviceA# show ipv6 pim sparse-mode mroute
IPv6 Multicast Routing Table

7. Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a multicast device.
- The SSM function is not enabled on a multicast device, or the SSM group address range on this multicast device is not consistent with the configuration on other multicast devices.
- The PIM-SMv6 function is not enabled on an interface, for example, the gateway interface connecting to hosts or a multicast source.
- The MLDv2 function is not enabled on an interface connected to hosts.

1 Configuring MLD

1.1 Introduction

The Multicast Listener Discovery (MLD) protocol manages IPv6 multicast members.

MLD defines how to establish and maintain membership between multicast devices and member hosts in an IPv6 network, to decide a forwarding path of multicast streams. Figure 1-1 shows the topology of MLD in an IPv6 multicast network.

Figure 1-1 Topology of MLD in a Multicast Network

O Interface with the MLD function enabled

There are two versions of MLD: MLDv1 is based on version 2 of the Internet Group Management Protocol (IGMP) and MLDv2 is based on version 3 of IGMP. A later MLD version is backward-compatible with an earlier MLD version. MLDv1 completes IPv6 member management based on the query and report mechanism. MLDv2 supports member hosts to decide whether to receive packets from a specified multicast source on the basis of MLDv1.

- MLD of both versions supports the Any-Source Multicast (ASM) model.
- MLDv2 can be directly applied to the Source-Specific Multicast (SSM) model.
- MLDv1 can be applied to the SSM model only when MLD SSM mapping is configured.

1.1.2 Working Principles of MLDv1

The querier election mechanism, general group query and report mechanism, join mechanism, and leave mechanism are defined in MLDv1.

1. Types of MLDv1 Packets

MLDv1 supports the following four types of packets:

- General group query packet: A querier sends general group query packets to all multicast devices and hosts in the same network segment to understand groups with members.
- Group-specific query packet: A querier sends query packets to specified multicast groups in the same network segment to understand whether these groups contain members.
- Report packet: A host sends report packets to the querier to respond to the query packets or join a group.
- Leave packet: A host sends leave packets to the querier when the host leaves a group, notifying the querier that it leaves the specified group.

2. Working Mechanisms of MLDv1

- Querier election

  If multiple multicast devices exist in a network segment, only one multicast device needs to send query packets as a querier. This avoids redundancy. When the querier in the network segment fails, other devices in the same network segment need to take the role and process MLD protocol packets. During querier election, interface addresses of the devices are compared. The device with a smallest IP address is elected as the querier, as shown in Figure 1-2.

  a Device A and Device B consider themselves as the querier and send query packets to the local network segment.

  b They compare the source IPv6 address in the received packets with the address of their interfaces. The address of Device A is smaller. Therefore, Device A acts as the querier to periodically send query packets.

  c Device B fails in the election and starts a query keepalive timer. When the timer expires, Device B considers that the querier fails and starts to send query packets to initiate a new round of querier election.

Figure 1-2 Querier Election Diagram

- General group query and report

  The MLD querier periodically sends general group query packets to all hosts and multicast devices in the local network segment, and understands and maintains group membership based on the report packets replied by the member hosts. Figure 1-3 shows the general group query and report procedure.

  a The MLD querier Device A periodically sends general group query packets to the destination address FF02::1.

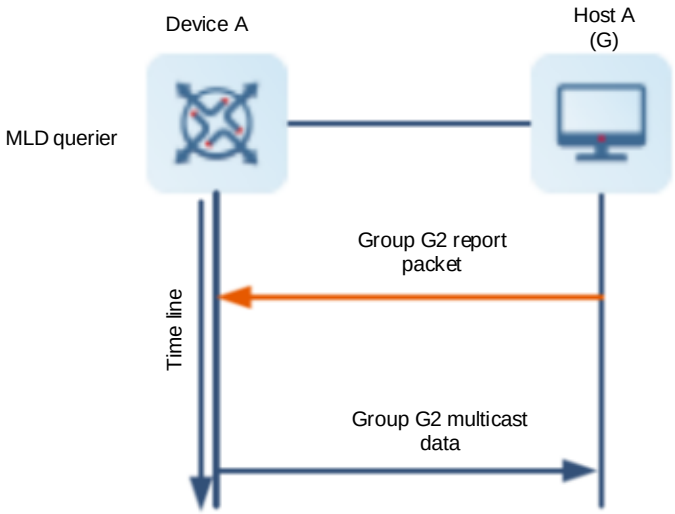
  b Upon receiving the general group query packets, Host A and Host B in the multicast group G start respective timers Timer-G-A and Timer-G-B.

  c The host whose timer expires first sends report packets destined for the multicast group G.

  If the timer Timer-G-A of Host A expires first, Host A sends report packets to the multicast group G. Upon receiving the report packets, Host B stops its timer and sends report packets in the network segment.

  d Upon receiving the report packets destined for the multicast group G from Host A, the MLD querier knows that there is member in the multicast group G. The multicast routing protocol generates an (*, G) entry. Upon receiving multicast data destined for the multicast group G, the MLD querier forwards the multicast data in the network segment.

Figure 1-3 General Group Query and Report Diagram



- Member join

  When a host tries to join a multicast group, it takes some time for the host to join the group if the host waits for a general group query packet from the querier and replies a report packet. If the host can proactively send a report packet to the MLD querier, the querier can immediately generate a multicast forwarding entry upon receiving the packet. If multicast devices in the group receive multicast data, the new host can quickly get multicast service. Figure 1-4 shows the new member join procedure.

  a Before receiving a general group query packet from Device A, Host A proactively sends a report packet destined for the multicast group G, to notify that Host A joins the multicast group G.

  b Upon receiving the report packet, the MLD querier Device A knows that there is a member in the multicast group G in the current network segment. The multicast routing protocol generates an (*, G) entry. Upon receiving multicast data destined for the multicast group G, the MLD querier forwards the multicast data in the network segment.

Figure 1-4 Member Join Diagram

- Member leave

  Upon receiving a leave packet from a member to plan to leave the multicast group G, the MLD querier sends a group-specific query packet to understand whether there is any other member existing in the group in the network segment. If not, the MLD querier deletes the corresponding membership to reduce redundant multicast traffic in the network and save bandwidth. Figure 1-5 shows the member leave procedure.

  a Host A sends a leave packet destined for all multicast devices in the local network segment to leave the multicast group G.

  b Upon receiving the leave packet, the MLD querier Device A sends a group-specific query packet destined for the multicast group G.

  c If there is any other member (for example, Host B) in the multicast group G, Host B sends a report packet for the multicast group G upon receiving the query packet. The MLD querier continues to maintain the membership of the multicast group G upon receiving the report packet. The (*, G) entry remains existent. Upon receiving multicast data destined for the multicast group G, the MLD querier forwards the multicast data in the network segment.

  d If there is no other member in the multicast group G, the querier receives no report packet for the multicast group G. After the timer expires, the (*, G) entry is deleted. Upon receiving multicast data destined for the multicast group G, the MLD querier does not forward the multicast data in the network segment.

Figure 1-5 Member Leave Diagram

1.1.3 Working Principles of MLDv2

1. Changes of MLDv2 from MLDv1

- In MLDv2, when you add a host to a group, you can specify the host to receive multicast data from specified sources. In MLDv1, you cannot specify sources for a host.
- In MLDv1, an MLDv1 packet can carry information of only one multicast group. In MLDv2, an MLDv2 packet can carry information of multiple multicast groups. This relieves the interaction problem of a great number of packets between hosts and the querier.

2. Types of MLDV2 Packets

- Query packets include general group query packet, group-specific query packet, and source-specific query packet (check whether members in a group receive multicast data from the specific source).
- Member report packets include multicast group and multicast source information. Asource can be filtered in INCLUDE or EXCLUDE mode. (G, INCLUDE, (S1, S2...)) means to receive multicast data sent only from specified sources S1, S2, ... to the group G. (G, EXCLUDE, (S1, S2...)) means to reject multicast data sent from specified sources S1, S2, ... to the group G.

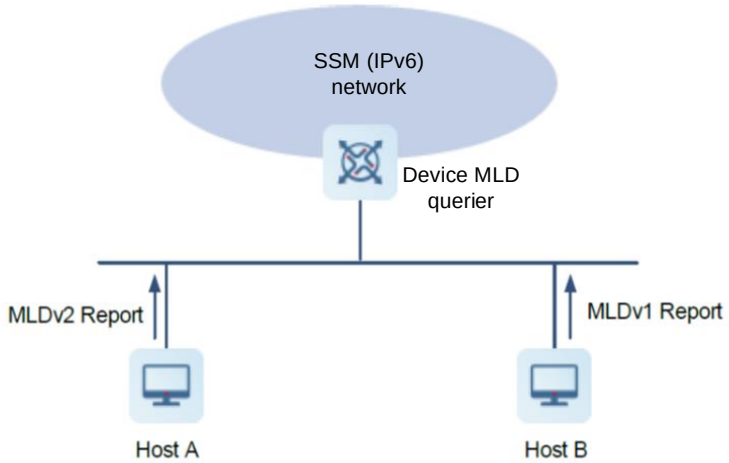
3. Working Mechanisms of MLDv2

Compared with MLDv1, MLDv2 supports you to select sources for a host to receive multicast data when you add the host.

- Specify sources to receive multicast data: You can specify sources for the host to receive multicast data when you add the host to a multicast group.
- Query a specified source: Upon receiving a report packet to modify the correspondence between multicast sources and groups from members, the MLD querier sends a specified source query packet. If you expect a member to receive multicast data from a specified source, configure a report packet. The MLD querier updates the source list of this group based on the report.

1.1.4 MLD SSM Mapping

In the source-specific multicast (SSM) model, a host must run MLDv2 if you want to specify source addresses for the host. If a host supports only MLDv1, a multicast source cannot be specified for the host. To enable a host that supports only MLDv1 to use the SSM service, you can enable the MLD SSM mapping function on the multicast device.



Based on the MLD SSM mapping mechanism, static SSM address mapping rules can be configured on the multicast device to convert the (*, G) information in MLDv1 report packets to (S, G) information so that the SSM service can be used by the host that supports only MLDv1.

In the SSM network shown in Figure 1-6, the MLD multicast device runs MLDv2, Host A supports only MLDv1, and Host B supports MLDv2. The MLD SSM mapping function can be enabled on the MLD querier to provide SSM service for Host A.

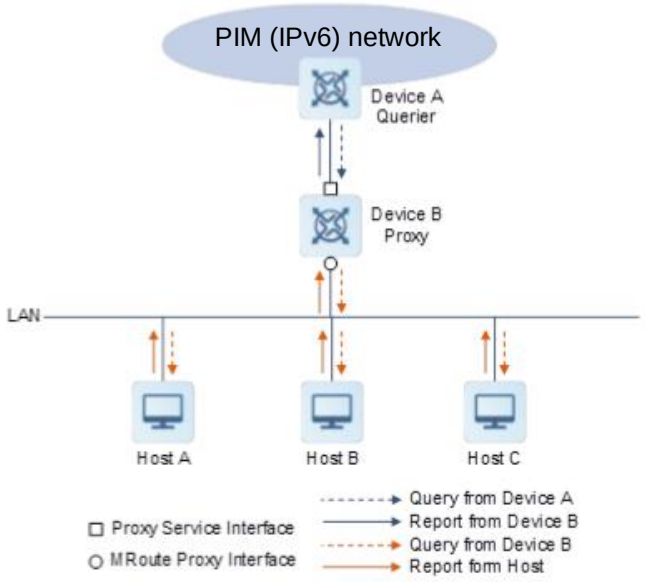
In this network, when the device receives an MLDv1 report packet from Host A, the device checks the address of the IPv6 multicast group G in the packet.

- If the multicast group G is not in the IPv6 SSM group address range, the ASM service is provided.
- If the multicast group G is in the IPv6 SSM group address range, whether the ASM service can be provided depends on the following situation:
  - If no MLD SSM mapping rule is configured on the device for the multicast group G, the SSM service cannot be provided and the packet is discarded.
  - If an MLD SSM mapping rule is configured on the device for the multicast group G, the (*, G) information in the MLDv1 report packet is mapped to (G, INCLUDE, (S1, S2)) and the SSM multicast service is provided.

Figure 1-6 Topology of MLD SSM Mapping

1.1.5 MLD Proxy

In some user scenarios, if you do not want devices connected to hosts to run complete multicast routing protocols, you can enable the MLD proxy function.



On the user side, the MLD proxy acts as a querier and periodically queries user information. On the route side, the MLD proxy acts a host and sends user information to a network when necessary. In this way, L2 multicast

flooding is suppressed, user information is more effectively obtained and controlled, and the protocol packets and network load are reduced to some extent.

Two types of MLD proxy interfaces are defined to facilitate understanding:

- MLD proxy service interface: This interface is responsible for behaviors of hosts. It receives query packets from uplink devices, replies report packets based on current group membership, and sends report or leave packets when the membership changes.
- MLD MRoute proxy interface: This interface is responsible for behaviors of the querier. It sends query packets, collects host information, and maintains membership.

Figure 1-7 Topology of MLD Proxy

1.1.6 Protocols and Standards

- RFC 2710: Multicast Listener Discovery (MLDv1) for IPv6
- RFC 3810: Multicast Listener Discovery Version 2 (MLDv2) for IPv6

1.2 Restrictions and Guidelines

- In an IPv6 network, all L3 devices must run the IPv6 PIM protocol before multicast forwarding entries can be established normally.
- Device interfaces must run MLDv2 before hosts supporting either MLD version can use the SSM service.
- A member host can be a PC or a set top box (STB), and it can normally receive multicast data by the multicast client software.

1.3 Configuration Task Summary

MLD configuration includes the following tasks:

(1) Configuring Basic Functions of MLD

(2) (Optional) Configuring an MLD Version

(3) Enabling Security Control for MLD Multicast. All the configuration tasks below are optional. Select the configuration tasks as required.

- Enabling Access Control for Multicast Groups
- Configuring the Maximum Number of Group Members

(4) Configuring MLD Querier Parameters. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Last Member Query Interval
- Configuring the Last Member Query Times
- Configuring the General Group Query Interval
- Configuring the Maximum Response Time of Query Packets
- Configuring the Other Querier Keepalive Time
- Configuring the Robustness Variable of the MLD Querier

(5) (Optional) Configuring Static MLD Groups

(6) (Optional) Configuring a Device Interface as a Simulated Host to Join a Group

(7) (Optional) Enabling the MLD Proxy Function

(8) (Optional) Enabling the SSM Mapping Function

1.4 Prerequisites

An IPv6 unicast routing protocol is configured to ensure that device nodes are reachable through IPv6 unicast routes.

1.5 Configuring Basic Functions of MLD

1.5.1 Overview

The multicast routing function is enabled on the local network and group information on the local network is collected so that member hosts can join multicast groups to receive multicast data packets.

1.5.2 Restrictions and Guidelines

- The IPv6 multicast routing function should be enabled on each multicast device on the local network unless otherwise specified.
- The PIM-SMv6 function should be enabled on interfaces connected to the local network unless otherwise specified.

1.5.3 Prerequisites

All PIM interfaces should be reachable through IPv6 unicast routes.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the IPv6 multicast routing function.

ipv6 multicast-routing

The IPv6 multicast routing function is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(5) Enable the PIM-SMv6 function.

ipv6 pim sparse-mode

The PIM-SMv6 function on an interface is disabled by default.

1.6 Configuring an MLD Version

1.6.1 Overview

At present, there are two versions of MLD. Multicast devices running MLDv2 can identify MLDv1 packets. Multicast devices running MLDv1 cannot identify MLDv2 packets.

1.6.2 Restrictions and Guidelines

- After an MLD version is configured, MLD automatically restarts.
- The MLD version on a multicast device must be later than or equal to the MLD version on a host.
- It is recommended that an MLD version be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.

1.6.3 Prerequisites

Configuring Basic Functions of MLD.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet*-type interface-number
- Enter the Layer 3 link aggregation configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Configure an MLD version.

ipv6 mld version { **1** | **2** }

MLDv2 is running on an interface by default.

1.7 Enabling Security Control for MLD Multicast

1.7.1 Overview

- To prevent a host from joining an IPv6 multicast group, you can enable the function of filtering the MLD group on the interface directly connected to a network segment.
- To prevent a great number of hosts from joining an IPv6 multicast group and affecting interface performance of devices, you can configure the maximum number of members on the interface directly connected to a network segment.
- To prevent a great number of hosts from joining an IPv6 multicast group and affecting the overall performance of devices, you can configure the maximum number of members on the devices.

1.7.2 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Enabling Access Control for Multicast Groups
- Configuring the Maximum Number of Group Members

1.7.3 Prerequisites

Configuring Basic Functions of MLD.

1.7.4 Enabling Access Control for Multicast Groups

1. Overview

After enabling access control for multicast groups on an interface, you can control hosts from joining groups in the directly connected network segment. ACLs are used to limit the group address range. Report packets denied by the ACLs are discarded.

When MLDv2 is enabled, this command supports extended ACLs to precisely filter source record information in MLDv2 packets. If the received MLD report packets follow the format of (S1, S2, S3, ..., Sn, G), the corresponding ACL must be configured for filtering. S1, S2, S3, ..., Sn correspond to source addresses in ACL entries, and G corresponds to the destination address in the ACL entries.

2. Restrictions and Guidelines

It is recommended that access control be enabled on all multicast device interfaces directly connected to the local network unless otherwise specified.

3. Prerequisites

Before a multicast group address range is configured, ensure that the corresponding ACL is created and a multicast group range is specified. For details about ACL configuration, see *Configuring ACL*.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Enable access control for multicast groups.

ipv6 mld access-group *acl-name*

An interface allows hosts to join any group by default.

1.7.5 Configuring the Maximum Number of Group Members

1. Overview

To prevent a great number of hosts from joining an IPv6 multicast group, you can limit the number of members.

- In the global configuration mode, the number of members in an MLD group on a device is limited.
- In the interface configuration mode, the number of members in an MLD group on an interface is limited.

If the number of group members exceeds the interface limit or global limit, subsequent report packets are ignored.

If an exceptional list is configured, report packets in a specified range can be normally processed, and the records about these group members are not counted.

Interface and global limits can be configured separately. If the global limit is smaller than the interface limit, the global limit prevails.

2. Restrictions and Guidelines

It is recommended that the maximum number of group members be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.

It is recommended that the maximum number of group members be configured on multicast devices directly connected to the local network unless otherwise specified.

3. Prerequisites

- Before an exceptional list is configured, ensure that the corresponding ACL is created and an exceptional multicast group range is specified. For details about ACL configuration, see *Configuring ACL*.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the maximum number of MLD group members. Select one of the following to configure.

- Configure the maximum number of MLD group members on a device.

  ipv6 mld limit *limit* [**except** *acl-name*]

- Configure the maximum number of MLD group members on an interface.

  interface *interface-type interface-number*

  ipv6 mld limit *limit* [**except** *acl-name*]

By default, the maximum number of MLD group members on a device is **64000**, and that on an interface is **4000**.

1.8 Configuring MLD Querier Parameters

1.8.1 Overview

MLD maintains IPv6 membership by query packets and report packets. If multiple multicast devices exist in a network segment, only one multicast device needs to send query packets as a querier. IP addresses of multicast devices are compared. The device with the smallest address is elected as the querier. The querier periodically sends query packets to obtain local member information and ensure that a group has at least one host. If no host is available in a group, the group is deleted by the device.

The MLD querier work can be adjusted using multiple parameters. When the default parameter values are used, the querier can normally work. Network optimization can be implemented by adjusting querier parameter values to avoid excessive protocol packets and network congestion. Also, membership can be updated and maintained in time.

1.8.2 Restrictions and Guidelines

- It is recommended that querier parameters be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.
- In actual network deployment, to accurately, timely, and stably maintain group membership and avoid

non-queriers from initiating a new round of election, ensure that the following durations are arranged in ascending order: Maximum response time of general group query packet < Sending interval of general group query packet < Other querier keepalive time.

1.8.3 Prerequisites

Configuring Basic Functions of MLD.

1.8.4 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Last Member Query Interval
- Configuring the Last Member Query Times
- Configuring the General Group Query Interval
- Configuring the Maximum Response Time of Query Packets
- Configuring the Robustness Variable of the MLD Querier
- Configuring the Other Querier Keepalive Time

1.8.5 Configuring the Last Member Query Interval

1. Overview

Before a host leaves a multicast group, the host sends a leave packet. Upon receiving the leave packet, the querier continuously sends group-specific/source-specific query packets and waits for responses from hosts. This parameter specifies the query packet sending interval.

2. Restrictions and Guidelines

- It is recommended that this parameter be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.
- The unit of the last member query interval is 0.1 seconds. If the parameter value is 10, the actual sending interval is 1 second.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet*-type interface-number

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure the last member query interval.

ipv6 mld last-member-query-interval *interval*

The group-specific query packet sending interval is **1** second by default.

1.8.6 Configuring the Last Member Query Times

1. Overview

Before a host leaves a multicast group, the host sends a leave packet. Upon receiving the leave packet, the querier continuously sends specific group/source query packets and waits for responses from the host. This parameter specifies the query packet sending times.

2. Restrictions and Guidelines

It is recommended that this parameter be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet*-type interface-number

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure the last member query times.

ipv6 mld last-member-query-count *count*

The group-specific query packet sending times is **2** by default.

1.8.7 Configuring the General Group Query Interval

1. Overview

The MLD querier periodically sends query packets to all hosts and multicast devices on the shared network. This parameter specifies the interval for sending query packets.

2. Restrictions and Guidelines

It is recommended that this parameter be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet*-type interface-number

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure the general group query interval.

ipv6 mld query-interval *interval*

The default interval for sending general group query packets is **125** seconds.

1.8.8 Configuring the Maximum Response Time of Query Packets

1. Overview

After the MLD querier sends query packets, member hosts reply upon receiving the query packets before the maximum response time expires. If no response is received after timeout, it is considered that no member exists in the group of the directly connected network segment and the group information is deleted.

2. Restrictions and Guidelines

It is recommended that this parameter be configured on all multicast device interfaces directly connected to the local network unless otherwise specified.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

interface *ethernet*-type interface-number

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure the maximum response time of query packets.

ipv6 mld query-max-response-time *max-response-time*

The maximum response time of query packets is **10** seconds by default.

1.8.9 Configuring the Other Querier Keepalive Time

1. Overview

When a non-querier does not receive a query packet in the same network segment within a specified period, the non-querier considers there is only querier (itself) in the directly connected network segment and initiates a new round of querier election. This parameter specifies the timeout time for the non-queriers to wait for query packets.

2. Restrictions and Guidelines

It is recommended that this parameter be configured on all interfaces where MLD is enabled on the local network unless otherwise specified.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet*-type interface-number

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure the other querier keepalive time.

ipv6 mld querier-timeout *timeout*

The keepalive time of other querier is **255** seconds by default.

1.8.10 Configuring the Robustness Variable of the MLD Querier

1. Overview

When the query packets sent by the querier are lost due to network instability, the query packets are retransmitted. The retransmission times are referred to as the robustness variable of the MLD querier.

In the event of packet loss, query packet retransmission occurs in either of the following situations:

- When the querier is started, it sends general group query packets.
- Upon receiving leave packets, the querier sends group-specific/source-specific query packets to check whether there are members existing in the specific multicast group.

2. Restrictions and Guidelines

It is recommended that this parameter be configured on all interfaces where MLD is enabled on the local network unless otherwise specified.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet*-type interface-number

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure the robustness variable of the MLD querier.

ipv6 mld robustness-variable *robustness*

The robustness variable of the MLD querier is **2** by default.

1.9 Configuring Static MLD Groups

1.9.1 Overview

In some application scenarios, a static multicast group may need to be configured on the interfaces connected to group members in the following cases:

(1) The group members are stable and multicast data needs to be quickly and stably forwarded to member interfaces.

(2) The group members cannot send report packets but need to receive certain multicast data. After the static multicast group is configured, the multicast devices consider that group members exist on these interfaces and forward multicast data to these interfaces.

1.9.2 Restrictions and Guidelines

A static multicast group must be manually configured on an interface connected to group members.

1.9.3 Prerequisites

Configuring Basic Functions of MLD.

1.9.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet*-type interface-number

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure a static MLD group.

ipv6 mld static-group *ipv6-group-address*

No interface is added to any static multicast group by default.

1.10 Configuring a Device Interface as a Simulated Host to Join a Group

1.10.1 Overview

In some test scenarios, no host is available or can be added to a multicast group. In this case, you need to configure device interfaces to simulate hosts and add the hosts to a specific multicast group.

1.10.2 Restrictions and Guidelines

- An interface can be added to multiple groups at the same time.

1.10.3 Prerequisites

The PIM protocol must be configured and the IPv6 multicast routing function must be enabled on the interfaces to be configured as hosts.

1.10.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet*-type interface-number

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure a device interface as a host to join a group.

ipv6 mld join-group *ipv6-group-address*

No interface is added to any multicast group by default.

1.11 Enabling the MLD Proxy Function

1.11.1 Overview

The MLD router proxy function collects local member information. For a host, the MLD proxy functions as a router and sends query packets.

For the querier, the MLD proxy functions as a host and sends report packets.

1.11.2 Restrictions and Guidelines

- The MLD proxy service interface is configured on the interface of routers directly connected to the upstream devices unless otherwise specified.
- The MRoute proxy interface is configured on the interface of hosts directly connected to the downstream devices unless otherwise specified.
- A maximum of 32 proxy service interfaces can be configured on a device. After receiving MLD query packets, the proxy service interface sends report packets based on the MLD group member records.

1.11.3 Prerequisites

Configuring Basic Functions of MLD.

1.11.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet*-type interface-number

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Enable the MLD proxy service function.

ipv6 mld proxy-service

The MLD proxy service function is disabled by default.

(5) Enable the MLD MRoute proxy function.

ipv6 mld mroute-proxy *interface-type interface-number*

The MRoute proxy function is disabled by default.

1.12 Enabling the SSM Mapping Function

1.12.1 Overview

MLDv2 supports source filtering while MLDv1 does not. However, the multicast devices provide the SSM mapping function to implement source filtering and enable MLDv1 hosts to use the SSM service. Multicast device interfaces run MLDv2. When receiving MLDv1 report packets, a multicast device adds the static mapping source address.

1.12.2 Restrictions and Guidelines

The SSM service must be enabled and the SSM group address range must be consistent on all multicast devices.

1.12.3 Prerequisites

- Configuring Basic Functions of MLD.
- Before a static mapping entry is configured, ensure that the corresponding ACL is created and a multicast group range is specified. For details about ACL configuration, see *Configuring ACL*.

1.12.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the SSM mapping function.

ipv6 mld ssm-map enable

The SSM mapping function is disabled by default.

(4) (Optional) Configure a static mapping entry.

ipv6 mld ssm-map static *acl-name ipv6-source-address*

No static mapping entry is configured by default.

1.13 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **clear** commands to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

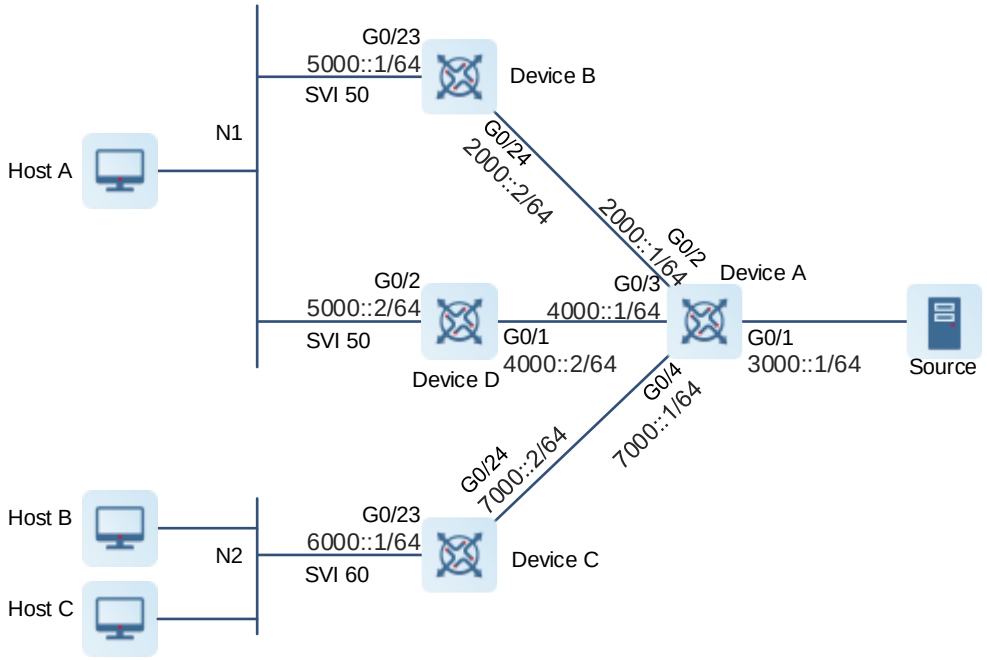
Table 1-1 Monitoring

Command	Purpose
clear ipv6 mld group [*ipv6-group-address*] [*interface-type interface-number*]	Clears dynamic group member records in the MLD cache.
clear ipv6 mld interface *interface-type interface-number*	Clears all MLD statistics and group member records on the interface.
show ipv6 mld global	Displays global MLD information.
show ipv6 mld groups [*ipv6-group-address* | *interface-type interface-number*] [**detail**]	Displays groups directly connected to the device and group information learned from MLD.
show ipv6 mld interface [*interface-type interface-number*]	Displays configurations of the interface.
show ipv6 mld restart	Displays information about restart of an MLD process.
show ipv6 mld ssm-mapping [*ipv6-group-address*]	Displays the SSM mapping information.
show debugging	Displays the MLD debugging switch status.
debug ipv6 mld all	Debugs all MLD information.

Command	Purpose
debug ipv6 mld decode	Debugs MLD packet resolution.
debug ipv6 mld encode	Debugs MLD packet encoding.
debug ipv6 mld events	Debugs MLD event information.
debug ipv6 mld fsm	Debugs MLD event information.
debug ipv6 mld tib	Debugs MLD state machine information.
debug ipv6 mld warning	Debugs MLD alarms.

1.14 Examples

1.14.1 Configuring Basic Functions of MLD



1. Requirements

As shown in Figure 1-8, Host A, Host B, and Host C residing in shared networks N1 and N2 of IPv6 want to receive video information from the source in multicast mode. The static multicast group FF13::1 is configured on N1 shared network, and hosts on N2 shared network can join the multicast group FF14::1.

- OSPFv3 runs in the network to make uniticast routes between anytwo nodes reachable.
- Device B and Device D are connected to the shared network N1 through SVI 50. The IPv6 address of Device B is smaller than the IPv6 address of Device D. Therefore, Device B acts as the querier, and Host A is the multicast information receiver in the shared network N1.
- Device C is connected to the shared network N2 through SVI 60, and Host B is the multicast information receiver in the shared network N2.
- Device B, Device C, and Device D are connected to other devices in the IPv6 PIM network through L3 interfaces.

2. Topology

Figure 1-8 Topology for Basic Functions of MLD

3. Notes

- Configure an IPv6 unicast routing protocol OSPFv3 on a multicast device and ensure that unicast routes are reachable to the Loopback interface.
- Enable the IPv6 multicast routing function on all multicast devices.
- Configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts, and interfaces connected to sources.
- Configure a static multicast group on the interfaces of the devices on shared network N1.
- Enable the multicast group access control function on the interfaces of the devices on shared network N2.

4. Procedure

(1) Configure an IPv6 address for each interface and configure the unicast routing protocol.

Configure an IPv6 address for the interface of Device A and configure the OSPFv3 protocol to implement internetworking. Perform the same configuration on Device B, Device C, and Device D.

```
DeviceA> enable
DeviceA# config terminal
DeviceA(config)# ipv6 router ospf 5050
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no switchport
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 address 3000::1/64
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 ospf 5050 area 0
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface GigabitEthernet 0/2
```

```
DeviceA(config-if-GigabitEthernet 0/2)# no switchport
DeviceA(config-if-GigabitEthernet 0/2)# ipv6 address 2000::1/64
DeviceA(config-if-GigabitEthernet 0/2)# ipv6 ospf 5050 area 0
DeviceA(config-if-GigabitEthernet 0/2)# exit
DeviceA(config)# interface GigabitEthernet 0/3
DeviceA(config-if-GigabitEthernet 0/3)# no switchport
DeviceA(config-if-GigabitEthernet 0/3)# ipv6 address 8000::1/64
DeviceA(config-if-GigabitEthernet 0/3)# ipv6 ospf 5050 area 0
DeviceA(config-if-GigabitEthernet 0/3)# exit
DeviceA(config)# interface GigabitEthernet 0/4
DeviceA(config-if-GigabitEthernet 0/4)# no switchport
DeviceA(config-if-GigabitEthernet 0/4)# ipv6 address 7000::1/64
DeviceA(config-if-GigabitEthernet 0/4)# ipv6 ospf 5050 area 0
DeviceA(config-if-GigabitEthernet 0/4)# exit
DeviceA(config)# interface loopback 0
DeviceA(config-if-Loopback 0)# ipv6 address 1111::1/128
DeviceA(config-if-Loopback 0)# ipv6 ospf 5050 area 0
DeviceA(config-if-Loopback 0)# exit
```

(2) Enable the IPv6 multicast routing function on all devices, and configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts, and interfaces connected to sources.

Enable the IPv6 multicast routing function and configure the PIM-SMv6 protocol on Device A. Perform the same configuration on Device B, Device C, and Device D.

```
DeviceA(config)# ipv6 multicast-routing
DeviceA(config)# interface GigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface GigabitEthernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/2)# exit
DeviceA(config)# interface GigabitEthernet 0/3
DeviceA(config-if-GigabitEthernet 0/3)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/3)# exit
DeviceA(config)# interface GigabitEthernet 0/4
DeviceA(config-if-GigabitEthernet 0/4)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/4)# exit
DeviceA(config)# interface loopback 0
DeviceA(config-if-Loopback 0)# ipv6 pim sparse-mode
DeviceA(config-if-Loopback 0)# exit
```

Configure an RP. Configure a C-BSR and a C-RP on Device A.

```
DeviceA(config)# ipv6 pim bsr-candidate Loopback 0
DeviceA(config)# ipv6 pim rp-candidate Loopback 0
```

(3) Configure a static multicast group on the interfaces of the devices on shared network N1.

Configure a static multicast group on SVI 50 of Device B, and set the static multicast group address to FF13::1. Perform the same configuration on Device D.

```
DeviceB> enable
DeviceB# config terminal
DeviceB(config)# interface VLAN 50
DeviceB (config-if-VLAN 50)# ipv6 mld static-group ff13::1
DeviceB(config-if-VLAN 50)# exit
DeviceB(config)# interface GigabitEthernet 0/23
DeviceB(config-if-GigabitEthernet 0/23)# switchport access vlan 50
DeviceB(config-if-GigabitEthernet 0/23)# exit
DeviceB(config)# interface TenGigabitEthernet 0/27
DeviceB(config-if-TenGigabitEthernet 0/27)# switchport mode trunk
DeviceB(config-if-TenGigabitEthernet 0/27)# switchport trunk native vlan 50
DeviceB(config-if-TenGigabitEthernet 0/27)# exit
```

(4) Enable the multicast group access control function on the interfaces of the devices on shared network N2.

Enable the multicast group access control function on SVI 60 of Device C, and add the hosts in network N2 to the multicast group FF14::1.

```
DeviceC> enable
DeviceC# config terminal
DeviceC(config)# ipv6 access-list ipv6-group
DeviceC(config-ipv6-acl)# permit ipv6 any host FF14::1
DeviceC(config-ipv6-acl)# exit
DeviceC(config)# interface VLAN 60
DeviceC(config-if-VLAN 60)# ipv6 mld access-group ipv6-group
DeviceC(config-if-VLAN 60)# exit
```

5. Verification

Run the **show ipv6 mld interface** command to display MLD configuration of each device. Device B is taken as an example. Device B is the querier, because the IPv6 address of SVI 50 on Device B in the shared network N1 is smaller.

```
DeviceB# show ipv6 mld interface VLAN 50
Interface VLAN 50 (Index 4146)
 MLD Enabled, Active, Querier, Version 2 (default)
 Internet address is fe80::274:9cff:feee:53cb
 MLD interface limit is 4000
 MLD interface has 0 group-record states
 MLD interface has 0 join-group records
 MLD interface has 1 static-group records
 MLD activity: 10 joins, 1 leaves
 MLD query interval is 125 seconds
 MLD querier timeout is 255 seconds
 MLD max query response time is 10 seconds
 Last member query response interval is 10 (1/10s)
 Last member query count is 2
 Group Membership interval is 260
 Robustness Variable is 2
```

Run the **show ipv6 pim sparse-mode mroute** command to display the multicast routing entries on each device. The multicast routing entries on Device B are as follows:

```
DeviceB# show ipv6 pim sparse-mode mroute
IPv6 Multicast Routing Table

FCR:
```

Run the **show ipv6 mld groups** command to display the static multicast group FF13::1 that SVI50 joins on Device B and Device D.

```
DeviceB# show ipv6 mld groups
MLD Connected Group Membership
Group Address                    Interface         Uptime    Expires   Last
Reporter
ff13::1                         VLAN 50           00:11:07  stopped   ::
```

Try to add a host to the multicast groups FF13::1 and FF14::1 through SVI 60, and run the **show ipv6 mld groups** command to display that the host joins in only the multicast group FF14::1 through SVI 60.

```
DeviceC# show ipv6 mld groups
MLD Connected Group Membership
Group Address                    Interface         Uptime    Expires   Last
Reporter
ff14::1                         VLAN 60           00:01:03  00:03:51
fe80::274:9cff:feee:f49f
```

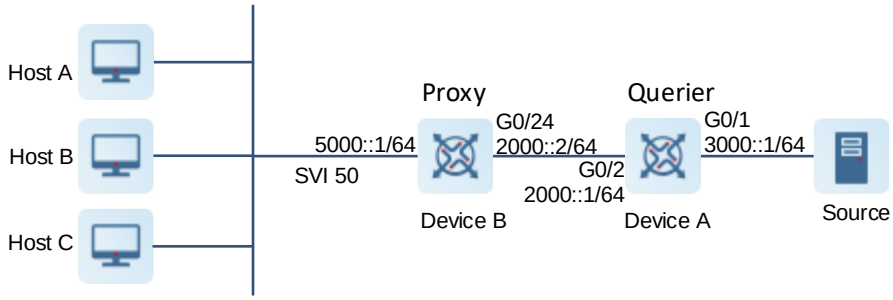
7. Common Errors

- The multicast routing function is not enabled on a multicast device.
- No multicast interface is available on the network.



1.14.2 Configuring the MLD Proxy Function

1. Requirements

As shown in Figure 1-9, the PIM-SMv6 protocol is configured in the network. Host A and Host B in the stub network receive multicast data from the source. The multicast group addresses are FF13::1 and FF14::1. The MLD proxy function is enabled on Device B to maintain membership and normal forwarding of multicast data.

2. Topology

Figure 1-9 Topology of the MLD Proxy

3. Notes

- Configure an IPv6 unicast routing protocol OSPFv3 on a multicast device and ensure that unicast routes are reachable to the Loopback interface.
- Enable the IPv6 multicast routing function on all multicast devices, and configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts, and interfaces connected to sources.
- Configure a proxy service interface.
- Configure an MRoute proxy interface.

4. Procedure

(1) Configure an IPv6 unicast routing protocol OSPFv3 on a multicast device and ensure that unicast routes are reachable to the Loopback interface.

Configure an IPv6 address for the interface of Device A and configure the OSPFv3 protocol to implement internetworking. Perform the same configuration on Device B.

```
DeviceA> enable
DeviceA# config terminal
DeviceA(config)# ipv6 router ospf 5050
DeviceA(config)# interface GigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no switchport
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 address 3000::1/64
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 ospf 5050 area 0
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface GigabitEthernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# no switchport
DeviceA(config-if-GigabitEthernet 0/2)# ipv6 address 2000::1/64
```

```
DeviceA(config-if-GigabitEthernet 0/2)# ipv6 ospf 5050 area 0
DeviceA(config-if-GigabitEthernet 0/2)# exit
DeviceA(config)# interface loopback 0
DeviceA(config-if-Loopback 0)# ipv6 address 1111::1/128
DeviceA(config-if-Loopback 0)# ipv6 ospf 5050 area 0
DeviceA(config-if-Loopback 0)# exit
```

(2) Enable the IPv6 multicast routing function on all multicast devices, and configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts, and interfaces connected to sources.

Enable the IPv6 multicast routing function and configure the PIM-SMv6 protocol on Device A. Perform the same configuration on Device B.

```
DeviceA(config)# ipv6 multicast-routing
DeviceA(config)# interface GigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface GigabitEthernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/2)# exit
DeviceA(config)# interface loopback 0
DeviceA(config-if-Loopback 0)# ipv6 pim sparse-mode
DeviceA(config-if-Loopback 0)# exit
```

Configure an RP. Configure a C-BSR and a C-RP on Device A.

```
DeviceA(config)# ipv6 pim bsr-candidate Loopback 0
DeviceA(config)# ipv6 pim rp-candidate Loopback 0
```

(3) Configure a proxy service interface.

Configure GigabitEthernet 0/24 on Device B as a proxy service interface.

```
DeviceB> enable
DeviceB# config terminal
DeviceB(config)# interface GigabitEthernet 0/24
DeviceB(config-if-GigabitEthernet 0/24)# ipv6 mld proxy-service
DeviceB(config-if-GigabitEthernet 0/24)# exit
```

(4) Configure an MRoute proxy interface.

Configure SVI 50 of Device B as an MRoute proxy interface.

```
DeviceB(config)# interface VLAN 50
DeviceB(config-if-VLAN 50)# ipv6 mld mroute-proxy GigabitEthernet 0/24
```

5. Verification

Run the **show ipv6 mld groups** command on Device B to displaythe proxy entries.

```
DeviceB# show ipv6 mld groups
MLD Connected Group Membership
Group Address                    Interface          Uptime    Expires   Last
Reporter
```

```
ff13::1                          VLAN 50           00:03:24  00:04:14
fe80::274:9cff:feee:f49f
ff14::1                          VLAN 50           00:00:06  00:04:14
fe80::274:9cff:feee:54cb

MLD Proxy-server Connected Group Membership
Group Address                     Interface            Uptime
ff13::1                          GigabitEthernet 0/24    00:03:24
ff14::1                          GigabitEthernet 0/24    00:00:06
```

Run the **show ipv6 mld groups** command on Device A to display that addresses of members joining the multicast groups FF13::1 and FF14::1 are IPv6 addresses of the Device B proxies.

```
DeviceA# show ipv6 mld groups
MLD Connected Group Membership
Group Address                     Interface          Uptime    Expires   Last
Reporter
ff13::1                          GigabitEthernet 0/2  00:09:56  00:03:44
fe80::274:9cff:feee:53cb
ff14::1                          GigabitEthernet 0/2  00:00:23  00:03:56
fe80::274:9cff:feee:53cb
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!

 ipv6 ospf 5050 area 0
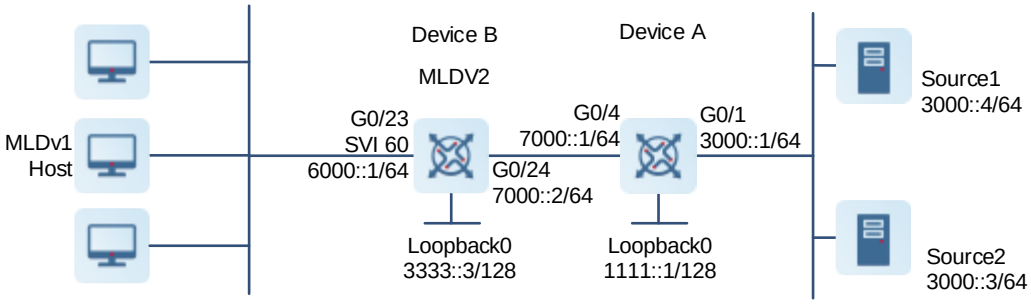
ipv6 mld mroute-proxy GigabitEthernet 0/24
 ipv6 pim sparse-mode
!
ipv6 router ospf 5050
 graceful-restart
!
End
```

7. Common Errors

The basic functions of MLD are not enabled.



1.14.3 Configuring SSM Mapping

1. Requirements

As shown in Figure 1-10, the SSM model is used to provide multicast service in an IPv6 multicast network. The default SSM group address range in the network is FF3X::/32. Hosts run MLDv1 and do not support MLDv2. Hosts are expected to receive multicast packets from Source 2 and ignore multicast packets from Source 1.

2. Topology

Figure 1-10 Topology of SSM Mapping

3. Notes

- Configure an IPv6 unicast routing protocol OSPFv3 on a multicast device and ensure that unicast routes are reachable to the Loopback interface.
- Enable the IPv6 multicast routing function on all multicast devices, and configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts, and interfaces connected to sources.
- Configure an SSM group address range.
- Enable the SSM mapping function.
- Configure an SSM mapping static linked list.

4. Procedure

(1) Configure an IPv6 unicast routing protocol OSPFv3 on a multicast device and ensure that unicast routes are reachable to the Loopback interface.

Configure an IPv6 address for the interface of Device A and configure the OSPFv3 protocol to implement internetworking. Perform the same configuration on Device B.

```
DeviceA> enable
DeviceA# config terminal
DeviceA(config)# ipv6 router ospf 5050
DeviceA(config)# interface GigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no switchport
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 address 3000::1/64
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 ospf 5050 area 0
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface GigabitEthernet 0/4
```

```
DeviceA(config-if-GigabitEthernet 0/4)# no switchport
DeviceA(config-if-GigabitEthernet 0/4)# ipv6 address 7000::1/64
DeviceA(config-if-GigabitEthernet 0/4)# ipv6 ospf 5050 area 0
DeviceA(config-if-GigabitEthernet 0/4)# exit
DeviceA(config)# interface loopback 0
DeviceA(config-if-Loopback 0)# ipv6 address 1111::1/128
DeviceA(config-if-Loopback 0)# ipv6 ospf 5050 area 0
DeviceA(config-if-Loopback 0)# exit
```

(2) Enable the IPv6 multicast routing function on all multicast devices, and configure the PIM-SMv6 protocol on the interconnected interfaces of devices, interfaces connected to hosts, and interfaces connected to sources.

Enable the IPv6 multicast routing function and configure the PIM-SMv6 protocol on Device A. Perform the same configuration on Device B.

```
DeviceA(config)# ipv6 multicast-routing
DeviceA(config)# interface GigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface GigabitEthernet 0/4
DeviceA(config-if-GigabitEthernet 0/4)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/4)# exit
DeviceA(config)# interface loopback 0
DeviceA(config-if-Loopback 0)# ipv6 pim sparse-mode
DeviceA(config-if-Loopback 0)# exit
```

Set the MLD version on SVI 60 connected to hosts to 2 on Device B.

```
DeviceB> enable
DeviceB# config terminal
DeviceB(config)# interface VLAN 60
DeviceB(config-if-VLAN 60)# ipv6 mld version 2
DeviceB(config-if-VLAN 60)# exit
```

(3) Configure an SSM group address range.

Configure an SSM multicast address range on all devices. Take Device A as an example and perform the same configuration on Device B.

```
DeviceB(config)# ipv6 pim ssm default
```

(4) Enable the SSM mapping function.

Enable the SSM mapping function on Device B.

```
DeviceB(config)# ipv6 mld ssm-map enable
```

(5) Configure an SSM mapping static linked list.

Map the multicast addresses in FF34::/64 to Source 1 on Device B.

```
DeviceB(config)# ipv6 access-list map-acl
DeviceB(config-ipv6-acl)# permit ipv6 any FF34::/64
DeviceB(config)# ipv6 mld ssm-map static map-acl 3000::3
```

5. Verification

Displaythe SSM mapping information.

```
DeviceB# show ipv6 mld ssm-mapping
SSM Mapping : Enabled
Database    : Static mappings configured
```

Displaymulticast source information corresponding to the multicast group FF34::1.

```
DeviceB# show  ipv6 mld ssm-mapping FF34::1
Group address: ff34::1
Database    : Static
Source list  : 3000::3
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ipv6 multicast-routing
!
interface GigabitEthernet 0/1
 no switchport
 ipv6 address 3000::1/64
 ipv6 ospf 5050 area 0
 ipv6 pim sparse-mode
!
interface GigabitEthernet 0/4
 no switchport
 ipv6 address 7000::1/64
 ipv6 ospf 5050 area 0
 ipv6 pim sparse-mode
!
interface Loopback 0
 ipv6 address 1111::1/128
 ipv6 ospf 5050 area 0
 ipv6 pim sparse-mode
!
ipv6 router ospf 5050
 graceful-restart
!
ipv6 pim ssm default
!
end
```

- Device B configuration file

```
hostname DeviceB
!
ipv6 access-list map-acl
```

```
 30 permit ipv6 any FF34::/64
!
ipv6 multicast-routing
!
vlan range 1,60
!
interface GigabitEthernet 0/23
 switchport access vlan 60
!
interface GigabitEthernet 0/24
 no switchport
 ipv6 address 7000::2/64
 ipv6 ospf 5050 area 0
 ipv6 pim sparse-mode
!
interface Loopback 0
 ipv6 address 3333::3/128
 ipv6 ospf 5050 area 0
 ipv6 pim sparse-mode
!
interface VLAN 60
 ipv6 address 6000::1/64
ipv6 ospf 5050 area 0
ipv6 pim sparse-mode
ipv6 mld version 2
!
ipv6 router ospf 5050
 graceful-restart
!
ipv6 mld ssm-map enable
ipv6 mld ssm-map static map-acl 3000::3
ipv6 pim ssm default
!
end
```

7. Common Errors

- The basic functions of MLD are not enabled.
- The SSM service is not enabled.
- No SSM address range is configured.

1.15 Common Misconfigurations

- Basic functions of MLD are not configured on the proxy service interface.
- No SSM service address is configured when the SSM service is used.
- The SSM service address ranges on different multicast devices are inconsistent.

1.15.1 What Can I Do when On-demand Multicast Service Is Unavailable on Client

- Fault Symptom

  The multicast function is enabled. But I failed to use the on-demand multicast service through a client.

- Troubleshooting

  a Check whether the connection between the on-demand client and multicast server is normal.

  Run the **show ipv6 route** command to check for any entry of unicast route to the multicast source on the server. If no, configure a unicast routing protocol.

  b Check configuration on the devices.

  Run the **show ipv6 pim** { **dense-mode | sparse-mode** } **interface** command to check for PIM information on an interface. If no information about the interface is displayed, the PIM-SMv6 function is not enabled. Run the **ipv6 pim sparse-mode** command to enable the PIM-SMv6 function on the interface.

  c Check whether the multicast receiver normally joins the group.

  Run the **show ipv6 mld groups** command to check whether the host joins the corresponding multicast group on the multicast device residing in the same network segment as the host.

  d Check whether the multicast entries on the multicast source and receiver are normal.

  Run the **show ipv6 pim** { **dense-mode | sparse-mode** } command to check whether the multicast entries on the devices are normal.

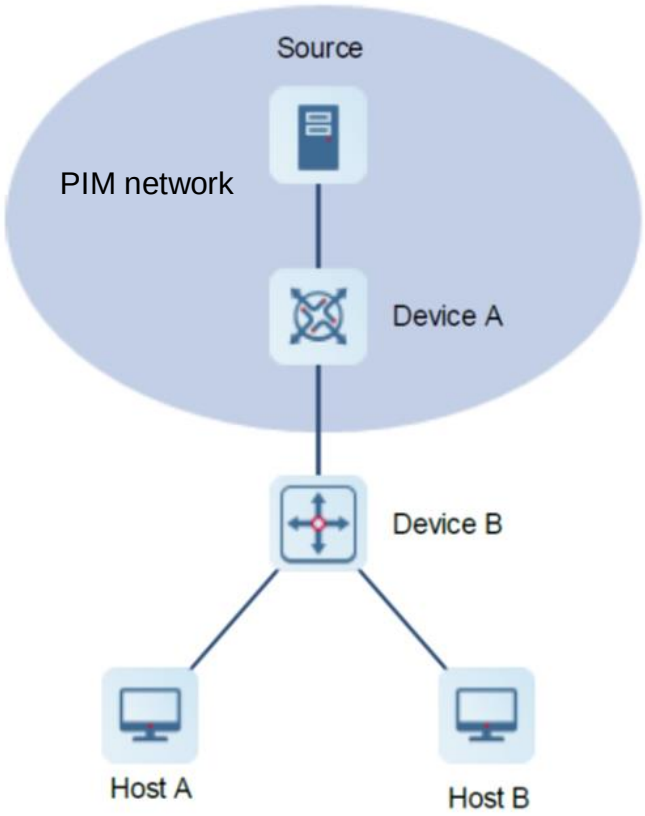
1.9.4 Configuring Static Ports to Implement L2 Multicast 36



1 Configuring MLD Snooping

1.1 Introduction

Multicast Listener Discovery (MLD) snooping is a process of snooping protocol packets between an L3 multicast device and hosts to manage and control forwarding of IPv6 multicast traffic at the data link layer, implementing L2 multicast.

Generally, multicast packets need to pass through L2 switches, especially in some local area networks (LANs). As shown in Figure 1-1, the Protocol Independent Multicast (PIM) multicast device sends packets to hosts through an L2 switch. Because multicast group addresses cannot be learned on L2 devices, the packets will be broadcast in the VLAN. This wastes bandwidth and affects security. After the MLD snooping function is configured, the L2 switch can listen to MLD packets between hosts and the uplink PIM multicast device and establish L2 multicast forwarding entries to ensure that multicast data is forwarded only to specific hosts. This prevents multicast data from being broadcast in the L2 network.

Figure 1-1 Network Topology

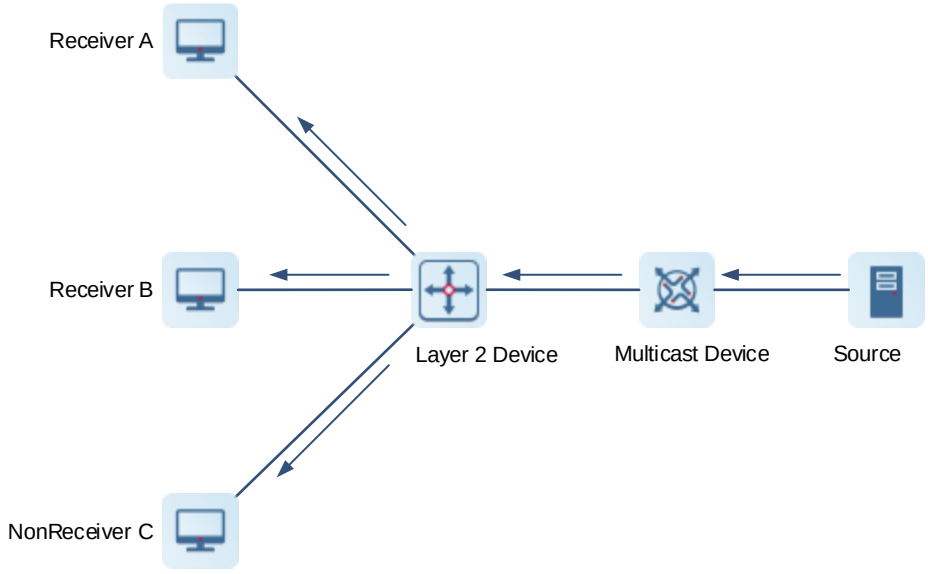
1.1.2 Principles

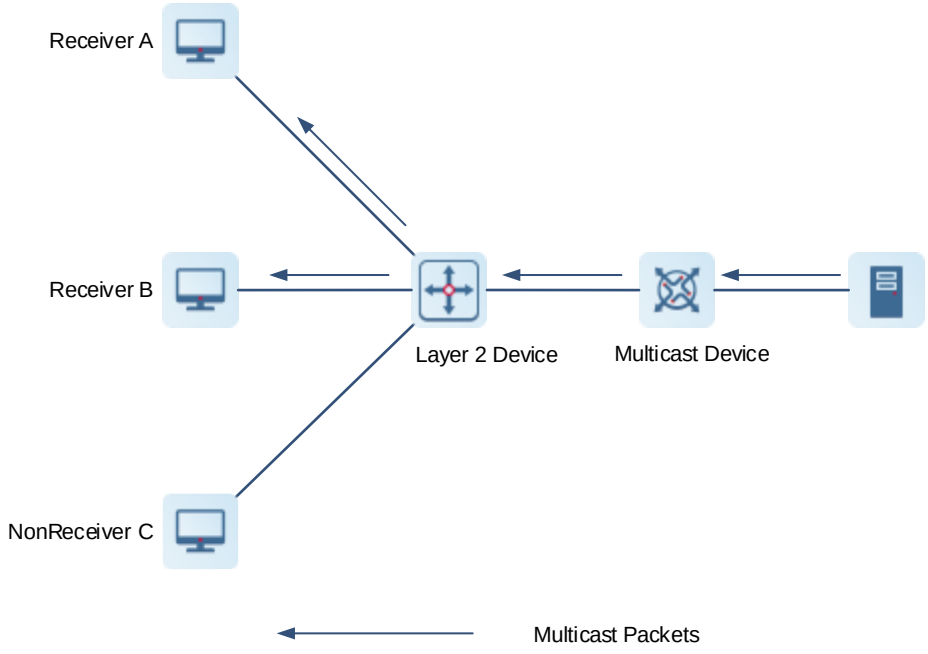
MLD snooping is a basic L2 multicast function that forwards and controls multicast data at the data link layer. By listening to and analyzing protocol packets between hosts and the L3 multicast device, the L2 device running

MLD snooping establishes and maintains L2 multicast forwarding entries to ensure on-demand forwarding of multicast data at the link layer.

As shown in Figure 1-2, when MLD snooping is not configured on the L2 device, IPv6 multicast packets are broadcast in the VLAN. As shown in Figure 1-3, when MLD snooping is enabled on the L2 device, IPv6 multicast packets are forwarded only to the member hosts of the multicast group. This prevents multicast data from being broadcast in the L2 network.

Figure 1-2 Multicast Data Transmission When MLD Snooping Is Disabled





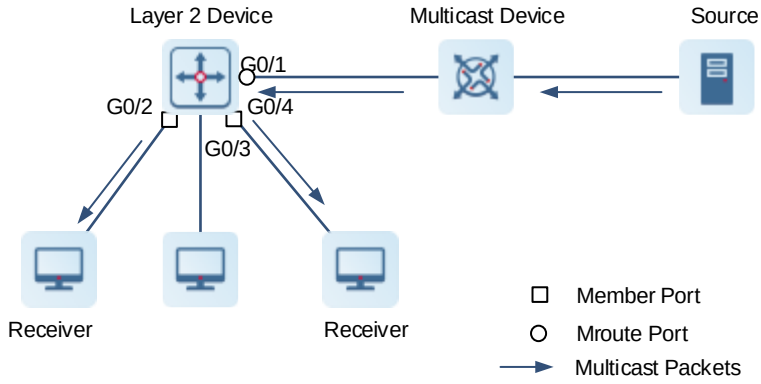


Figure 1-3 Multicast Data Transmission When MLD Snooping Is Enabled

1.1.3 Port Types

MLD snooping is enabled on a per-VLAN basis. MLD snooping ports are ports in a VLAN. The device running MLD snooping identifies ports in a VLAN as multicast router ports or member ports to manage and control forwarding of IP multicast data in the VLAN.

Figure 1-4 MLD Snooping Ports

- A multicast router port connects the L2 multicast device to an L3 multicast device, and indicates the direction of the multicast source. By listening to MLD packets, the L2 multicast device can automatically discover and maintain dynamic multicast router ports. You can also configure static multicast router ports.
- A member port connects the L2 multicast device to a host in a multicast group, and indicates the direction of a multicast group member. It is also called a listener port. By listening to MLD packets, the L2 multicast device can automatically discover and maintain dynamic member ports. You can also configure static member ports.

As shown in Figure 1-4, MLD snooping is enabled on the L2 multicast device, and the multicast data is received from a multicast router port and sent out from a member port.

1.1.4 Working Mechanism

A device running MLD snooping analyzes received MLD packets to discover and identify multicast router ports and member ports and establish and maintain MLD snooping forwarding entries. The device can identify and process the following types of MLD packets:

1. Query Packets

An L3 multicast device regularly sends an MLD general Query packet to all hosts and other multicast devices (with the address of FF02::1) in the local network segment to query the IPv6 multicast group members in this network segment. When receiving the MLD general Query packet, a multicast device forwards the packet through all ports in the VLAN except the one receiving the packet and processes the port receiving the packet as follows:

- Reset the aging timer of the port if the port is in the multicast router port list.
- Add the port to the multicast router port list if the port is not in the multicast router port list and start the aging timer of the port.
- When the L2 multicast device receives an MLD group-specific Query packet, it does not update the preceding timers.

2. Report Packets

When a member host receives a Query packet, the host will respond with a Report packet. If a host wants to join a multicast group, the host will proactively send a Report packet.

When receiving a Report packet, the device running MLD snooping forwards it to all multicast router ports in the VLAN, retrieves the address of the IPv6 multicast group that the host needs to join from the packet, and processes the port receiving the packet as follows:

- The device creates a forwarding entry for the IPv6 multicast group if no forwarding entry for the IPv6 multicast group exists, adds the port to the outbound port list as a dynamic member port, and starts the aging timer of the port.
- The device adds the port to the outbound port list as a dynamic member port and starts its aging timer if the forwarding entry of the IPv6 multicast group exists but the port is not contained in the outbound port list.
- The device resets the aging timer of the port if the forwarding entry of the IPv6 multicast group exists and the port is contained in the outbound port list.

3. Leave Packets

When a host leaves an IPv6 multicast group, it sends an MLD Leave packet (with the address of FF02::2) to notify the multicast device. When receiving a Leave packet, the device running MLD snooping performs the following actions in the VLAN:

- The device forwards the Leave packet through all multicast router ports.
- If the port receiving the Leave packet is a dynamic member port and the fast leave function is configured, the device immediately deletes the port from the MLD snooping forwarding entry of the corresponding multicast group. The port is no longer used as a dynamic member port of the group.
- If the port receiving the Leave packet is a dynamic member port but the fast leave function is not configured, the port status remains unchanged. When the aging timer of the port times out, the device deletes the port from the MLD snooping forwarding entry of the corresponding multicast group. The port is no longer used as a dynamic member port of the group.

1.1.5 Protocols and Standards

- RFC 4541: Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches

1.2 Configuration Task Summary

MLD snooping configuration includes the following tasks:

(1) Configuring Basic MLD Snooping Functions Select either of the following configuration tasks to configure.

- Configuring Basic MLD Snooping Functions in IVGL Mode
- Configuring Basic MLD Snooping Functions in SVGL Mode
- Configuring Basic MLD Snooping Functions in IVGL-SVGL Mode

(2) (Optional) Configuring the MLD Snooping Version

(3) Configuring Protocol Packet Processing Parameters All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Static Multicast Router Port

- Configuring a Static Member Port
- Configuring Report Packet Suppression
- Configuring Port Fast Leave
- Configuring Dynamic Multicast Router Port Learning
- Configuring the Aging Time for Dynamic Multicast Router Ports
- Configuring the Aging Time for Dynamic Member Ports
- Configuring the Maximum Response Time for Query Packets

(4) Configuring Multicast Security Control All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Profile
- Configuring Multicast Group Filtering on a Port
- Configuring the Maximum Number of Multicast Groups That Can Be Dynamically Learned by a Port
- Configuring Source Port Check

(5) (Optional) Configuring QinQ Processing

1.3 Configuring Basic MLD Snooping Functions

1.3.1 Overview

The device running MLD snooping can provide independent or shared multicast services for user VLANs when operating in the following modes:

- Independent VLAN Group Learning (IVGL): provides independent multicast services for each user VLAN.
- Shared VLAN Group Learning (SVGL): provides shared multicast services for multiple user VLANs.
- IVGL-SVGL: provides both shared and independent multicast services for user VLANs.

1.3.2 Restrictions and Guidelines

- The SVGL mode and the IPv6 multicast function are mutually exclusive. If the IPv6 multicast function needs to be enabled on the device running MLD snooping, the device can operate only in IVGL mode.
- If the device running MLD snooping operates in SVGL or IVGL-SVGL mode, a profile must be defined to specify the multicast groups associated with the SVGL mode.

1.3.3 Configuration Tasks

Basic MLD snooping function configuration includes the following tasks. Please configure only one task.

- Configuring Basic MLD Snooping Functions in IVGL Mode
- Configuring Basic MLD Snooping Functions in SVGL Mode
- Configuring Basic MLD Snooping Functions in IVGL-SVGL Mode

Basic MLD snooping function configuration includes the following tasks.

- Configuring Basic MLD Snooping Functions in IVGL Mode

1.3.4 Configuring Basic MLD Snooping Functions in IVGL Mode

1. Overview

In IVGL mode, the device running MLD snooping provides independent multicast services for each user VLAN. Multicast traffic can be forwarded only in the belonged VLAN, and hosts can request multicast traffic only in the belonged VLAN.

2. Restrictions and Guidelines

- Unless otherwise specified, you are advised to enable MLD snooping globally on all L2 access devices connecting to hosts.
- After MLD snooping is enabled globally, it takes effect to all VLANs. You can disable MLD snooping on any VLAN. When the multicast service is disabled on a VLAN, the multicast services on other VLANs are not affected.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the IPv6 MLD snooping function and run the IVGL mode.

ipv6 mld snooping ivgl

MLD snooping is disabled by default.

(4) (Optional) Disable MLD snooping on a specified VLAN.

no ipv6 mld snooping vlan *vlan-id*

After MLD snooping is enabled globally, it takes effect to all VLANs by default. If MLD snooping is disabled globally, it is ineffective on all VLANs.

You can disable MLD snooping on a VLAN only after MLD snooping is enabled globally.

1.3.5 Configuring Basic MLD Snooping Functions in SVGL Mode

1. Overview

In SVGL mode, the device running MLD snooping can provide shared multicast services for multiple user VLANs. Shared multicast services are usually used to provide the same video on demand (VOD) service for users in multiple VLANs. Compared with independent multicast services, shared multicast services save bandwidth.

VLANs for shared multicast services are classified into a shared VLAN and sub VLANs. Multicast traffic of multicast groups applied in SVGL mode on the shared VLAN is forwarded from the shared VLAN to sub VLANs, and hosts on sub VLANs request multicast traffic of multicast groups applied in SVGL mode from the shared VLAN.

2. Restrictions and Guidelines

- Multicast services can be shared among VLANs. After configuring the SVGL mode, you need to configure multicast groups applied in SVGL mode.

- Shared multicast services apply only to the shared VLAN and sub VLANs and use group addresses applied in SVGL mode.

3. Prerequisites

Before configuring multicast groups associated with the SVGL mode, ensure that the corresponding profile is created and a range of multicast groups that are permitted or denied by the filter is specified. For details about profile configuration, see 1.6.4 Configuring a Profile.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the IPv6 MLD snooping function and run the SVGL mode.

ipv6 mld snooping svgl

MLD snooping is disabled by default.

(4) Configure multicast groups associated with the SVGL mode.

ipv6 mld snooping svgl profile *profile-number*

No multicast group is associated with the SVGL mode by default.

(5) (Optional) Specify a shared VLAN.

ipv6 mld snooping svgl vlan *vlan-id*

The default shared VLAN in SVGL mode is VLAN 1.

1.3.6 Configuring Basic MLD Snooping Functions in IVGL-SVGL Mode

1. Overview

The IVGL-SVGL mode is also called the hybrid mode. In IVGL-SVGL mode, the device running MLD snooping can provide both shared and independent multicast services for user VLANs.

- In the shared VLAN and sub VLANs, shared multicast services apply to the multicast traffic of multicast groups applied in SVGL mode, and independent multicast services apply to other multicast traffic.
- In other VLANs (except the shared VLAN and sub VLANs), independent multicast services are provided.

2. Restrictions and Guidelines

- After configuring the IVGL-SVGL mode, you must specify the multicast groups associated with the SVGL mode.
- When a user VLAN is configured as a shared VLAN or sub VLAN, the user VLAN enjoys both shared and independent multicast services. When a user VLAN is configured as other VLANs, it enjoys only independent multicast services.

3. Prerequisites

Before configuring multicast groups associated with the SVGL mode, ensure that the corresponding profile is created and a range of multicast groups that are permitted or denied by the filter is specified. For details about profile configuration, see 1.6.4 Configuring a Profile.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the IPv6 MLD snooping function and run the IVGL-SVGL mode.

ipv6 mld snooping ivgl-svgl

MLD snooping is disabled by default.

(4) (Optional) Specify a shared VLAN.

ipv6 mld snooping svgl vlan *vlan-id*

The default shared VLAN in SVGL mode is VLAN 1.

1.4 Configuring the MLD Snooping Version

1.4.1 Overview

You can configure the MLD snooping version to specify the version of MLD packets that can be processed by the device running MLD snooping.

- When MLD snooping v2 is configured, the device can process all information in MLDv1 and MLDv2 packets.
- When MLD snooping v1 is configured, the device does not process source information carried in MLDv2 packets.

1.4.2 Restrictions and Guidelines

When the version is changed, the corresponding MLD snooping dynamic forwarding entries will be deleted.

1.4.3 Prerequisites

Configuring Basic MLD Snooping Functions

1.4.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the MLD snooping version.

ipv6 mld snooping version { **1** | **2** }

MLD snooping v1 is run by default.

1.5 Configuring Protocol Packet Processing Parameters

1.5.1 Overview

By controlling protocol packet processing, an L2 multicast device can establish static or dynamic multicast forwarding entries. In addition, the device can adjust parameters to refresh dynamic multicast forwarding entries and MLD snooping membership quickly.

1.5.2 Restrictions and Guidelines

Configuring Basic MLD Snooping Functions Related configuration functions take effect only after basic MLD snooping functions are configured.

1.5.3 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Static Multicast Router Port
- Configuring a Static Member Port
- Configuring Report Packet Suppression
- Configuring Port Fast Leave
- Configuring Dynamic Multicast Router Port Learning
- Configuring the Aging Time for Dynamic Multicast Router Ports
- Configuring the Aging Time for Dynamic Member Ports
- Configuring the Maximum Response Time for Query Packets

1.5.4 Configuring a Static Multicast Router Port

1. Overview

A multicast router port is used to receive uplink multicast data and forward MLD Report and Leave packets. Static multicast router ports never age and can forward MLD Report and Leave packets to the uplink MLD querier stably.

2. Restrictions and Guidelines

- In SVGL mode, if no sub VLAN is configured, the configuration of static multicast router ports is valid only in the shared VLAN. In other VLANs, static multicast router ports can be configured but do not take effect. If sub VLANs are configured, the configuration of static multicast router ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static multicast router ports can be configured but do not take effect.
- In SVGL-IVGL mode, if no sub VLAN is configured, the configuration of static multicast router ports is valid in all VLANs. If sub VLANs are configured, the configuration of static multicast router ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static multicast router ports can be configured but do not take effect.
- In IVGL mode, the configuration of static multicast router ports is valid in all VLANs.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a static multicast router port.

ipv6 mld snooping vlan *vlan-id* **mrouter interface** *interface-type interface-number*

No static multicast router port is configured by default.

1.5.5 Configuring a Static Member Port

1. Overview

When a member port connecting to a member host is configured as a static member port, the host can receive multicast traffic from the specified multicast group no matter whether the host joins the multicast group. Static member ports never age.

2. Restrictions and Guidelines

- In SVGL mode, if no sub VLAN is configured, the configuration of static member ports is valid only in the shared VLAN. In other VLANs, static member ports can be configured but do not take effect. If sub VLANs are configured, the configuration of static member ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static member ports can be configured but do not take effect.
- In SVGL-IVGL mode, if no sub VLAN is configured, the configuration of static member ports is valid in all VLANs. If sub VLANs are configured, the configuration of static member ports is valid in the shared VLAN and non-sub VLANs. In sub VLANs, static member ports can be configured but do not take effect.
- In IVGL mode, the configuration of static member ports is valid in all VLANs.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a static member port.

ipv6 mld snooping vlan *vlan-id* **static** *ipv6-group-address* **interface** *interface-type interface-number*

No static member port is configured by default.

1.5.6 Configuring Report Packet Suppression

1. Overview

MLD Query and Report packets are exchanged periodically to maintain the group membership. When many hosts in a network join the same multicast group, many MLD packets will be sent to the MLD multicast device, which wastes network bandwidth and affects the performance of the MLD multicast device. Report packet suppression can optimize this situation.

When Report packet suppression is configured, the MLD multicast device forwards only the first Report packet from a specific VLAN for a multicast group to the multicast router port and suppresses subsequent Report

packets for the same multicast group during one query interval. This function helps reduce the number of packets in the network.

2. Restrictions and Guidelines

Only MLDv1 Report packets can be suppressed, and MLDv2 Report packets cannot be suppressed.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure Report packet suppression.

ipv6 mld snooping suppression enable

Report packet suppression is disabled by default.

1.5.7 Configuring Port Fast Leave

1. Overview

When the port fast leave function is enabled and a port receives a Leave packet (including the MLDv1 Leave packet and MLDv2 Report packet of the INCLUDE type without carrying any source address), the port is directly deleted from the member port list of the corresponding multicast forwarding entry. When receiving group-specific Query packets and multicast data, the device does not forward the packets to this port.

2. Restrictions and Guidelines

The port fast leave function is applicable when only one host is connected to each port. This function helps save bandwidth and resources.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the port fast leave function.

ipv6 mld snooping fast-leave enable

The port fast leave function is disabled by default.

1.5.8 Configuring Dynamic Multicast Router Port Learning

1. Overview

In some test scenarios, a user host may send Query packets and PIMv6 neighbor messages. When the L2 device receives such Query packets or PIM neighbor messages, the L2 device will set the port receiving the packets as a dynamic multicast router port. All multicast packets in the VLAN will be forwarded to this port, and the host receives a large number of useless multicast packets. In addition, Query packets and PIMv6 neighbor messages sent by user hosts may affect the status of the L3 multicast routing protocol, such as the querier and

designated router (DR) election. In this case, you can disable dynamic multicast router port learning to resolve this problem and improve network security.

2. Restrictions and Guidelines

Disabling dynamic multicast router port learning and enabling a static multicast router port do not affect each other.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure dynamic multicast router port learning.

ipv6 mld snooping [**vlan** *vlan-id*] **mrouter learn**

Dynamic multicast router port learning is enabled by default.

1.5.9 Configuring the Aging Time for Dynamic Multicast Router Ports

1. Overview

A multicast router port is used to receive uplink multicast data and forward MLD Report and Leave packets. After enabling MLD snooping, an L2 device can dynamically learn multicast router ports to forward multicast packets for the unplink device. If a dynamic multicast router port does not receive a Query packet or neighbor message from the uplink device within the aging time due to unstable network or packet congestion, the L2 device will delete the dynamic multicast router port, which may cause multicast data interruption.

2. Restrictions and Guidelines

You can adjust the aging time of dynamic multicast router ports based on the network load. When the network load is heavy, set the aging time to a larger value. A too short aging time may cause dynamic multicast router ports to be added and deleted frequently, resulting in data interruption.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the aging time for dynamic multicast router ports.

ipv6 mld snooping dyn-mr-aging-time *dynamic-mroute-aging-time*

The default aging time of dynamic multicast router ports is 300s.

1.5.10 Configuring the Aging Time for Dynamic Member Ports

1. Overview

When the device running MLD snooping receives an MLD Join packet from a host to join an IP multicast group, the device adds the port receiving the packet to the member port list and sets an aging time for the port. If the

port is already in the member port list, the device resets the aging timer of the port. If the timer times out, it is deemed that no user host receives multicast packets through this port, and the multicast device deletes the port from the MLD snooping member port list.

2. Restrictions and Guidelines

- You can adjust the aging time of dynamic member ports based on the network load. When the network load is heavy, set the aging time to a larger value. A too short aging time may cause dynamic member ports to be added and deleted frequently, resulting in data interruption.
- After this command is configured, the aging timer value of dynamic member ports is *host-aging-time* for subsequent MLD Join packets. The aging time takes effect immediately after configuration and the started member port timers are updated.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the aging time for dynamic member ports.

ipv6 mld snooping host-aging-time *host-aging-time*

The default aging time of dynamic member ports is 260s.

1.5.11 Configuring the Maximum Response Time for Query Packets

1. Overview

When hosts in the directly-connected network segment of the device serving as the MLD snooping querier receive a Query packet from the device, the hosts need to return a Report packet within the maximum response time. This function allows you to configure the maximum response time for Query packets on the device. If no host returns a Report packet within the maximum response time, the device considers that no group member exists in the directly-connected network segment and deletes the group information.

2. Restrictions and Guidelines

- When receiving an MLD general Query packet, the multicast device will update the aging timers of all member ports. The timer time is the maximum response time for Query packets. After the timer expires, the device regards that no group member receives multicast traffic through a port and deletes the port from the MLD snooping forwarding table.
- When receiving an MLD group-specific Query packet, the multicast device will start the aging timers of all member ports of the specific group. The timer time is the maximum response time for Query packets. After the timer expires, the device regards that no group member receives multicast traffic through a port and deletes the port from the MLD snooping forwarding table.
- For MLDv2 group-specific Query packets, the multicast device does not update the timers.
- The configured maximum response time for Query packets takes effect when the next Query packet is received.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the maximum response time for Query packets.

ipv6 mld snooping query-max-response-time *query-max-response-time*

The maximum response time for Query packets is 10s by default.

1.6 Configuring Multicast Security Control

1.6.1 Overview

After multicast security control is configured, the device running MLD snooping can control the multicast service scope and load to prevent invalid multicast traffic and improve L2 multicast network security.

1.6.2 Prerequisites

Configuring Basic MLD Snooping Functions

1.6.3 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Profile
- Configuring Multicast Group Filtering on a Port
- Configuring the Maximum Number of Multicast Groups That Can Be Dynamically Learned by a Port
- Configuring Source Port Check

1.6.4 Configuring a Profile

1. Overview

A profile is used to define a range of multicast groups that permit or deny user access for reference by other functions.

- When the SVGL mode is enabled, a profile is used to define a range of multicast groups applied in SVGL mode.
- When multicast filtering is configured on a port, a profile is used to define a range of multicast groups that permit or deny user access through the port.
- When multicast filtering is configured on a VLAN, a profile is used to define a range of multicast groups that permit or deny user access on the VLAN.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a profile.

ipv6 mld profile *profile-number*

No profile is created by default.

(4) Define a range of multicast groups for a profile.

range *start-ipv6-address* [*end-ipv6-address*]

No multicast group range is defined for a profile by default.

Multiple multicast group ranges can be configured at the same time. If two multicast group ranges overlap, the ranges will be merged automatically.

(5) Configure the filtering action for a profile. The configuration steps below are mutually exclusive. Please configure only one task.

- Set the filtering action of a profile to Deny.

  deny

  If only the Deny action is configured and no multicast group range is configured, no group is denied. The effect is the same as permitting all groups.

- Set the filtering action of a profile to Permit.

  permit

  If only the Permit action is configured and no multicast group range is configured, no group is permitted. The effect is the same as denying all groups.

The Deny action is performed for a profile by default.

1.6.5 Configuring Multicast Group Filtering on a Port

1. Overview

Generally, the device running ports can join any multicast group. By configuring a range of multicast groups that permit or deny user access, you can customize the multicast service scope for users to guarantee the interest of operators and prevent invalid multicast traffic.

2. Restrictions and Guidelines

By applying a profile to a port, you can restrict the multicast groups that users can join on the port.

3. Prerequisites

Before configuring a range of multicast groups for a profile, ensure that the corresponding profile is created and a range of multicast groups that are permitted or denied by the filter is specified. For details about profile configuration, see 1.6.4 Configuring a Profile.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure multicast group filtering on a port.

ipv6 mld snooping filter *profile-number*

The multicast group filtering function is disabled on a port by default.

1.6.6 Configuring the Maximum Number of Multicast Groups That Can Be Dynamically Learned by a Port

1. Overview

If too much multicast traffic is requested concurrently, the multicast device will be severely burdened. Configuring the maximum number of multicast groups allowed for concurrent request can guarantee the bandwidth. You can limit the number of multicast groups allowed for concurrent request on a port.

2. Restrictions and Guidelines

Only dynamically learned multicast groups on a port are counted. Statically configured multicast groups are excluded.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure the maximum number of multicast groups that can be dynamically learned by a port.

ipv6 mld snooping max-groups *max-groups-number*

The maximum number of multicast groups that can be dynamically learned by a port is 64,000 by default.

1.6.7 Configuring Source Port Check

1. Overview

The source port check function restricts users to receive only multicast traffic on multicast router ports to prevent users from sending invalid multicast traffic.

- After the source port check function is enabled, only multicast traffic received on multicast router ports is

valid. Multicast traffic received on other ports is invalid and will be discarded.

- When the source port check function is disabled, multicast traffic received on any port is valid.

2. Restrictions and Guidelines

- To restrict users to receive multicast traffic only on multicast router ports, configure this function.
- If no multicast router port exists after the source port check function is enabled, the device will discard received multicast traffic.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure source port check.

ipv6 mld snooping source-check port

Source port check is disabled by default.

1.7 Configuring QinQ Processing

1.7.1 Overview

On a device with MLD snooping enabled and a dot1q-tunnel (QinQ) port configured, MLD snooping will process the MLD packets received on the QinQ port using the following two modes:

- Mode 1: Create multicast entries on the VLAN where the MLD packets are located. Forwarding MLD packets on the VLAN where these packets are located is called transparent transmission. For example, MLD snooping is enabled for a device, Port A on the device is designated as the QinQ port, the default VLAN of this port is VLAN 1, and Port A allows the passage of VLAN 1 and VLAN 10 packets. When an MLD Report packet is sent from VLAN 10 to Port A, MLD snooping establishes a multicast entry for VLAN 10 and forwards the MLD Report packet to the multicast router port of VLAN 10.
- Mode 2: Create multicast entries on the default VLAN of the QinQ port. Encapsulate the MLD packets with the VLAN tag of the default VLAN where the QinQ port is located and forward the packets within the default VLAN. For example, MLD snooping is enabled for a device, Port A on the device is designated as the QinQ port, the default VLAN of this port is VLAN 1, and Port A allows the passage of VLAN 1 and VLAN 10 packets. When an MLD Report packet is sent from VLAN 10 to Port A, MLD snooping establishes a multicast entry for VLAN 1, encapsulates the MLD Report packet with the tag of VLAN 1, and forwards the packet to the multicast router port of VLAN 1.

1.7.2 Restrictions and Guidelines

If the QinQ port needs to forward multicast packets on the VLANs specified by the VLAN IDs (VIDs) of the packets, transparent packet transmission needs to be configured on the QinQ port.

1.7.3 Prerequisites

- Configuring Basic MLD Snooping Functions.

- Configure basic QinQ functions. For details about QinQ configuration, see *Configuring QinQ*.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure transparent packet transmission on the QinQ port.

ipv6 mld snooping tunnel

The function of transparent MLD packet transmission on the QinQ port is disabled by default.

1.8 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

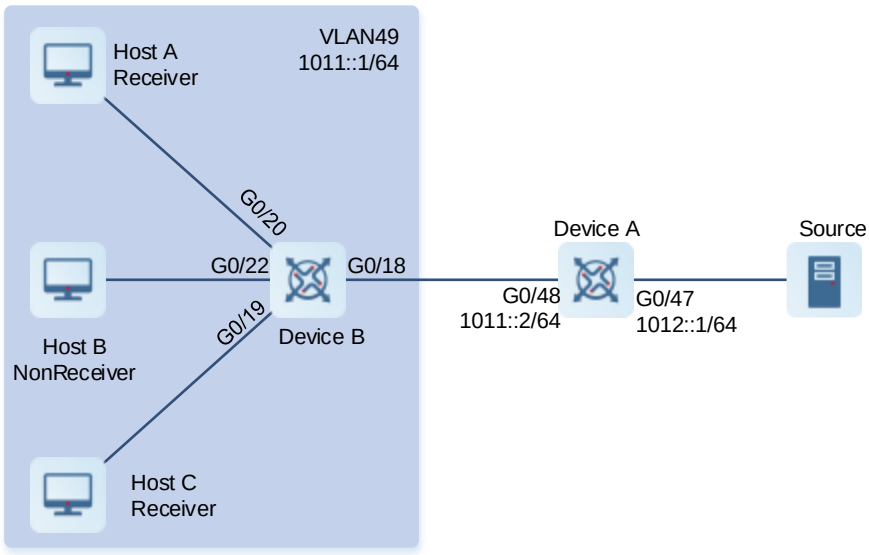
Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
clear ipv6 mld snooping gda-table	Clears MLD snooping multicast forwarding entries.
clear ipv6 mld snooping statistics	Clears MLD snooping statistics.
show ipv6 mld snooping	Displays the current MLD snooping mode.
show ipv6 mld snooping exclude-source	Displays the excluded source node list of Multicast Listener Discovery Version 2 (MLDv2) snooping.
show ipv6 mld snooping gda-table	Displays MLD snooping forwarding entries.
show ipv6 mld snooping statistics	Displays MLD snooping statistics.
show ipv6 mld snooping mrouter	Displays MLD snooping multicast router ports.
show ipv6 mld snooping interfaces [*interface-type interface-type interface-number*]	Displays MLD snooping interface information, interface filtering profile, and maximum number of multicast groups that can be dynamically learned by a port.
show ipv6 mld snooping vlan *vlan-id*	Displays multicast information about a single VLAN, on which MLD snooping is configured.
show ipv6 mld profile *profile-number*	Displays an MLD profile.

1.9 Configuration Examples



1.9.1 Configuring Basic MLD Snooping Functions in IVGL Mode

1. Requirements

In the multicast network shown in Figure 1-5, the router (Device A) connects to the user network through the switch (Device B), and MLD snooping is run on Device A. The multicast source sends data to multicast group FF14::10. There are three hosts (Host A, Host B, and Host C) in the network. Host A and Host C join multicast group FF14::10. Only Host A and Host B can receive multicast data that the multicast source sends to multicast group FF14::10.

2. Topology

Figure 1-5 Topology of Basic MLD Snooping Functions in IVGL Mode

3. Notes

Configure basic MLD snooping functions on Device B.

- Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and PIM-SMv6 related functions on Device A.
- Enable MLD snooping and run the IVGL mode on Device B.

4. Procedure

(1) Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IPv6 address and unicast routing protocol on Device A.

```
DeviceA> enable
DeviceA# configure terminal
```

```
DeviceA(config)# interface GigabitEthernet 0/47
DeviceA(config-if-GigabitEthernet 0/47)# no switchport
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 address 1012::1/64
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/47)# exit
DeviceA(config)# interface GigabitEthernet 0/48
DeviceA(config-if-GigabitEthernet 0/48)# no switchport
DeviceA(config-if-GigabitEthernet 0/48)# ipv6 address 1011::2/64
DeviceA(config-if-GigabitEthernet 0/48)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/48)# exit
DeviceA(config)# ipv6 router ospf 4949
DeviceA(config-router)# exit
```

Configure the IPv6 address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# vlan 49
DeviceB(config-vlan)# exit
DeviceB(config)# interface vlan 49
DeviceB(config-if-VLAN 49)# ipv6 address 1011::1/64
DeviceB(config-if-VLAN 49)# ipv6 ospf 4949 area 0
DeviceB(config-if-VLAN 49)# exit
DeviceB(config)# interface GigabitEthernet 0/18
DeviceB(config-if-GigabitEthernet 0/18)# switchport access vlan 49
DeviceB(config-if-GigabitEthernet 0/18)# exit
DeviceB(config)# interface GigabitEthernet 0/19
DeviceB(config-if-GigabitEthernet 0/19)# switchport access vlan 49
DeviceB(config-if-GigabitEthernet 0/19)# exit
DeviceB(config)# interface GigabitEthernet 0/20
DeviceB(config-if-GigabitEthernet 0/20)# switchport access vlan 49
DeviceB(config-if-GigabitEthernet 0/20)# exit
DeviceB(config)# interface GigabitEthernet 0/22
DeviceB(config-if-GigabitEthernet 0/22)# switchport access vlan 49
DeviceB(config-if-GigabitEthernet 0/22)# exit
DeviceB(config)# ipv6 router ospf 4949
DeviceB(config-router)# exit
```

(2) Enable multicast routing and PIM-SMv6 related functions on Device A.

```
DeviceA(config)# ipv6 multicast-routing
DeviceA(config)# interface GigabitEthernet 0/47
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/47)# exit
DeviceA(config)# interface GigabitEthernet 0/48
DeviceA(config-if-GigabitEthernet 0/48)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/48)# exit
DeviceA(config)# ipv6 pim bsr-candidate GigabitEthernet 0/47
DeviceA(config)# ipv6 pim rp-candidate GigabitEthernet 0/47
```

(3) Enable MLD snooping and run the IVGL mode on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ipv6 mld snooping ivgl
```

5. Verification

Send packets from the multicast source (1012::2) to multicast group G (FF14::10). Enable Host A and Host C to join G.

Run the **show ipv6 mld snooping gda-table** command on Device B to display the MLD snooping forwarding entry and check whether the member port list contains only GigabitEthernet 0/19 and GigabitEthernet 0/20.

```
DeviceB# show ipv6 mld snooping gda-table
Multicast Switching Cache Table
  D: DYNAMIC
  S: STATIC
  M: MROUTE
(*, FF14::10, 49):
  VLAN(49) 3 OPORTS:
    GigabitEthernet 0/18(M)
    GigabitEthernet 0/19(M)
    GigabitEthernet 0/20(DM)

DeviceB#
```

Run the **show ipv6 mld snooping** command on Device B and check whether the MLD snooping working mode is IVGL.

```
DeviceB# show ipv6 mld snooping
MLD-snooping mode: IVGL
Source port check: Disable
MLD Fast-Leave: Disable
MLD Report suppress: Disable
Query Max Response Time: 10 (Seconds)
Dynamic Mroute Aging Time: 300(Seconds)
Dynamic Host Aging Time: 260(Seconds)
MLD Snooping version: 1
MLD Tunnel: Disable

vlan 49
-------------
MLD Snooping state: Enabled
Multicast router learning mode: Enable
MLD Fast-Leave: Enabled
MLD VLAN Mode: STATIC
DeviceB#
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ipv6 multicast-routing
!
interface GigabitEthernet 0/47
 no switchport
 ipv6 address 1012::1/64
 ipv6 ospf 4949 area 0
ipv6 pim sparse-mode
!
interface GigabitEthernet 0/48
 no switchport
ipv6 address 1011::2/64
ipv6 ospf 4949 area 0
ipv6 pim sparse-mode
!
ipv6 router ospf 4949
graceful-restart
!
ipv6 pim bsr-candidate GigabitEthernet 0/47
ipv6 pim rp-candidate GigabitEthernet 0/47
!
```

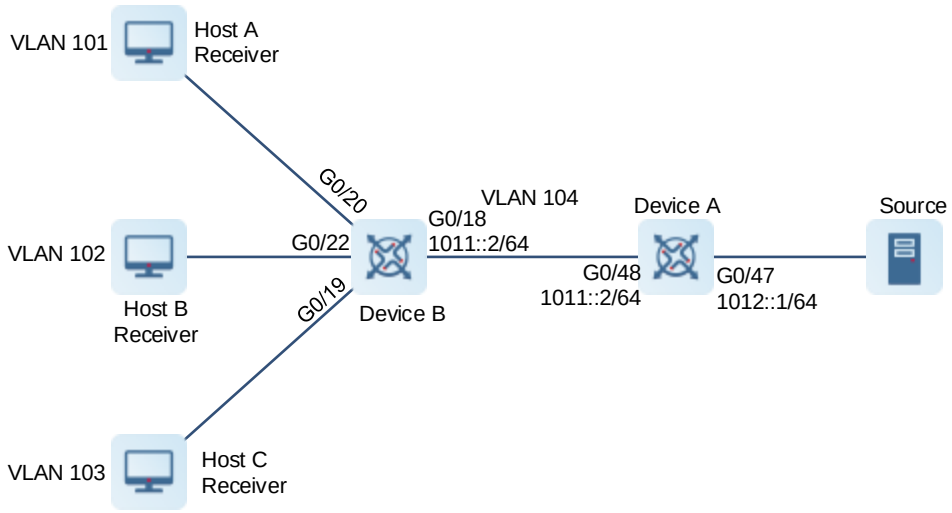
- Device B configuration file

```
hostname DeviceB
!
vlan range 1,49
!
interface GigabitEthernet 0/18
 switchport access vlan 49
!
interface GigabitEthernet 0/19
 switchport access vlan 49
!
interface GigabitEthernet 0/20
 switchport access vlan 49
!
interface GigabitEthernet 0/22
 switchport access vlan 49
!
interface VLAN 49
 ipv6 address 1011::1/64
 ipv6 ospf 4949 area 0
!
```

```
ipv6 router ospf 4949
graceful-restart
!
ipv6 mld snooping ivgl
!
```

7. Common Errors

- The working mode of MLD snooping is improper.



1.9.2 Configuring Basic MLD Snooping Functions in SVGL Mode

1. Requirements

In the multicast network shown in Figure 1-6, the router (Device A) connects to the user network through the switch (Device B), MLD snooping is run on Device A, and Device A directly connects to the multicast source. The multicast source sends data to multicast group FF14::10. Host A, Host B, and Host C are connected to VLAN 101, VLAN 102, and VLAN 103, respectively, and the three hosts join multicast group FF14::10. Host A, Host B, and Host C can receive multicast data that the multicast source sends to multicast group FF14::10.

2. Topology

Figure 1-6 Topology of Basic MLD Snooping Functions in SVGL Mode

3. Notes

Configure basic MLD snooping functions on Device B.

- Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and PIM-SMv6 related functions on Device A.
- Enable MLD snooping and run the SVGL mode on Device B.
- Configure the multicast groups associated with the MLD snooping SVGL mode on Device B and specify the shared VLAN and sub VLANs.

4. Procedure

(1) Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IP address and unicast routing protocol on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface GigabitEthernet 0/47
DeviceA(config-if-GigabitEthernet 0/47)# no switchport
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 address 1012::1/64
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/47)# exit
DeviceA(config)# vlan 104
DeviceA(config)# interface vlan 104
DeviceA(config-if-VLAN 104)# ipv6 address 1011::2/64
DeviceA(config-if-VLAN 104)# ipv6 ospf 4949 area 0
DeviceA(config-if-VLAN 104)# exit
DeviceA(config)# interface GigabitEthernet 0/48
DeviceA(config-if-GigabitEthernet 0/48)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/48)# switchport trunk native vlan 104
DeviceA(config-if-GigabitEthernet 0/48)# exit
DeviceA(config)# ipv6 router ospf 4949
DeviceA(config-router)# exit
```

Configure the IPv6 address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# vlan range 101-104
DeviceB(config-vlan-range)# exit
DeviceB(config)# interface VLAN 101
DeviceB(config-if-VLAN 101)# ipv6 address 1010::1/64
DeviceB(config-if-VLAN 101)# ipv6 ospf 4949 area 0
DeviceB(config-if-VLAN 101)# exit
DeviceB(config)# interface VLAN 102
DeviceB(config-if-VLAN 102)# ipv6 address 1020::1/64
DeviceB(config-if-VLAN 102)# ipv6 ospf 4949 area 0
DeviceB(config-if-VLAN 102)# exit
DeviceB(config)# interface VLAN 103
DeviceB(config-if-VLAN 103)# ipv6 address 1030::1/64
DeviceB(config-if-VLAN 103)# ipv6 ospf 4949 area 0
DeviceB(config-if-VLAN 103)# exit
DeviceB(config)# interface VLAN 104
DeviceB(config-if-VLAN 104)# ipv6 address 1011::2/64
DeviceB(config-if-VLAN 104)# ipv6 ospf 4949 area 0
DeviceB(config-if-VLAN 104)# exit
DeviceB(config)# interface GigabitEthernet 0/18
DeviceB(config-if-GigabitEthernet 0/18)# switchport mode trunk
```

```
DeviceB(config-if-GigabitEthernet 0/18)# switchport trunk native vlan 104
DeviceB(config-if-GigabitEthernet 0/18)# exit
DeviceB(config)# interface GigabitEthernet 0/19
DeviceB(config-if-GigabitEthernet 0/19)# switchport access vlan 103
DeviceB(config-if-GigabitEthernet 0/19)# exit
DeviceB(config)# interface GigabitEthernet 0/20
DeviceB(config-if-GigabitEthernet 0/20)# switchport access vlan 101
DeviceB(config-if-GigabitEthernet 0/20)# exit
DeviceB(config)# interface GigabitEthernet 0/22
DeviceB(config-if-GigabitEthernet 0/22)# switchport access vlan 102
DeviceB(config-if-GigabitEthernet 0/22)# exit
DeviceB(config)# ipv6 router ospf 4949
DeviceB(config-router)# exit
```

(2) Enable multicast routing and PIM-SM related functions on Device A.

```
DeviceA(config)# ipv6 multicast-routing
DeviceA(config)# interface GigabitEthernet 0/47
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/47)# exit
DeviceA(config)# interface vlan 104
DeviceA(config-if-VLAN 104)# ipv6 pim sparse-mode
DeviceA(config-if-VLAN 104)# exit
DeviceA(config)# ipv6 pim bsr-candidate GigabitEthernet 0/47
DeviceA(config)# ipv6 pim rp-candidate GigabitEthernet 0/47
```

(3) Enable MLD snooping and run the IVGL mode on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ipv6 mld snooping svgl
```

(4) Configure the multicast groups associated with the MLD snooping SVGL mode on Device B and specify the shared VLAN.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ipv6 mld profile 1
DeviceB(config-profile)# permit
DeviceB(config-profile)# range ff13::1 ff14::fff
DeviceB(config-profile)# exit
DeviceB(config)# ipv6 mld snooping svgl profile 1
DeviceB(config)# ipv6 mld snooping svgl vlan 104
```

5. Verification

Send packets from the multicast source (1012::2) to multicast group G (FF14::10). Enable Host A, Host B, and Host C to join G.

Run the **show ipv6 mld snooping gda-table** command on Device B to display the MLD snooping forwarding entry and check whether the member port list contains GigabitEthernet 0/19, GigabitEthernet 0/20, and GigabitEthernet 0/22.

```
DeviceB# show ipv6 mld snooping gda-table
Multicast Switching Cache Table
  D: DYNAMIC
  S: STATIC
  M: MROUTE
(*, FF14::10, 104):
  VLAN(104) 1 OPORTS:
    GigabitEthernet 0/18(M)

  VLAN(101) 1 OPORTS:
    GigabitEthernet 0/20(D)

  VLAN(103) 1 OPORTS:
    GigabitEthernet 0/19(D)

  VLAN(102) 1 OPORTS:
    GigabitEthernet 0/22(D)

DeviceB#
```

Run the **show ipv6 mld snooping** command on Device B and check whether the MLD snooping working mode is SVGL.

```
DeviceB# show ipv6 mld snooping
MLD-snooping mode: SVGL
SVGL vlan: 104
SVGL profile number: 1
Source port check: Disable
MLD Fast-Leave: Disable
MLD Report suppress: Disable
Query Max Response Time: 10 (Seconds)
Dynamic Mroute Aging Time: 300(Seconds)
Dynamic Host Aging Time: 260(Seconds)
MLD Snooping version: 1
MLD Tunnel: Disable
DeviceB#
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA

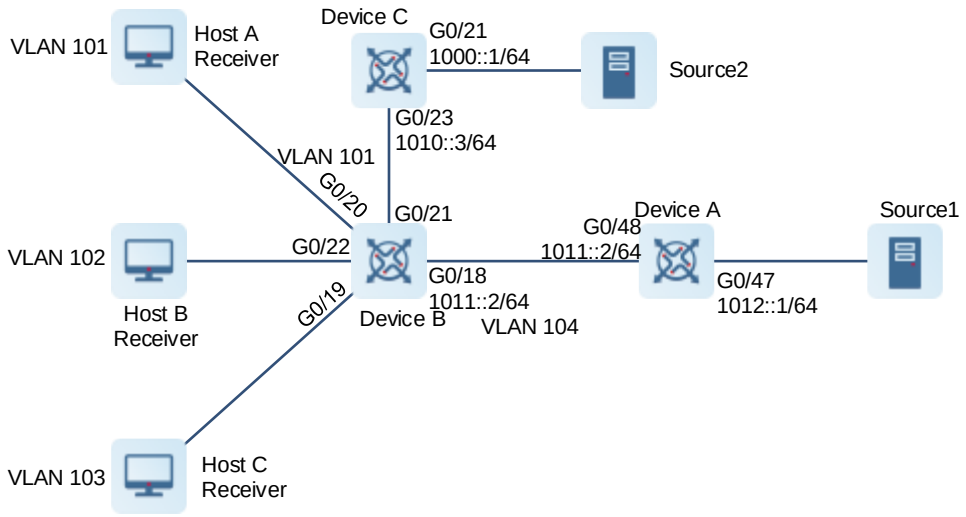
7. Common Errors

- The multicast groups associated with the SVGL mode are not configured.
- The address of the sent multicast traffic is not within the range of multicast groups associated with the SVGL mode.



1.9.3 Configuring Basic MLD Snooping Functions in IVGL-SVGL Mode

1. Requirements

In the multicast network shown in Figure 1-7, the routers (Device A and Device C) connect to the user network through the switch (Device B), MLD snooping is run on Device A and Device C, and Device A and Device C directly connect to the multicast sources. Multicast source 1 sends data to multicast group FF14::10, and multicast source 2 sends data to multicast group FF15::11. Host A, Host B, and Host C are connected to VLAN 101, VLAN 102, and VLAN 103, respectively. Host B and Host C join multicast group FF14::10, and Host A joins multicast groups FF14::10 and FF15::11. Host B and Host C can receive multicast data that source 1 sends to multicast group FF14::10, and Host A can receive multicast data that source 1 sends to multicast group FF14::10 and multicast data that source 2 sends to multicast group FF15::11. Host A, Host B, and Host C enjoy shared multicast services, and Host A also enjoy independent multicast services.

2. Topology

Figure 1-7 Topology of Basic MLD Snooping Functions in IVGL-SVGL Mode

3. Notes

Configure basic MLD snooping functions in IVGL-SVGL mode on Device B.

- Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and PIM-SMv6 related functions on Device A and Device C.
- Enable MLD snooping and run the IVGL-SVGL mode on Device B.
- Configure the multicast groups associated with the MLD snooping SVGL mode on Device B and specify the shared VLAN and sub VLANs.

4. Procedure

(1) Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IPv6 address and unicast routing protocol on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface GigabitEthernet 0/47
DeviceA(config-if-GigabitEthernet 0/47)# no switchport
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 address 1012::1/64
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/47)# exit
DeviceA(config)# vlan 104
DeviceA(config)# interface vlan 104
DeviceA(config-if-VLAN 104)# ipv6 address 1011::2/64
DeviceA(config-if-VLAN 104)# ipv6 ospf 4949 area 0
DeviceA(config-if-VLAN 104)# exit
DeviceA(config)# interface GigabitEthernet 0/48
```

```
DeviceA(config-if-GigabitEthernet 0/48)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/48)# switchport trunk native vlan 104
DeviceA(config-if-GigabitEthernet 0/48)# exit
DeviceA(config)# ipv6 router ospf 4949
DeviceA(config-router)# exit
```

Configure the IPv6 address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# vlan range 101-104
DeviceB(config-vlan-range)# exit
DeviceB(config)# interface VLAN 101
DeviceB(config-if-VLAN 101)# ipv6 address 1010::1/64
DeviceB(config-if-VLAN 101)# ipv6 ospf 4949 area 0
DeviceB(config-if-VLAN 101)# exit
DeviceB(config)# interface VLAN 102
DeviceB(config-if-VLAN 102)# ipv6 address 1020::1/64
DeviceB(config-if-VLAN 102)# ipv6 ospf 4949 area 0
DeviceB(config-if-VLAN 102)# exit
DeviceB(config)# interface VLAN 103
DeviceB(config-if-VLAN 103)# ipv6 address 1030::1/64
DeviceB(config-if-VLAN 103)# ipv6 ospf 4949 area 0
DeviceB(config-if-VLAN 103)# exit
DeviceB(config)# interface VLAN 104
DeviceB(config-if-VLAN 104)# ipv6 address 1011::2/64
DeviceB(config-if-VLAN 104)# ipv6 ospf 4949 area 0
DeviceB(config-if-VLAN 104)# exit
DeviceB(config)# interface GigabitEthernet 0/18
DeviceB(config-if-GigabitEthernet 0/18)# switchport mode trunk
DeviceB(config-if-GigabitEthernet 0/18)# switchport trunk native vlan 104
DeviceB(config-if-GigabitEthernet 0/18)# exit
DeviceB(config)# interface GigabitEthernet 0/19
DeviceB(config-if-GigabitEthernet 0/19)# switchport access vlan 103
DeviceB(config-if-GigabitEthernet 0/19)# exit
DeviceB(config)# interface GigabitEthernet 0/20
DeviceB(config-if-GigabitEthernet 0/20)# switchport access vlan 101
DeviceB(config-if-GigabitEthernet 0/20)# exit
DeviceB(config)# interface GigabitEthernet 0/21
DeviceB(config-if-GigabitEthernet 0/21)# switchport access vlan 101
DeviceB(config-if-GigabitEthernet 0/21)# exit
DeviceB(config)# interface GigabitEthernet 0/22
DeviceB(config-if-GigabitEthernet 0/22)# switchport access vlan 102
DeviceB(config-if-GigabitEthernet 0/22)# exit
DeviceB(config)# ipv6 router ospf 4949
DeviceB(config-router)# exit
```

Configure the IPv6 address and unicast routing protocol on Device C.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# interface GigabitEthernet 0/21
DeviceC(config-if-GigabitEthernet 0/21)# no switchport
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 address 1000::1/64
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/21)# exit
DeviceC(config)# interface GigabitEthernet 0/23
DeviceC(config-if-GigabitEthernet 0/23)# no switchport
DeviceC(config-if-GigabitEthernet 0/23)# ipv6 address 1010::3/64
DeviceC(config-if-GigabitEthernet 0/23)# ipv6 ospf 4949 area 0
DeviceC(config-if-GigabitEthernet 0/23)# exit
DeviceC(config)# ipv6 router ospf 4949
DeviceC(config-router)# exit
```

(2) Enable IPv6 multicast routing and PIM-SMv6 related functions on Device A and Device C.

Enable IPv6 multicast routing and PIM-SMv6 related functions on Device A.

```
DeviceA(config)# ipv6 multicast-routing
DeviceA(config)# interface GigabitEthernet 0/47
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/47)# exit
DeviceA(config)# interface vlan 104
DeviceA(config-if-VLAN 104)# ipv6 pim sparse-mode
DeviceA(config-if-VLAN 104)# exit
DeviceA(config)# ipv6 pim bsr-candidate GigabitEthernet 0/47
DeviceA(config)# ipv6 pim rp-candidate GigabitEthernet 0/47
```

Enable multicast routing and PIM-SMv6 related functions on Device C.

```
DeviceC(config)# ipv6 multicast-routing
DeviceC(config)# interface GigabitEthernet 0/21
DeviceC(config-if-GigabitEthernet 0/21)# no switchport
DeviceC(config-if-GigabitEthernet 0/21)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/21)# exit
DeviceC(config)# interface GigabitEthernet 0/23
DeviceC(config-if-GigabitEthernet 0/23)# ipv6 pim sparse-mode
DeviceC(config-if-GigabitEthernet 0/23)# exit
```

(3) Enable MLD snooping and run the IVGL-SVGL mode on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ipv6 mld snooping ivgl-svgl
```

(4) Configure the multicast groups associated with the MLD snooping SVGL mode on Device B and specify the shared VLAN.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ipv6 mld profile 1
DeviceB(config-profile)# permit
```

```
DeviceB(config-profile)# range ff13::1 ff14::fff
DeviceB(config-profile)# exit
DeviceB(config)# ipv6 mld snooping svgl profile 1
DeviceB(config)# ipv6 mld snooping svgl vlan 104
```

5. Verification

Run the **show ipv6 mld snooping gda-table** command on Device B to display the MLD snooping forwarding entries and check whether the member port list of entry (*, FF14::10, 104) contains GigabitEthernet 0/22, GigabitEthernet 0/20, and GigabitEthernet 0/19 and the member port list of entry (*, FF15::11, 101) contains GigabitEthernet 0/20.

```
DeviceB# show ipv6 mld snooping gda-table
Multicast Switching Cache Table
  D: DYNAMIC
  S: STATIC
  M: MROUTE
(*, FF15::11, 101):
  VLAN(101) 2 OPORTS:
    GigabitEthernet 0/20(D)
    GigabitEthernet 0/21(M)

(*, FF14::10, 104):
  VLAN(104) 1 OPORTS:
    GigabitEthernet 0/18(M)

  VLAN(103) 1 OPORTS:
    GigabitEthernet 0/19(D)

  VLAN(102) 1 OPORTS:
    GigabitEthernet 0/22(D)

  VLAN(101) 1 OPORTS:
    GigabitEthernet 0/20(D)

DeviceB#
```

Run the **show ipv6 mld snooping** command on Device B and check whether the MLD snooping working mode is IVGL-SVGL.

```
DeviceB# show ipv6 mld snooping
MLD-snooping mode: IVGL-SVGL
SVGL vlan: 104
SVGL profile number: 1

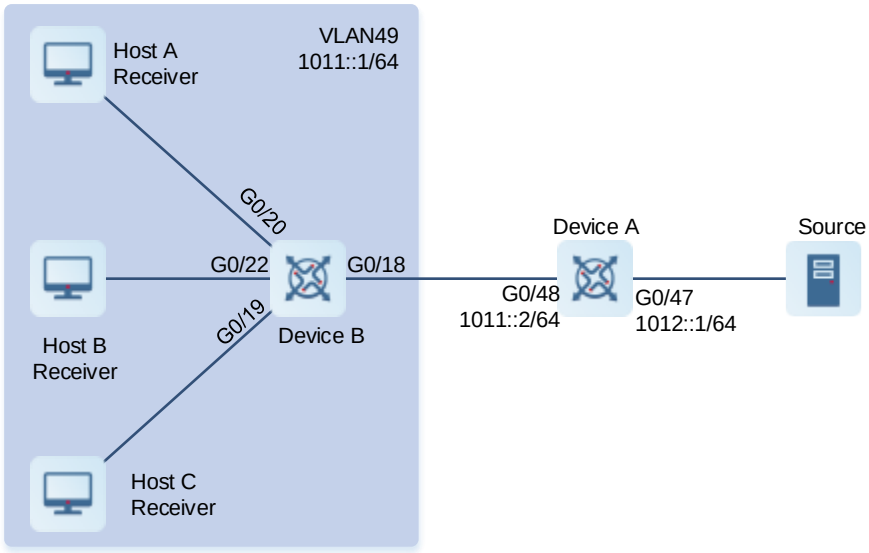
7. Common Errors

- The multicast groups associated with the SVGL mode are not configured.
- The address of sent multicast traffic is not within the range of multicast groups associated with the SVGL mode.
- The multicast group addresses of multicast traffic in IVGL mode are within the multicast group range in SVGL mode. As a result, IVGL forwarding cannot be implemented.



1.9.4 Configuring Static Ports to Implement L2 Multicast

1. Requirements

In the multicast network shown in Figure 1-8, Host A, Host B, and Host C need to receive data that a multicast source sends to a specific multicast group stably. The router (Device A) connects to the user network through the L2 device (Device B). The static MLD multicast groups FF14::10 to FF14::12 are configured on the user-side port on Device A. Host A and Host B want to receive data of multicast group FF14::10 stably, and Host C wants to receive data of multicast group FF14::11.

2. Topology

Figure 1-8 Topology of Static Ports to Implement L2 Multicast

3. Notes

Configure MLD snooping static multicast router ports and member ports on Device B.

- Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.
- Enable multicast routing and MLD static multicast groups on Device A.
- Enable MLD snooping on Device B.
- Configure static multicast router ports and member ports on Device B.

4. Procedure

(1) Configure the IPv6 addresses, VLANs, and unicast routing protocols of the network nodes to ensure reachability of the network nodes using unicast routing.

Configure the IPv6 address and unicast routing protocol on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface GigabitEthernet 0/47
DeviceA(config-if-GigabitEthernet 0/47)# no switchport
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 address 1012::1/64
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/47)# exit
DeviceA(config)# interface GigabitEthernet 0/48
DeviceA(config-if-GigabitEthernet 0/48)# no switchport
DeviceA(config-if-GigabitEthernet 0/48)# ipv6 address 1011::2/64
DeviceA(config-if-GigabitEthernet 0/48)# ipv6 ospf 4949 area 0
DeviceA(config-if-GigabitEthernet 0/48)# exit
DeviceA(config)# ipv6 router ospf 4949
DeviceA(config-router)# exit
```

Configure the IPv6 address, VLAN, and unicast routing protocol on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# vlan 49
DeviceB(config-vlan)# exit
DeviceB(config)# interface vlan 49
DeviceB(config-if-VLAN 49)# ipv6 address 1011::1/64
DeviceB(config-if-VLAN 49)# ipv6 ospf 4949 area 0
DeviceB(config-if-VLAN 49)# exit
DeviceB(config)# interface GigabitEthernet 0/18
DeviceB(config-if-GigabitEthernet 0/18)# switchport access vlan 49
DeviceB(config-if-GigabitEthernet 0/18)# exit
DeviceB(config)# interface GigabitEthernet 0/19
DeviceB(config-if-GigabitEthernet 0/19)# switchport access vlan 49
DeviceB(config-if-GigabitEthernet 0/19)# exit
DeviceB(config)# interface GigabitEthernet 0/20
DeviceB(config-if-GigabitEthernet 0/20)# switchport access vlan 49
DeviceB(config-if-GigabitEthernet 0/20)# exit
DeviceB(config)# interface GigabitEthernet 0/22
DeviceB(config-if-GigabitEthernet 0/22)# switchport access vlan 49
DeviceB(config-if-GigabitEthernet 0/22)# exit
DeviceB(config)# ipv6 router ospf 4949
DeviceB(config-router)# exit
```

(2) Enable IPv6 multicast routing and PIM-SMv6 related functions on Device A.

```
DeviceA(config)# ipv6 multicast-routing
DeviceA(config)# interface GigabitEthernet 0/47
```

```
DeviceA(config-if-GigabitEthernet 0/47)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/47)# exit
DeviceA(config)# interface GigabitEthernet 0/48
DeviceA(config-if-GigabitEthernet 0/48)# ipv6 mld static-group ff14::10
DeviceA(config-if-GigabitEthernet 0/48)# ipv6 mld static-group ff14::11
DeviceA(config-if-GigabitEthernet 0/48)# ipv6 mld static-group ff14::12
DeviceA(config-if-GigabitEthernet 0/48)# ipv6 pim sparse-mode
DeviceA(config-if-GigabitEthernet 0/48)# exit
DeviceA(config)# ipv6 pim bsr-candidate GigabitEthernet 0/47
DeviceA(config)# ipv6 pim rp-candidate GigabitEthernet 0/47
```

(3) Enable MLD snooping functions on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ipv6 mld snooping ivgl
```

(4) Configure static multicast router ports and member ports on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ipv6 mld snooping vlan 49 static ff14::11 interface
GigabitEthernet 0/19
DeviceB(config)# ipv6 mld snooping vlan 49 static ff14::10 interface
GigabitEthernet 0/22
DeviceB(config)# ipv6 mld snooping vlan 49 static ff14::10 interface
GigabitEthernet 0/20
DeviceB(config)# ipv6 mld snooping vlan 49 mrouter interface GigabitEthernet 0/18
```

5. Verification

Run the **show ipv6 mld snooping mrouter** command and check whether the static router port is GigabitEthernet 0/18.

```
DeviceB# show ipv6 mld snooping mrouter
Multicast Switching Mroute Port
  D: DYNAMIC
  S: STATIC
(*, *, 49):
  VLAN(49)  1 MROUTES:
    GigabitEthernet 0/18(DS)

(*, *, 101):
  VLAN(101)  1 MROUTES:
    GigabitEthernet 0/21(D)

DeviceB#
```

Run the **show ipv6 mld snooping gda-table** command and check whether the static member ports of multicast group FF14::10 are GigabitEthernet 0/20 and GigabitEthernet 0/22 and the static member port of multicast group FF14::11 is GigabitEthernet 0/19.

```
DeviceB# show ipv6 mld snooping gda-table
Multicast Switching Cache Table
  D: DYNAMIC
  S: STATIC
  M: MROUTE
(*, FF14::10, 49):
  VLAN(49) 3 OPORTS:
    GigabitEthernet 0/18(M)
    GigabitEthernet 0/20(S)
    GigabitEthernet 0/22(S)

(*, FF14::11, 49):
  VLAN(49) 2 OPORTS:
    GigabitEthernet 0/18(M)
    GigabitEthernet 0/19(S)

DeviceB#
```

6. Configuration Files

- Device A configuration file

```

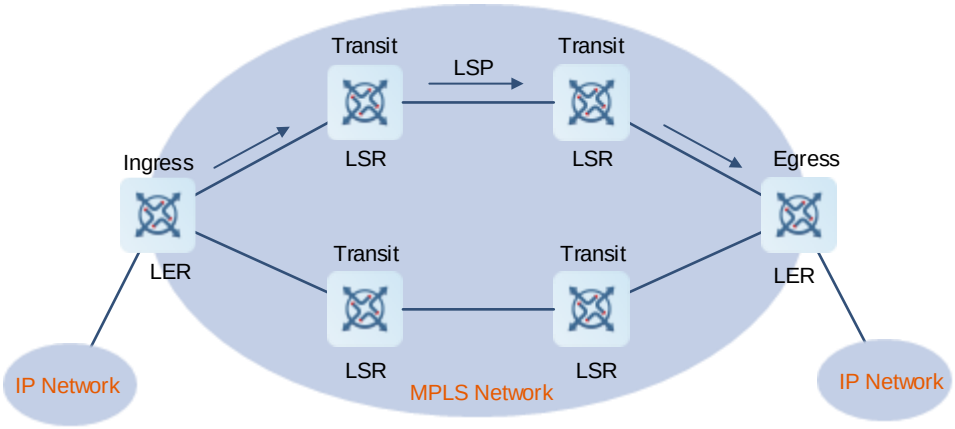
1 Configuring MPLS Basics

1.1 Introduction

Multiprotocol Label Switching (MPLS) is a tunneling technology that uses labels for efficient data transmission on backbone networks. MPLS supports multiple network layer protocols, such as Internet Protocol (IP), IPv6, and Internetwork Packet Exchange (IPX) and is compatible with various link layer technologies, such as Asynchronous Transfer Mode (ATM), frame relay, Ethernet, and Point-to-Point Protocol (PPP).



MPLS was first introduced to enhance the forwarding rate of routing devices. With MPLS, a device needs to analyze only the headers of forwarding IP packets at the MPLS network edge and does not need to analyze each hop on the MPLS network. This reduces the processing time when compared with traditional IP routing. With the development of hardware technologies and network processors, MPLS has gradually lost its appeal in efficient forwarding. However, MPLS provides connection-oriented label switching attributes to connectionless IP networks and integrates the flexibility of IP routing and the simplicity of L2 switching. Due to the innate advantage of combining L2 switching and L3 routing technologies, MPLS still has unprecedented edges over other technologies in terms of virtual private networks (VPNs) and traffic engineering (TE). Therefore, MPLS is widely used in VPN and TE scenarios.

1.1.1 MPLS Network Structure

An MPLS network comprises label edge routers (LERs) and label switching routers (LSRs).

- LERs are located at the edges of an MPLS network. An ingress LER classifies packets entering the MPLS network, adds labels to the packets, and encapsulates the packets into MPLS packets to forward. An egress LER pops the labels off outgoing MPLS packets and restores the packets to original ones. An LER provides traffic classification, label mapping, and label removal functions.
- LSRs are located at the core of an MPLS network, run an MPLS signaling protocol, and forward packets based on labels.

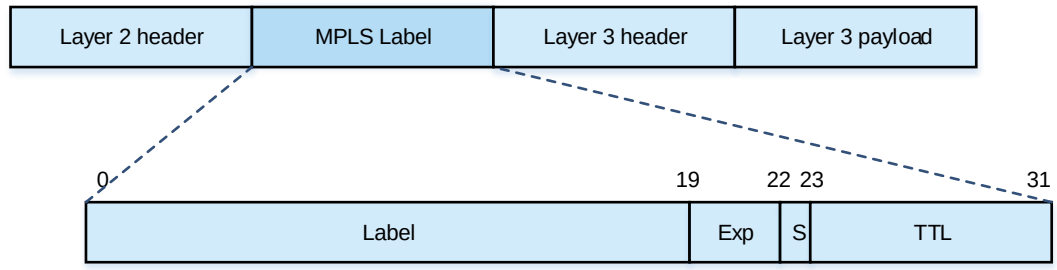
Figure 1-1 MPLS Network Structure

A label-switched path (LSP) is the path along which IP packets travel through an MPLS network. It is a collection of LSRs and can be regarded as a tunnel traversing the MPLS core network.

Devices running MPLS are MPLS nodes. As shown in Figure 1-1, the LERs and LSRs on the MPLS network are MPLS nodes. MPLS nodes can identify MPLS signaling protocols, run one or more L3 routing protocols (including static routing protocols), and forward packets based on MPLS labels. Generally, MPLS nodes are also capable of forwarding original L3 packets (such as IP packets).

- The LER at the entry of an LSP is called the ingress LER, an LSR in the middle of the LSP is called a transit LSR, and the LER at the exit of the LSP is called the egress LER. An LSP may have no, one, or multiple transit LSRs but can have only one ingress LER and one egress LER.
- An LSP is a unidirectional path based on the data flow.
- According to the LSP direction, MPLS packets are forwarded from the ingress LER to the egress LER. Therefore, the ingress LER is an upstream node of the transit LSR, and the transit LSR is a downstream node of the ingress LER. In the same way, the transit LSR is an upstream node of the egress LER, and the egress LER is a downstream node of the transit LSR.

1.1.2 MPLS Label



1. FEC

MPLS groups packets with the same characteristics into an FEC. In IP unicast routing, FECs are classified based on the destination address prefixes. All packets to the same destination belong to the same FEC. That is, one route corresponds to one FEC. Packets of the same FEC are handled in the same way on an MPLS network.

2. Label

A label is a short identifier with fixed length and of local significance. Labels are distributed and transmitted only between two adjacent MPLS nodes. Therefore, they are valid only between the adjacent MPLS nodes.

Figure 1-2 MPLS Label Structure

A label is 32-bit long and consists of the following four fields:

- Label field

  This field is 20-bit long and used to store the label value. Each label uniquely identifies an FEC. The Internet Engineering Task Force (IETF) defines 0 to 15 as special labels. The following table describes the meanings of these special labels.

Table 1-1 Special Labels

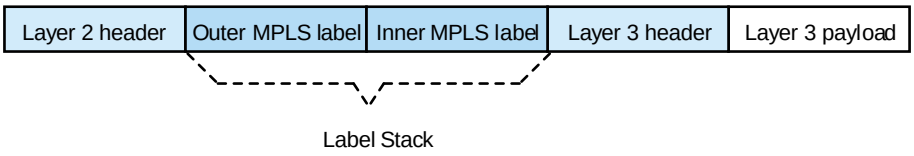
Label	Description
0	Indicates the IPv4 explicit null label. During IPv4 packet forwarding, if the outgoing label of the penultimate LSR is 0, the penultimate LSR must push label 0 to the top of the label stack before forwarding the packet to the next hop. When the last hop receives the packet with label 0, it pops label 0 off.
1	Indicates the router alert label. This label is not allowed at the bottom of the label stack. It is similar to the Router Alert Option of IP packets. When receiving packets with label 1, a router must send the packets to the local software module to process. Actually, the packets are forwarded based on the label below label 1. Before packet forwarding, however, label 1 must be pushed to the label stack again. Each LSR must check MPLS packets that carry label 1.
2	Indicates the IPv6 explicit null label. During IPv6 packet forwarding, if the outgoing label of the penultimate LSR is 2, the penultimate LSR must push label 2 to the top of the label stack before forwarding the packet to the next hop. When the last hop receives the packet with label 2, it pops label 2 off.
3	Indicates the implicit null label. This label can be distributed by the Label Distribution Protocol (LDP) but can never be transmitted in the label stacks of MPLS packets. When an LSR swaps the label for an MPLS packet and finds that the top label to be swapped is 3, the LSR pops the top label off rather than replacing it. Label 3 is used in the Penultimate Hop Popping (PHP) function.
4–15	Reserved

- Exp field

  This field is 3-bit long and used to store the MPLS quality of service (QoS) information.

- S tag

  This field is 1-bit long and used to identify the stack bottom. MPLS supports label nesting. When multiple labels exist, the S bit is set to **1** for the stack bottom label and to **0** for other labels. When only one label exists, the S bit is set to **1**.



- TTL

  This field is 8-bit long and similar to the time to live (TTL) value in IP packet headers.

3. Label Stack

An MPLS packet can carry multiple layers of labels, that is, a label stack. The label stack enables MPLS to support hierarchical network systems. As shown in Figure 1-3, the label that is close to the link layer header is the top label, and the label that is next to the IP header is the bottom label. An LSR always swaps labels based on the top label. When multiple labels exist, each label must be complete and have 32 bits.

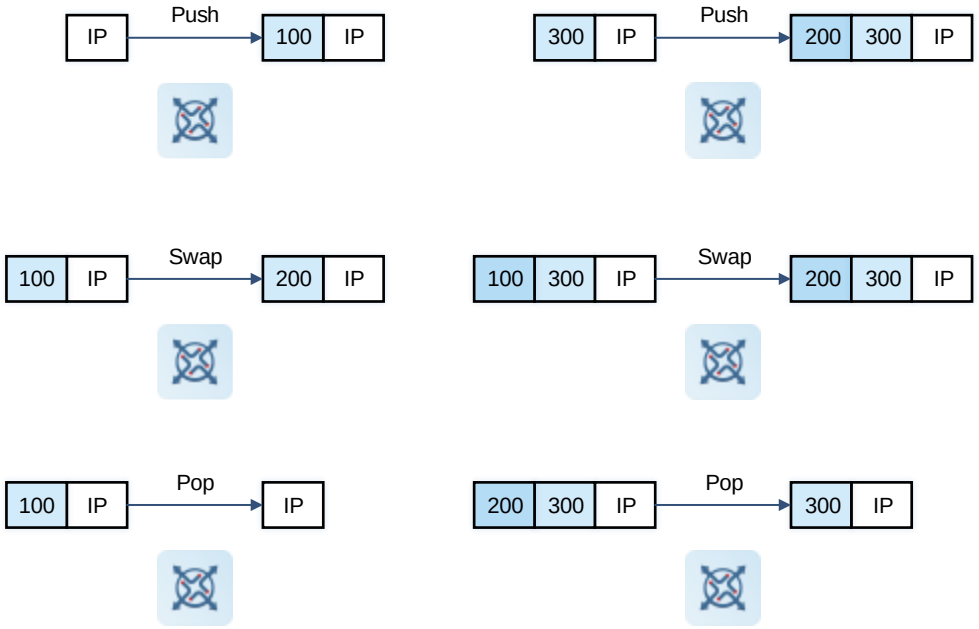


Figure 1-3 MPLS Label Stack

4. Operation Methods of Labels

MPLS nodes can push, swap, and pop labels.

Figure 1-4 Basic Label Operations

- Push

  The ingress LER inserts a label between the link layer header and network layer header, or a transit LSR pushes a new label to the stack top of an MPLS packet.

- Swap

  A transit LSR swaps the top label of an MPLS packet based on the incoming label map (ILM).

- Pop

  The egress LER pops labels off an MPLS packet to restore the IP packet, or a transit LSR pops the top label off to reduce the layers of a label stack.

1.1.3 MPLS Forwarding

1. MPLS Forwarding Tables

During MPLS packet forwarding, three tables are involved, that is, the next hop label forwarding entry (NHLFE), FEC-to-NHLFE (FTN), and Incoming Label Map (ILM).

- NHLFE

The NHLFE table is used to store the next-hop information of MPLS packets. Generally, it contains the following content:

- Next hop of data packets
- Link layer encapsulation of data packets to be forwarded
- Encoding method in the label stack of data packets to be forwarded
- Operations to the label stack of data packets

- FTN

  The FTN table maps each FEC to a series of NHLFEs (multiple NHLFEs indicate multiple paths). The FTN table is used when an LER receives packets to be forwarded without labels. When an LER receives an IP data packet without labels, the LER matches the destination address of the IP data packet using the maximum matching rule according to the FTN table. If a next hop is found, the LER encapsulates the IP data packet with a label and forwards it.

- ILM

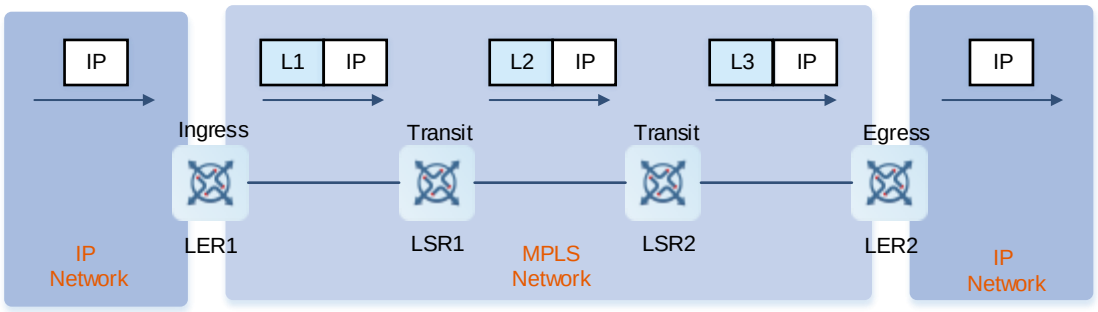
  The ILM table maps each incoming label to a series of NHLFEs (multiple NHLFEs indicate multiple paths). The ILM table is applied when an LSR receives and forwards labeled MPLS packets.

2. MPLS LSP Setup

MPLS nodes can forward packets between each other only after they have reached a consensus on the labels used for the packets and set up an LSP. LSPs can be manually configured or dynamically set up using an MPLS signaling protocol.

- Static LSPs

  Static LSPs are set up by manually distributing labels on MPLS nodes. Static LSPs do not need control packet exchange and consume fewer resources than dynamic LSPs. However, you need to manually configure static LSPs one by one. In addition, static LSPs cannot automatically adapt to network topology changes. Therefore, static LSPs are suitable only for small-scale networks with simple and stable topologies.



- Dynamic LSPs

  MPLS signaling protocols classify FECs, distribute labels, and set up and maintain LSPs. MPLS signaling protocols include protocols designed specifically for label distribution, such as LDP, and protocols extended to support label distribution, such as Resource Reservation Protocol-Traffic Engineering (RSVP-TE) and Multiprotocol Border Gateway Protocol (MP-BGP).

3. MPLS Packet Forwarding Process

On an MPLS network, the MPLS nodes enable traditional IP routing protocols (such as OSPF and IS-IS) and create IP routing tables. The LDP creates LSPs based on IP routing tables and distributes labels to MPLS nodes.

Figure 1-5 MPLS Packet Forwarding Process

As shown in Figure 1-5, the MPLS packet forwarding process is as follows:

(1) The ingress LER (LER1) receives an IP packet, analyses the packet header, associates it with an FEC, adds label L1 corresponding to the FEC to the packet, and sends the labeled packet to the next-hop LSR through the LSP of L1.

(2) After receiving the labeled packet, the next-hop transit LSR (LSR1) searches the ILM based on the top label L1, replaces L1 with new label L2, and forwards the packet to the next-hop LSR (LSR2).

(3) LSR2 processes the packet similar to LSR1.

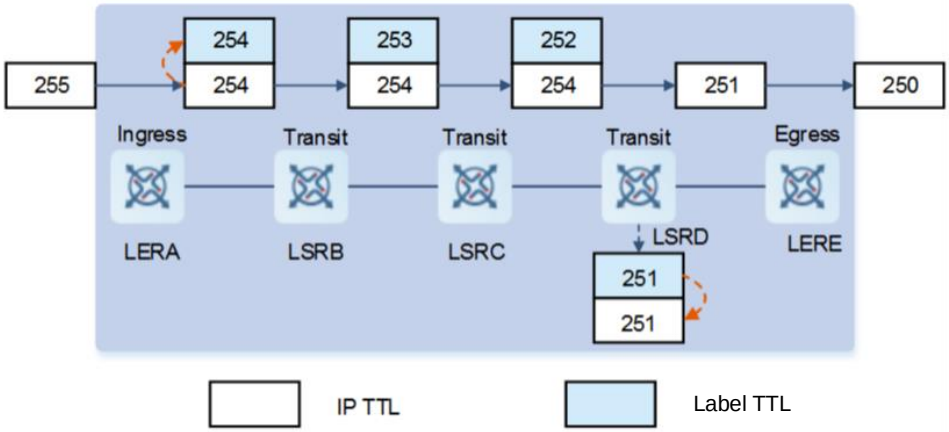
(4) After receiving the labeled packet, the egress LER (LER2) pops the label off the packet and forwards the packet based on the IP routing table.

4. PHP

After receiving a labeled packet, the egress LER on an MPLS network needs to search the ILM and pop the label off before forwarding the packet. To reduce the burden of the egress LER, the PHP function is introduced. The PHP function is implemented by assigning a null label. It ensures that labels are popped off on the penultimate LSR. In this case, the egress LER only needs to perform one table lookup. PHP-assigned null labels include explicit and implicit null labels.

- The explicit null label is 0. When the penultimate LSR receives a labeled packet and finds that the outgoing label of the packet is 0 according to the ILM, the penultimate LSR replaces the outermost label of the packet with label 0 and sends the packet to the egress LER. After receiving the packet with label 0, the egress LER pops label 0 off the packet and forwards the packet based on the IP routing table.
- The implicit null label is 3. When the penultimate LSR receives a labeled packet and finds that the outgoing label of the packet is 3 according to the ILM, the penultimate LSR pops the label off and sends the original IP packet to the egress LER. After receiving the original IP packet, the egress LER forwards the packet based on the IP routing table.

5. TTL Processing Mode



The TTL field in MPLS packets is processed using two modes: TTL replication and TTL non-replication.

- TTL replication mode

  When an IP packet enters an MPLS network, the ingress LER pushes a label to the IP packet by decreasing the TTL value of the IP packet by 1 and then copying the TTL value to the TTL field of the new label. The TTL value in the top label is decreased by 1 each time the packet passes through an LSR. When the egress LER pops the label off, it decreases the TTL value in the label by 1 and copies the TTL value to the TTL field

of the IP packet. In TTL replication mode, the TTL value of the inner header is not copied but retained if it is smaller than the TTL value of the outer header.

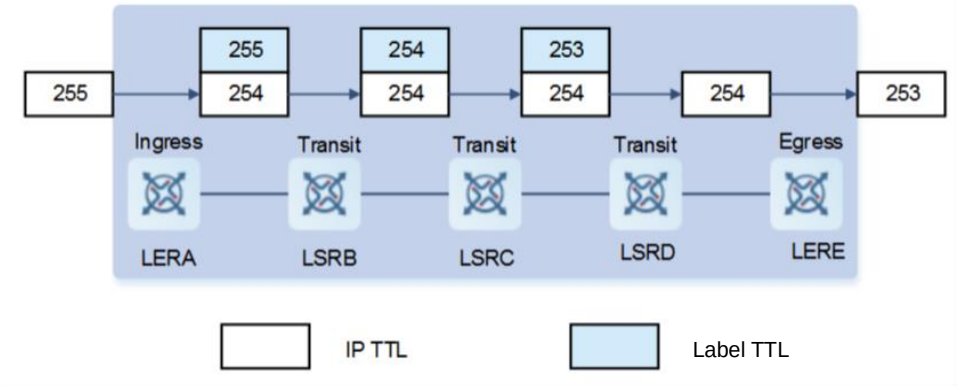


Figure 1-6 Packet Processing in TTL Replication Mode

- TTL non-replication mode

  When an IP packet enters an MPLS network, the ingress LER pushes a label to the IP packet by decreasing the TTL value in the IP packet by 1 and setting the TTL value in the new label to 255. The TTL value in the top label is decreased by 1 each time the packet passes through an LSR, and the TTL value of the IP packet remains unchanged. When the egress LER pops the label off, it decreases the TTL value of the IP packet by 1.

Figure 1-7 Packet Processing in TTL Non-Replication Mode

In TTL replication mode, a customer edge (CE) can use the tracert tool to trace all nodes that a packet passes through on an MPLS backbone network. To ensure network security, you are advised to use the TTL non-replication mode. In this case, the TTL value of an IP packet is decreased by 1 only at the ingress LER and egress LER regardless of how many hops the packet passes through on an MPLS network. This helps hide the MPLS network structure.

6. LSP Connectivity Test

When a data forwarding fault occurs along an LSP on an MPLS network, the control plane that is responsible for establishing the LSP cannot perceive the fault. This results in complex network maintenance. To reduce the network maintenance costs and improve the MPLS network availability, two LSP connectivity test tools are introduced, that is, MPLS ping and MPLS traceroute.

Similar to traditional ping and traceroute, LSP connectivity test is based on the echo request and echo reply mode. The only difference is that MPLS ping and MPLS traceroute are implemented based on User Datagram Protocol (UDP) instead of Internet Control Message Protocol (ICMP). Echo requests use UDP port 3503, and only devices with MPLS enabled can identify this port.

- MPLS ping

  MPLS ping is used to check the LSP connectivity. The ingress LER pushes the label of the LSP to be tested to an MPLS Echo Request packet and forwards the packet to the egress LER along the LSP. The egress LER returns an MPLS Echo Reply packet. If the MPLS Echo Reply packet received by the ingress LER is normal, the LSP forwards data normally. If the MPLS Echo Reply packet received by the ingress LER carries an error code, the LSP is faulty.

- MPLS traceroute

  MPLS traceroute is used to trace LSRs between the ingress LER and egress LER. In addition to checking the LSP connectivity, MPLS traceroute can locate the network fault. The ingress LER sends MPLS Echo Request packets continuously along the LSP. Each LSR along the LSP returns an MPLS Echo Reply packet after receiving a Request packet. Therefore, the ingress LER can collect information of each LSR and locate the fault position. In addition, MPLS traceroute can collect labels assigned to LSRs and other important information.

1.1.4 MPLS Static LSPs

To implement basic MPLS forwarding functions, you can statically configure LSPs rather than using the LDP. On each hop of an MPLS network, you can statically configure the incoming and outgoing labels, next hop, and other information to generate an ILM and set up an MPLS LSP, which is called a static LSP.

Note

Static LSP configuration is independent of the LDP and does not rely on IPv4 routes. Even if no IPv4 routes exist on a network, a static LSP takes effect as long as the physical network is reachable.

A static LSP is set up as follows:

(1) Create a static FTN entry (including the outgoing label of the destination network segment and LSP next hop or the outbound interface to the next hop) for an FEC on the ingress LER and bind the FEC to a label. When receiving an IP data packet, the ingress LER queries the FTN table for the next hop using the maximum matching rule based on the destination address of the packet. If a next hop is found, the ingress LER adds the outgoing label of the FEC to the packet, imports the IP traffic to the LSP, and forwards the packet to the specified next hop or through the outbound interface.

(2) Create a static ILM entry (including the outgoing label corresponding to the incoming label and LSP next hop or the outbound interface to the next hop) on the transit LSR and map the incoming label to the outgoing label. When the transit LSR receives a labeled data packet, it queries the ILM table for the next hop based on the label value carried in the packet. If a next hop is found, the transit LSR replaces the label in the packet

with the outgoing label corresponding to this label and forwards the packet to the specified next hop or through the outbound interface. If PHP is enabled on the penultimate LSR (that is, the ILM outgoing label on the LSR is the implicit null label 3), the penultimate LSR pops the label off before forwarding the packet.

(3) If the outgoing label of the penultimate LSR is not set to 0 or 3, configure a static ILM entry on the egress LER. The packet received by the egress LER still carries a label value. The egress LER needs to pop the label off based on the ILM entry and forward the packet. If the outgoing label of the penultimate LSR is set to 0 or 3, the egress LER receives a common IP packet and can directly forward it.

1.1.5 MPLS LDP

1. Introduction

LDP is a process of reaching a consensus on the meaning of labels used for traffic transmission between two LSRs. With the LDP, an LSR can map IP routing information to an MPLS LSP and advertise the label binding information to the adjacent LSR to establish a dynamic LSP.

LDP is mainly used to exchange label binding information for IP unicast routes and Martini L2VPN.

Note

This section describes how to establish LSPs for IP unicast routing. For details about LSP configuration and application in Martini L2VPN, see *Configuring VPN L2VPN*.

2. Basic Concepts

- LDP peers

  LDP peers are LDP instances on two LSRs that exchange label binding information.

- LDP router ID

  An LDP router ID, that is, an LSR ID, uniquely identifies an LSR in a domain. It is expressed in IPv4 address format. The system router ID is used as the LDP router ID by default. The LDP router ID must be globally unique.

- LDP session

  An LDP session is established between LDP peers to exchange label binding information. Transmission Control Protocol (TCP) connections are used to establish LDP sessions.

3. Working Process

The LDP working process includes three phases: LDP peer discovery and maintenance, LDP session establishment and maintenance, and LSP setup.

- LDP peer discovery and maintenance

  An LDP instance periodically sends Hello packets to advertise itself and monitors the Hello packets to discover LDP peers. If no Hello packet is received from an LDP peer within a specified time, it is regarded that the LDP peer is invalid. This period is called the hold time of Hello packets.

- LDP session establishment and maintenance

  After an LDP instance finds an LDP peer by using Hello packets, the LDP instance establishes a TCP connection based on the transport address advertised in the Hello packets and exchanges initial messages on the connection to negotiate LDP session parameters and establish an LDP session.

After an LDP session is established, both parties periodically send keepalive packets to monitor the TCP connection. If no keepalive packet is received from the peer within a specified time, the other party regards that the connection is invalid and proactively disconnects the session. This period is called the hold time of keepalive packets.

To enhance the security of LDP sessions, you can configure the MD5 authentication for the TCP connections used by the LDP sessions.

- LSP setup

  After an LDP session is established, the LDP peers exchange label messages and bind labels to create LSPs for FECs.

  LSP setup is in fact the process of binding FECs to labels and notifying adjacent LSRs of the bindings. For details about the LDP implementation process, see RFC 3036.

4. LDP Label Distribution and Control

- LDP label distribution mode

  During LSP setup, there are two label distribution modes: downstream on demand (DoD) and downstream unsolicited (DU), as shown in Figure 1-8.

Figure 1-8 LDP Label Distribution Mode

  - In DoD mode, an MPLS node responds a label binding message only after receiving a label request from an adjacent LSR.
  - In DU mode, an MPLS node proactively sends label binding messages to its adjacent LSRs even if it does not receive any request.

- LDP label control mode

  During LSP setup, there are two label control modes: independent control and ordered control, as shown in Figure 1-9.

Figure 1-9 LDP Label Independent Control

In independent control mode, each MPLS node announces to its adjacent nodes the binding between labels and FECs at any required time.

- In independent control and DoD mode, one LSR can immediately respond to the label mapping request from the upstream node without needing to wait for the label mapping message from the next hop.
- In independent control and DU mode, one LSR can announce the label mapping message of an FEC at any time deemed as proper.

In ordered control mode, one LSR binds an FEC to a label and sends the binding upstream only when the FEC has the next-hop label mapping or the LSR is the egress of the FEC. Otherwise, the LSR binds the FEC to a label and sends the binding upstream until it receives the label mapping of the FEC from a downstream LSR.

- In DU distribution mode, one LSR announces the label to an upstream LSR only when the LSR is the egress of the FEC or the LSR receives the label distributed by a downstream LSR.
- If the label distribution mode of the downstream LSR is DoD, the LSR passes the label request from an upstream LSR to its downstream device.

5. LDP Label Retention Mode

During LSP setup, if a received label mapping message is not from the next hop of the corresponding FEC or does not match any existing FEC, the message is processed based on the configured local label retention mode.

- Liberal label retention mode: The FEC-label binding learned from neighbors is retained.
- Conservative label retention mode: The FEC-label binding learned from neighbors is not retained.

In conservative label retention mode, an LSR uses and maintains a small number of labels. However, the LSR needs to re-obtain the label values in the case of route changes, prolonging the response time. In liberal label retention mode, an LSR responds rapidly to route changes but distributes and maintains unnecessary label mappings.

6. LDP Loop Control

To ensure that LSP loops can be detected in a timely manner, the loop detection mechanism is used during LSP setup. Two LSP loop detection methods are provided: maximum number of hops and path vector.

- Maximum number of hops

  In loop detection based on the maximum number of hops, a label binding message records the number of bypassing LSRs, and the number increases by 1 each time the message passes through an LSR. If the number exceeds the specified maximum value, the system considers that a loop occurs and terminates the LSP.

- Path vector

  In loop detection based on the path vector, a label binding message records the IDs of bypassing LSRs. Each time the message passes through an LSR, the ID of the LSR is recorded to the vector table of the message. Upon receiving a label binding message, an LSR checks whether its own ID is included in the vector table. If not, the LSR adds its own ID to the record when distributing the message; if yes, the LSR considers that a loop occurs and terminates the LSP.

7. LDP Session Protection

When the direct link of a local LDP session is faulty, the LDP adjacency becomes invalid and the LDP session is interrupted. When the link recovers, the LDP session is re-established and label bindings are re-switched for LDP convergence. However, this process causes LDP LSP traffic loss. To reduce LDP LSP traffic loss, the LDP session protection function is introduced.

After the LDP session between two LSRs is protected, the two LSRs will send link Hello messages to each other to establish the link Hello adjacency and send targeted Hello messages to establish targeted Hello adjacency. When the direct link between two LSRs is faulty, the link Hello adjacency will be disconnected. However, the targeted Hello adjacency can be maintained as long as a replaceable path is available between them. When the direct link recovers, the LDP session does not need to be re-established. This improves the LDP convergence efficiency.

Figure 1-10 LDP Session Protection

As shown in Figure 1-10, devices R1, R2, and R3 can communicate with each other at the data link layer and are enabled with Open Shortest Path First (OSPF). LDP is enabled on R1 and R2. Link Hello adjacency is established between R1 and R2 to establish an LDP session. To protect the LDP session between R1 and R2, you can enable LDP session protection on R1 and R2 to establish targeted Hello adjacency between them.

When the link between R1 and R2 fails, the link Hello adjacency is disconnected. However, the path R1-R3-R2 is available for reaching R2. Therefore, the targeted Hello adjacency maintains the LDP session. When the link between R1 and R2 recovers, the LDP session between them does not need to be re-established and label binding does not need to be re-switched.

The LDP session protection function protects the LDP session between two directly connected LSRs and LDP over TE. It speeds up LDP convergence when a link recovers, especially when a link fails for a short time.

8. LDP Label Management Policy

LDP label management policies include the label distribution control policy and label reception control policy.

- Label distribution control

  The LDP distributes labels to all valid interior gateway protocol (IGP) routes (excluding BGP routes) by default. In some special situations, you may want to distribute labels only to some routes or only to certain LDP peers. To reduce the device and network burden, you can use the label distribution control policy to reduce the using of labels and the number of LSPs. The label distribution control policy achieves the following effects:

  - The policy distributes label mapping messages only for FECs corresponding to specified IP routes.
  - The policy distributes label mapping messages only to specified LDP peers.
  - The policy achieves both of the preceding two effects at the same time.

- Label reception control

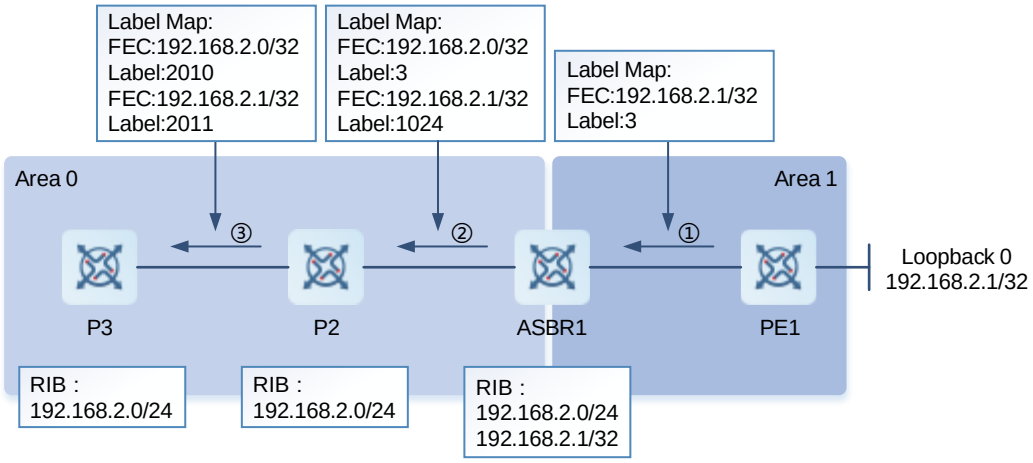
  By default, an LDP instance receives all label mapping messages in LDP sessions regardless of the session mode (DU or DoD). For sessions in DoD mode, the LDP will send label request messages for LDP peers to an LDP peer with this peer as the next hop. The label reception control policy achieves the following effects:

  - The policy receives only label mapping messages of FECs corresponding to specified IP routes from specified peers.
  - The policy sends label request messages of specified FECs only to specified LDP peers.
  - The policy rejects label mapping messages from specified peers.
  - The policy does not send label request messages to specified peers.

9. LDP Inter-Area LSP

An LDP inter-area LSP is a label switching path across multiple IGP areas in an autonomous system (AS). When an AS is grouped into multiple IGP areas, route aggregation is configured on area border routers (ABRs) to reduce the size of routing tables and improve network efficiency. For OSPF, ABRs are nodes connecting the backbone area to other areas. For IS-IS, ABRs are level 1 or level 2 nodes. To configure route aggregation on ABRs, you can adopt the LDP inter-area LSP technology to build a label switching path for aggregated host routes across multiple IGP areas in an AS. The LDP inter-area LSP technology is extension for maximum route matching of LDP.

Note



When an autonomous system (AS) is grouped into multiple IGP areas and route aggregation is enabled on area border routers (ABRs), you can enable LDP inter-area LSP to build an LSP for aggregated host routes across multiple IGP areas.

When LDP inter-area LSP is disabled, the LDP forwards only labels corresponding to exactly matched routes and distributes label mapping messages to all LDP neighbors. When LDP inter-area LSP is enabled and LDP receives a downstream label mapping message, LDP adds a forwarding entry and distributes the label mapping message to all LDP neighbors if the device has the maximum matching route corresponding to the FEC of the label mapping message and the LDP neighbor that sends the label mapping message is the next hop of the maximum matching route. The FEC refers to that in the received label mapping message but not that obtained from the routing table.

- Setting up an LDP inter-area LSP

Figure 1-11 shows how to set up an LDP inter-area LSP.

Figure 1-11 Setting up an LDP Inter-area LSP

(1) Configure ABR1 to advertise route aggregation to the backbone area. The routing table of ABR1 contains the aggregated route 192.168.2.0/24 and the host route 192.168.2.1/32.

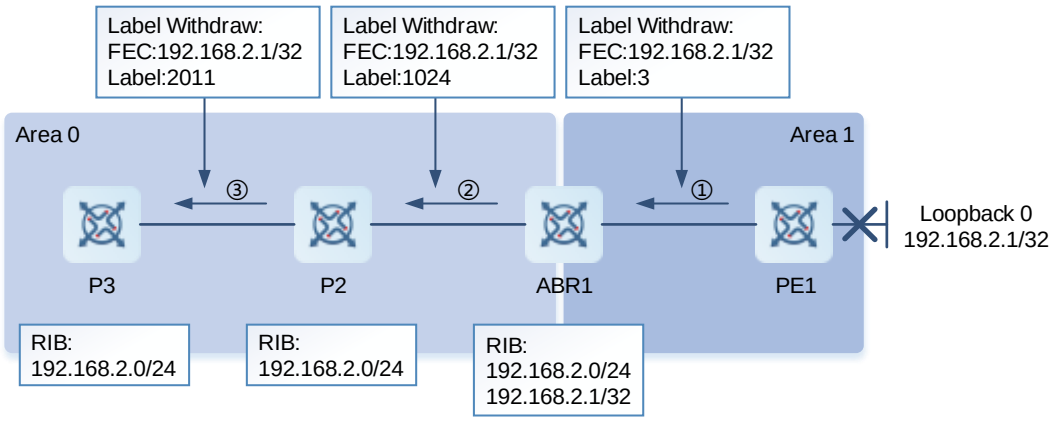
(2) PE1 sends a label mapping message of FEC 192.168.2.1/32 to ABR1.

(2) ABR1 sends label mapping messages of FEC 192.168.2.0/24 and FEC 192.168.2.1/32 to the upstream node P2.

(3) The routing table of P2 contains the aggregated route 192.168.2.0/24 only. When receiving the label mapping message of FEC 192.168.2.0/24, P2 sends the message to the upstream node P3. When receiving the label mapping message of FEC 192.168.2.1/32, P2 also sends the message to the upstream node P3 because the routing table contains a maximum matching route (192.168.2.0/24) with the FEC and the neighbor (ABR1) that sends the label mapping message is the next hop of the route.

(4) P3 performs the same as P2.

(5) After the preceding steps, an inter-area LSP, which is P3-P2-ABR1-PE1 (192.168.2.1/32) is established between Area 0 and Area 1.



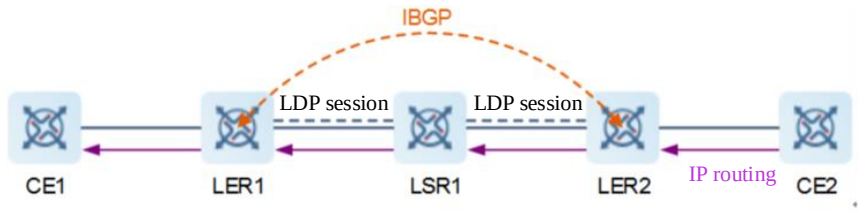
This method is similar to the DU distribution mode + ordered control mode. LSPs built in this mode also apply to the IGP shortest path. Because only aggregated routes are available for the upstream, LDP inter-area LSP is not applicable in DoD mode.

- Removing an LDP inter-area LSP

To delete an MPLS forwarding entry added because of the maximum matching route, which is indicated in the label removal message or because the maximum matching route is deleted, a label removal message must be sent to the upstream regardless of the label distribution control mode (ordered mode or independent mode).

Figure 1-12 shows how to remove an LDP inter-area LSP.

Figure 1-12 Removing an LDP Inter-area LSP



The route platform advertises LDP maximum matching route update or removal once the route of the MPLS forwarding entry added because of the maximum matching route changes (a better maximum matching route exists or the depending maximum matching route is deleted), to ensure more exact LSP.

10. Iterating IP Routes to LDP LSPs

The next hop of an IP route is not always directly connected. For example, the next hops between IBGP neighbors are the router IDs of two BGP nodes. Because the network between IBGP neighbors and the BGP routes are isolated, traffic match the BGP routes cannot be directly forwarded to the remote BGP neighbors. In this case, a tunnel needs to be established between IBGP neighbors to ensure that traffic match the route can be forwarded to the remote BGP neighbors through the tunnel. An MPLS LSP is a natural tunnel that can meet this requirement.

Figure 1-13 Iterating IGP Routes to LDP LSPs

As shown in Figure 1-13, LER2 learns the route of CE2 through the IBGP or static routing protocol and advertises the CE2 route to LER1 using IBGP. LER1 releases the CE2 route to CE1. A route entry is generated on LER1 for the CE2 route, and the next hop is the next-hop address advertised by the IBGP neighbor. Because LSR1 does not learn the CE2 route, it cannot forward the traffic from LER1 to CE2 based on IP routing. In this case, an MPLS LSP needs to be set up between LER1 and LER2 to forward traffic from LER1 to LER2. Then, IP routing is performed to send the traffic to CE2.

The process of iterating IP routes to LDP LSPs is as follows:

(1) Set up an LDP LSP. Establish LDP neighbor relationship among LER1, LSR1, and LER2 and set up an LDP LSP. For the detailed process, see 1.1.5 MPLS LDP.

(2) Iterate IP routes to the LDP LSP.

(3) Enable the function of iterating IP routes to LDP LSPs on LER1 to iterate the CE2 route on LER1 to the LDP LSP. To ensure successful iteration, an FTN entry with the IP route next hop as the FEC must exist on LER1.

1.1.6 Protocols and Standards

- RFC 3032: MPLS Label Stack Encoding
- RFC 3036: LDP Specification
- RFC 4182: Removing a Restriction on the use of MPLS Explicit NULL
- RFC 5283: LDP Extension for Inter-Area Label Switched Paths (LSPs)

1.2 Restrictions and Guidelines

- MPLS interface-related commands can be configured on L3 interfaces only. Non-L3 interfaces can configure MPLS related commands only after they are converted to L3 interfaces.
- On some platforms, if an MPLS signaling protocol, such as LDP is enabled when MPLS forwarding is disabled globally, IP packet forwarding may be invalid. If MPLS forwarding is not required, you are advised to disable the related MPLS signaling protocol at the same time.

1.3 Configuration Task Summary

MPLS configuration includes the following tasks:

(1) Configuring MPLS Public Functions

(2) Configuring a Static LSP

(3) Configuring Basic LDP Functions

(4) (Optional) Configuring an LDP LSP

(5) Configuring an LDP IPv6 LSP

(6) Configuring LDP Session Protection

(7) Configuring LDP Inter-Area LSP

(8) Iterating IP Routes to LDP LSPs

(9) (Optional) Configuring LSP Connectivity Detection

1.4 Configuring MPLS Public Functions

1.4.1 Configuration Tasks

MPLS public function configuration includes the following tasks:

(1) Configuring MPLS Forwarding

(2) (Optional) Configuring the MPLS MTU for an Interface

(3) (Optional) Fragmenting MPLS Packets

(4) (Optional) Configuring the Processing Method for ICMP Error Messages

(5) (Optional) Configuring MPLS TTL Replication

1.4.2 Configuring MPLS Forwarding

1. Overview

After MPLS forwarding is enabled, a device preferentially forwards packets according to their labels. If packet forwarding based on labels fails, the device then attempts to forward the packets according to their IP addresses.

2. Restrictions and Guidelines

- Unless otherwise specified, enable MPLS forwarding globally on each LSR that an LSP passes through.
- Unless otherwise specified, enable MPLS forwarding on each interface that an LSP passes through.
- When labeled MPLS packet forwarding is enabled on an interface, adjust the maximum transmission unit (MTU) on the interface based on the service type. Otherwise, transmission of large packets may be affected.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable MPLS forwarding globally.

mpls ip

MPLS forwarding is disabled globally by default.

To implement MPLS forwarding on a device, enable MPLS forwarding globally first.

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

(5) Enable an interface to forward labeled MPLS packets.

label-switching

Labeled MPLS packet forwarding is disabled on an interface by default.

1.4.3 Configuring the MPLS MTU for an Interface

1. Overview

The MPLS MTU determines whether MPLS packets need be fragmented when being forwarded. The MPLS MTU indicates the overall length of the MPLS encapsulation and encapsulated (such as IP) layers. Devices that support MPLS packet fragmentation will fragment MPLS packets based on the MPLS MTU of an interface when the packet length is longer than the MPLS MTU of the interface after MPLS label encapsulation. Devices that

do not support MPLS packet fragmentation will discard packets whose length is longer than the MTU of an interface after MPLS label encapsulation.

2. Restrictions and Guidelines

The MPLS MTU on an interface cannot exceed the actual packet transmission capability of the interface. To adjust the MTU of an interface, run the **MTU** command in interface configuration mode.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Configure the MPLS MTU for an interface.

mpls mtu *mpls-mtu*

The MTU of MPLS packets that can be transmitted by an interface is the same as the MTU of the interface by default.

1.4.4 Fragmenting MPLS Packets

1. Overview

MPLS packets whose length exceeds the MPLS MTU of an interface need to be fragmented. When the length of an IP packet encapsulated with an MPLS label exceeds the MPLS MTU of an interface, the original IP packet needs to be fragmented and then encapsulated with the MPLS label. Devices cannot forward packets whose length exceeds the MPLS MTU.

2. Restrictions and Guidelines

- The MPLS packet fragmentation command does not take effect to devices that do not support MPLS packet fragmentation.
- The MPLS packet fragmentation command takes effect only to IP packets.
- Unless otherwise specified, the MPLS packet fragmentation function needs to be enabled for each LSR that an LSP passes through, and it is enabled by default. Otherwise, the LSRs cannot process packets whose length exceeds the MTU.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the MPLS packet fragmentation function.

mpls ip fragment

The MPLS packet fragmentation function is enabled by default.

1.4.5 Configuring the Processing Method for ICMP Error Messages

1. Overview

Configure the processing method for Internet Control Message Protocol (ICMP) error messages (such as typical MPLS TTL timeout messages) generated during the forwarding of MPLS packets. ICMP error messages are encapsulated with the original label stack and forwarded along the original LSP to the egress LER by default. The egress LER pops the label stack off and selects a route based on the IP addresses to forward the messages. However, you can specify the number of labels carried in packets to be forwarded to process ICMP error messages in different ways.

- When the number of labels carried in packets to be forwarded is greater than the configured label quantity, ICMP error messages are forwarded along the LSP of the original label stack.
- When the number of labels carried in packets to be forwarded is less than or equal to the configured label quantity, ICMP error messages are forwarded according to the IP routing table where the FEC corresponding to the top label resides.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the processing method for ICMP error messages generated during the forwarding of MPLS packets.

mpls ip icmp-error pop *labels*

ICMP error messages are encapsulated with the original label stack and forwarded along the original LSP by default.

1.4.6 Configuring MPLS TTL Replication

1. Overview

The TTL field in MPLS packets is processed using two modes: TTL replication and TTL non-replication. To hide the internal topology of the MPLS network, disable the MPLS TTL replication function on each LSR that an LSP passes through.

2. Restrictions and Guidelines

After TTL replication is enabled, the TTL of the inner header is not copied but retained if it is smaller than the TTL of the outer header.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the MPLS TTL replication function.

mpls ip ttl propagate { **public** | **vpn** }

The MPLS TTL replication function is enabled for packets sent and forwarded by a device by default.

1.5 Configuring a Static LSP

1.5.1 Overview

To implement basic MPLS forwarding functions, you can configure static LSPs. Static LSP configuration is independent of the LDP and does not rely on IPv4 routes. Even if no IPv4 routes exist on the network, a static LSP takes effect as long as the physical network is reachable.

On the ingress LER, set up an FTN entry for an FEC, that is, bind the FEC to a label. On the transit LSRs, configure ILM entries to map incoming labels to outgoing ones to forward labeled packets based on labels. On the penultimate LSR, enable PHP. In this case, the ILM entry of the penultimate LSR is different from other transit LSRs. The outgoing label of the penultimate LSR must be implicit null label 3.

1.5.2 Restrictions and Guidelines

- For two adjacent LSRs, the outgoing label of the upstream LSR must be the same as the incoming label of the downstream LSR.
- LSP is a unidirectional path. Therefore, you need to configure static LSPs in both data transmission directions.
- The static FTN entry with the outgoing label set to 3 takes effect only after an IP route with the same prefix as the FTN entry is configured.
- An FTN entry with the destination address and mask set to 0 takes effect when the corresponding default route exists in the IP routing forwarding table.
- It is recommended that the outgoing label of the penultimate LSR be set to 3. In this case, the egress LER can directly receive IP packets. Otherwise, the egress LER needs to configure the corresponding static ILM entry.

1.5.3 Prerequisites

- MPLS forwarding has been configured on all LSRs.
- MPLS forwarding has been enabled globally and on an interface.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a static FTN entry on the ingress LER.

mpls static ftn *ipv4-address/mask-length* **out-label** *label* **nexthop** *interface-type interface-number nexthop-ipv4-address*

To import IP traffic to an LSP, an ingress LER must be configured with an FTN entry.

(4) Configure static ILM entries on transit LSRs. Configure one of the following tasks.

- Configure static ILM entries applied to L3VPN.

  (IPv4 network)

  mpls static ilm in-label *in-label* **forward-action pop-l3vpn-nexthop** *vrf-name* **nexthop** *interface-type interface-number nexthop-ipv4-address* **fec** *ipv4-address/mask-length*

  (IPv6 network)

  mpls static ilm in-label *in-label* **forward-action pop-l3vpn-nexthop** *vrf-name* **nexthop** *interface-type interface-number nexthop-ipv6-address* **fec** *ipv6-address/prefix-length*

- Configure static ILM entries applied to the public network.

  (IPv4 network)

  mpls static ilm in-label *in-label* **forward-action swap-label** *swap-label* **nexthop** *interface-type interface-number nexthop-ipv4-address* **fec** *ipv4-address/mask-length*

  (IPv6 network)

  mpls static ilm in-label *in-label* **forward-action swap-label** *swap-label* **nexthop** *interface-type interface-number nexthop-ipv4-address* **fec** *ipv6-address/prefix-length*

A transit LSR can forward MPLS packets only after an ILM entry is configured on it.

1.6 Configuring Basic LDP Functions

1.6.1 Overview

An LDP session can be established between adjacent LSRs to switch label bindings.

1.6.2 Configuration Tasks

The configuration of LDP basic functions includes the following tasks:

(1) Enabling LDP Globally

(2) (Optional) Configuring the LDP Router ID

(3) Enabling LDP on an Interface

(4) (Optional) Configuring the Transport Address

(5) Configuring an LDP Remote Peer

(6) Configuring Targeted Hello Packet Receiving on an LDP Instance

(7) Configuring the Time Interval for Hello Packets

(8) (Optional) Configuring the Hold Time of Hello Packets

(9) (Optional) Configuring the Hold Time of Keepalive Packets

(10) (Optional) Configuring the Maximum PDU

(11) (Optional) Configuring LDP MD5 Authentication

1.6.3 Enabling LDP Globally

1. Restrictions and Guidelines

- LDP needs to be enabled globally on the LSRs at both ends of an LDP session.
- The number of LDP instances supported on a device is limited by the number of VPN Routing and Forwarding (VRF) tables on the device. Each VRF instance can start an LDP instance.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable LDP globally and enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

LDP is disabled by default.

If no VRF instance is specified, LDP is enabled or disabled for the global VRF instance by default.

1.6.4 Configuring the LDP Router ID

1. Restrictions and Guidelines

- In actual applications, the LDP router ID needs to be configured. If the LDP router ID is not configured, the router ID may be changed after the LDP is restarted, resulting in invalidity of some functions, for example, LDP MD5 authentication configured using the original router ID.
- It is recommended that the router ID be configured on LSRs at both ends of a session to ensure stable and reliable LDP functions.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Configure the LDP router ID.

ldp router-id { *ipv4-address* | **interface** *interface-type interface-number* [**force**] }

The system router ID is used as the LDP router ID by default.

If **force** is specified, the new router ID is forced to take effect immediately. Otherwise, the new router ID does not take effect immediately.

1.6.5 Enabling LDP on an Interface

1. Restrictions and Guidelines

If a local LDP session is established, enable LDP on an interface in interface configuration mode.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Enable LDP on an interface.

mpls ip

LDP is disabled on an interface by default.

1.6.6 Configuring the Transport Address

1. Restrictions and Guidelines

- If a local LDP session is established, you can configure the global transport address in LDP configuration mode. If a neighbor requires a specified transport address, configure the specified transport address on the interface connected to the neighbor.
- If a remote LDP session is established, no transport address needs to be configured.
- You can use the primary address of an interface or specify an IP address as the transport address to set up an LDP session on the interface. There are two configuration methods. Use the transport address configuration command in interface configuration mode or use the command in LDP configuration mode to globally configure a transport address for all LDP sessions.
- The global transport address configuration command for local LDP sessions takes effect only to local LDP sessions established using the LDP basic discovery mechanism. It is invalid to remote LDP sessions established using the LDP extended discovery mechanism. Remote LDP sessions always use the LDP router ID as the transport address.
- The transport address configuration command for local LDP sessions on an interface takes effect only to local LDP sessions established using the LDP basic discovery mechanism. It is invalid to remote LDP sessions established using the LDP extended discovery mechanism. The transport address configuration command on an interface takes effect only to local LDP sessions established after this command is configured. It is invalid to previously established local LDP sessions. If a transport address is configured on

an interface and globally, the transport address configured on the interface takes effect preferentially.

2. Prerequisites

For the configuration of a transport address for LDP peers, a reachable IP route is required. You can configure a static route in global configuration mode or establish a route using an IGP, such as OSPF.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Configure a global transport address for local LDP sessions.

transport-address { **interface** | *ipv4-address* | *interface-type interface-number* }

The LDP router ID is used as the LDP session transport address by default.

(5) Exit the LDP configuration mode.

exit

(6) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(7) Configure the transport address for local LDP sessions on an interface.

mpls ldp transport-address { **interface** | *ipv4-address* }

The LDP router ID is used as the LDP session transport address by default.

1.6.7 Configuring an LDP Remote Peer

1. Overview

Create an LDP remote peer.

2. Restrictions and Guidelines

To establish a remote LDP session, you must configure remote peers in LDP configuration mode.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Configure an LDP remote peer.

neighbor *ipv4-address*

No LDP remote peer is configured by default.

1.6.8 Configuring Targeted Hello Packet Receiving on an LDP Instance

1. Restrictions and Guidelines

When you configure two devices as remote peers, you can configure **neighbor** on one end and enable targeted Hello packet receiving on the other end. To delete remote peers, you only need to delete the **neighbor** configuration.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Configure targeted Hello packet receiving on an LDP instance.

discovery targeted-hello accept [**from** *acl-name*]

An LDP instance receives targeted Hello packets only from remote peers by default.

Only targeted Hello packets from neighbors that meet access control list (ACL) rules will be received.

1.6.9 Configuring the Time Interval for Hello Packets

1. Restrictions and Guidelines

- If a local LDP session is established, configure the time interval for Hello packets in interface configuration mode.
- If a remote LDP session is established, configure the time interval for Hello packets in LDP configuration mode.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Configure the interval for sending link Hello packets.

mpls ldp hello-interval *hello-interval*

The default interval for sending link Hello packets is 5s.

(5) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(6) Configure the interval for sending targeted Hello packets.

discovery targeted-hello interval *targeted-hello-interval*

The default interval for sending targeted Hello packets is 5s.

1.6.10 Configuring the Hold Time of Hello Packets

1. Restrictions and Guidelines

- If a local LDP session is established, configure the hold time of Hello packets in interface configuration mode.
- If a remote LDP session is established, configure the hold time of Hello packets in LDP configuration mode.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Configure the hold time of link Hello packets.

mpls ldp hello-holdtime *hello-holdtime*

The default hold time of link Hello packets is 15s.

(5) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(6) Configure the hold time of targeted Hello packets.

discovery targeted-hello holdtime *targeted-hello-holdtime*

The default hold time of targeted Hello packets is 45s.

1.6.11 Configuring the Hold Time of Keepalive Packets

1. Restrictions and Guidelines

- If a local LDP session is established, configure the hold time of keepalive packets in interface configuration mode.
- If a remote LDP session is established, configure the hold time of keepalive packets in LDP configuration mode.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Configure the hold time of keepalive packets in local LDP sessions on an interface.

mpls ldp keepalive-holdtime *keepalive-holdtime*

The default hold time of keepalive packets on an interface is 45s. The default interval for sending keepalive packets is one third of the hold time.

(5) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(6) Configure the hold time of keepalive packets in remote LDP sessions.

targeted-session holdtime *targeted-session-hold-time*

The default hold time of keepalive packets in remote LDP session established using the LDP extended discovery mechanism is 180s, and the interval for sending keepalive packets is one third of the hold time.

1.6.12 Configuring the Maximum PDU

1. Overview

The messages exchanged between LDP devices are all contained in protocol data units (PDUs). This function allows you to specify the maximum PDU length allowed for each LDP message.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Configure the maximum PDU length.

mpls ldp max-pdu *max-pdu*

The maximum PDU length allowed for each LDP message is 4096 bytes by default.

1.6.13 Configuring LDP MD5 Authentication

1. Overview

To enhance the security of LDP sessions, you can configure LDP-MD5 authentication on LSRs at both ends of an LDP session.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Configure a device to adopt MD5 authentication for the TCP connections with its peer.

neighbor *ipv4-address* **password** [**0** | **7**] *password-string*

The LDP MD5 authentication function is disabled by default.

1.7 Configuring an LDP LSP

1.7.1 Overview

Set up an LSP for an IPv4 unicast route by using LDP.

1.7.2 Restrictions and Guidelines

The LDP needs to use existing unicast routes on the network. Therefore, IP unicast routes must be configured on the network.

1.7.3 Configuration Tasks

All the configuration tasks below are optional. Select them based on your requirement. LDP LSP configuration includes the following tasks:

(1) Configuring LDP Loop Detection

(2) Enabling the Label Release Message Transfer Switch

(3) Configuring the LDP Label Distribution Mode

(4) Configuring the LDP Label Distribution Control Mode

(5) Configuring the LDP Label Retention Mode

(6) Configuring a Label Distribution Policy for an LDP Instance

(7) Configuring a Label Reception Policy for an LDP Instance

(8) Configuring a Policy for Distributing Explicit Null Labels

1.7.4 Configuring LDP Loop Detection

1. Overview

If loop detection is enabled and the number of hops in an LDP message exceeds the preset value, it is considered that a loop occurs.

The maximum path vector value allowed for loop detection is the maximum number of LSRs included in the path vector list of loop detection. When loop detection is enabled, an LSR considers that a loop occurs if the LSR detects its own LSR ID in the path vector list or the number of LSR IDs in the path vector list exceeds the preset value.

2. Restrictions and Guidelines

If an IP route is statically configured instead of being dynamically generated by using IGP, you are advised to enable the loop detection function on all LSRs that an LSP passes through to prevent loops caused by incorrect configuration.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Enable loop detection.

loop-detection

Loop detection is disabled by default.

(5) Exit the LDP configuration mode and return to the global configuration mode.

exit

(6) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(7) Configure the maximum number of hops allowed for loop detection.

mpls ldp max-hop-count *max-hop-count*

The maximum number of hops allowed for loop detection on an interface is 254 by default.

(8) Configure the maximum path vector value allowed for loop detection on an interface.

mpls ldp max-path-vector *number*

The maximum path vector value allowed for loop detection on an interface is 254 by default.

1.7.5 Enabling the Label Release Message Transfer Switch

1. Overview

When an FEC becomes invalid, the LDP sends label release messages from upstream nodes to downstream nodes to unbind the label from the FEC. Each LDP device on an LSP determines whether to transfer label release messages from upstream nodes to downstream nodes based on the setting of the label release message transfer mode.

2. Restrictions and Guidelines

The label release message transfer switch affects only label release messages received by LDP instances after the switch is enabled and not those received before the switch is enabled.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Enable the transfer switch for label release messages received by LDP instances.

propagate-release

The transfer switch for label release messages is disabled by default.

1.7.6 Configuring the LDP Label Distribution Mode

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Configure the LDP label distribution mode.

mpls ldp distribution-mode { **dod** | **du** }

The LDP uses the DU mode on each interface by default.

1.7.7 Configuring the LDP Label Distribution Control Mode

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Configure the LDP label distribution control mode.

lsp-control-mode { **independent** | **ordered** }

The default LDP label distribution control mode is the independent mode.

1.7.8 Configuring the LDP Label Retention Mode

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Configure the LDP label retention mode.

label-retention-mode { **liberal | conservative** }

The default label retention mode is the liberal mode.

1.7.9 Configuring a Label Distribution Policy for an LDP Instance

1. Overview

Configure a policy for distributing labels to IP route FECs.

2. Restrictions and Guidelines

- You can run the **advertise-labels for bgp-routes** command to enable the function of distributing labels to BGP routes.
- An LDP instance distributes implicit null label 3 to default routes by default. Therefore, the LDP instance does not set up LSPs for default routes.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Configure a label distribution policy.

advertise-labels [**for acl** [**ipv6**] *prefix-access-list* [**to** *peer-access-list*] | **for bgp-routes** [**acl** [**ipv6**] *acl_name*] | **for default-route** | **for host-routes**]

By default, an LDP instance distributes labels only to IGP routes, and distributes implicit null label 3 to default routes, but does not distribute labels or add FTN entries for BGP routes.

1.7.10 Configuring a Label Reception Policy for an LDP Instance

1. Restrictions and Guidelines

- The **neighbor** command takes effect only to label mapping messages with IP route FECs. It is invalid to other types of FECs, such as pseudo wire (PW) FECs.
- After an ACL rule for incoming label mapping messages is configured by running the **neighbor** command, an LDP instance receives FEC-label mapping messages that come from specified neighbors and meet the ACL rule, and discards FEC-label messages not meeting the ACL rule. However, the LDP instance can receive label mapping messages from other neighbors.
- If the **neighbor** command is configured for a neighbor but no ACL rule is specified, the LDP instance discards all FEC-label mapping messages sent from the neighbor. After an ACL rule is canceled by running the **no** form of the **neighbor** command, FEC-label mapping messages that have been discarded based on the ACL rule cannot be re-obtained, and only newly received FEC-label mapping messages are affected. You need to run the **clear mpls ldp neighbor** command to reset the LDP session to restore it to the normal status.
- Only one rule can be configured for each neighbor, and the newly configured rule will overwrite the existing one.
- Each LDP instance can configure ACL rules for a maximum of 64 neighbors.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Configure a label reception policy.

neighbor *ipv4-address* **labels accept** [**ipv6**] *acl-name*

No ACL rule is configured by default.

If **ipv6** is not specified, the configured policy applies only to standard and extended IP ACLs. If **ipv6** is specified, the configured policy applies only to extended IPv6 ACLs.

1.7.11 Configuring a Policy for Distributing Explicit Null Labels

1. Restrictions and Guidelines

A policy for distributing explicit null labels can be configured only for global LDP instances. This function is not supported on VPN instances.

Specification

When the EA/EB series line cards of the S79 series products function as P nodes and have PHP enabled, the IPv4 explicit null label distribution and IPv6 explicit explicit null label distribution must be configured on MPLS LDP mode on the connected PE.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Configure an LDP instance to distribute explicit null labels to all direct routes or routes that meet an ACL rule.

explicit-null [**for** *prefix-acl-name*] [**to** *peer-acl-name*]

Implicit null labels are distributed to direct routes by default.

1.8 Configuring an LDP IPv6 LSP

1.8.1 Overview

Set up an IPv6 LSP using LDP. After LDP is enabled, you need to configure the LDP IPv6 transport address. There are two configuration methods:

- All LDP sessions use a specified IPv6 global unicast address as the transport address.
- All LDP sessions use the primary IPv6 address of a specified interface as the transport address.

1.8.2 Restrictions and Guidelines

- MPLS forwarding needs to be enabled globally and on each interface that an IPv6 LSP passes through.
- You need to manually configure an LDP IPv6 transport address. If no transport address is configured or the configured address is invalid, a device will not send LDP IPv6 Hello packets.
- If all LDP sessions use the primary IPv6 address of a specified interface as the transport address, the configuration takes effect only when an IPv6 global unicast address exists on the interface.
- You need to enable the LDP IPv6 function globally and on an interface on each LSR that an IPv6 LSP passes through.
- To enhance the security of LDP sessions, you can configure LDP-MD5 authentication on LSRs at both ends of an LDP IPv6 session.
- To establish an extended LDP session, configure each other as the remote peer on LSRs at both ends of the session. Alternatively, configure one end as the remote peer and configure the **discovery target-hello accept** command on the other end.
- When all neighbors support the LDP IPv6 function, you can enable the function of ignoring adjacent negotiation. If some neighbors do not support the LDP IPv6 function, you are not advised to enable the function of ignoring adjacent negotiation. If the function is enabled, the neighbors that do not support the LDP IPv6 function may receive LDP IPv6 label mapping messages, causing processing errors.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the LDP.

mpls router ldp

LDP is disabled by default.

(4) Enable LDP IPv6 globally.

ipv6 enable

LDP IPv6 is disabled by default.

The LDP IPv6 function must be enabled globally. Otherwise, the local end does not send LDP IPv6 Hello packets.

(5) Configure the LDP IPv6 transport address.

ipv6 transport-address { *ipv6-address* | *interface-type interface-number* }

If a device interface does not have an IPv4 address, the LDP router ID must be configured.

(6) (Optional) Create an IPv6 remote peer for an LDP instance.

ipv6 neighbor *ipv6-address*

No IPv6 remote peer is configured for an LDP instance by default.

When configuring an IPv6 remote peer, you are advised to specify the IPv6 transport address of the remote peer.

(7) (Optional) Configure the function of ignoring IPv6 adjacency negotiation.

ignore ipv6-adj negotiation [**to** *peer-access-list*]

(8) (Optional) Configure a device to adopt MD5 authentication for the TCP connections with its peer.

ipv6 neighbor *ipv6-address* **password** [**0** | **7**] *password-string*

LDP IPv6 MD5 authentication is disabled by default.

(9) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(10) Enable LDP IPv6 on an interface.

mpls ipv6

LDP IPv6 is disabled on an interface by default.

This command cannot be configured on interfaces bound to a single-protocol VRF. After enabling the LDP IPv6 function on an interface, you must run the **label-switching** command to enable MPLS packet forwarding on the interface.

(11) Enable labeled MPLS packet forwarding on an interface.

label-switching

Forwarding labeled MPLS packets is disabled on an interface by default.

To enable MPLS packet forwarding on an interface, you must run the **label-switching** command on the interface.

1.9 Configuring LDP Session Protection

1.9.1 Overview

This function protects LDP sessions between two directly-connected LSRs.

1.9.2 Restrictions and Guidelines

- To ensure that the LDP session protection function works properly, enable it on LSRs at both ends of an LDP session.
- If only one LSR of an LDP session supports LDP session protection, you can enable the function on this LSR and configure receiving and responding to targeted Hello packets on the other LSR. You can run the **neighbor** *ipv4-address* command to specify a remote peer or run the **discovery targeted-hello accept** command to receive and respond to targeted Hello packets.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Enable LDP session protection.

session protection [**for acl** *acl-name*] [**duration** { **infinite** | *duration-time* }]

LDP session protection is disabled by default.

1.10 Configuring LDP Inter-Area LSP

1.10.1 Overview

When an AS is grouped into multiple IGP areas and route aggregation is enabled on ABRs, you can configure LDP inter-area LSP to build a label switching path for aggregated host routes across multiple IGP areas.

1.10.2 Restrictions and Guidelines

- The LDP inter-area LSP function takes effect only in liberal label retention mode.
- The LDP inter-area LSP function does not apply to the DoD mode.
- The LDP inter-area LSP function needs to be enabled on all LSRs of the LSP corresponding to the aggregated route.
- The LDP inter-area LSP function takes effect only to aggregated host routes. When maximum route matching is performed for an aggregated non-host route based on an ACL rule, this function is invalid.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Configure the LDP inter-area LSP function.

inter-area-lsp [**for acl** *acl_name*]

The LDP inter-area LSP function is disabled by default.

The LDP inter-area LSP function needs to be enabled on all devices between PEs.

1.11 Iterating IP Routes to LDP LSPs

1.11.1 Overview

Iterate non-direct IP routes to LDP LSPs to forward traffic to the remote ends through the LSPs.

1.11.2 Restrictions and Guidelines

- The FEC of an LDP LSP to which an IP route is iterated must be a host route.
- The function of iterating IP routes to LDP LSPs needs to be enabled only on the LERs and does not need to be enabled on the LSRs.
- All IP routes can be iterated, including but not limited to static routes and BGP routes.

1.11.3 Prerequisites

- LDP is configured in global configuration mode.
- LDP is enabled on each LSR that an LSP passes through.
- MPLS forwarding is enabled on each interface that an LSP passes through.
- (Optional) A remote peer is configured to establish an extended LDP session.

1.11.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Iterate IP routes to LDP LSPs.

recursive-route to mpls

The function of recurring and iterating IP routes to LDP LSPs is disabled by default.

1.12 Configuring LSP Connectivity Detection

1.12.1 Overview

In an MPLS network, common LSP connectivity detection tools include MPLS ping and MPLS traceroute. MPLS ping is used to manually detect the connectivity of an LSP. MPLS traceroute is used to trace LSRs between the ingress LER and egress LER. In addition to detecting LSP connectivity, MPLS traceroute can locate the network fault.

1.12.2 Restrictions and Guidelines

Both **ping mpls** and **traceroute mpls** support the following two parameter specification methods:

- Enter a command with specified parameters.
- Enter **ping mpls** or **traceroute mpls** and press **Enter** to enter the interactive input mode and then specify parameters.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Detect the connectivity of an MPLS LSP.

ping mpls ipv4 *ipv4-address/mask-length* [**destination** *destination-ipv4-address* | **dsmap** | **flags fec** | **force-explicit-null** | **interval** *interval* | **pad** *pattern* | **repeat** *repeat-count* | **reply mode** { **ipv4** | **router-alert** } | **size** *size* | **source** *source-ipv4-address* | **timeout** *timeout* | **ttl** *time-to-live* | **verbose**] *

(3) Trace the MPLS nodes that an LSP passes through.

traceroute mpls ipv4 *ipv4-address/mask-length* [**destination** *destination-ipv4-address* | **flags fec** | **force-explicit-null** | **reply mode** { **ipv4** | **router-alert** } | **source** *source-ipv4-address* | **timeout** *timeout* | **ttl** *time-to-live* | **verbose**] *

1.13 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Run the **debug** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-2 Monitoring

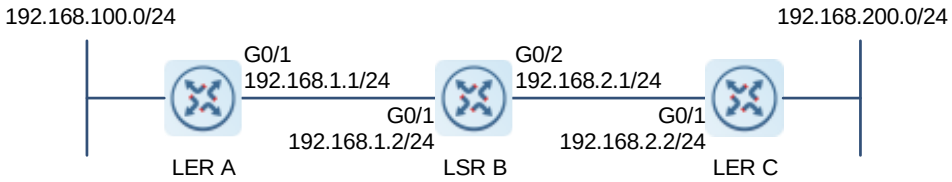
Command	Purpose
show mpls client	Displays client information about MPLS connection.
show mpls dep { **down** | **up** } [**vrf** *vrf-name*] **fec** *ipv4-address/mask-length* [**summary**] **show mpls dep ipv6** { **down** | **up** } [**vrf** *vrf-name*] **fec** *ipv6-address/mask-length* [**summary**]	Displays the global configuration of MPLS recursive entries.
show mpls dep process-list [**vrf** *vrf-name*] [**summary**]	Displays MPLS recursive entries to be updated.
show mpls forwarding-i capability	Displays MPLS capability information.

Command	Purpose
show mpls forwarding-table [**frr**] [**detail**] **show mpls forwarding-table** { *ipv4-address/mask-length* | *ipv6-address/prefix-length* } [**frr**] [**detail**] **show mpls forwarding-table** { **ftn** | **ilm** } [**ip** | **ipv6**] [**frr**] [**detail**] **show mpls forwarding-table** { **global** | **vrf** *vrf-name* } [**ftn** | **ilm**] [**frr**] [**detail**] **show mpls forwarding-table interface** *interface-type interface-number* [**frr**] [**detail**] **show mpls forwarding-table next-hop** { *ipv4-address* | *ipv6-address* } [**frr**] [**detail**] **show mpls forwarding-table summary**	Displays MPLS forwarding table information.
show mpls forwarding-table l3inter	Displays interface information in an L3VPN forwarding table.
show mpls forwarding-table recursive-ftn [**frr** | **ip** | **ipv6**] [**detail**]	Displays FTN entries advertised by the NSM.
show mpls forwarding-table-i [**vrf** *vrf-name*] [**ipv6**]	Displays MPLS forwarding entries.
show mpls ftn-table-i [**fec** *ipv4-address/mask-length* | **owner** *protocol-type*] **show mpls ftn-table-i ipv6** [**fec** *ipv6-address/mask-length* | **owner** *protocol-type*]	Displays FTN entry information.
show mpls ilm-detail-table-i [**in-label** *label* | **owner** *protocol-type*]	Displays detailed information about ILM entries.
show mpls index-manager { **cross-connect** | **ftn** | **out-segment** | **vrf** *vrf-name* } [*index*]	Displays bitmap index management information.
show mpls interface [*interface-type interface-number*]	Displays MPLS interface information.
show mpls ip-linkage [**vrf** *vrf-name*] **fec** { *ipv4-address/mask-length* | *ipv6-address/mask-length* }	Displays IP entry information.
show mpls key-event-history	Displays MPLS log information about key events.
show mpls label-pool [*label-space*]	Displays label pool usage of a specified label space.
show mpls label-pool-i	Displays the usage of an MPLS label pool.

Command	Purpose
show mpls ldp bindings [**all** | **vrf** *vrf-name*] [*ipv4-address/mask-length* | *ipv6-address/prefix-length* | **ipv4** | **ipv6** | **label** *label*] [**local** | **remote**]	Displays LDP label binding information.
show mpls ldp discovery [**all** | **vrf** *vrf-name*] [**detail**]	Displays LDP neighbor discovery information of all or specified VRF instances.
show mpls ldp interface [**all** | **vr**f *vrf-name* | *interface-type interface-number*]	Displays interfaces enabled with LDP.
show mpls ldp neighbor [**all** | **vrf** *vrf-name*] [*ipv4-address*] [**detail**]	Displays LDP neighbors of all or specified VRF instances.
show mpls ldp parameters [**all** | **vrf** *vrf-name*]	Displays LDP parameters of all or specified VRF instances.
show mpls ref ftn-ipv4 [**global** | **vrf** *vrf-name*] [*ipv4-address/mask-length*] [**detail**] **show mpls ref ftn-ipv6** [**global** | **vrf** *vrf-name*] [*ipv6-address/prefix-length*] [**detail**] **show mpls ref ilm** [**in-label** *in-label* [**detail**] | **summary**] **show mpls ref nhlfe** [[*nhlfe-id* [**detail**]] | **summary**] **show mpls ref summary**	Displays MPLS quick forwarding information.
show mpls memory	Displays the memory usage of MPLS.
show mpls nhlfe-table-i	Displays NHLFEs of MPLS.
show mpls psn notify-entry { **all** | **l2vpn** | **l3vpn** { **global** | **vrf** *vrf-name* } }	Displays PSN notification entries.
show mpls recursive-route [*ipv4-address* | *ipv6-address*]	Displays LSP information parsed according to next hops of BGP routes.
show mpls rib [**all** | **vrf** *vrf-name*] [**ipv6**]	Displays MPLS RIB routing table information.
show mpls statistics	Displays MPLS statistics.
show mpls summary	Displays MPLS global configurations.
show mpls vrf [**name** *vrf-name*] [**detail**]	Displays MPLS VRF information.
show mpls vrf-table-i [**vrf** *vrf-name*] [**fec** *ipv4-address/mask-length* | **owner** *protocol-name*] **show mpls vrf-table-i ipv6** [**vrf** *vrf-name*] [**fec** *ipv6-address/mask-length* | **owner** *protocol-name*]	Displays MPLS VRF entries.

Command	Purpose
clear mpls ldp neighbor [**all** | **vrf** *vrf-name*] [***** | *ipv4-address*]	Clears established LDP sessions.
debug mpls	Debugs MPLS entry internal processing.
debug mpls ldp binding	Debugs LDP label binding.
debug mpls ldp message [**hello** | **keepalive**] [**received** | **sent**]	Debugs LDP session messages.
debug mpls lspv { **all** | **error** | **event** | **packet** | **tlv** }	Debugs the **ping mpls** and **traceroute mpls** execution processes.
debug mpls msg [**send** | **recv**]	Debugs MPLS messages.
debug mpls ref [**control** | **packet**]	Debugs MPLS quick forwarding (control plane or forwarding plane).

1.14 Configuration Examples



1.14.1 Configuring a Static LSP

1. Requirements

Configure static MPLS entries on LER A, LSR B, and LER C to set up an LSP and ensure that VPN sites can interconnect with each other through the MPLS network. LER A, LSR B, and LER C need to support the MPLS function.

2. Topology

Figure 1-14 Configuring a Static LSP

3. Notes

- Configure interface IP addresses and an IPv4 unicast routing protocol (for example, OSPF) on the devices to ensure that the routes between the devices are reachable.
- Enable MPLS forwarding globally and label forwarding on an interface.
- Configure static FTN entries on LER A and LER C, configure static ILM entries on LSR B, and set up static LSPs from LER A to LER C and from LER C to LER A. The outgoing label of the ILM entries on LSR B is implicit null label 3.

4. Procedure

(1) Configure interface IP addresses and OSPF on the devices to ensure that the routes between the devices are reachable.

Configure LER A.

```
LERA> enable
LERA# configure terminal
LERA(config)# interface gigabitethernet 0/1
LERA(config-if-GigabitEthernet 0/1)# no switchport
LERA(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
LERA(config-if-GigabitEthernet 0/1)# exit
LERA(config)# router ospf 10
LERA(config-router)# network 192.168.1.0 0.0.0.255 area 0
LERA(config-router)# network 192.168.100.0 0.0.0.255 area 0
LERA(config-router)# exit
```

Configure LSR B.

```
LSRB> enable
LSRB# configure terminal
LSRB(config)# interface gigabitethernet 0/1
LSRB(config-if-GigabitEthernet 0/1)# no switchport
LSRB(config-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
LSRB(config-if-GigabitEthernet 0/1)# exit
LSRB(config)# interface gigabitethernet 0/2
LSRB(config-if-GigabitEthernet 0/2)# no switchport
LSRB(config-if-GigabitEthernet 0/2)# ip address 192.168.2.1 255.255.255.0
LSRB(config-if-GigabitEthernet 0/2)# exit
LSRB(config)# router ospf 10
LSRB(config-router)# network 192.168.1.0 0.0.0.255 area 0
LSRB(config-router)# network 192.168.2.0 0.0.0.255 area 0
LSRB(config-router)# exit
```

Configure LER C.

```
LERC> enable
LERC# configure terminal
LERC(config)# interface gigabitethernet 0/1
LERC(config-if-GigabitEthernet 0/1)# no switchport
LERC(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
LERC(config-if-GigabitEthernet 0/1)# exit
LERC(config)# router ospf 10
LERC(config-router)# network 192.168.2.0 0.0.0.255 area 0
LERC(config-router)# network 192.168.200.0 0.0.0.255 area 0
LERC(config-router)# exit
```

(2) Enable MPLS forwarding globally and label forwarding on an interface.

Configure LER A.

```
LERA(config)# mpls ip
```

```
LERA(config)# interface gigabitethernet 0/1
LERA(config-if-GigabitEthernet 0/1)# label-switching
LERA(config-if-GigabitEthernet 0/1)# exit
```

Configure LSR B.

```
LSRB(config)# mpls ip
LSRB(config)# interface gigabitethernet 0/1
LSRB(config-if-GigabitEthernet 0/1)# label-switching
LSRB(config-if-GigabitEthernet 0/1)# exit
LSRB(config)# interface gigabitethernet 0/2
LSRB(config-if-GigabitEthernet 0/2)# label-switching
LSRB(config-if-GigabitEthernet 0/2)# exit
```

Configure LER C.

```
LERC(config)# mpls ip
LERC(config)# interface gigabitethernet 0/1
LERC(config-if-GigabitEthernet 0/1)# label-switching
LERC(config-if-GigabitEthernet 0/1)# exit
```

(3) Configure static FTN entries on LER A and LER C, configure static ILM entries on LSR B, and set up static LSPs from LER A to LER C and from LER C to LER A.

Configure LER A.

```
LERA(config)# mpls static ftn 192.168.200.0/24 out-label 16 nexthop
gigabitethernet 0/1 192.168.1.2
LERA(config)# exit
```

Configure LSR B.

```
LSRB(config)# mpls static ilm in-label 16 forward-action swap-label 3 nexthop
gigabitethernet 0/2 192.168.2.2 fec 192.168.200.0/24
LSRB(config)# mpls static ilm in-label 17 forward-action swap-label 3 nexthop
gigabitethernet 0/1 192.168.1.1 fec 192.168.100.0/24
LSRB(config)# exit
```

Configure LER C.

```
LERC(config)# mpls static ftn 192.168.100.0/24 out-label 17 nexthop
gigabitethernet 0/1 192.168.2.1
LERC(config)# exit
```

5. Verification

After the configuration is completed, run the **show mpls forwarding-table** command on devices to display MPLS entries.

Display MPLS entries on LER A.

```
LERA# show mpls forwarding-table
Label Operation Code:
PH--PUSH label
PP--POP label
SW--SWAP label
SP--SWAP topmost label and push new label
```

```
DP--DROP packet
PC--POP label and continue lookup by IP or Label
PI--POP label and do ip lookup forward
PN--POP label and forward to nexthop
PM--POP label and do MAC lookup forward
PV--POP label and output to VC attach interface
IP--IP lookup forward
 s--stale
  Local   Outgoing OP FEC                    Outgoing       Nexthop
  label   label                             interface
  --      16      PH 192.168.200.0/24         Gi0/1          192.168.1.2
```

Display MPLS entries on LSR B.

```
LSRB# show mpls forwarding-table
Label Operation Code:
PH--PUSH label
PP--POP label
SW--SWAP label
SP--SWAP topmost label and push new label
DP--DROP packet
PC--POP label and continue lookup by IP or Label
PI--POP label and do ip lookup forward
PN--POP label and forward to nexthop
PM--POP label and do MAC lookup forward
PV--POP label and output to VC attach interface
IP--IP lookup forward
 s--stale
  Local   Outgoing OP FEC                    Outgoing       Nexthop
  label   label                             interface
  16      imp-null PP 192.168.200.0/24        Gi0/2          192.168.2.2
  17      imp-null PP 192.168.100.0/24        Gi0/1          192.168.1.1
```

Display MPLS entries on LER C.

```
LERC# show mpls forwarding-table
Label Operation Code:
PH--PUSH label
PP--POP label
SW--SWAP label
SP--SWAP topmost label and push new label
DP--DROP packet
PC--POP label and continue lookup by IP or Label
PI--POP label and do ip lookup forward
PN--POP label and forward to nexthop
PM--POP label and do MAC lookup forward
PV--POP label and output to VC attach interface
IP--IP lookup forward
 s--stale
```

```
 Local   Outgoing OP FEC                    Outgoing       Nexthop
 label   label                             interface
 --      17      PH 192.168.100.0/24         Gi0/1          192.168.2.1
```

6. Configuration Files

- LER A configuration file

```
hostname LERA
!

!
```

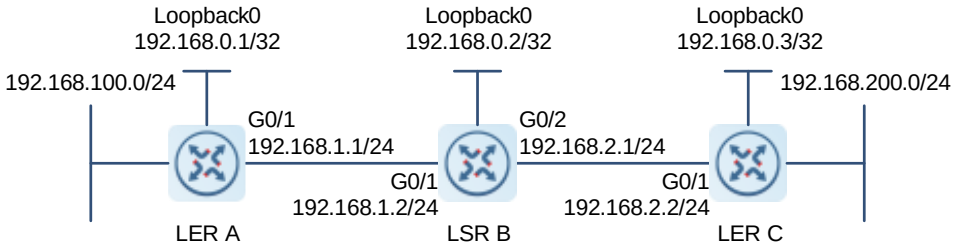
7. Common Errors

- MPLS forwarding is not enabled globally.
- MPLS forwarding is not enabled on an interface.



1.14.2 Configuring an LDP LSP

1. Requirements

Configure local LDP sessions among LER A, LSR B, and LER C to set up an LDP LSP and ensure that VPN sites can interconnect with each other through the MPLS network. LER A, LSR B, and LER C need to support the MPLS function.

2. Topology

Figure 1-15 Configuring an LDP LSP

3. Notes

- Configure interface IP addresses and an IPv4 unicast routing protocol (for example, OSPF) on the devices to ensure that the routes between the devices are reachable.
- Enable MPLS forwarding globally.

- Configure the LDP and LDP router ID.
- Enable the LDP function and label forwarding capability on an interface.

4. Procedure

(1) Configure interface IP addresses and OSPF on the devices to ensure that the routes between the devices are reachable.

Configure LER A.

```
LERA> enable
LERA# configure terminal
LERA(config)# interface gigabitethernet 0/1
LERA(config-if-GigabitEthernet 0/1)# no switchport
LERA(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
LERA(config-if-GigabitEthernet 0/1)# exit
LERA(config)# interface loopback 0
LERA(config-if-Loopback 0)# ip address 192.168.0.1 255.255.255.255
LERA(config-if-Loopback 0)# exit
LERA(config)# router ospf 10
LERA(config-router)# network 192.168.1.0 0.0.0.255 area 0
LERA(config-router)# network 192.168.0.1 0.0.0.0 area 0
LERA(config-router)# network 192.168.100.0 0.0.0.255 area 0
LERA(config-router)# exit
```

Configure LSR B.

```
LSRB> enable
LSRB# configure terminal
LSRB(config)# interface gigabitethernet 0/1
LSRB(config-if-GigabitEthernet 0/1)# no switchport
LSRB(config-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
LSRB(config-if-GigabitEthernet 0/1)# exit
LSRB(config)# interface gigabitethernet 0/2
LSRB(config-if-GigabitEthernet 0/2)# no switchport
LSRB(config-if-GigabitEthernet 0/2)# ip address 192.168.2.1 255.255.255.0
LSRB(config-if-GigabitEthernet 0/2)# exit
LSRB(config)# interface loopback 0
LSRB(config-if-Loopback 0)# ip address 192.168.0.2 255.255.255.255
LSRB(config-if-Loopback 0)# exit
LSRB(config)# router ospf 10
LSRB(config-router)# network 192.168.1.0 0.0.0.255 area 0
LSRB(config-router)# network 192.168.2.0 0.0.0.255 area 0
LSRB(config-router)# network 192.168.0.2 0.0.0.0 area 0
LSRB(config-router)# exit
```

Configure LER C.

```
LERC> enable
LERC# configure terminal
LERC(config)# interface gigabitethernet 0/1
```

```
LERC(config-if-GigabitEthernet 0/1)# no switchport
LERC(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
LERC(config-if-GigabitEthernet 0/1)# exit
LERC(config)# interface loopback 0
LERC(config-if-Loopback 0)# ip address 192.168.0.3 255.255.255.255
LERC(config-if-Loopback 0)# exit
LERC(config)# router ospf 10
LERC(config-router)# network 192.168.2.0 0.0.0.255 area 0
LERC(config-router)# network 192.168.0.3 0.0.0.0 area 0
LERC(config-router)# network 192.168.200.0 0.0.0.255 area 0
LERC(config-router)# exit
```

(2) Enable MPLS forwarding globally. LER A is used as an example. Configurations on LSR B and LER C are similar to those on LER A.

```
LERA(config)# mpls ip
```

(3) Configure the LDP and LDP router ID. LER A is used as an example. Configurations on LSR B and LER C are similar to those on LER A.

```
LERA(config)# mpls router ldp
LERA(config-mpls-router)# ldp router-id interface loopback 0 force
LERA(config-mpls-router)# exit
```

(4) Enable the LDP function and label forwarding capability on an interface.

Configure LER A.

```
LERA(config)# interface gigabitethernet 0/1
LERA(config-if-GigabitEthernet 0/1)# mpls ip
LERA(config-if-GigabitEthernet 0/1)# label-switching
LERA(config-if-GigabitEthernet 0/1)# end
```

Configure LSR B.

```
LSRB(config)# interface gigabitethernet 0/1
LSRB(config-if-GigabitEthernet 0/1)# mpls ip
LSRB(config-if-GigabitEthernet 0/1)# label-switching
LSRB(config-if-GigabitEthernet 0/1)# exit
LSRB(config)# interface gigabitethernet 0/2
LSRB(config-if-GigabitEthernet 0/2)# mpls ip
LSRB(config-if-GigabitEthernet 0/2)# label-switching
LSRB(config-if-GigabitEthernet 0/2)# end
```

Configure LER C.

```
LERC (config)# interface gigabitethernet 0/1
LERC(config-if-GigabitEthernet 0/1)# mpls ip
LERC(config-if-GigabitEthernet 0/1)# label-switching
LERC(config-if-GigabitEthernet 0/1)# end
```

5. Verification

(1) After the configuration is completed, run the **show mpls ldp neighbor** command to check whether the status of LDP sessions among LER A, LSR B, and LER C is "OPERATIONAL."

Display LDP session information on LER A.

```
LERA# show mpls ldp neighbor
Default VRF:
   Peer LDP Ident: 192.168.0.2:0; Local LDP Ident: 192.168.0.1:0
      TCP connection: 192.168.0.2.45063 - 192.168.0.1.646
      State: OPERATIONAL; Msgs sent/recv: 606/606; UNSOLICITED
      Up time: 02:28:09
      Graceful Restart enabled; Peer reconnect time (msecs): 300000
      LDP discovery sources:
        Link Peer on GigabitEthernet 0/1, Src IP addr: 192.168.1.2
      Addresses bound to peer LDP Ident:
        192.168.1.2    192.168.2.1    192.168.0.2
```

Display LDP session information on LSR B.

```
LSRB# show mpls ldp neighbor
Default VRF:
   Peer LDP Ident: 192.168.0.1:0; Local LDP Ident: 192.168.0.2:0
      TCP connection: 192.168.0.1.646 - 192.168.0.2.45063
      State: OPERATIONAL; Msgs sent/recv: 650/653; UNSOLICITED
      Up time: 02:39:26
      Graceful Restart enabled; Peer reconnect time (msecs): 300000
      LDP discovery sources:
        Link Peer on GigabitEthernet 0/1, Src IP addr: 192.168.1.1
      Addresses bound to peer LDP Ident:
        192.168.0.1    192.168.1.1
   Peer LDP Ident: 192.168.0.3:0; Local LDP Ident: 192.168.0.2:0
      TCP connection: 192.168.0.3.41299 - 192.168.0.2.646
      State: OPERATIONAL; Msgs sent/recv: 335/336; UNSOLICITED
      Up time: 01:21:20
      Graceful Restart enabled; Peer reconnect time (msecs): 300000
      LDP discovery sources:
        Link Peer on GigabitEthernet 0/2, Src IP addr: 192.168.2.2
      Addresses bound to peer LDP Ident:
        192.168.2.2    192.168.0.3    192.168.200.1
```

Display LDP session information on LER C.

```
LERC# show mpls ldp neighbor
Default VRF:
   Peer LDP Ident: 192.168.0.2:0; Local LDP Ident: 192.168.0.3:0
      TCP connection: 192.168.0.2.646 - 192.168.0.3.41299
      State: OPERATIONAL; Msgs sent/recv: 344/345; UNSOLICITED
      Up time: 01:23:33
      Graceful Restart enabled; Peer reconnect time (msecs): 300000
      LDP discovery sources:
        Link Peer on GigabitEthernet 0/1, Src IP addr: 192.168.2.1
      Addresses bound to peer LDP Ident:
        192.168.1.2    192.168.2.1    192.168.0.2
```

(2) Run the **show mpls forwarding-table** command to display MPLS forwarding entries on LER A, LSR B, and LER C and verify that the LDP LSP is set up.

Display MPLS forwarding entries on LER A.

```
LERA# show mpls forwarding-table
Label Operation Code:
PH--PUSH label

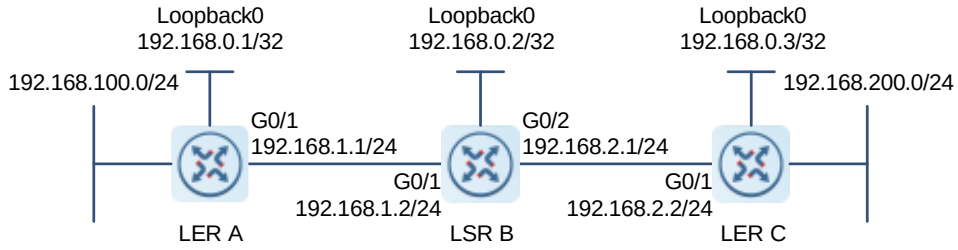
 network 192.168.200.0 0.0.0.255 area 0
!
mpls router ldp
 ldp router-id interface loopback 0 force
!
```

7. Common Errors

- An IPv4 unicast route is incorrectly configured.
- MPLS forwarding is not enabled globally.
- LDP is not configured.
- LDP is not enabled on an interface.
- The label forwarding capability is not enabled on an interface.



1.14.3 Configuring a Remote LDP Session

1. Requirements

Establish a remote LDP session.

2. Topology

Figure 1-16 Establishing a Remote LDP Session

3. Notes

- Configure an IPv4 unicast routing protocol (such as OSPF) on the devices and ensure that the loopback interfaces are accessible via unicast routes.
- Enable MPLS forwarding and LDP globally and configure the LDP router ID.
- Configure remote peers.

4. Procedure

(1) Configure interface IP addresses and OSPF on the devices to ensure communication between them.

Configure LER A.

```
LERA> enable
LERA# configure terminal
```

```
LERA(config)# interface gigabitethernet 0/1
LERA(config-if-GigabitEthernet 0/1)# no switchport
LERA(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
LERA(config-if-GigabitEthernet 0/1)# exit
LERA(config)# interface loopback 0
LERA(config-if-Loopback 0)# ip address 192.168.0.1 255.255.255.255
LERA(config-if-Loopback 0)# exit
LERA(config)# router ospf 10
LERA(config-router)# network 192.168.1.0 0.0.0.255 area 0
LERA(config-router)# network 192.168.0.1 0.0.0.0 area 0
LERA(config-router)# network 192.168.100.0 0.0.0.255 area 0
LERA(config-router)# exit
```

Configure LSR B.

```
LSRB> enable
LSRB# configure terminal
LSRB(config)# interface gigabitethernet 0/1
LSRB(config-if-GigabitEthernet 0/1)# no switchport
LSRB(config-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
LSRB(config-if-GigabitEthernet 0/1)# exit
LSRB(config)# interface gigabitethernet 0/2
LSRB(config-if-GigabitEthernet 0/2)# no switchport
LSRB(config-if-GigabitEthernet 0/2)# ip address 192.168.2.1 255.255.255.0
LSRB(config-if-GigabitEthernet 0/2)# exit
LSRB(config)# interface loopback 0
LSRB(config-if-Loopback 0)# ip address 192.168.0.2 255.255.255.255
LSRB(config-if-Loopback 0)# exit
LSRB(config)# router ospf 10
LSRB(config-router)# network 192.168.1.0 0.0.0.255 area 0
LSRB(config-router)# network 192.168.0.2 0.0.0.0 area 0
LSRB(config-router)# network 192.168.2.0 0.0.0.255 area 0
LSRB(config-router)# exit#
```

Configure LER C.

```
LERC> enable
LERC# configure terminal
LERC(config)# interface gigabitethernet 0/1
LERC(config-if-GigabitEthernet 0/1)# no switchport
LERC(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
LERC(config-if-GigabitEthernet 0/1)# exit
LERC(config)# interface loopback 0
LERC(config-if-Loopback 0)# ip address 192.168.0.3 255.255.255.255
LERC(config-if-Loopback 0)# exit
LERC(config)# router ospf 10
LERC(config-router)# network 192.168.2.0 0.0.0.255 area 0
LERC(config-router)# network 192.168.0.3 0.0.0.0 area 0
LERC(config-router)# network 192.168.200.0 0.0.0.255 area 0
```

```
LERC(config-router)# exit
```

(2) Enable MPLS forwarding and LDP globally and configure the LDP router ID. LER A is used as an example. Configurations on LER C are similar to those on LER A.

Configure LER A.

```
LERA(config)# mpls ip
LERA(config)# mpls router ldp
LERA(config-mpls-router)# ldp router-id interface loopback 0 force
```

(3) Configure remote peers.

Configure LER A.

```
LERA(config-mpls-router)# neighbor 192.168.0.3
LERA(config-mpls-router)# end
```

Configure LER C.

```
LERC(config-mpls-router)# neighbor 192.168.0.1
LERC(config-mpls-router)# end
```

5. Verification

Run the **show mpls ldp neighbor** command to check whether an LDP session is established between LER A and LER C.

Check whether an LDP session to LER C is established on LER A.

```
LERA# show mpls ldp neighbor
Default VRF:
   Peer LDP Ident: 192.168.0.3:0; Local LDP Ident: 192.168.0.1:0
      TCP connection: 192.168.0.3.36809 - 192.168.0.1.646
      State: OPERATIONAL; Msgs sent/recv: 15/16; UNSOLICITED
      Up time: 00:10:52
      Graceful Restart enabled; Peer reconnect time (msecs): 300000
      LDP discovery sources:
        Targeted Hello 192.168.0.1 -> 192.168.0.3, active, passive;
      Addresses bound to peer LDP Ident:
        192.168.2.2    192.168.0.3
```

Check whether an LDP session to LER A is established on LER C.

```
LERC# show mpls ldp neighbor
Default VRF:
   Peer LDP Ident: 192.168.0.1:0; Local LDP Ident: 192.168.0.3:0
      TCP connection: 192.168.0.1.646 - 192.168.0.3.36809
      State: OPERATIONAL; Msgs sent/recv: 17/18; UNSOLICITED
      Up time: 00:12:02
      Graceful Restart enabled; Peer reconnect time (msecs): 300000
      LDP discovery sources:
        Targeted Hello 192.168.0.3 -> 192.168.0.1, active, passive;
      Addresses bound to peer LDP Ident:
        192.168.1.1    192.168.0.1
```

6. Configuration Files

- LER A configuration file

```
hostname LERA
!

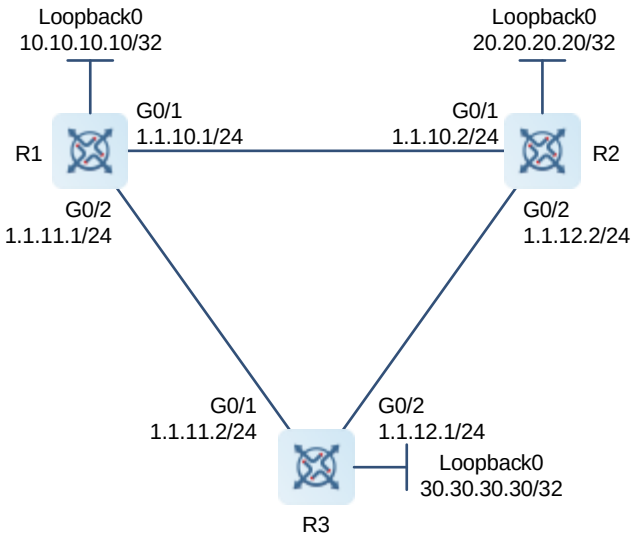
7. Common Errors

- An IPv4 unicast route is incorrectly configured.
- MPLS forwarding is not enabled globally.
- LDP is not configured.
- Remote peers are not configured.



1.14.4 Configuring LDP Session Protection

1. Requirements

Enable LDP session protection on R1 and R2 to protect the LDP session between them.

2. Topology

Figure 1-17 Configuring LDP Session Protection

3. Notes

- Configure interface IP addresses and OSPF on the devices to ensure that the routes between the devices are reachable.
- Enable MPLS forwarding globally and on an interface, configure the LDP, and set up an LDP LSP.
- Enable LDP session protection on R1 and R2.

4. Procedure

(1) Configure interface IP addresses and OSPF on the devices to ensure that the routes between the devices are reachable.

Configure R1.

```
R1> enable
R1# configure terminal
R1(config)# interface loopback 0
R1(config-if-Loopback 0)# ip address 10.10.10.10 255.255.255.255
R1(config-if-Loopback 0)# exit
R1(config)# interface gigabitethernet 0/1
R1(config-if-GigabitEthernet 0/1)# no switchport
R1(config-if-GigabitEthernet 0/1)# ip address 1.1.10.1 255.255.255.0
R1(config-if-GigabitEthernet 0/1)# exit
R1(config)# interface gigabitethernet 0/2
R1(config-if-GigabitEthernet 0/2)# no switchport
R1(config-if-GigabitEthernet 0/2)# ip address 1.1.11.1 255.255.255.0
R1(config-if-GigabitEthernet 0/2)# exit
R1(config)# router ospf 1
R1(config-router)# network 1.1.10.0 0.0.0.255 area 0
```

```
R1(config-router)# network 1.1.11.0 0.0.0.255 area 0
R1(config-router)# network 10.10.10.10 0.0.0.0 area 0
R1(config-router)# exit
```

Configure R2.

```
R2> enable
R2# configure terminal
R2(config)# interface loopback 0
R2(config-if-Loopback 0)# ip address 20.20.20.20 255.255.255.255
R2(config-if-Loopback 0)# exit
R2(config)# interface gigabitethernet 0/1
R2(config-if-GigabitEthernet 0/1)# no switchport
R2(config-if-GigabitEthernet 0/1)# ip address 1.1.10.2 255.255.255.0
R2(config-if-GigabitEthernet 0/1)# exit
R2(config)# interface gigabitethernet 0/2
R2(config-if-GigabitEthernet 0/2)# no switchport
R2(config-if-GigabitEthernet 0/2)# ip address 1.1.12.2 255.255.255.0
R2(config-if-GigabitEthernet 0/2)# exit
R2(config)# router ospf 1
R2(config-router)# network 1.1.10.0 0.0.0.255 area 0
R2(config-router)# network 1.1.12.0 0.0.0.255 area 0
R2(config-router)# network 20.20.20.20 0.0.0.0 area 0
R2(config-router)# exit
```

Configure R3.

```
R3> enable
R3# configure terminal
R3(config)# interface loopback 0
R3(config-if-Loopback 0)# ip address 30.30.30.30 255.255.255.255
R3(config-if-Loopback 0)# exit
R3(config)# interface gigabitethernet 0/1
R3(config-if-GigabitEthernet 0/1)# no switchport
R3(config-if-GigabitEthernet 0/1)# ip address 1.1.11.2 255.255.255.0
R3(config-if-GigabitEthernet 0/1)# exit
R3(config)# interface gigabitethernet 0/2
R3(config-if-GigabitEthernet 0/2)# no switchport
R3(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0
R3(config-if-GigabitEthernet 0/2)# exit
R3(config)# router ospf 1
R3(config-router)# network 1.1.11.0 0.0.0.255 area 0
R3(config-router)# network 1.1.12.0 0.0.0.255 area 0
R3(config-router)# network 30.30.30.30 0.0.0.0 area 0
R3(config-router)# exit
```

(2) Enable MPLS forwarding globally and on an interface, configure the LDP, and set up an LDP LSP.

Configure R1.

```
R1(config)# mpls ip
```

```
R1(config)# mpls router ldp
R1(config-mpls-router)# ldp router-id interface loopback 0 force
R1(config-mpls-router)# exit
R1(config)# interface gigabitethernet 0/1
R1(config-if-GigabitEthernet 0/1)# mpls ip
R1(config-if-GigabitEthernet 0/1)# label-switching
R1(config-if-GigabitEthernet 0/1)# exit
R1(config)# interface gigabitethernet 0/2
R1(config-if-GigabitEthernet 0/2)# mpls ip
R1(config-if-GigabitEthernet 0/2)# label-switching
R1(config-if-GigabitEthernet 0/2)# exit
```

Configure R2.

```
R2(config)# mpls ip
R2(config)# mpls router ldp
R2(config-mpls-router)# ldp router-id interface loopback 0 force
R2(config-mpls-router)# exit
R2(config)# interface gigabitethernet 0/1
R2(config-if-GigabitEthernet 0/1)# mpls ip
R2(config-if-GigabitEthernet 0/1)# label-switching
R2(config-if-GigabitEthernet 0/1)# exit
R2(config)# interface gigabitethernet 0/2
R2(config-if-GigabitEthernet 0/2)# mpls ip
R2(config-if-GigabitEthernet 0/2)# label-switching
R2(config-if-GigabitEthernet 0/2)# exit
```

Configure R3.

```
R3(config)# mpls ip
R3(config)# mpls router ldp
R3(config-mpls-router)# ldp router-id interface loopback 0 force
R3(config-mpls-router)# exit
R3(config)# interface gigabitethernet 0/1
R3(config-if-GigabitEthernet 0/1)# mpls ip
R3(config-if-GigabitEthernet 0/1)# label-switching
R3(config-if-GigabitEthernet 0/1)# exit
R3(config)# interface gigabitethernet 0/2
R3(config-if-GigabitEthernet 0/2)# mpls ip
R3(config-if-GigabitEthernet 0/2)# label-switching
```

(3) Enable LDP session protection on R1 and R2. R1 is used as an example. Configurations on R2 are similar to those on R1.

Configure R1.

```
R1(config)# mpls router ldp
R1(config-router)# session protection
R1(config-router)# session protection duration 300
```

5. Verification

After the configuration is completed, run the **show mpls ldp neighbor detail** command to check whether LDP session protection is enabled. R1 is used as an example.

```
R1# show mpls ldp neighbor detail
Default VRF:
   Peer LDP Ident: 20.20.20.20:0; Local LDP Ident: 10.10.10.10:0
      TCP connection: 20.20.20.20.41475 - 10.10.10.10.646

1.14.5 Configuring LDP Inter-Area LSP (OSPF Networking)

1. Requirements

To set up an LSP across multiple areas between PE1 and PE2, enable LDP inter-area LSP.

2. Topology

Figure 1-18 Configuring LDP Inter-Area LSP (OSPF Networking)

3. Notes

- Configure interface IP addresses and OSPF on the devices to ensure communication between them.
- Enable MPLS forwarding globally and on an interface and configure the LDP to ensure MPLS traffic forwarding.
- Configure VPN instances and MP-IBGP neighbors and VPN routing information delivery on the PEs.
- Configure aggregation route advertisement on the ABRs.
- Enable LDP inter-area LSP on each device.

4. Procedure

(1) Configure interface IP addresses and OSPF on the devices to ensure communication between them.

Configure PE1.

```
PE1> enable
PE1# configure terminal
PE1(config)# interface loopback 0
PE1(config-if-Loopback 0)# ip address 8.8.8.8 255.255.255.255
PE1(config-if-Loopback 0)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# ip address 1.1.1.2 255.255.255.0
PE1(config-if-GigabitEthernet 0/2)# exit
PE1(config)# router ospf 1
PE1(config-router)# network 1.1.1.0 0.0.0.255 area 1
PE1(config-router)# network 8.8.8.8 0.0.0.0 area 1
PE1(config-router)# exit
```

Configure ABR1.

```
ABR1> enable
ABR1# configure terminal
ABR1(config)# interface loopback 0
ABR1(config-if-Loopback 0)# ip address 10.10.10.10 255.255.255.255
ABR1(config-if-Loopback 0)# exit
ABR1(config)# interface gigabitethernet 0/1
```

```
ABR1(config-if-GigabitEthernet 0/1)# ip address 1.1.1.1 255.255.255.0
ABR1(config-if-GigabitEthernet 0/1)# exit
ABR1(config)# interface gigabitethernet 0/2
ABR1(config-if-GigabitEthernet 0/2)# ip address 1.1.2.2 255.255.255.0
ABR1(config-if-GigabitEthernet 0/2)# exit
ABR1(config)# router ospf 1
ABR1(config-router)# network 1.1.1.0 0.0.0.255 area 1
ABR1(config-router)# network 1.1.2.0 0.0.0.255 area 0
ABR1(config-router)# network 10.10.10.10 0.0.0.0 area 1
ABR1(config-router)# exit
```

Configure P1.

```
P1> enable
P1# configure terminal
P1(config)# interface loopback 0
P1(config-if-Loopback 0)# ip address 20.20.20.20 255.255.255.255
P1(config-if-Loopback 0)# exit
P1(config)# interface gigabitethernet 0/1
P1(config-if-GigabitEthernet 0/1)# ip address 1.1.2.1 255.255.255.0
P1(config-if-GigabitEthernet 0/1)# exit
P1(config)# interface gigabitethernet 0/2
P1(config-if-GigabitEthernet 0/2)# ip address 1.1.3.2 255.255.255.0
P1(config-if-GigabitEthernet 0/2)# exit
P1(config)# router ospf 1
P1(config-router)# network 1.1.2.0 0.0.0.255 area 0
P1(config-router)# network 1.1.3.0 0.0.0.255 area 0
P1(config-router)# network 20.20.20.20 0.0.0.0 area 0
P1(config-router)# exit
```

Configure PE2.

```
PE2> enable
PE2# configure terminal
PE2(config)# interface loopback 0
PE2(config-if-Loopback 0)# ip address 9.9.9.9 255.255.255.255
PE2(config-if-Loopback 0)# exit
PE2(config)# interface gigabitethernet 0/2
PE2(config-if-GigabitEthernet 0/2)# ip address 1.1.4.1 255.255.255.0
PE2(config-if-GigabitEthernet 0/2)# exit
PE2(config)# router ospf 1
PE2(config-router)# network 1.1.4.0 0.0.0.255 area 2
PE2(config-router)# network 9.9.9.9 0.0.0.0 area 2
PE2(config-router)# exit
```

Configure ABR2.

```
ABR2> enable
ABR2# configure terminal
ABR2(config)# interface loopback 0
ABR2(config-if-Loopback 0)# ip address 30.30.30.30 255.255.255.255
```

```
ABR2(config-if-Loopback 0)# exit
ABR2(config)# interface gigabitethernet 0/1
ABR2(config-if-GigabitEthernet 0/1)# ip address 1.1.3.1 255.255.255.0
ABR2(config-if-GigabitEthernet 0/1)# exit
ABR2(config)# interface gigabitethernet 0/2
ABR2(config-if-GigabitEthernet 0/2)# ip address 1.1.4.2 255.255.255.0
ABR2(config-if-GigabitEthernet 0/2)# exit
ABR2(config)# router ospf 1
ABR2(config-router)# network 1.1.3.0 0.0.0.255 area 0
ABR2(config-router)# network 1.1.4.0 0.0.0.255 area 2
ABR2(config-router)# network 30.30.30.30 0.0.0.0 area 2
ABR2(config-router)# exit
```

(2) Enable MPLS forwarding globally, configure the LDP, and configure an LDP Router ID.

Configure PE1.

```
PE1(config)# mpls ip
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# mpls ip
PE1(config-if-GigabitEthernet 0/2)# label-switching
PE1(config-if-GigabitEthernet 0/2)# exit
```

Configure ABR1.

```
ABR1(config)# mpls ip
ABR1(config)# mpls router ldp
ABR1(config-mpls-router)# ldp router-id interface loopback 0 force
ABR1(config-mpls-router)# exit
ABR1(config)# interface gigabitethernet 0/1
ABR1(config-if-GigabitEthernet 0/1)# mpls ip
ABR1(config-if-GigabitEthernet 0/1)# label-switching
ABR1(config-if-GigabitEthernet 0/1)# exit
ABR1(config)# interface gigabitethernet 0/2
ABR1(config-if-GigabitEthernet 0/2)# mpls ip
ABR1(config-if-GigabitEthernet 0/2)# label-switching
ABR1(config-if-GigabitEthernet 0/2)# exit
```

Configure P1.

```
P1(config)# mpls ip
P1(config)# mpls router ldp
P1(config-mpls-router)# ldp router-id interface loopback 0 force
P1(config-mpls-router)# exit
P1(config)# interface gigabitethernet 0/1
P1(config-if-GigabitEthernet 0/1)# mpls ip
P1(config-if-GigabitEthernet 0/1)# label-switching
P1(config-if-GigabitEthernet 0/1)# exit
```

```
P1(config)# interface gigabitethernet 0/2
P1(config-if-GigabitEthernet 0/2)# mpls ip
P1(config-if-GigabitEthernet 0/2)# label-switching
```

Configure PE2.

```
PE2(config)# mpls ip
PE2(config)# mpls router ldp
PE2(config-mpls-router)# ldp router-id interface loopback 0 force
PE2(config-mpls-router)# exit
PE2(config)# interface gigabitethernet 0/2
PE2(config-if-GigabitEthernet 0/2)# mpls ip
PE2(config-if-GigabitEthernet 0/2)# label-switching
PE2(config-if-GigabitEthernet 0/2)# exit
```

Configure ABR2.

```
ABR2(config)# mpls ip
ABR2(config)# mpls router ldp
ABR2(config-mpls-router)# ldp router-id interface loopback 0 force
ABR2(config-mpls-router)# exit
ABR2(config)# interface gigabitethernet 0/1
ABR2(config-if-GigabitEthernet 0/1)# mpls ip
ABR2(config-if-GigabitEthernet 0/1)# label-switching
ABR2(config-if-GigabitEthernet 0/1)# exit
ABR2(config)# interface gigabitethernet 0/2
ABR2(config-if-GigabitEthernet 0/2)# mpls ip
ABR2(config-if-GigabitEthernet 0/2)# label-switching
ABR2(config-if-GigabitEthernet 0/2)# exit
```

(3) Configure VPN instances and MP-IBGP neighbors on PE1 and PE2 to transmit VPN routing information.

Configure PE1.

```
PE1(config)# ip vrf vpn1
PE1(config-vrf)# rd 65001:20
PE1(config-vrf)# route-target both 65001:20
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# ip vrf forwarding vpn1
PE1(config-if-GigabitEthernet 0/1)# ip address 2.1.1.1 255.255.255.0
PE1(config)# router bgp 65001
PE1(config-router)# neighbor 9.9.9.9 remote-as 65001
PE1(config-router)# neighbor 9.9.9.9 update-source Loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 9.9.9.9 activate
PE1(config-router-af)# neighbor 9.9.9.9 send-community both
PE1(config-router-af)# exit
PE1(config-router)# address-family ipv4 vrf vpn1
PE1(config-router-af)# redistribute connected
PE1(config-router-af)# exit
```

```
PE1(config-router)# exit
```

Configure PE2.

```
PE2(config)# ip vrf vpn1
PE2(config-vrf)# rd 65001:20
PE2(config-vrf)# route-target both 65001:20
PE2(config-vrf)# exit
PE2(config)# interface gigabitethernet 0/1
PE2(config-if-GigabitEthernet 0/1)# ip vrf forwarding vpn1
PE2(config-if-GigabitEthernet 0/1)# ip address 2.1.2.1 255.255.255.0
PE2(config)# router bgp 65001
PE2(config-router)# neighbor 8.8.8.8 remote-as 65001
PE2(config-router)# neighbor 8.8.8.8 update-source Loopback 0
PE2(config-router)# address-family vpnv4
PE2(config-router-af)# neighbor 8.8.8.8 activate
PE2(config-router-af)# neighbor 8.8.8.8 send-community both
PE2(config-router-af)# exit
PE2(config-router)# address-family ipv4 vrf vpn1
PE2(config-router-af)# redistribute connected
PE2(config-router-af)# exit
PE2(config-router)# exit
```

(4) Configure aggregation route advertisement on the ABRs.

Configure ABR1.

```
ABR1(config)# router ospf 1
ABR1(config-router)# area 1 range 8.0.0.0 255.0.0.0
```

Configure ABR2.

```
ABR2(config)# router ospf 1
ABR2(config-router)# area 2 range 9.0.0.0 255.0.0.0
```

(5) Enable LDP inter-area LSP on PE1 and PE2.

Configure PE1.

```
PE1(config)# mpls router ldp
PE1(config-router)# inter-area-lsp
PE1(config-router)# end
```

Configure PE2.

```
PE2(config)# mpls router ldp
PE2(config-router)# inter-area-lsp
PE2(config-router)# end
```

5. Verification

Run the **show mpls ldp parameters** command to check whether LDP inter-area LSP is enabled, and run the **show mpls ldp bindings** command to check whether an LDP entry is added based on the maximum matching route rule. PE1 is used as an example.

```
PE1# show mpls ldp parameters
Default VRF:
```

```
  Protocol version: 1
    Ldp Router ID: 8.8.8.8
    Control Mode: INDEPENDENT
    Propogate Release: FALSE
    Label Merge: TRUE
    Label Retention Mode: LIBERAL
Loop Detection Mode: off
Inter Area Lsp: TRUE
    Session Protection: FALSE
    Targeted Session Keepalive HoldTime/Interval: 180/60 sec
Targeted Hello HoldTime/Interval: 90/10 sec

PE1# show mpls ldp bindings
Default VRF:
  lib entry: 10.10.10.10/32
     local binding:  to lsr:   10.10.10.10:0, label: 1027
     local binding:  to lsr:   30.30.30.30:0, label: 1027
     remote binding: from lsr: 10.10.10.10:0, label: imp-null
     remote binding: from lsr: 30.30.30.30:0, label: 1030 (not in FIB)
  lib entry: 9.9.9.9/32, (IA)
     local binding:  to lsr:   10.10.10.10:0, label: 1028
     local binding:  to lsr:   30.30.30.30:0, label: 1028
     remote binding: from lsr: 10.20.10.10:0, label: 1027 (not in FIB)
     remote binding: from lsr: 30.30.30.30:0, label: 1031
```

1.14.6 Configuring LDP Inter-Area LSP (IS-IS Networking)

1. Requirements

To set up an LSP across multiple areas between PE1 and PE2, enable LDP inter-area LSP.

2. Topology

Figure 1-19 Configuring LDP Inter-Area LSP (IS-IS Networking)

3. Notes

- Configure interface IP addresses and IS-IS on the devices to ensure communication between them.
- Configure VPN instances and MP-IBGP neighbors and VPN routing information delivery on the PEs.
- Configure aggregation route advertisement on the ABRs.
- Enable LDP inter-area LSP on each device.

4. Procedure

(1) Configure interface IP addresses and IS-IS on the devices to ensure communication between them.

Configure PE1.

```
PE1> enable
PE1# configure terminal
PE1(config)# router isis
```

```
PE1(config-router)# net 49.0001.0000.0000.0003.00
PE1(config-router)# is-type level-1
PE1(config-router)# exit
PE1(config)# interface loopback 0
PE1(config-if-Loopback 0)# ip address 8.8.8.8 255.255.255.255
PE1(config-if-Loopback 0)# ip router isis
PE1(config-if-Loopback 0)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# ip address 1.1.1.2 255.255.255.0
PE1(config-if-GigabitEthernet 0/2)# ip router isis
PE1(config-if-GigabitEthernet 0/2)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# ip address 2.1.1.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/1)# exit
```

Configure ABR1.

```
ABR1> enable
ABR1# configure terminal
ABR1(config)# router isis
ABR1(config-router)# net 49.0001.0000.0000.0002.00
ABR1(config-router)# is-type level-1-2
ABR1(config-router)# exit
ABR1(config)# interface loopback 0
ABR1(config-if-Loopback 0)# ip address 10.10.10.10 255.255.255.255
ABR1(config-if-Loopback 0)# ip router isis
ABR1(config-if-Loopback 0)# exit
ABR1(config)# interface gigabitethernet 0/1
ABR1(config-if-GigabitEthernet 0/1)# ip address 1.1.1.1 255.255.255.0
ABR1(config-if-GigabitEthernet 0/1)# ip router isis
ABR1(config-if-GigabitEthernet 0/1)# exit
ABR1(config)# interface gigabitethernet 0/2
ABR1(config-if-GigabitEthernet 0/2)# ip address 1.1.2.2 255.255.255.0
ABR1(config-if-GigabitEthernet 0/2)# ip router isis
ABR1(config-if-GigabitEthernet 0/2)# exit
```

Configure P1.

```
P1> enable
P1# configure terminal
P1(config)# router isis
P1(config-router)# net 50.0001.0000.0000.0001.00
P1(config-router)# is-type level-2-only
P1(config-router)# exit
P1(config)# interface loopback 0
P1(config-if-Loopback 0)# ip address 20.20.20.20 255.255.255.255
P1(config-if-Loopback 0)# ip router isis
P1(config-if-Loopback 0)# exit
P1(config)# interface gigabitethernet 0/1
```

```
P1(config-if-GigabitEthernet 0/1)# ip address 1.1.2.1 255.255.255.0
P1(config-if-GigabitEthernet 0/1)# ip router isis
P1(config-if-GigabitEthernet 0/1)# exit
P1(config)# interface gigabitethernet 0/2
P1(config-if-GigabitEthernet 0/2)# ip address 1.1.3.2 255.255.255.0
P1(config-if-GigabitEthernet 0/2)# ip router isis
P1(config-if-GigabitEthernet 0/2)# exit
P1(config-if-GigabitEthernet 0/2)# end
```

Configure ABR2.

```
ABR2> enable
ABR2# configure terminal
ABR2(config)# router isis
ABR2(config-router)# net 49.0002.0000.0000.0002.00
ABR2(config-router)# is-type level-1-2
ABR2(config-router)# exit
ABR2(config)# interface loopback 0
ABR2(config-if-Loopback 0)# ip address 30.30.30.30 255.255.255.255
ABR2(config-if-Loopback 0)# ip router isis
ABR2(config-if-Loopback 0)# exit
ABR2(config)# interface gigabitethernet 1/1
ABR2(config-if-GigabitEthernet 1/1)# ip address 1.1.3.1 255.255.255.0
ABR2(config-if-GigabitEthernet 1/1)# ip router isis
ABR2(config-if-GigabitEthernet 1/1)# exit
ABR2(config)# interface gigabitethernet 1/2
ABR2(config-if-GigabitEthernet 1/2)# ip address 1.1.4.2 255.255.255.0
ABR2(config-if-GigabitEthernet 1/2)# ip router isis
ABR2(config-if-GigabitEthernet 1/2)# exit
```

Configure PE2.

```
PE2> enable
PE2# configure terminal
PE2(config)# router isis
PE2(config-router)# net 49.0002.0000.0000.0003.00
PE2(config-router)# is-type level-1
PE2(config-router)# exit
PE2(config)# interface loopback 0
PE2(config-if-Loopback 0)# ip address 9.9.9.9 255.255.255.255
PE2(config-if-Loopback 0)# ip router isis
PE2(config-if-Loopback 0)# exit
PE2(config)# interface gigabitethernet 0/2
PE2(config-if-GigabitEthernet 0/2)# ip address 1.1.4.1 255.255.255.0
PE2(config-if-GigabitEthernet 0/2)# ip router isis
PE2(config-if-GigabitEthernet 0/2)# exit
PE2(config)# interface gigabitethernet 0/1
PE2(config-if-GigabitEthernet 0/1)# ip address 2.1.2.1 255.255.255.0
PE2(config-if-GigabitEthernet 0/1)# exit
```

(2) Enable MPLS forwarding globally, configure the LDP, and configure an LDP Router ID.

Configure PE1.

```
PE1(config)# mpls ip
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# mpls ip
PE1(config-if-GigabitEthernet 0/2)# label-switching
PE1(config-if-GigabitEthernet 0/2)# exit
```

Configure ABR1.

```
ABR1(config)# mpls ip
ABR1(config)# mpls router ldp
ABR1(config-mpls-router)# ldp router-id interface loopback 0 force
ABR1(config-mpls-router)# exit
ABR1(config)# interface gigabitethernet 0/1
ABR1(config-if-GigabitEthernet 0/1)# mpls ip
ABR1(config-if-GigabitEthernet 0/1)# label-switching
ABR1(config-if-GigabitEthernet 0/1)# exit
ABR1(config)# interface gigabitethernet 0/2
ABR1(config-if-GigabitEthernet 0/2)# mpls ip
ABR1(config-if-GigabitEthernet 0/2)# label-switching
ABR1(config-if-GigabitEthernet 0/2)# exit
```

Configure P1.

```
P1(config)# mpls ip
P1(config)# mpls router ldp
P1(config-mpls-router)# ldp router-id interface loopback 0 force
P1(config-mpls-router)# exit
P1(config)# interface gigabitethernet 0/1
P1(config-if-GigabitEthernet 0/1)# mpls ip
P1(config-if-GigabitEthernet 0/1)# label-switching
P1(config-if-GigabitEthernet 0/1)# exit
P1(config)# interface gigabitethernet 0/2
P1(config-if-GigabitEthernet 0/2)# mpls ip
P1(config-if-GigabitEthernet 0/2)# label-switching
P1(config-if-GigabitEthernet 0/2)# exit
```

Configure ABR2.

```
ABR2(config)# mpls ip
ABR2(config)# mpls router ldp
ABR2(config-mpls-router)# ldp router-id interface loopback 0 force
ABR2(config-mpls-router)# exit
ABR2(config)# interface gigabitethernet 1/1
ABR2(config-if-GigabitEthernet 1/1)# mpls ip
ABR2(config-if-GigabitEthernet 1/1)# label-switching
```

```
ABR2(config-if-GigabitEthernet 1/1)# exit
ABR2(config)# interface gigabitethernet 1/2
ABR2(config-if-GigabitEthernet 1/2)# mpls ip
ABR2(config-if-GigabitEthernet 1/2)# label-switching
ABR2(config-if-GigabitEthernet 1/2)# exit
```

Configure PE2.

```
PE2(config)# mpls ip
PE2(config)# mpls router ldp
PE2(config-mpls-router)# ldp router-id interface loopback 0 force
PE2(config-mpls-router)# exit
PE2(config)# interface gigabitethernet 0/2
PE2(config-if-GigabitEthernet 0/2)# mpls ip
PE2(config-if-GigabitEthernet 0/2)# label-switching
PE2(config-if-GigabitEthernet 0/2)# exit
```

(3) Configure VPN instances and MP-IBGP neighbors on PE1 and PE2 to transmit VPN routing information.

Configure PE1.

```
PE1(config)# ip vrf vpn1
PE1(config-vrf)# rd 65001:20
PE1(config-vrf)# route-target both 65001:20
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# ip vrf forwarding vpn1
PE1(config)# router bgp 65001
PE1(config-router)# neighbor 9.9.9.9 remote-as 65001
PE1(config-router)# neighbor 9.9.9.9 update-source Loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 9.9.9.9 activate
PE1(config-router-af)# neighbor 9.9.9.9 send-community both
PE1(config-router-af)# exit
PE1(config-router)# address-family ipv4 vrf vpn1
PE1(config-router-af)# redistribute connected
PE1(config-router-af)# exit
PE1(config-router)# exit
```

Configure PE2.

```
PE2(config)# ip vrf vpn1
PE2(config-vrf)# rd 65001:20
PE2(config-vrf)# route-target both 65001:20
PE2(config-vrf)# exit
PE2(config)# interface gigabitethernet 0/1
PE2(config-if-GigabitEthernet 0/1)# ip vrf forwarding vpn1
PE2(config)# router bgp 65001
PE2(config-router)# neighbor 8.8.8.8 remote-as 65001
PE2(config-router)# neighbor 8.8.8.8 update-source Loopback 0
PE2(config-router)# address-family vpnv4
```

```
PE2(config-router-af)# neighbor 8.8.8.8 activate
PE2(config-router-af)# neighbor 8.8.8.8 send-community both
PE2(config-router-af)# exit
PE2(config-router)# address-family ipv4 vrf vpn1
PE2(config-router-af)# redistribute connected
PE2(config-router-af)# exit
PE2(config-router)# exit
```

(4) Configure aggregation route advertisement on the ABRs.

Configure ABR1.

```
ABR1(config)# router isis
ABR1(config-router)# summary-address 8.0.0.0 255.0.0.0
ABR1(config-router)# exit
```

Configure ABR2.

```
ABR2(config)# router isis
ABR2(config-router)# summary-address 9.0.0.0 255.0.0.0
ABR2(config-router)# exit
```

(5) Enable LDP inter-area LSP on PE1 and PE2.

Configure PE1.

```
PE1(config)# mpls router ldp
PE1(config-router)# inter-area-lsp
PE1(config-router)# exit
```

Configure PE2.

```
PE2(config)# mpls router ldp
PE2(config-router)# inter-area-lsp
PE2(config-router)# exit
```

5. Verification

Run the **show mpls ldp parameters** command to check whether LDP inter-area LSP is enabled, and run the **show mpls ldp bindings** command to check whether an LDP entry is added based on the maximum matching route rule. P1 is used as an example.

```
P1# show mpls ldp parameters
Default VRF:
  Protocol version: 1
    Ldp Router ID: 8.8.8.8
    Control Mode: INDEPENDENT
    Propogate Release: FALSE
    Label Merge: TRUE
    Label Retention Mode: LIBERAL
Loop Detection Mode: off
Inter Area Lsp: TRUE
    Session Protection: FALSE
    Targeted Session Keepalive HoldTime/Interval: 180/60 sec
Targeted Hello HoldTime/Interval: 90/10 sec
```

```
P1# show mpls ldp bindings
Default VRF:
  lib entry: 10.10.10.10/32
     local binding:  to lsr:   10.10.10.10:0, label: 1027
     local binding:  to lsr:   30.30.30.30:0, label: 1027
     remote binding: from lsr: 10.10.10.10:0, label: imp-null
     remote binding: from lsr: 30.30.30.30:0, label: 1030 (not in FIB)
  lib entry: 9.9.9.9/32, (IA)
     local binding:  to lsr:   10.10.10.10:0, label: 1028
     local binding:  to lsr:   30.30.30.30:0, label: 1028
     remote binding: from lsr: 10.20.10.10:0, label: 1027 (not in FIB)
     remote binding: from lsr: 30.30.30.30:0, label: 1031
```

1.14.7 Configuring an LDP IPv6 LSP

1. Requirements

Configure an LDP IPv6 LSP.

2. Topology

Figure 1-20 Configuring an LDP IPv6 LSP

3. Notes

- Configure IPv6 addresses and OSPF on the devices to ensure communication between them (the loopback interfaces are accessible via unicast routes).
- Configure the LDP router ID and LDP IPv6 transport address, and enable LDP IPv6 globally.
- Enable the LDP IPv6 function and label forwarding capability on an interface.

4. Procedure

(1) Configure interface IP addresses and OSPF on the devices to ensure communication between them.

Configure LER A.

```
LERA> enable
LERA# configure terminal
LERA(config)# interface loopback 0
LERA(config-if-Loopback 0)# ipv6 address 1001::1/128
LERA(config-if-Loopback 0)# exit
LERA(config)# interface gigabitethernet 0/1
LERA(config-if-GigabitEthernet 0/1)# no switchport
LERA(config-if-GigabitEthernet 0/1)# ipv6 address 2001::12:1/64
LERA(config-if-GigabitEthernet 0/1)# exit
LERA(config)# ipv6 router ospf 1
```

```
LERA(config-router)# router-id 1.1.1.1
Change router-id and update OSPFv3 process! [yes/no]:yes
LERA(config-router)# exit
LERA(config)# interface gigabitethernet 0/1
LERA(config-if-GigabitEthernet 0/1)# ipv6 ospf 1 area 0
LERA(config-if-GigabitEthernet 0/1)# exit
LERA(config)# interface loopback 0
LERA(config-if-Loopback 0)# ipv6 ospf 1 area 0
LERA(config-if-Loopback 0)# exit
```

Configure LSR B.

```
LSRB> enable
LSRB# configure terminal
LSRB(config)# interface loopback 0
LSRB(config-if-Loopback 0)# ipv6 address 2002::2/128
LSRB(config-if-Loopback 0)# exit
LSRB(config)# interface gigabitethernet 0/1
LSRB(config-if-GigabitEthernet 0/1)# no switchport
LSRB(config-if-GigabitEthernet 0/1)# ipv6 address 2001::12:2/64
LSRB(config-if-GigabitEthernet 0/1)# exit
LSRB(config)# interface gigabitethernet 0/2
LSRB(config-if-GigabitEthernet 0/2)# no switchport
LSRB(config-if-GigabitEthernet 0/2)# ipv6 address 2003::23:2/64
LSRB(config-if-GigabitEthernet 0/2)# exit
LSRB(config)# ipv6 router ospf 1
LSRB(config-router)# router-id 2.2.2.2
Change router-id and update OSPFv3 process! [yes/no]:yes
LSRB(config-router)# exit
LSRB(config)# interface gigabitethernet 0/1
LSRB(config-if-GigabitEthernet 0/1)# ipv6 ospf 1 area 0
LSRB(config-if-GigabitEthernet 0/1)# exit
LSRB(config)# interface gigabitethernet 0/2
LSRB(config-if-GigabitEthernet 0/2)# ipv6 ospf 1 area 0
LSRB(config-if-GigabitEthernet 0/2)# exit
LSRB(config)# interface loopback 0
LSRB(config-if-Loopback 0)# ipv6 ospf 1 area 0
LSRB(config-if-Loopback 0)# exit
```

Configure LER C.

```
LERC> enable
LERC# configure terminal
LERC(config)# interface gigabitethernet 0/1
LERC(config-if-GigabitEthernet 0/1)# no switchport
LERC(config-if-GigabitEthernet 0/1)# ipv6 address 2003::23:3/64
LERC(config-if-GigabitEthernet 0/1)# exit
LERC(config)# interface loopback 0
LERC(config-if-Loopback 0)# ipv6 address 3003::3/128
```

```
LERC(config-if-Loopback 0)# exit
LERC(config)# ipv6 router ospf 1
LERC(config-router)# router-id 3.3.3.3
Change router-id and update OSPFv3 process! [yes/no]:yes
LERC(config-router)# exit
LERC(config)# interface gigabitethernet 0/1
LERC(config-if-GigabitEthernet 0/1)# ipv6 ospf 1 area 0
LERC(config)# interface loopback 0
LERC(config-if-Loopback 0)# ipv6 ospf 1 area 0
LERC(config-if-Loopback 0)# exit
```

(2) Configure the LDP router ID and LDP IPv6 transport address, and enable LDP IPv6 globally.

Configure LER A.

```
LERA(config)# mpls router ldp
LERA(config-mpls-router)# ldp router-id 1.1.1.1
LERA(config-mpls-router)# ipv6 transport-address loopback 0
LERA(config-mpls-router)# ipv6 enable
LERA(config-mpls-router)# exit
```

Configure LSR B.

```
LSRB(config)# mpls router ldp
LSRB(config-mpls-router)# ldp router-id 2.2.2.2
LSRB(config-mpls-router)# ipv6 transport-address loopback 0
LSRB(config-mpls-router)# ipv6 enable
LSRB(config-mpls-router)# exit
```

Configure LER C.

```
LERC(config)# mpls router ldp
LERC(config-mpls-router)# ldp router-id 3.3.3.3
LERC(config-mpls-router)# ipv6 transport-address loopback 0
LERC(config-mpls-router)# ipv6 enable
LERC(config-mpls-router)# exit
```

(3) Enable the LDP IPv6 and label forwarding capability on an interface.

Configure LER A.

```
LERA(config)# interface gigabitethernet 0/1
LERA(config-if-GigabitEthernet 0/1)# mpls ipv6
LERA(config-if-GigabitEthernet 0/1)# label-switching
LERA(config-if-GigabitEthernet 0/1)# end
```

Configure LSR B.

```
LSRB(config)# interface gigabitethernet 0/1
LSRB(config-if-GigabitEthernet 0/1)# mpls ipv6
LSRB(config-if-GigabitEthernet 0/1)# label-switching
LSRB(config-if-GigabitEthernet 0/1)# exit
LSRB(config)# interface gigabitethernet 0/2
LSRB(config-if-GigabitEthernet 0/2)# mpls ipv6
LSRB(config-if-GigabitEthernet 0/2)# label-switching
```

```
LSRB(config-if-GigabitEthernet 0/2)# end
```

Configure LER C.

```
LERC(config)# interface gigabitethernet 0/1
LERC(config-if-GigabitEthernet 0/1)# mpls ipv6
LERC(config-if-GigabitEthernet 0/1)# label-switching
LERC(config-if-GigabitEthernet 0/1)# end
```

5. Verification

Run the **show mpls forwarding-table** command to check whether MPLS entries are generated on each device.

Check MPLS entries on LER A.

```
LERA# show mpls forwarding-table
Label Operation Code:
PH--PUSH label
PP--POP label
SW--SWAP label
SP--SWAP topmost label and push new label
DP--DROP packet
PC--POP label and continue lookup by IP or Label
PI--POP label and do ip lookup forward
PN--POP label and forward to nexthop
PM--POP label and do MAC lookup forward
PV--POP label and output to VC attach interface
IP--IP lookup forward
 s--stale
  Local   Outgoing OP FEC                    Outgoing       Nexthop
  label   label                             interface
  --     imp-null PH 2002::2/128             Gi0/1

mpls router ldp
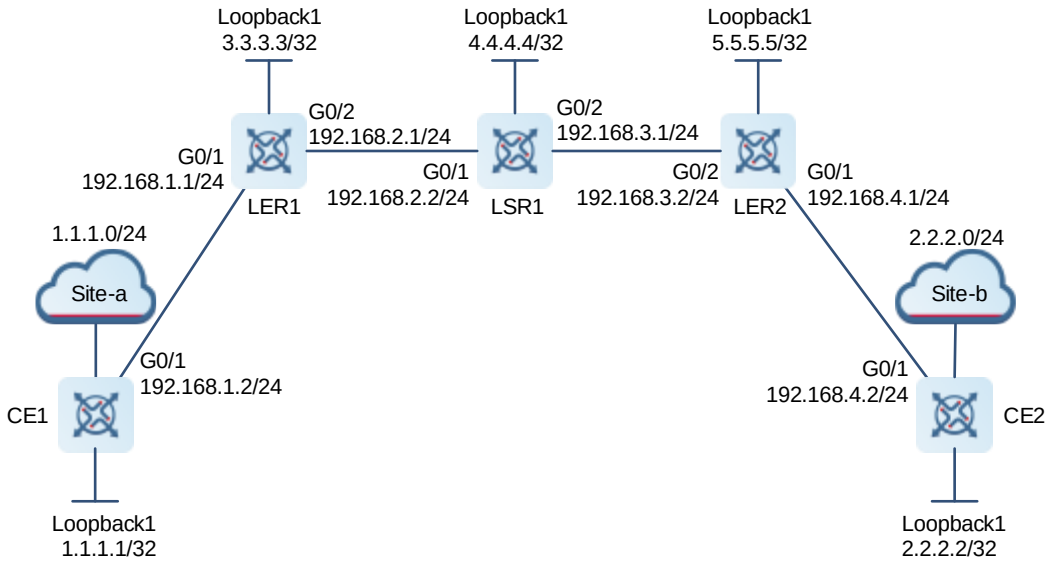
 ldp router-id 3.3.3.3
 ipv6 transport-address Loopback 0
 ipv6 enable
!
```

7. Common Errors

- LDP IPv6 is not enabled globally.
- LDP IPv6 is not enabled on an interface.



1.14.8 Iterating IP Routes to LDP LSPs

1. Requirements

Iterate IP routes to LDP LSPs.

2. Topology

Figure 1-21 Iterating IP Routes to LDP LSPs

3. Notes

- Configure IP addresses and IS-IS on LER1, LSR1, and LER2 and establish IS-IS unicast neighbors.
- Configure the LDP on LER1, LSR1, and LER2 and establish LDP neighbors.
- Configure IP addresses and OSPF and establish OSPF neighbors between CE1 and LER1, and between CE2 and LER2, respectively.
- Configure a static route from LER1 to CE2, configure a static route from LER2 to CE1, and re-distribute the static routes to OSPF.
- Enable the function of iterating IP routes to LDP LSPs on LER1 and LER2.

4. Procedure

(1) Configure IP addresses and IS-IS on LER1, LSR1, and LER2 and establish IS-IS unicast neighbors.

Configure LER1.

```
LER1> enable
LER1# configure terminal
LER1(config)# router isis
LER1(config-router)# net 49.0001.0000.0000.0001.00
LER1(config-router)# exit
LER1(config)# interface loopback 1
LER1(config-if-Loopback 1)# ip address 3.3.3.3 255.255.255.255
LER1(config-if-Loopback 1)# ip router isis
LER1(config-if-Loopback 1)# exit
LER1(config)# interface gigabitethernet 0/2
LER1(config-if-GigabitEthernet 0/2)# no switchport
LER1(config-if-GigabitEthernet 0/2)# ip address 192.168.2.1 255.255.255.0
```

```
LER1(config-if-GigabitEthernet 0/2)# ip router isis
LER1(config-if-GigabitEthernet 0/2)# exit
```

Configure LSR1.

```
LSR1> enable
LSR1# configure terminal
LSR1(config)# router isis
LSR1(config-router)# net 49.0001.0000.0000.0002.00
LSR1(config-router)# exit
LSR1(config)# interface loopback 1
LSR1(config-if-Loopback 1)# ip address 4.4.4.4 255.255.255.255
LSR1(config-if-Loopback 1)# ip router isis
LSR1(config-if-Loopback 1)# exit
LSR1(config)# interface gigabitethernet 0/1
LSR1(config-if-GigabitEthernet 0/1)# no switchport
LSR1(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
LSR1(config-if-GigabitEthernet 0/1)# ip router isis
LSR1(config-if-GigabitEthernet 0/1)# exit
LSR1(config)# interface gigabitethernet 0/2
LSR1(config-if-GigabitEthernet 0/2)# no switchport
LSR1(config-if-GigabitEthernet 0/2)# ip address 192.168.3.1 255.255.255.0
LSR1(config-if-GigabitEthernet 0/2)# ip router isis
LSR1(config-if-GigabitEthernet 0/2)# exit
```

Configure LER2.

```
LER2> enable
LER2# configure terminal
LER2(config)# router isis
LER2(config-router)# net 49.0001.0000.0000.0003.00
LER2(config-router)# exit
LER2(config)# interface loopback 1
LER2(config-if-Loopback 1)# ip address 5.5.5.5 255.255.255.255
LER2(config-if-Loopback 1)# ip router isis
LER2(config-if-Loopback 1)# exit
LER2(config)# interface gigabitethernet 0/2
LER2(config-if-GigabitEthernet 0/2)# no switchport
LER2(config-if-GigabitEthernet 0/2)# ip address 192.168.3.2 255.255.255.0
LER2(config-if-GigabitEthernet 0/2)# ip router isis
LER2(config-if-GigabitEthernet 0/2)# exit
```

(2) Configure the LDP on LER1, LSR1, and LER2 and establish LDP neighbors.

Configure LER1.

```
LER1(config)# mpls router ldp
LER1(config-mpls-router)# ldp router-id interface loopback 1 force
LER1(config-mpls-router)# exit
LER1(config)# interface gigabitethernet 0/2
LER1(config-if-GigabitEthernet 0/2)# mpls ip
```

```
LER1(config-if-GigabitEthernet 0/2)# label-switching
LER1(config-if-GigabitEthernet 0/2)# exit
```

Configure LSR1.

```
LSR1(config)# mpls router ldp
LSR1(config-mpls-router)# ldp router-id interface loopback 1 force
LSR1(config-mpls-router)# exit
LSR1(config)# interface gigabitethernet 0/1
LSR1(config-if-GigabitEthernet 0/1)# mpls ip
LSR1(config-if-GigabitEthernet 0/1)# label-switching
LSR1(config-if-GigabitEthernet 0/1)# exit
LSR1(config)# interface gigabitethernet 0/2
LSR1(config-if-GigabitEthernet 0/2)# mpls ip
LSR1(config-if-GigabitEthernet 0/2)# label-switching
LSR1(config-if-GigabitEthernet 0/2)# exit
```

Configure LER2.

```
LER2(config)# mpls router ldp
LER2(config-mpls-router)# ldp router-id interface loopback 1 force
LER2(config-mpls-router)# exit
LER2(config)# interface gigabitethernet 0/2
LER2(config-if-GigabitEthernet 0/2)# mpls ip
LER2(config-if-GigabitEthernet 0/2)# label-switching
LER2(config-if-GigabitEthernet 0/2)# exit
```

(3) Configure IP addresses and OSPF and establish OSPF neighbors between CE1 and LER1, and between CE2 and LER2, respectively.

Configure CE1.

```
CE1> enable
CE1# configure terminal
CE1(config)# interface gigabitethernet 0/1
CE1(config-if-GigabitEthernet 0/1)# no switchport
CE1(config-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
CE1(config-if-GigabitEthernet 0/1# exit
CE1(config)# interface loopback 1
CE1(config-if-Loopback 1)# ip address 1.1.1.1 255.255.255.255
CE1(config-if-Loopback 1)# exit
CE1(config)# router ospf 1
CE1(config-router)# network 192.168.1.0 0.0.0.255 area 0
CE1(config-router)# network 1.1.1.0 0.0.0.255 area 0
CE1(config-router)# end
```

Configure LER1.

```
LER1(config)# interface gigabitethernet 0/1
LER1(config-if-GigabitEthernet 0/1)# no switchport
LER1(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
LER1(config-if-GigabitEthernet 0/1)# exit
LER1(config)# router ospf 1
```

```
LER1(config-router)# network 192.168.1.0 0.0.0.255 area 0
LER1(config-router)# exit
```

Configure LER2.

```
LER2(config)# interface gigabitethernet 0/1
LER2(config-if-GigabitEthernet 0/1)# no switchport
LER2(config-if-GigabitEthernet 0/1)# ip address 192.168.4.1 255.255.255.0
LER2(config-if-GigabitEthernet 0/1)# exit
LER2(config)# router ospf 1
LER2(config-router)# network 192.168.4.0 0.0.0.255 area 0
LER2(config-router)# exit
```

Configure CE2.

```
CE2> enable
CE2# configure terminal
CE2(config)# interface gigabitethernet 0/1
CE2(config-if-GigabitEthernet 0/1)# no switchport
CE2(config-if-GigabitEthernet 0/1)# ip address 192.168.4.2 255.255.255.0
CE2(config-if-GigabitEthernet 0/1# exit
CE2(config)# interface loopback 1
CE2(config-if-Loopback 1)# ip address 2.2.2.2 255.255.255.255
CE2(config-if-Loopback 1)# exit
CE2(config)# router ospf 1
CE2(config-router)# network 192.168.4.0 0.0.0.255 area 0
CE2(config-router)# network 2.2.2.0 0.0.0.255 area 0
```

(4) Configure a static route from LER1 to CE2, configure a static route from LER2 to CE1, and re-distribute the static routes to OSPF.

Configure LER1.

```
LER1(config)# ip route 2.2.2.0 255.255.255.0 5.5.5.5
LER1(config)# router ospf 1
LER1(config-router)# redistribute static subnets
LER1(config-router)# exit
```

Configure LER2.

```
LER2(config)# ip route 1.1.1.0 255.255.255.0 3.3.3.3
LER2(config)# router ospf 1
LER2(config-router)# redistribute static subnets
LER2(config-router)# exit
```

(5) Enable the function of iterating IP routes to LDP LSPs on LER1 and LER2. LER1 is used as an example. Configurations on LER2 are similar to those on LER1.

Configure LER1.

```
LER1(config)# recursive-route to mpls
LER1(config)# end
```

5. Verification

Run the **show mpls forwarding-table** command to check that LER1 and LER2 have public FTN entries to the peer and traffic forwarding between CE1 and CE2 is normal.

DisplayLER1 entries.

```
LER1# show mpls forwarding-table
Label Operation Code:
PH--PUSH label

7. Common Errors

- MPLS forwarding is not enabled globally.
- LDP is not enabled on an interface.

1 Configuring MPLS GR

1.1 Introduction

1.1.1 Overview

Multiprotocol Label Switching (MPLS) Graceful Restart (GR) indicates that the packet forwarding path remains unchanged and system data forwarding is not interrupted during Label Distribution Protocol (LDP) restart, ensuring high reliability for MPLS application services. MPLS GR functions include LDP GR and layer 3 VPN (L3VPN) GR.

LDP GR indicates uninterruptable data forwarding of a device upon an active/standby switchover or LDP restart with the help of a neighboring device.

L3VPN GR indicates uninterruptable forwarding of L3VPN service data. When the control plane of a device is faulty, the forwarding plane can still forward VPN data normally. This ensures that VPN services in the network are not affected.

1.1.2 GR Devices

1. GR Devices Classified by Capability

GR devices are classified by capability into GR-capable devices, GR-aware devices, and GR-unaware devices.

- GR-capable devices

  A GR-capable router has the GR capability and is equipped with two Supervisor Engines working in 1+1 master/slave mode generally. During a switchover between the master and slave Supervisor Engines, the GR-capable router sends an advertisement packet to its neighboring devices and inform them to keep its forwarding entries. After the switchover between the master and slave Supervisor Engines, routing tables are re-established without causing route flapping or changing the packet forwarding path, thus guaranteeing uninterrupted data forwarding in the system.

- GR-aware devices

  A GR-aware router has the GR detection capability. It may not be equipped with two Supervisor Engines but can detect GR of its neighbors and assist its neighbors completing GR.

- GR-unaware devices

  A GR-unaware router does not have the GR detection capability. It cannot detect GR of its neighbors or assist its neighbors completing GR. Generally, the system software of a GR-unaware device does not support the GR function or the GR function is disabled.

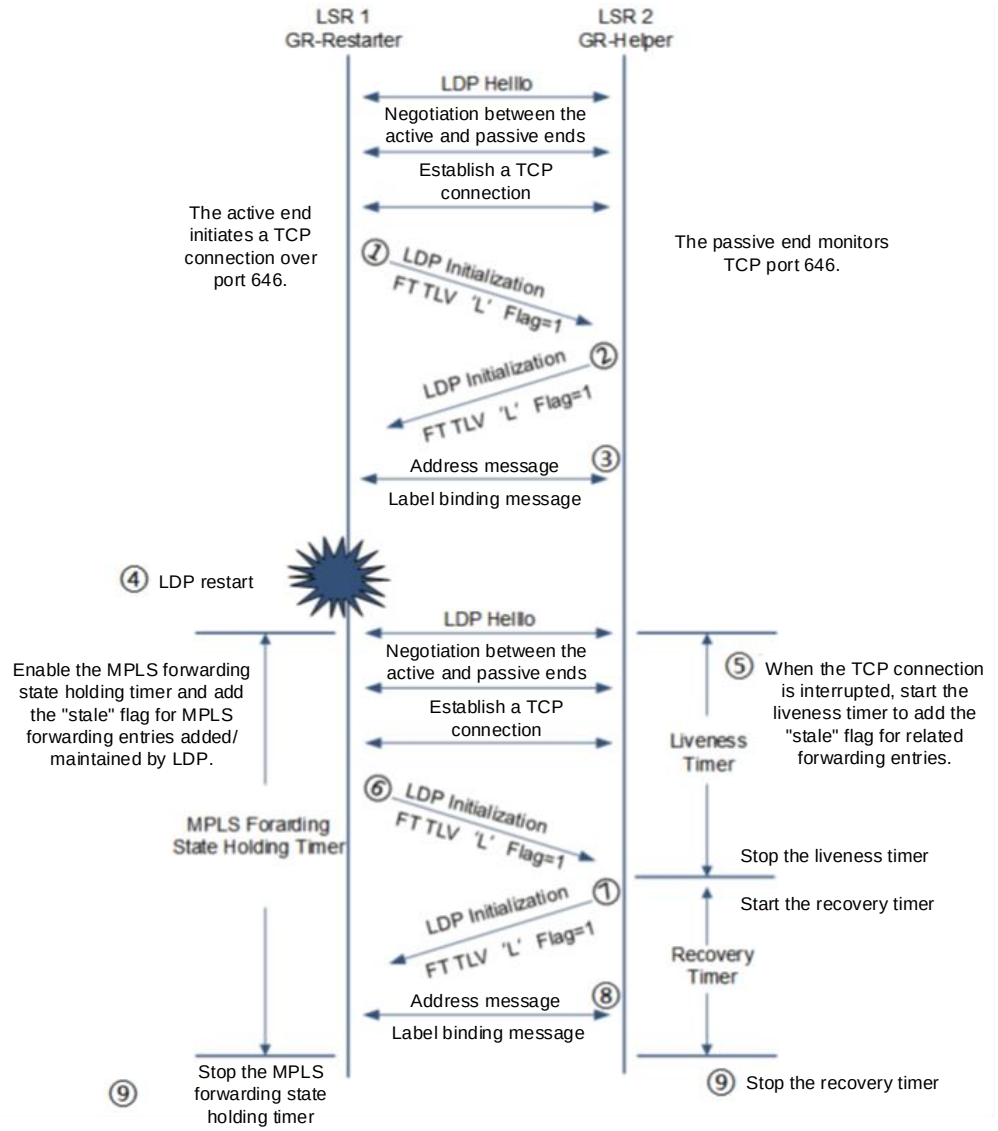
2. GR Devices Classified by Role

GR devices are classified by role during router restart into GR restarters and GR helpers.

- GR restarters
- A GR restarter has the GR capability, such as a GR-capable device, and its restart is triggered by administrators or faults.
- GR helpers

A GR helper is a neighbor of a GR restarter. It must have at least the GR detection capability, for example, a GR-capable device or GR-aware device.

1.1.3 MPLS GR



LDP GR can be used together with Interior Gateway Protocol (IGP) GR to ensure uninterruptable data forwarding in a common MPLS network and be used together with Border Gateway Protocol (BGP) GR to ensure uninterruptable data forwarding in an L3VPN.

To establish a GR-capable LDP session, devices at both ends of the session need to support and enable LDP GR. If LDP GR is not supported by any end during LDP session establishment, a common LDP session is established. If the session initiator supports and enables LDP GR, it includes **FT Session TLV** in the Initialization message.

After receiving an Initialization message carrying **FT Session TLV** during LDP session establishment, the receiver determines whether to carry **FT Session TLV** in the Initialization message according to its own situation. If the receiver supports and enables LDP GR, it carries **FT Session TLV** in the Initialization message to establish a GR-capable LDP session. If the receiver does not carry **FT Session TLV** in the Initialization message, a common LDP session without GR capability is established. If the Initialization message received by the receiver does not carry **FT Session TLV**, a common LDP session without GR capability is established no matter whether the receiver carries **FT Session TLV** in the Initialization message.

Figure 1-1 shows the process of establishing an LDP session between two label switching devices (LSRs) that support LDP GR.

Figure 1-1 LDP GR Process

(1) LSR 1 carries the optional parameter **FT Session TLV** in the Initialization message sent to LSR 2 to indicate its support to LDP GR.

(2) After receiving the Initialization message, LSR 2 also carries the optional parameter **FT Session TLV** in the Initialization message to LSR 1 since it supports LDP GR.

(3) After LSR 1 receives the Initialization message from LSR 2, a GR-capable LDP session is established.

(4) LSR 1 and LSR 2 exchange address information and label mapping information.

(5) For some reasons, the LDP process of LSR 1 is restarted. LSR 1 retains all MPLS forwarding entries added/maintained by LDP, marks them as "stale", and enables the MPLS forwarding state holding timer.

(6) LSR 2 detects that its GR-capable LDP session with LSR 1 is disconnected. It retains the MPLS forwarding entries related to this session and marks them as "stale". Meanwhile, it uses the smaller value between **Liveness Timer** configured and **FT Reconnect Timeout** in **FT Session TLV** received to start the liveness timer and retains these "stale" forwarding entries before the timer expires.

(7) When LSR 1 reestablishes a session with LSR 2, it sets **Recovery Time** in **FT Session TLV** carried by the Initialization message to the residual value of the MPLS forwarding state holding timer.

(8) After receiving the Initialization message carrying **FT Session TLV** sent by LSR 1, LSR 2 detects that **Recovery Time** is not **0**. It continues to retain the "stale" forwarding entries and stop the liveness timer at the same time. Meanwhile, it uses the smaller value between **Recovery Time** configured and **Recovery Time** in **FT Session TLV** received to start the recovery timer, and retains these "stale" forwarding entries before the timer expires.

(9) LSR 1 and LSR 2 re-exchange address information and label mapping information, and remove or retain MPLS forwarding entries marked as "stale" according to the information exchanged.

(10) The GR process ends. LSR 1 and LSR 2 delete their own MPLS forwarding entries marked as "stale".

1.1.4 Protocols and Standards

- RFC 3036: LDP Specification
- RFC 3037: LDP Applicability
- RFC 3215: LDP State Machine
- RFC 3478: Graceful Restart Mechanism for Label Distribution Protocol
- RFC 3479: Fault Tolerance for the Label Distribution Protocol (LDP)
- RFC 4724: Graceful Restart Mechanism for BGP
- RFC 4781: Graceful Restart Mechanism for BGP with MPLS

1.2 Configuration Task Summary

MPLS GR configuration includes the following tasks:

- Configuring LDP GR

1.3 Configuring LDP GR

1.3.1 Overview

When an LDP restart or manual master/slave switchover occurs, a device with LDP GR enabled can retain original MPLS forwarding entries and forward packets based on the original entries, ensuring uninterruptable traffic forwarding.

- LDP neighbor liveness time
  - Only GR helpers use the LDP neighbor liveness time.
  - A GR helper uses the smaller value between configured *neighbor-liveness-time* and received LDP session reconnection time to start the liveness timer and retains these "stale" forwarding entries before the timer expires.
- LDP session reconnection time
  - During the GR process, both the GR restarter and GR helper use the LDP session reconnection time.
  - For the GR restarter, the LDP session reconnection time is the time for retaining "stale" forwarding entries.
- LDP session recovery time
  - Only GR helpers use the LDP session recovery time.
  - A GR helper uses the smaller value between configured *recovery-time* and received LDP session recovery time to start the recovery timer and retains these "stale" forwarding entries before the timer

expires.

1.3.2 Restrictions and Guidelines

- The LDP neighbor liveness time is the time when the GR helper waits for the GR restarter to restart and reestablish a session. If it takes a long time for the GR restarter to restart, increase the LDP neighbor liveness time.
- The LDP session reconnection time is the time when the GR restarter retains "stale" forwarding entries. If many services and MPLS entries are configured on a device, it takes a long time to reconnect to a neighbor when a fault occurs. To ensure that the neighbor can wait for the local device to complete a restart, adjust *reconnection-time* of the local device and LDP neighbor liveness time of the neighboring device. In typical layer 3 virtual private network (L3VPN) scenarios, the time is increased by one minute for every 100 VPN services.
- The LDP session recovery time is the time when the helper assists the restarter in recovering entries after a session is reestablished between the helper and restarter. When many MPLS entries exist, it takes a long time to recover entries and therefore the LDP session recovery time needs to be prolonged.
- Enabling LDP GR does not affect the LDP session, namely it does not cause an LDP session restart or other exceptions.
- New LDP GR changes take effect after the LDP session is restarted and do not affect previously established LDP sessions.
- The new LDP neighbor liveness time takes effect after the LDP session is restarted.
- The new LDP session reconnection time takes effect after the LDP session is restarted.
- The new LDP session recovery time takes effect after the LDP session is restarted.
- If the topology is changed during GR (for example, the IP address corresponding to the LSR ID used before GR is deleted or the link is changed), GR may be invalid and causes traffic interruption.

1.3.3 Prerequisites

- Before configuring MPLS LDP GR, complete the following tasks:
  - Configure IGP GR.
  - Configure an MPLS LDP session.
- Before configuring MPLS LDP GR, prepare the following data:
  - LDP neighbor liveness time
  - LDP session reconnection time
  - LDP session recovery time

1.3.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable LDP and enter the LDP configuration mode.

mpls router ldp [*vrf-name*]

(4) Enable LDP GR.

graceful-restart

LDP GR is enabled automatically for devices enabled with LDP by default.

The GR function is enabled by default to support process restart. Unless otherwise specified, do not disable the LDP GR function.

(5) (Optional) Configure the LDP neighbor liveness time.

graceful-restart timer neighbor-liveness *neighbor-liveness-time*

The default LDP neighbor liveness time is 120s.

(6) (Optional) Configure the LDP session reconnection time.

graceful-restart timer reconnect *reconnect-time*

The default LDP session reconnection time is 300s.

(7) (Optional) Configure the LDP session recovery time.

graceful-restart timer recovery *recovery-time*

The default LDP session recovery time is 120s.

1.4 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect. Run the **debug** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

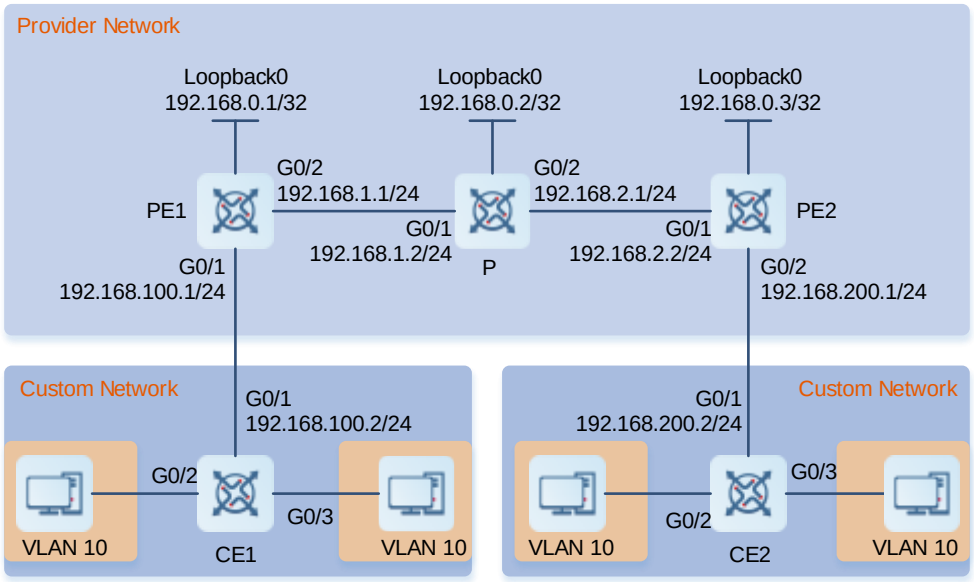
Table 1-1 Monitoring

Command	Purpose
show mpls ldp graceful-restart [**all** | **vrf** *vrf-name*]	Displays LDP GR sessions and session parameters.
debug mpls ldp graceful-restart	Debugs LDP GR.

1.5 Configuration Examples

1.5.1 Configuring LDP GR

1. Requirements



Data forwarding is not interrupted upon a master/slave switchover or an LDP restart.

- Provider edges (PEs) and provider (P) form an MPLS network.
- PEs and P support LDP and have the GR capability.

- Use PE1 and P as examples to configure the LDP GR function. PE1 is a GR-capable device and serves as the GR restarter, and P is a GR-aware device and serves as the GR helper.

2. Topology

Figure 1-2 Configuring LDP GR

3. Notes

- Configure interface IP addresses and Open Shortest Path First (OSPF) on devices to ensure communication between them.
- Enable MPLS forwarding globally and on interfaces and configure LDP to ensure MPLS traffic forwarding in the network.
- Enable OSPF GR and LDP GR, and configure LDP GR parameters.
- Restart the LDP session for the configurations to take effect.

4. Procedure

(1) Configure interface IP addresses and OSPF on devices to ensure communication between them.

Configure PE1.

```
PE1> enable
PE1# configure terminal
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-Gigabitethernet 0/1)# ip address 192.168.100.1 255.255.255.0
PE1(config-if-Gigabitethernet 0/1)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-Gigabitethernet 0/2)# ip address 192.168.1.1 255.255.255.0
PE1(config-if-Gigabitethernet 0/2)# exit
PE1(config)# interface loopback 0
PE1(config-Loopback 0)# ip address 192.168.0.1 255.255.255.255
PE1(config-Loopback 0)# exit
```

```
PE1(config)# router ospf 1
PE1(config-router)# network 192.168.100.0 0.0.0.255 area 0
PE1(config-router)# network 192.168.1.0 0.0.0.255 area 0
PE1(config-router)# network 192.168.0.1 0.0.0.0 area 0
PE1(config-router)# exit
```

Configure P.

```
P> enable
P# configure terminal
P(config)# interface gigabitethernet 0/1
P(config-if-Gigabitethernet 0/1)# ip address 192.168.1.2 255.255.255.0
P(config-if-Gigabitethernet 0/1)# exit
P(config)# interface gigabitethernet 0/2
P(config-if-Gigabitethernet 0/2)# ip address 192.168.2.1 255.255.255.0
P(config-if-Gigabitethernet 0/2)# exit
P(config)# interface loopback 0
P(config-Loopback 0)# ip address 192.168.0.2 255.255.255.255
P(config-Loopback 0)# exit
P(config)# router ospf 1
P(config-router)# network 192.168.1.0 0.0.0.255 area 0
P(config-router)# network 192.168.2.0 0.0.0.255 area 0
P(config-router)# network 192.168.0.2 255.255.255.255 area 0
P(config-router)# exit
```

(2) Configure MPLS forwarding and LDP.

Configure PE1.

```
PE1(config)# mpls ip
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-Gigabitethernet 0/2)# label-switching
PE1(config-if-Gigabitethernet 0/2)# mpls ip
PE1(config-if-Gigabitethernet 0/2)# exit
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
```

Configure P.

```
P(config)# mpls ip
P(config)# interface gigabitethernet 0/1
P(config-if-Gigabitethernet 0/1)# label-switching
P(config-if-Gigabitethernet 0/1)# mpls ip
P(config-if-Gigabitethernet 0/1)# exit
P(config)# interface gigabitethernet 0/2
P(config-if-Gigabitethernet 0/2)# label-switching
P(config-if-Gigabitethernet 0/2)# mpls ip
P(config-if-Gigabitethernet 0/2)# exit
P(config)# mpls router ldp
P(config-mpls-router)# ldp router-id interface loopback 0 force
```

```
P(config-mpls-router)# exit
```

(3) Enable OSPF GR and LDP GR, and configure LDP GR parameters.

Configure PE1.

```
PE1(config)# router ospf 1
PE1(config-router)# graceful-restart
PE1(config-router)# exit
PE1(config)# mpls router ldp
PE1(config-mpls-router)# graceful-restart
PE1(config-mpls-router)# graceful-restart timer reconnect 300
PE1(config-mpls-router)# graceful-restart timer neighbor-liveness 120
PE1(config-mpls-router)# graceful-restart timer recovery 120
PE1(config-mpls-router)# end
```

Configure P.

```
P(config)# router ospf 1
P(config-router)# graceful-restart
P(config-router)# exit
P(config)# mpls router ldp
P(config-mpls-router)# graceful-restart
P(config-mpls-router)# graceful-restart timer reconnect 300
P(config-mpls-router)# graceful-restart timer neighbor-liveness 120
P(config-mpls-router)# graceful-restart timer recovery 120
P(config-mpls-router)# end
```

(4) Restart the LDP session for the configurations to take effect. PE1 is used as an example. Configurations on P are similar to those on PE1.

Configure PE1.

```
PE1# clear mpls ldp neighbor all *
```

5. Verification

On PE1 and P, run the **show mpls ldp graceful-restart** command to display GR-capable LDP sessions and run the **show mpls ldp neighbors** command to check whether a session has the GR capability.

PE1 verification result

```
PE1# show mpls ldp graceful-restart

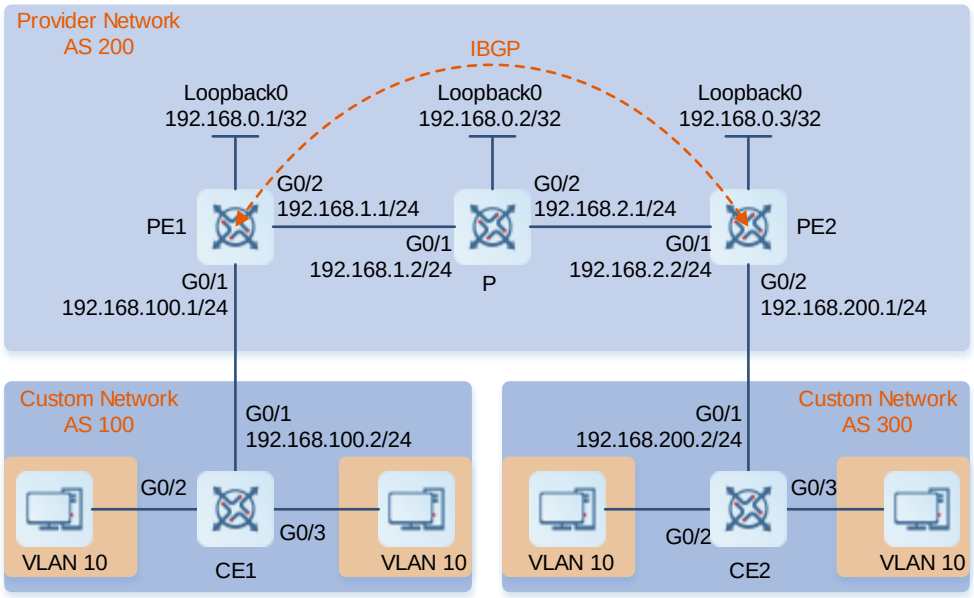
1.5.2 Configuring L3VPN GR



1. Requirements

Data forwarding of L3VPN services is not interrupted. When the control plane of a device is faulty, the forwarding plane can still forward VPN data normally. This ensures that VPN services in the network are not affected.

- CEs represent the customer network and run IGP or External BGP (EBGP).
- PEs and P form an ISP network and run IGP.
- A label switched path (LSP) is established among PE1, P, and PE2 using LDP.
- A private network tunnel is established between PE1 and PE2 using Internal BGP (IBGP).
- IGP, GBP, and LDP have the GR capability.
- PEs are GR-capable devices, and P is a GR-aware device.

2. Topology

Figure 1-3 Configuring L3VPN GR

3. Notes

- Configure interface IP addresses and OSPF on MPLS backbone network nodes to ensure communication between them.
- Enable MPLS forwarding globally and on interfaces and configure LDP to ensure MPLS traffic forwarding in the network.
- Configure VPN route instances on PE1 and PE2 and connect CE1 to PE1 and CE2 to PE2.
- Configure MP-IBGP neighbor relationship between PE1 and PE2 and between PE1 and PE3 to transmit VPN routing information.
- Enable OSPF GR, LDP GR, and BGP GR and configure LDP GR parameters. Restart the LDP session for the configurations to take effect.

4. Procedure

(1) Configure interface IP addresses and OSPF on MPLS backbone network nodes to ensure communication between them.

Configure PE1.

```
PE1> enable
PE1# configure terminal
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-Gigabitethernet 0/2)# ip address 192.168.1.1 255.255.255.0
PE1(config-if-Gigabitethernet 0/2)# exit
PE1(config)# interface loopback 0
PE1(config-Loopback 0)# ip address 192.168.0.1 255.255.255.255
PE1(config-Loopback 0)# exit
PE1(config)# router ospf 10
PE1(config-router)# network 192.168.0.1 0.0.0.0 area 0
PE1(config-router)# network 192.168.1.0 0.0.0.255 area 0
PE1(config-router)# exit
```

Configure P.

```
P> enable
P# configure terminal
P(config)# interface gigabitethernet 0/1
P(config-if-Gigabitethernet 0/1)# ip address 192.168.1.2 255.255.255.0
P(config-if-Gigabitethernet 0/1)# exit
P(config)# interface gigabitethernet 0/2
P(config-if-Gigabitethernet 0/2)# ip address 192.168.2.1 255.255.255.0
P(config-if-Gigabitethernet 0/2)# exit
P(config)# interface loopback 0
P(config-Loopback 0)# ip address 192.168.0.2 255.255.255.255
P(config-Loopback 0)# exit
P(config)# router ospf 10
P(config-router)# network 192.168.1.0 0.0.0.255 area 0
P(config-router)# network 192.168.2.0 0.0.0.255 area 0
P(config-router)# network 192.168.0.2 0.0.0.0 area 0
P(config-router)# exit
```

Configure PE2.

```
PE2> enable
PE2# configure terminal
PE2(config)# interface gigabitethernet 0/1
PE2(config-if-Gigabitethernet 0/1)# ip address 192.168.2.2 255.255.255.0
PE2(config-if-Gigabitethernet 0/1)# exit
PE2(config)# interface loopback 0
PE2(config-Loopback 0)# ip address 192.168.0.3 255.255.255.255
PE2(config-Loopback 0)# exit
PE2(config)# router ospf 10
PE2(config-router)# network 192.168.0.3 0.0.0.0 area 0
PE2(config-router)# network 192.168.2.0 0.0.0.255 area 0
PE2(config-router)# exit
```

(2) Enable MPLS forwarding globally and on interfaces and configure LDP to ensure MPLS traffic forwarding in the network.

Configure PE1.

```
PE1(config)# mpls ip
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-Gigabitethernet 0/2)# label-switching
PE1(config-if-Gigabitethernet 0/2)# mpls ip
PE1(config-if-Gigabitethernet 0/2)# exit
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
```

Configure P.

```
P(config)# mpls ip
P(config)# interface gigabitethernet 0/1
P(config-if-Gigabitethernet 0/1)# label-switching
P(config-if-Gigabitethernet 0/1)# mpls ip
P(config-if-Gigabitethernet 0/1)# exit
P(config)# interface gigabitethernet 0/2
P(config-if-Gigabitethernet 0/2)# label-switching
P(config-if-Gigabitethernet 0/2)# mpls ip
P(config-if-Gigabitethernet 0/2)# exit
P(config)# mpls router ldp
P(config-mpls-router)# ldp router-id interface loopback 0 force
P(config-mpls-router)# exit
```

Configure PE2.

```
PE2(config)#mpls ip
PE2(config)# interface gigabitethernet 0/1
PE2(config-if-Gigabitethernet 0/1)# label-switching
PE2(config-if-Gigabitethernet 0/1)# mpls ip
Router(config-if-Gigabitethernet 0/1)# exit
PE2(config)# mpls router ldp
PE2(config-mpls-router)# ldp router-id interface loopback 0 force
PE2(config-mpls-router)# exit
```

(3) Configure VPN route instances on PE1 and PE2 and connect CE1 to PE1 and CE2 to PE2.

Configure PE1.

```
PE1(config)# ip vrf 10
PE1(config-vrf)# rd 1:100
PE1(config-vrf)# route-target both 1:100
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-Gigabitethernet 0/1)# ip vrf forwarding 10
PE1(config-if-Gigabitethernet 0/1)# ip address 192.168.100.1 255.255.255.0
PE1(config-if-Gigabitethernet 0/1)# exit
```

Configure PE2.

```
PE2> enable
PE2# configure terminal
PE2(config)# ip vrf 10
```

```
PE2(config-vrf)# rd 1:100
PE2(config-vrf)# route-target both 1:100
PE2(config-vrf)# exit
PE2(config)# interface gigabitethernet 0/2
PE2(config-if-Gigabitethernet 0/2)# ip vrf forwarding 10
PE2(config-if-Gigabitethernet 0/2)# ip address 192.168.200.1 255.255.255.0
PE2(config-if-Gigabitethernet 0/2)# exit
```

(4) Configure MP-IBGP neighbor relationship between PE1 and PE2 to transmit VPN routing information.

Configure PE1.

```
PE1(config)# router bgp 200
PE1(config-router)# address-family ipv4 vrf 10
PE1(config-router-af)# neighbor 192.168.100.2 remote-as 100
PE1(config-router-af)# neighbor 192.168.100.2 update-source Gigabitethernet 0/1
PE1(config-router-af)# neighbor 192.168.100.2 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# address-family ipv4
PE1(config-router-af)# neighbor 192.168.0.3 remote-as 200
PE1(config-router-af)# neighbor 192.168.0.3 update-source loopback 0
PE1(config-router-af)# neighbor 192.168.0.3 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# address-family vpnv4 unicast
PE1(config-router-af)# neighbor 192.168.0.3 activate
PE1(config-router-af)# exit-address-family
PE1(config-router-af)# exit
```

Configure PE2.

```
PE2(config)# router bgp 200
PE2(config-router)# address-family ipv4 vrf 10
PE2(config-router-af)# neighbor 192.168.200.2 remote-as 300
PE2(config-router-af)# neighbor 192.168.200.2 update-source Gigabitethernet 0/2
PE2(config-router-af)# neighbor 192.168.200.2 activate
PE2(config-router-af)# exit-address-family
PE2(config-router)# address-family ipv4
PE2(config-router-af)# neighbor 192.168.0.1 remote-as 200
PE2(config-router-af)# neighbor 192.168.0.1 update-source loopback 0
PE2(config-router-af)# neighbor 192.168.0.1 activate
PE2(config-router-af)# exit-address-family
PE2(config-router)# address-family vpnv4 unicast
PE2(config-router-af)# neighbor 192.168.0.1 activate
PE2(config-router-af)# exit-address-family
PE2(config-router-af)# exit
```

(5) Enable OSPF GR, LDP GR, and BGP GR and configure LDP GR parameters.

Configure PE1.

```
PE1(config)# router ospf 10
PE1(config-router)# graceful-restart
```

```
PE1(config-router)# exit
PE1(config)# mpls router ldp
PE1(config-mpls-router)# graceful-restart
PE1(config-mpls-router)# graceful-restart timer reconnect 300
PE1(config-mpls-router)# graceful-restart timer neighbor-liveness 120
PE1(config-mpls-router)# graceful-restart timer recovery 120
PE1(config-mpls-router)# exit
PE1(config)# router bgp 200
PE1(config-router)# bgp graceful-restart
PE1(config-router)# end
```

Configure P.

```
P(config)# router ospf 10
P(config-router)# graceful-restart
P(config-router)# exit
P(config)# mpls router ldp
P(config-mpls-router)# graceful-restart
P(config-mpls-router)# graceful-restart timer reconnect 300
P(config-mpls-router)# graceful-restart timer neighbor-liveness 120
P(config-mpls-router)# graceful-restart timer recovery 120
P(config-mpls-router)# end
```

Configure PE2.

```
PE2(config)# router ospf 10
PE2(config-router)# graceful-restart
PE2(config-router)# exit
PE2(config)# mpls router ldp
PE2(config-mpls-router)# graceful-restart
PE2(config-mpls-router)# graceful-restart timer reconnect 300
PE2(config-mpls-router)# graceful-restart timer neighbor-liveness 120
PE2(config-mpls-router)# graceful-restart timer recovery 120
PE2(config-mpls-router)# exit
PE2(config)# router bgp 200
PE2(config-router)# bgp graceful-restart
PE2(config-router)# end
```

(6) Restart the LDP session for the configurations to take effect. PE1 is used as an example. Configurations on P and PE2 are similar to those on PE1.

Configure PE1.

```
PE1# clear mpls ldp neighbor all
```

5. Verification

On PE1, P, and PE2, run the **show mpls ldp graceful-restart** command to display GR-capable LDP sessions and run the **show bgp vpnv4 unicast all neighbor** command to display the BGP neighbor status.

PE1 verification result

```
PE1# show mpls ldp graceful-restart
Default VRF:
```

```
  LDP Graceful Restart is enabled
  Neighbor Liveness Timer: 120 seconds
  Max Recovery Time: 120 seconds
  Forwarding State Holding Time: 300 seconds
  Down Neighbor Database (0 records):
  Graceful Restart-enabled Sessions:
    Peer LDP Ident: 192.168.0.2:0, State: estab
PE1# show bgp vpnv4 unicast all neighbor
BGP neighbor is 192.168.0.3, remote AS 200, internal link
BGP version 4, remote router ID 192.168.0.3
BGP state = Established, up for 02:49:47
Last read 00:00:47, hold time is 180, keepalive interval is 60 seconds
Neighbor capabilities:
Route refresh: advertised and received(new)
Address family VPNv4 Unicast: advertised and received
Graceful Restart Capabilty: advertised and received
Remote Restart timer is 120 seconds
Address families preserved by peer:
VPNv4 Unicast
```

P verification result

```
P# show mpls ldp graceful-restart
Default VRF:
  LDP Graceful Restart is enabled
  Neighbor Liveness Timer: 120 seconds
  Max Recovery Time: 120 seconds
  Forwarding State Holding Time: 300 seconds
  Down Neighbor Database (0 records):
  Graceful Restart-enabled Sessions:
Peer LDP Ident: 192.168.0.1:0, State: estab
Peer LDP Ident: 192.168.0.3:0, State: estab
```

PE2 verification result

```
PE2# show mpls ldp graceful-restart
Default VRF:
  LDP Graceful Restart is enabled
  Neighbor Liveness Timer: 120 seconds
  Max Recovery Time: 120 seconds
  Forwarding State Holding Time: 300 seconds
  Down Neighbor Database (0 records):
  Graceful Restart-enabled Sessions:
    Peer LDP Ident: 192.168.0.2:0, State: estab
PE2# show bgp vpnv4 unicast all neighbor
BGP neighbor is 192.168.0.1, remote AS 200, internal link
BGP version 4, remote router ID 192.168.0.1
BGP state = Established, up for 02:49:47
Last read 00:00:47, hold time is 180, keepalive interval is 60 seconds
```

```
Neighbor capabilities:
Route refresh: advertised and received(new)
Address family VPNv4 Unicast: advertised and received
Graceful Restart Capabilty: advertised and received
Remote Restart timer is 120 seconds
Address families preserved by peer:
VPNv4 Unicast
```

1.6 Common Errors

- Basic MPLS or L3VPN environment setup is not complete. As a result, data forwarding fails.
- The GR function is configured on the restarter but not configured on the adjacent helper.
- The IGP or BGP GR function is not configured.
- Many routing entries exist, but the configured LDP GR timer time is short. As a result, some entries are not restored when GR is complete.
- The topology or configuration is changed during GR, resulting in traffic interruption.

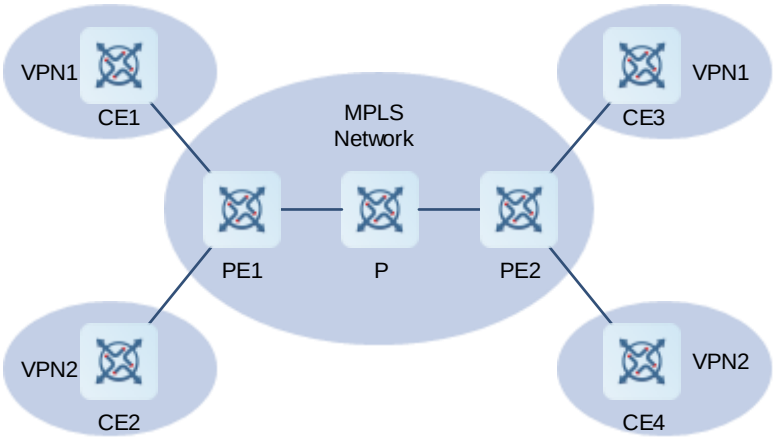
1 Configuring MPLS L3VPN

1.1 Introduction

1.1.1 Overview

Multiprotocol Label Switching (MPLS) layer 3 virtual private network (L3VPN) interconnects geographically dispersed VPN sites by using Border Gateway Protocol (BGP) to exchange VPN routes and labels and using MPLS to forward VPN packets through public network tunnels between edge devices on networks of service providers (SPs). In this way, the networks are unified. An MPLS L3VPN is also called a BGP/MPLS IP VPN.



ISPs run MPLS on their IP backbone networks to provide VPN services for users' private networks. The implementation of VPN through MPLS has natural edges. VPN users no longer need dedicated VPN devices and can directly use traditional routers to build VPNs. MPLS L3VPN supports address overlapping between different VPNs, provides flexible networking modes, and has excellent scalability. MPLS L3VPNs managed by Internet service providers (ISPs) have more flexible and advanced dynamic tunnel mechanisms, more reasonable network structures, and more scalable route control and access control, helping enterprise customers dramatically reduce the VPN setup and maintenance costs. MPLS L3VPN has become an important method for ISPs to provide value-added services.

1.1.2 Basic MPLS L3VPN Architecture

1. Network Structure

Figure 1-1 shows the network structure of an MPLS L3VPN.

Figure 1-1 MPLS L3VPN Structure

An MPLS L3VPN comprises the following three important roles:

- Customer edge (CE): A CE is located at customer network edge, and logically belongs to a user VPN. A CE directly connects to a service provider edge (PE). A CE can be a host, router, or switch, as CE1, CE2, CE3, and CE4 in Figure 1-1. A CE may not support MPLS.
- PE: A PE is an edge device on an ISP's backbone network and logically belongs to an SP. A PE is mainly

responsible for receiving the VPN information from CEs and transmitting the information to other PEs, or receiving the VPN information from other PEs and sending it to the CEs. A PE is directly connected to one or more CEs. A PE can be a router, Asynchronous Transfer Mode (ATM) switch, or frame relay (FR) switch, as PE1 and PE2 in Figure 1-1. The PEs must support MPLS.

- Provider (P): P is a core device on the SP backbone network. A P is responsible for routing and fast forwarding and is not directly connected to CEs. A P knows the routes to any destination on the backbone network but does not know the routes to a VPN. As a device on the core MPLS backbone network, a P must support MPLS.

2. Application Features

MPLS L3VPN has the following features:

- VPN tunnels are set up on the PEs of an ISP, and VPN routes are transmitted between PEs. In this manner, users do not need to maintain VPN information.
- MPLS L3VPN utilizes existing routing protocols to dynamically set up VPN tunnels and advertise routes. This facilitates VPN expansion.
- Address overlapping is supported. Different VPN users can use the same address space.
- On SP networks, VPN services are exchanged according to labels rather than traditional routes.
- MPLS L3VPN is as secure as user dedicated lines.

3. Implementation Mechanism

The basic MPLS L3VPN implementation mechanism includes the following features:

- Utilize the Label Distribution Protocol (LDP) to set up label switched paths (LSPs) on the backbone network. This process is generally completed when the SP network is established and the topology becomes stable.
- Forward data packets based on the pushed labels and the local mapping table.
- Use Multiprotocol Border Gateway Protocol (MP-BGP) to transmit VPN routes and carry VPN attributes and labels.
- Manage VPN routes, including setup of multiple routing tables and VPN routing information maintenance.

4. VRF

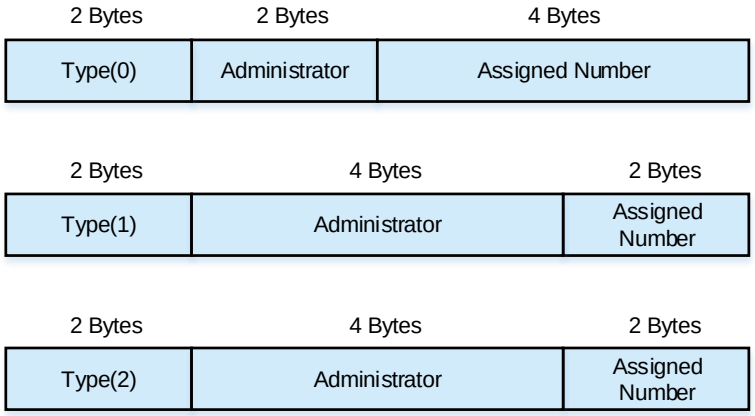
A VPN routing and forwarding (VRF) instance addresses local route conflicts.

Each connection between a PE and a CE is associated with a VRF instance. One PE can have several VRF instances to exchange routing information with CEs. You can consider each VRF instance as a virtual router, which connects to a CE to receive routing information from the CE or notify the CE of the VPN routing information. VRF instances address the problem of conflict local routes on a PE due to the adoption of the same address space by different VPNs.

One VRF instance includes the following:

- An independent routing table
- A group of interfaces that belong to the VRF instance
- A group of routing protocols that are used in the VRF instance

5. RD



Route Distinguisher (RD) is an important VPN route attribute used to address route conflicts during transmission. If different VPNs use the same network address and advertise their routing information on the backbone network through BGP, the BGP chooses only the best route from the overlapped addresses to advertise. As a result, some VPNs cannot obtain their routing information. To resolve this problem, you can add different RD values to the overlapped addresses. Based on the different RD values carried in VPN information, the BGP can distinguish VPNs with the same network address, and therefore each VPN can obtain its own routing information.

RD is used to distinguish routing information of different VPNs with the same network address. If address overlapping does not exist between different VPNs, you do not need to configure RD values.

Generally speaking, a unique RD value is specified for each VPN. This ensures normal transmission of routing information of different VPNs on the backbone network. The RD value is generally defined as xx:xx, such as RD 1:100, among which 1 stands for the autonomous system (AS) number of the backbone network and 100 is a number specified by the user. A VPN route carries only one RD value.

An RD consists of three fields: **Type**, **Administrator**, and **Assigned Number**. Based on the value of the **Type** field, three encoding formats are adopted.

Figure 1-2 RD Structure

- When **Type** is set to **0**, the **Administrator** field has two bytes and is marked by a public AS number. The **Assigned Number** field has four bytes and is managed by the SP.
- When **Type** is set to **1**, the **Administrator** field has four bytes and uses a global IPv4 address. The **Assigned Number** field has two bytes and is managed by the SP.
- When **Type** is set to **2**, the **Administrator** field has four bytes and is marked by a four-byte AS number. The **Assigned Number** field has two bytes and is managed by the SP.

6. RT

Route-Target (RT) is an important VPN route attribute that enables a device to choose its route selection mode.

The RT attribute is further classified into Export Route-Target and Import Route-Target attributes. A PE adds the Export Route-Target attribute to the VPN routes received from CEs and then notifies other PEs of the VPN routes. The PE determines whether to import the routes received from other PEs to the VRF instance based on the Import Route-Target attribute. One principle is that when a PE receives a VPN route, the PE imports the

route to the VRF instance only when at least one RT attribute carried in the route is the same as the Import Route-Target attribute in the VRF instance of the PE. In this manner, you can flexibly control the advertising of VPN routes. A VPN route can carry multiple RT values.

Figure 1-3 RT Structure

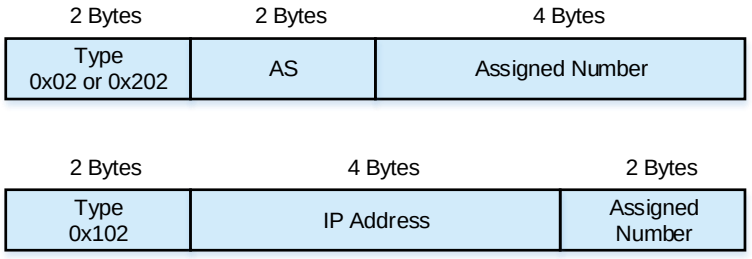


Figure 1-3 shows the decoding structure of RT carried in extended community attributes defined in BGP. The definition of RT is similar to that of RD. When **Type** is set to **0x02** or **0x202**, the AS number must be a public one. When **Type** is set to **0x102**, the IPv4 address must be a global one rather than a private address.

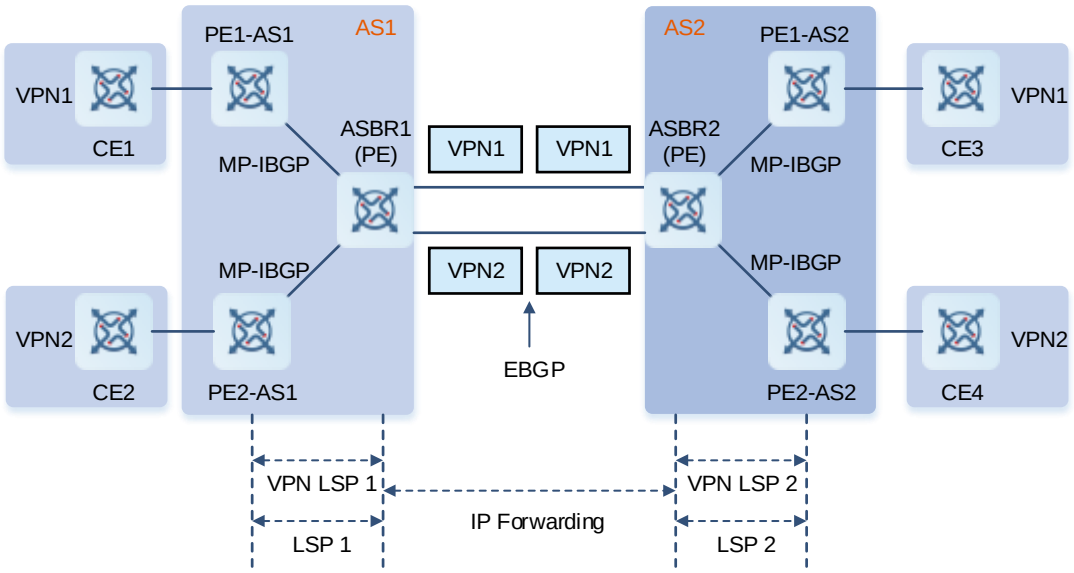
7. MP-BGP

The VPN routing information is transmitted on the backbone network through BGP. The Export Route-Target attribute is carried in extended community attributes defined in BGP.

The traditional BGP4 transmits only IPv4 route information and cannot carry VPN information that includes RD. Therefore, the BGP needs to be extended to introduce new attributes. MP-BGP introduces new attributes to support multiple protocols. MP-BGP can carry VPN information. A VPN route is composed of RD and IP address prefix. By adding RD values to VPN routes exchanged between PEs, the MP-BGP allows VPN users to change IPv4 routes to VPN-IPv4 routes and transmit them on the MPLS backbone network.

1.1.3 Inter-AS VPN Service Model

On an actual network, different sites of a VPN may be located in different ASs. The inter-AS VPN technology ensures communication between VPN sites in different ASs. In this case, VPN routes can be exchanged between different ASs.



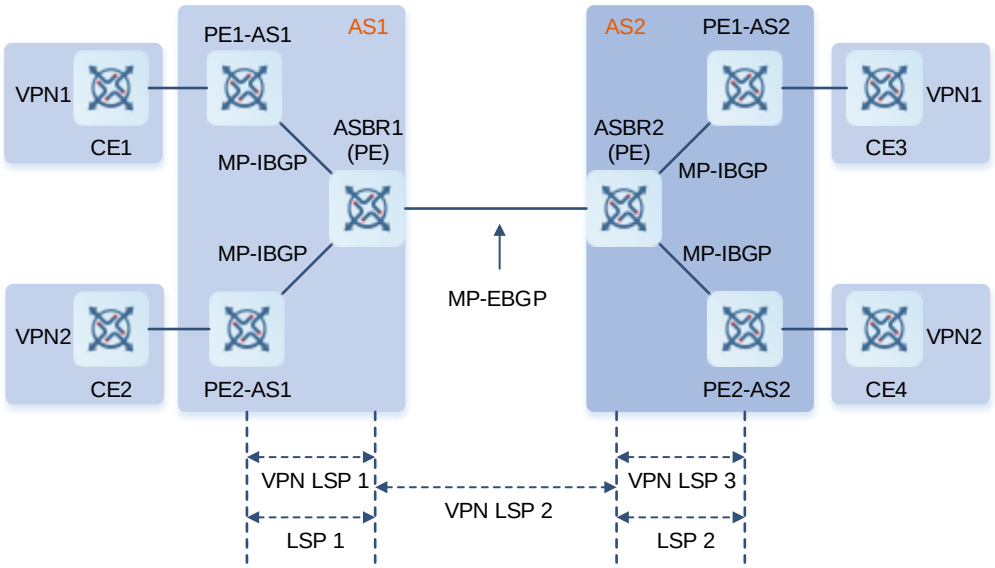
RFC 4364 provides the following three inter-AS VPN solutions:

- Option A: VRF-to-VRF mode
- Option B: single-hop MP-EBGP mode
- Option C: multi-hop MP-EBGP mode

1. Option A: VRF-to-VRF Mode

The VRF-to-VRF mode is also called the VRF back-to-back. An AS Border Router (ASBR) of an AS creates a VRF instance for each inter-AS VPN and binds the VRF instance to an interface to receive VPN routes from the local AS. The VRF instances on different ASBRs exchange VPN routes through bound interfaces. A VRF instance establishes an External Border Gateway Protocol (EBGP) connection with a VRF instance in another AS to exchange IPv4 routes.

Figure 1-4 VRF-to-VRF Inter-AS VPN



As shown in Figure 1-4, the VRF instances on two ASBRs establish a common EBGP session to exchange IPv4 routes, and the ASBRs and PEs in the same ASs establish MP-IBGP sessions to exchange VPN routes. For the VRF instance on an ASBR, the other VRF instance, with which an EBGP session is established, is equivalent to a CE. The Option A configuration solution is similar to a common intra-domain configuration solution. The ASBRs and PEs in the same ASs establish MP-IBGP sessions to exchange VPN routes. The VRF instances on different ASBRs establish EBGP sessions in BGP VRF address family mode to exchange IPv4 routes.

The VRF-to-VRF mode is easy to implement by directly using MP-IBGP. The service deployment is also simple. This configuration solution, however, requires an interface (generally a logical subinterface) be configured for each inter-AS VPN on an ASBR one after another, complicating network expansion. In addition, the number of bound interfaces should be at least equal to the number of inter-AS VPNs. The separate creation of interfaces for each VPN poses high requirements on ASBRs. As a result, the Option A solution is generally applicable to networks with a small number of inter-AS VPNs.

2. Option B: Single-Hop MP-EBGP Mode

In the Option A solution, you need to configure a VRF instance for each VPN and bind the VRF instance to an interface on an ASBR. This is because VPN routes cannot be directly transmitted between EBGP peers and can be carried only through MP-IBGP. If VPN routes can be directly transmitted between EBGP peers, you do not need to configure VRF instances on ASBRs. The Option B solution extends MP-IBGP to enable VPN routes to be directly distributed between ASBRs. The Option B solution is called the single-hop MP-EBGP solution. Figure 1-5 shows the topology.

Figure 1-5 Option B Inter-AS VPN

The advantage of this single-hop MP-EBGP solution is that you do not need to configure a sub-interface for each VPN site on an ASBR or set up an inter-AS LSP. The VPN routes can be directly transmitted between single-hop MP-EBGP neighbors. The Option B solution is applicable to networks with lots of inter-AS VPN services. The VPN routing information, however, is maintained and spread by the ASBRs between ASs. A large number of VPN routes generate a heavy workload on the ASBRs. Since the ASBRs also generally forward IP packets on the public network, high requirements are imposed on these devices. In addition, the ASBRs cancel the RT filtering function for received VPN routes. The VPN routes on PEs may be spread to the ASBRs in another AS, resulting in VPN route leakage. The USPs, who exchange VPN routes, must reach trust agreements on route exchanging. The ASBRs should trust each other and perform corresponding route filtering policies. This increases ISPs' O&M costs.

Option B supports two implementation solutions: The ASBRs do not change the next hop of a VPN route, and the ASBRs change the next hop of a VPN route. The following describes the configuration procedures of these two implementation solutions.

- Solution 1: ASBRs do not change the next hop of a VPN route.

  When an ASBR receives a VPN route sent from an ASBR in another AS and sends the route to an MP-IBGP neighbor in the local AS, the ASBR does not change the next hop of the VPN route. In this solution, the PEs and ASBRs in the same ASs establish MP-IBGP sessions to exchange VPN routes, and ASBRs in different ASs establish MP-EBGP sessions to directly exchange VPN routes. When an ASBR sends a route received from an MP-EBGP neighbor to another MP-IBGP neighbor, it does not change the next hop of the route. Therefore, the PE in the AS must have a route to the next hop (ASBR in another AS). An ASBR can redistribute a route destined for the peer ASBR to the IGP domain in the local AS so that the address of the ASBR in another AS becomes reachable. LSPs can be established via LDP.

- Solution 2: ASBRs change the next hop of a VPN route.

  When an ASBR receives a VPN route sent from an ASBR in another AS and sends the route to a PE in the local AS, the ASBR changes the next hop of the VPN route to the ASBR itself. In this solution, the PEs and ASBRs in the same ASs establish MP-IBGP sessions to exchange VPN routes, and ASBRs in different ASs establish MP-EBGP sessions to directly exchange VPN routes. When an ASBR receives a VPN route from

the other ASBR and advertises the VPN route to the MP-IBGP peer in the local AS, the ASBR changes the next hop of the VPN route to the ASBR itself.

3. Option C: Multi-Hop MP-EBGP Mode

Both Option A and Option B can meet inter-AS VPN networking requirements. However, the ASBRs need to maintain and advertise VPN routes. When each AS has considerable inter-AS VPN routes to be advertised, the ASBRs may become the bottleneck of further network expansion. To address this problem, the Option C solution is developed, that is, the multi-hop MP-EBGP solution. The multi-hop MP-EBGP solution enables PEs in different ASs to establish multi-hop MP-EBGP sessions to directly exchange VPN routes. In this mode, ASBRs do not need to maintain or distribute VPN routes.

Figure 1-6 Option C Multi-Hop MP-EBGP

In multi-hop MP-EBGP mode, only PEs rather than ASBRs are required to store VPN information. However, configuration of multi-hop MP-EBGP is complex. The solution is applicable to scenarios in which large-scale inter-AS VPN services are required.

To facilitate scale expansion in Option C, each AS is generally deployed with a route reflector (RR). The RRs in two ASs establish a multi-hop MP-EBGP session to exchange VPN routes. Judged from deployment, Option C can be referred to as the solution of multi-hop MP-EBGP session setup between RRs.

Option C has the following two implementation solutions:

- Solution 1: Enable label switching for IPv4 routes only between EBGP neighbors.

  In this solution, ASBRs need to run IGP (such as OSPF or RIP) to redistribute BGP routes so that each device in an AS has routes to PEs in another AS. In an AS, you can use the LDP to distribute labels for routes to PEs in another AS and set up LSPs. On the directly-connected ASBRs in two ASs, enable label switching for IPv4 routes. In this manner, BGP serves as the MPLS signaling protocol to distribute labels to routes destined to PEs in another AS and sets up inter-AS LSPs.

- Solution 2: Enable label switching for IPv4 routes between EBGP and IBGP neighbors.

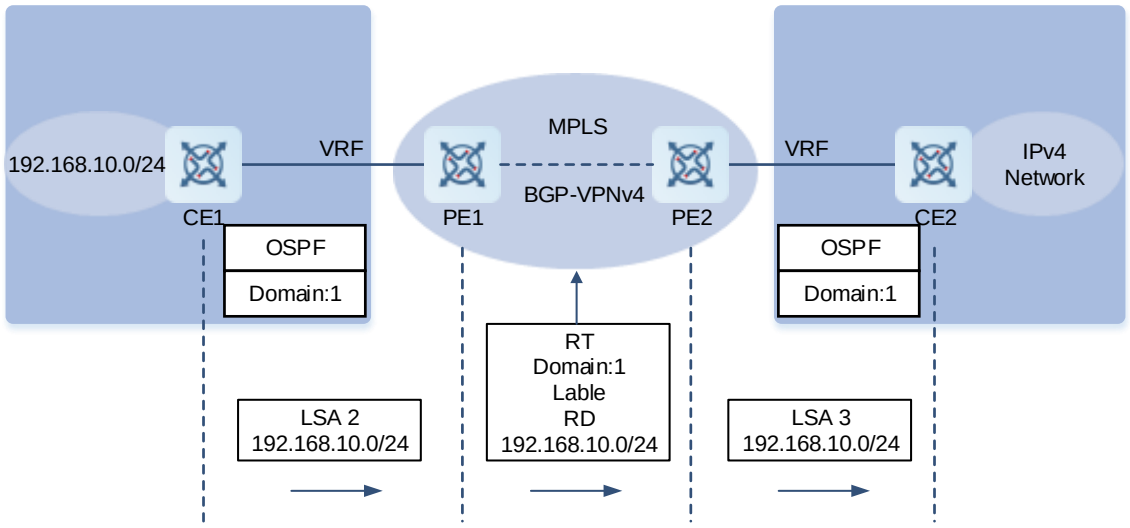
  In solution 1, the IGP and LDP in one AS are required to maintain the PE routes in another AS. That is, inter-AS PE routes should be advertised to each device in the other AS. In view of the AS security in actual

applications, the PE routes of another AS are generally not advertised to each device in the local AS. These routes need to be owned only by the BGP and therefore are transparent to the IGP and LDP in the local AS. To achieve this, you can enable label switching for IPv4 routes between EBGP and IBGP neighbors.

This solution differs from solution 1 in that the IGP on an ASBR is not required to redistribute BGP routes and the LDP is not required to distribute labels to BGP routes and only needs to set up LSPs in the local AS. However, label switching for IPv4 routes needs to be enabled between both IBGP and EBGP neighbors to set up inter-AS LSPs. In addition, PEs are required to push three consecutive layers of labels.

1.1.4 OSPF VPN Extended Features

Open Shortest Path First (OSPF) is a widely used IGP. In most of the existing application scenarios, VPN users select OSPF as the internal routing protocol. If OSPF is also used between a PE and a CE, you do not need to run other routing protocols. This simplifies CE configuration and management.



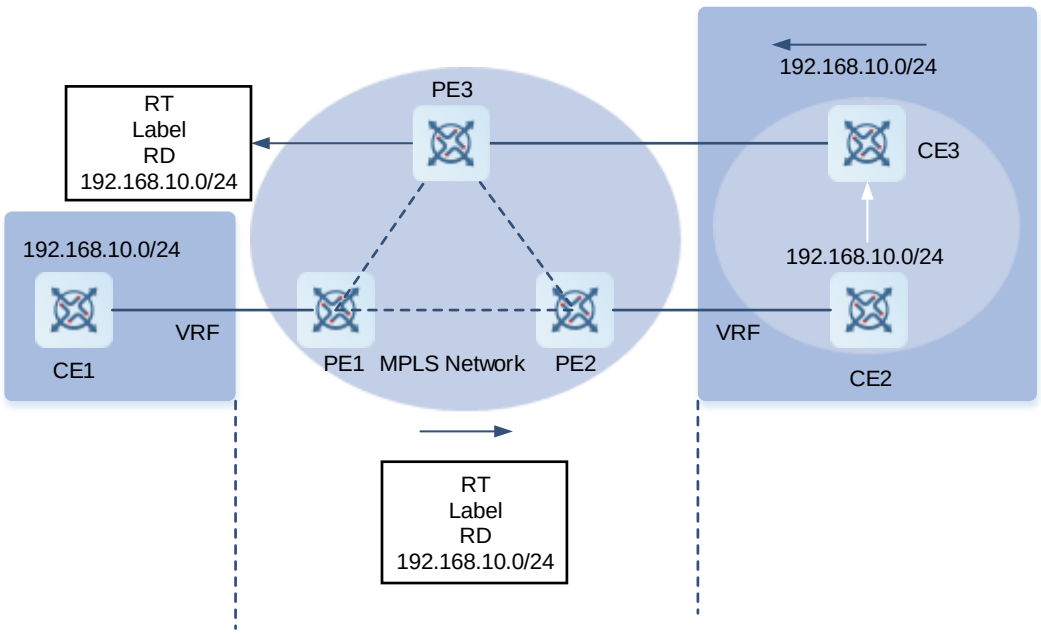
The following describes OSPF extended features between PEs and CEs.

1. Domain ID

A domain ID refers to the ID of an OSPF domain to which a route belongs. When a CE learns an OSPF route in a VPN site and this route is advertised to a PE as a type 1/2/3 link-state advertisement (LSA) and is redistributed to the BGP domain to form a VPN route, the domain ID is also redistributed to the BGP domain along with the route and advertised as an extended community attribute of the VPN route. When another PE receives this VPN route and redistributes it to a VRF-associated OSPF process, the domain ID is redistributed to the VRF-associated OSPF process along with the route. If the VRF-associated OSPF process confirms that the domain ID in the route is the same as that of the local VRF-associated OSPF process, it advertises the route to the CE as an internal route. If the VRF-associated OSPF process confirms that the domain ID in the route is different from that of the local VRF-associated OSPF process, the VRF-associated OSPF process advertises the route to the CE as an external route.

As shown in Figure 1-7, CE1 advertises routes to the same OSPF domain to PE1 as type 2 LSAs. PE1 converts them into VPN routes and advertises them to PE2. After receiving the routes, PE2 redistributes them to the VRF-associated OSPF process. The domain ID of the VRF-associated OSPF process is the same as that of the VPN routes. Therefore, the sites with the same domain ID are advertised to the VPN site as internal routes.

Figure 1-7 Domain ID



2. DN Bit

The DN bit is a loop detection technology between a PE and a CE running OSPF. In some scenarios, loops may arise when OSPF runs between a PE and a CE. For example, multiple PEs are connected to one VPN site. If one PE advertises learned VPN routes to the VPN site, which advertises the routes to another PE via OSPF, a loop may occur.

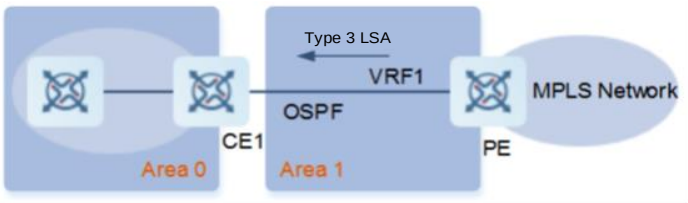
As shown in Figure 1-8, PE1 advertises the 192.168.10.0/24 route to PE2 and PE3, CE2 advertises the route to CE3 via OSPF, and CE3 advertises the route to PE3. PE3 preferentially selects the route that is redistributed by OSPF instead of BGP, converts this route into a VPNv4 route, and advertises it. As a result, a loop may occur.

Figure 1-8 DN Bit

To prevent such possible loops, the DN bit is set in an optional field of a type 3/5/7 LSA advertised from a PE to a CE. If another PE receives an LSA with the DN bit contained in an optional field, the OSPF of the PE will not use this LSA for OSPF route calculation.

3. VPN Route Tag

The VPN router tag is another loop detection technology between a PE and a CE running OSPF. When OSPF runs between a PE and a CE, the VRF-associated OSPF process of the PE has a router tag by default, which is called the VPN router tag. When the VRF-associated OSPF process of the PE imports a VPN route, converts it into a type 5/7 LSA, and advertises it to a CE, the LSA carries the VPN router tag. When multiple PEs are connected to one VPN site, the type 5/7 LSA received by a PE contains the VPN router tag, and the VPN router tag is the same as that of the OSPF process, the LSA is not used for OSPF route calculation.



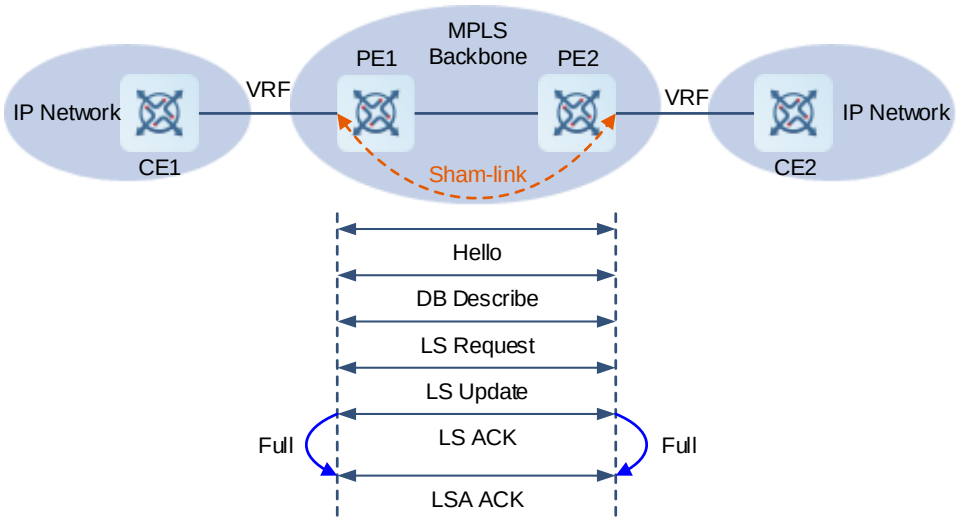
4. Area Deployment

In normal cases, the link between a PE and a CE may belong to any OSPF area. If it belongs to a non-zero area, the PE is an ABR for the OSPF area where the CE resides. This may cause problems because the ABR running OSPF has the following features:

- The ABR calculates type 3 LSAs in the backbone area only.
- The ABR forwards only type 3 LSAs in the backbone area to a non-backbone area.

As shown in Figure 1-9, if the link between the PE and CE1 belongs to a non-zero area, the PE redistributes the VPNv4 routes advertised by MP-BGP neighbors to the OSPF domain, restores them to type 3 LSAs, and advertises them to CE1. CE1 does not calculate LSAs in non-backbone areas. These LSAs are not advertised to routers in Area 0, and sites of a VPN cannot learn routes of other sites. Therefore, exercise caution during OSPF area deployment when the link between a PE and a CE belongs to a non-zero area.

Figure 1-9 Area Deployment



In general, if OSPF is run between a PE and a CE to exchange VPN routes in L3VPN applications, do not deploy backbone areas at VPN internal sites. If a router at a VPN internal site belongs to a backbone area in addition to a PE, at least one router at the VPN internal site must be connected to the PE and the link between the CE and PE must belong to Area 0. In this way, inter-area routes and external routes can be transmitted between the PE and the VPN site.

5. Sham Link

A sham link is not a real link but a virtual link established between VRF instances of two PEs. Like a normal OSPF link, a sham link has its OSPF interfaces and can send OSPF packets, establish neighbor relationships, and send LSAs. When LSAs are flooded on a sham link, the types of all OSPF routes do not change, as shown in Figure 1-10.

Figure 1-10 Sham Link

The purposes of establishing sham links between VRF-associated OSPF processes of different PEs are as follows:

- When the MP-IBGP is used to carry private routes, it only transfers routes. After the routes reach the peer PE and are restored, the MP-IBGP imports the original OSPF routes in a best-effort manner, and the OSPF topology information cannot be communicated properly. With a sham link, an OSPF link can be established to interconnect OSPF processes at each site and establish a complete topology.
- Different sites in the same VPN exchange information through the MPLS backbone network. However, a link is connected between these sites within the VPN to ensure that these VPN sites can communicate with each other through this link when the MPLS backbone network is unavailable. This link is called a backdoor link. If two VPN sites belong to the same OSPF area and one backdoor link is connected between the sites, routes inside the two sites are exchanged through either the MPLS backbone network or the backdoor link. Routes exchanged through the MPLS backbone network are inter-domain routes while routes exchanged through the backdoor link are intra-domain routes. The intra-domain routes advertised by the backdoor link are prior to the inter-domain routes advertised by the MPLS backbone network. Therefore, routes inside two sites are preferentially forwarded through the backdoor link, which is against the intention of the backdoor link connection for VPN users. In this case, a sham link is also required.

1.1.5 6VPE Service Model

IPv6 VPN Provider Edge Router (6VPE) is a technology that uses IPv4 BGP/MPLS VPN to provide VPN services for IPv6 networks. In 6VPE mode, CEs use addresses in the IPv6 address family and the MPLS backbone network is still an IPv4 network. 6VPE is an IPv6 extension of IPv4 BGP/MPLS VPN.

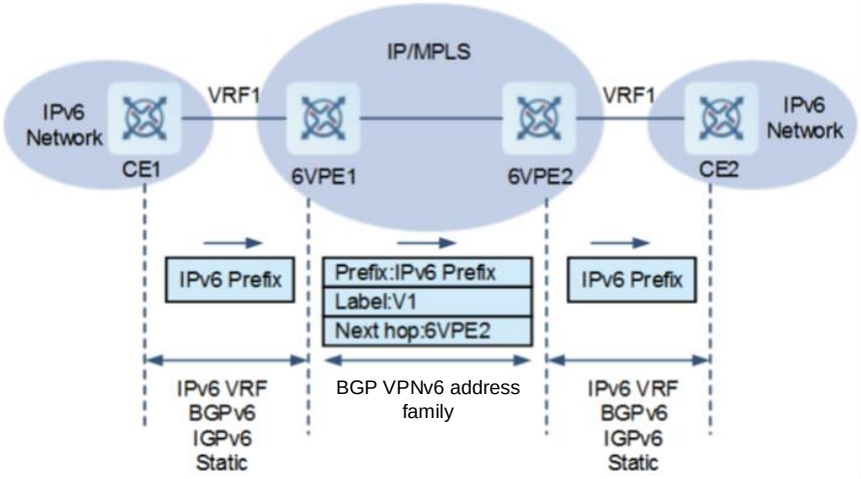
The 6VPE technology helps retain the existing network base and upgrades PEs to smoothly transit from IPv4 access to IPv6 access and from IPv4 VPN services to IPv6 VPN services. Regardless of the network or service, 6VPE is an IPv4-to-IPv6 evolution solution with less investment.

In addition to IPv4 MPLS backbone networks, 6VPE supports IPv6 MPLS backbone networks. The two have similar principles and configurations. This document describes 6VPE in case of IPv4 MPLS backbone networks.

1. Route Distribution Process

The route distribution process in the control plane of a 6VPE device includes the following steps:

(1) Routing relationship between PEs and Ps are established using IPv4 IGP (such as RIP, OSPFv2, IS-IS, and BGP) or IPv6 IGP (such as RIPng and OSPFv3) to advertise the loopback address of the 6VPE device to all Ps and other 6VPE devices on the network.



(2) The IPv4 or IPv6 label distribution protocol (such as LDP) is used to establish LSPs, that is, MPLS tunnels between 6VPE devices.

(3) 6VPE devices exchange routing information (IPv6 routing protocol or statically configured routes) between VRF instances and IPv6 CEs.

(4) Through BGP extended attributes, 6VPE devices advertise route reachability information and distribute labels for address prefixes in VPNs. If a 6VPE device connects to a user network using IPv6, the route reachability information uses the newly defined VPNv6 address family.

(5) 6VPE devices advertise IPv6 route reachability information to CEs using an IPv6 routing protocol.

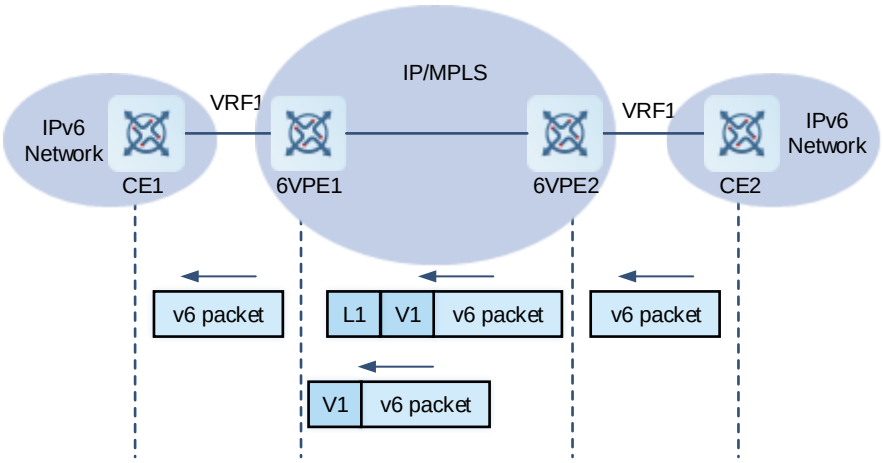


Figure 1-11 Control Plane Exchange

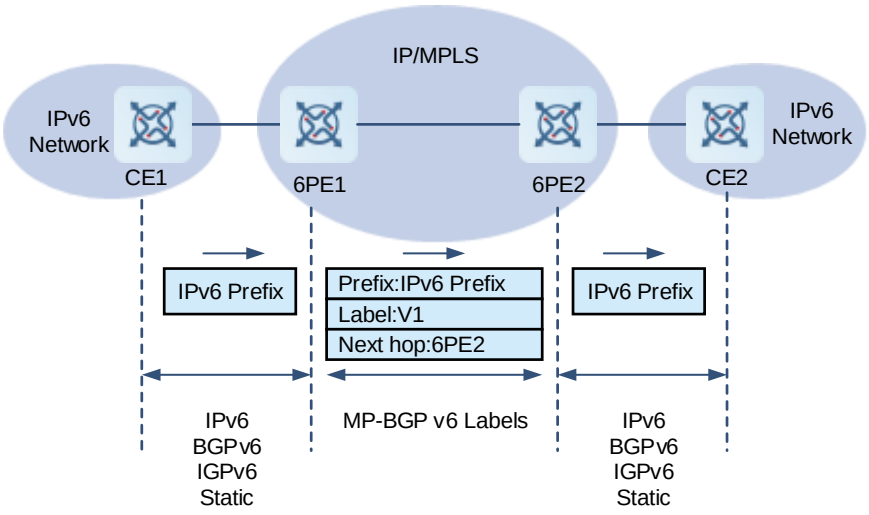
2. Packet Forwarding Process

When forwarding IPv6 packets of a VRF instance, a 6VPE device encapsulates MPLS labels for packets that need to enter the backbone network tunnels and forwards them to the egress 6VPE device along the LSP.

Figure 1-12 Forwarding Plane Exchange

1.1.6 6PE Service Model

IPv6 Provider Edge (6PE) is an IPv6 transition technology that allows CEs in IPv6 islands (non-VPN service) to communicate with each other through the existing IPv4 MPLS backbone network.



With the 6PE technology, ISPs can use existing IPv4 MPLS backbone networks to provide access services for scattered IPv6 networks. ISPs need to perform IPv6 upgrade only for PEs and do not need to upgrade or reconfigure the existing IPv4 MPLS backbone networks. This protects investment on existing backbone networks. For ISPs, the 6PE technology is an efficient and low-risky solution for IPv6 transition.

In addition to IPv4 MPLS backbone networks, 6PE supports IPv6 MPLS backbone networks.

1. Route Distribution Process

As shown in Figure 1-13, PEs and CEs run IPv6 and have IPv6 connections established. The backbone network is an IP MPLS network (IPv4 or IPv6 MPLS). This document uses the IPv4 MPLS network as an example. 6PE devices learn IPv6 routes from CEs, distribute labels to the IPv6 routes, and transfer the routes to other 6PE devices through BGP sessions.

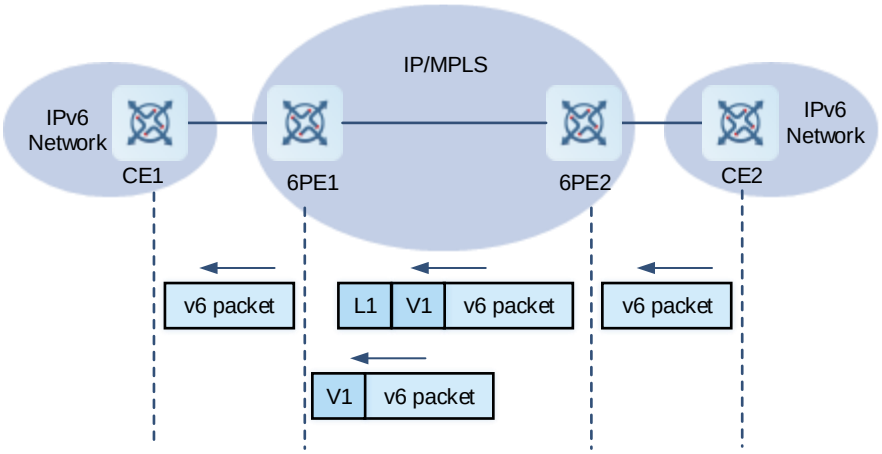


Figure 1-13 Route Distribution

2. Packet Forwarding Process

When forwarding IPv6 packets, a 6PE device encapsulates MPLS labels for packets that need to enter the backbone network tunnels, and forwards them to the egress PE along the LSP.

Figure 1-14 Packet Forwarding

1.1.7 Protocols and Standards

- RFC 4364: BGP/MPLS IP Virtual Private Networks (VPNs)
- RFC 4659: BGP-MPLS IP Virtual Private Network (VPN) Extension for IPv6 VPN
- RFC 4577: OSPF as the Provider/Customer Edge Protocol for BGP/MPLS IP Virtual Private Networks (VPNs)
- RFC 4798: 6PE

1.2 IPv4 MPLS L3VPN Configuration Task Summary

IPv4 MPLS L3VPN configuration includes the following tasks:

(1) Configuring Basic IPv4 MPLS L3VPN Functions

- a Configuring an MPLS Network
- b Configuring a VPN Routing Instance
- c Configuring VPN Route Exchange Between PEs
- d Configuring VPN Route Exchange Between PEs and CEs
- e (Optional) Configuring the Label Distribution Mode for VPN Routes
- f (Optional) Configuring the Import and Export Policies for VPN Routes
- g (Optional) Configuring Static L3VPN FTN and ILM

(2) (Optional) Configuring the Inter-AS VPN Service Model – Option A

(3) (Optional) Configuring the Inter-AS VPN Service Model – Option B (ASBRs Do Not Change the Next Hops of VPN Routes)

a Configuring Route Exchange Between PEs and CEs

b Configuring IGP and MPLS Signaling Protocol in an AS

c Configuring an ASBR to Cancel the Default RT Filtering Function

d Configuring PEs and ASBRs in the Same AS to Exchange VPN Routing Information

e Establishing an MP-EBGP Session Between ASBRs in Different ASs

f (Optional) Configuring Route Map Rules to Filter VPN Routes

g Configuring an IGP to Redistribute ASBR Routes of Another AS

(4) (Optional) Configuring Inter-AS VPN Service Model – Option B (ASBRs Change the Next Hops of VPN Routes)

a Configuring Route Exchange Between PEs and CEs

b Configuring IGP and MPLS Signaling Protocol in an AS

c Configuring an ASBR to Cancel the Default RT Filtering Function

d Establishing an MP-IBGP Session Between an ASBR and a PE and Changing the Next Hop Address to the ASBR Address

e Establishing an MP-EBGP Session Between ASBRs

f (Optional) Configuring Route Map Rules to Filter VPN Routes

(5) (Optional) Configuring Inter-AS VPN Service Model – Option C (Enabling Label Switching for IPv4 Routes Only with EBGP Neighbors)

a Configuring Route Exchange Between PEs and CEs in the Same ASs

b Configuring IGP and MPLS Signaling Protocol in an AS

c Establishing an EBGP Session Between ASBRs to Distribute Labels to IPv4 Routes

d Configuring an ASBR to Redistribute PE Routes Learned from the EBGP Domain to the IGP Domain

e Configuring a Multi-Hop MP-EBGP Session

(6) (Optional) Configuring the Inter-AS VPN Service Model – Option C (Enabling Label Switching for IPv4 Routes with EBGP and IBGP Neighbors)

a Configuring Route Exchange Between PEs and CEs in the Same ASs

b Configuring IGP and MPLS Signaling Protocol in an AS

c Establishing an IBGP Session Between a PE and an ASBR to Distribute Labels to IPv4 Routes

d Establishing an EBGP Session Between ASBRs to Distribute Labels to IPv4 Routes

e Configuring a Multi-Hop MP-EBGP Session

(7) (Optional) Configuring the Inter-AS VPN Service Model – Option C (Establishing a Multi-Hop MP-EBGP Session Between RRs)

a Configuring Route Exchange Between PEs and CEs

b Configuring IGP and MPLS Signaling Protocol in an AS

c Establishing an MP-IBGP Session Between an RR and a PE and Enabling Label Switching for IPv4 Routes

d Establishing an IBGP Session Between an RR and an ASBR and Enabling Label Switching for IPv4 Routes

e Establishing an EBGP Session Between ASBRs to Distribute Labels for IPv4 Routes

f Configuring a Multi-Hop MP-EBGP Session

(8) (Optional) Configuring OSPF VPN Extended Features

a Configuring the Domain ID

b Configuring the VPN Route Tag

c Configuring a Sham Link

d Configuring Loop Detection for a VRF-associated OSPF process

e Configuring Extended Community Attributes of VPN Routes

f Disabling Loop Detection Based on the DN Bit Carried in LSAs

g Disabling Loop Detection Based on the Route Tag Carried in LSAs

1.3 Configuring Basic IPv4 MPLS L3VPN Functions

1.3.1 Overview

After basic IPv4 MPLS L3VPN functions are configured, BGP/MPLS VPN services can be provided in an AS on an ISP's network.

1.3.2 Restrictions and Guidelines

- MPLS L3VPN supports only L3 routing interfaces.
- The LDP router ID must be 32 bits.
- The BGP router ID must be 32 bits.
- The **mpls ip** and **label-switch** commands must be configured for PE interfaces used to connect to the public network.

1.3.3 Configuration Tasks

Configuration of basic IPv4 MPLS L3VPN functions includes the following tasks:

(1) Configuring an MPLS Network

(2) Configuring a VPN Routing Instance

(3) Configuring VPN Route Exchange Between PEs

(4) Configure VPN route exchange between PEs and CEs. Configure one of the following tasks.

- Running BGP Between PEs and CEs
- Running OSPF Between PEs and CEs
- Running RIP Between PEs and CEs
- Configuring Static Routes Between PEs and CEs

(5) (Optional) Configuring the Label Distribution Mode for VPN Routes

(6) (Optional) Configuring the Import and Export Policies for VPN Routes

(7) (Optional) Configuring Static L3VPN FTN and ILM

1.3.4 Configuring an MPLS Network

1. Overview

To use MPLS on the backbone network, you must configure the MPLS LDP on the Ps and PEs to establish public tunnels. This means that you have to configure LDP on MPLS devices and enable MPLS forwarding on each interface.

2. Procedure on Ps and PEs

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable MPLS forwarding globally.

mpls ip

MPLS forwarding is disabled globally by default.

To implement MPLS forwarding on a device, enable MPLS forwarding globally first.

(4) Enable LDP and enter the LDP configuration mode.

mpls router ldp

LDP is disabled by default.

(5) Configure the LDP router ID.

ldp router-id { *ipv4-address* | **interface** *interface-type interface-number* [**force**] }

The system router ID is used as the LDP router ID by default.

Generally, the loopback interface address is used as the router ID. If **force** is specified, the new router ID is forced to take effect immediately. Otherwise, the new router ID does not take effect immediately.

(6) Exit the LDP configuration mode.

exit

(7) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

interface loopback *interface-number*

(8) Configure an IP address for the interface.

ip address *ipv4-address mask-length*

No IP address is configured for an interface by default.

(9) Enable labeled MPLS packet forwarding on the public interface.

label-switching

Forwarding labeled MPLS packets is disabled on an interface by default.

(10) Enable LDP on the interface.

mpls ip

LDP is disabled on an interface by default.

1.3.5 Configuring a VPN Routing Instance

1. Overview

To configure an VPN routing instance, define a VRF instance, configure RD and RT values for the VRF instance, and associate the VRF instance with an interface.

2. Restrictions and Guidelines

- VRF instances need to be configured on PEs rather than CEs or Ps.
- If the RD value of a VRF instance is defined on a PE or the PE is enabled with BGP VRF, the RD value cannot be modified or deleted. You can only delete and re-create the VRF instance to set the RD value.
- VRF instances on a PE must have unique RD values.
- When the **ip vrf forwarding** *vrf-name* command is run on an interface configured with an IP address, the configured IP address is deleted. In this case, you need to re-configure an IP address for the interface in interface configuration mode.

3. Procedure on PEs

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a VRF instance and enter the VRF instance configuration mode.

ip vrf *vrf-name*

No VRF instance is created by default.

(4) Configure the RD value.

rd *rd-value*

No RD value is configured by default.

(5) Configure the RT value.

route-target { **both | export | import** } *rt-value*

No RT value is configured by default.

(6) Exit the VRF instance configuration mode.

exit

(7) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the tunnel interface configuration mode.

  interface tunnel *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(8) Associate the VRF instance with an interface.

ip vrf forwarding *vrf-name*

An interface does not belong to any VRF instance by default.

(9) Configure an IP address for the interface.

ip address *ipv4-address mask-length*

No IP address is configured for an interface by default.

1.3.6 Configuring VPN Route Exchange Between PEs

1. Overview

PEs exchange routing information through BGP, and only common IPv4 routing information is exchanged by default. If a PE needs to exchange VPN routing information with another PE, enter the VPN address family configuration mode and enable VPN route exchange with peer PEs.

2. Procedure on PEs

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a BGP domain and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(4) Configure a BGP session.

neighbor *ipv4-address* **remote-as** *asn-number*

No BGP peer is configured by default.

(5) Configure the interface address used to establish the MP-IBGP session as the source address. Generally, the loopback interface address is used as the source address.

neighbor *ipv4-address* **update-source** *interface-type interface-number*

The optimal local interface is used as the outbound interface by default.

(6) Enter the VPN address family configuration mode.

address-family vpnv4

No VPNv4 address family is defined by default.

(7) Activate VPN route exchange in the BGP session.

neighbor *ipv4-address* **activate**

VPN route exchange is enabled in an IPv4 unicast address family by default.

1.3.7 Running BGP Between PEs and CEs

1. Overview

Establish BGP sessions between PEs and between PEs and CEs to connect to CEs in private networks using BGP. Redistribute private routes and BGP routes on CEs to ensure private network connectivity.

2. Restrictions and Guidelines

- During PE configuration in BGP VRF address family configuration mode, if no RD value is specified for a VRF instance and **address-family ipv4 vrf** *vrf-name* is run to enter the address family configuration mode of the VRF instance, the system displays a prompt indicating that no RD value is configured and does not allow users to enter the address family configuration mode.
- Any dynamic or static routing protocol may run in users' private networks.

3. Procedure on PEs

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a BGP domain and enter the BGP configuration mode.

router bgp *pe-asn-number*

BGP is disabled by default.

(4) Configure the associated VRF instance and enter the BGP VRF address family configuration mode.

address-family ipv4 vrf *vrf-name*

No IPv4 VRF address family is configured by default.

(5) Establish EBGP sessions with CEs.

neighbor *ipv4-address* **remote-as** *ce-asn-num*

No BGP peer is configured by default.

4. Procedure on CEs

On CEs, establish BGP sessions with PEs to import private network routes to BGP. Any dynamic or static routing protocol may run in users' private networks. OSPF is used as an example here.

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a BGP domain and enter the BGP configuration mode.

router bgp *ce-asn-number*

BGP is disabled by default.

(4) Establish EBGP sessions with PEs.

neighbor *ipv4-address* **remote-as** *ce-as-number*

No BGP peer is configured by default.

(5) Configure BGP to redistribute OSPF routes.

redistribute ospf *ospf-id*

The route redistribution function is disabled by default.

(6) Exit the BGP configuration mode.

exit

(7) Enter the OSPF configuration mode.

router ospf *process–id*

The OSPF routing process is disabled by default.

(8) Configure OSPF to redistribute BGP routes.

redistribute bgp subnets

The route redistribution function is disabled by default.

1.3.8 Running OSPF Between PEs and CEs

1. Overview

If OSPF is run in users' private networks, continue to run OSPF between PEs and CEs without extra configuration on CEs.

To run OSPF between a PE and a CE, you must configure an OSPF process for the corresponding VRF instance on the PE. The PE then uses the OSPF process to exchange routing information with the CE. By redistributing BGP routes, the OSPF sends the VPN routes received from other PEs to the CE. By redistributing OSPF routes, the BGP sends the VPN routing information from the CE to the PE to other PE peers.

2. Restrictions and Guidelines

OSPF must be enabled for interfaces on CEs used to connect to PEs, and no passive ports or other route exchange restrictions are set.

3. Procedure on PEs

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an OSPF process and enter the OSPF configuration mode.

router ospf *process-id* [**vrf** *vrf-name*]

The OSPF routing process is disabled by default.

(4) Configure links added to the OSPF area.

network *ipv4-address mask-length* **area** *area-id*

No interface IP address is added to the OSPF area by default.

(5) Configure OSPF to redistribute BGP routes.

redistribute bgp subnets

Route redistribution is not configured by default.

(6) Exit the OSPF configuration mode.

exit

(7) Enable BGP and enter the BGP configuration mode.

router bgp *as-number*

BGP is disabled by default.

(8) Enter the BGP VRF configuration mode.

address-family ipv4 vrf *vrf-name*

No IPv4 VRF address family is configured by default.

(9) Redistribute OSPF routes.

redistribute ospf *process-id*

The route redistribution function is disabled by default.

1.3.9 Running RIP Between PEs and CEs

1. Overview

If Routing Information Protocol (RIP) is run in users' private networks, continue to run RIP between PEs and CEs without extra configuration on CEs.

The VRF instance on a PE uses RIP to exchange routing information with a CE. By redistributing BGP routes, the RIP sends the VPN routes received from other PEs to the CE. By redistributing RIP routes, the BGP sends the VPN routing information from the CE to the PE to other PE peers.

2. Restrictions and Guidelines

RIP must be enabled for the interface on a CE used to connect to a PE, and route exchange is not restricted.

3. Procedure on PEs

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an RIP instance and enter the RIP configuration mode.

router rip

(4) Enter the RIP VRF address family configuration mode.

address-family ipv4 vrf *vrf-name*

No IPv4 VRF address family is configured by default.

(5) Configure the RIP version number.

version 2

By default, route update packets of RIPv1 and RIPv2 can be received, but only route update packets of RIPv1 are sent.

(6) Configure RIP used to communicate with a CE.

network *network-number* [*wildcard*]

No local network is advertised by default.

(7) Configure RIP to redistribute BGP routes.

redistribute bgp

Route redistribution is not configured by default.

(8) Exit the address family configuration mode.

exit

(9) Enable BGP and enter the BGP configuration mode.

router bgp *as-number*

BGP is disabled by default.

(10) Enter the BGP VRF configuration mode.

address-family ipv4 vrf *vrf-name*

No IPv4 VRF address family is configured by default.

(11) Redistribute RIP routes.

redistribute rip

The route redistribution function is disabled by default.

1.3.10 Configuring Static Routes Between PEs and CEs

1. Overview

Configure a static route from a PE to a CE and redistribute the static route to the BGP VRF instance. Configure a static route from a CE to a PE and import the static route to the private network. In simple network environments, static routes are generally configured.

2. Procedure on PEs

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a static route.

ip route [**vrf** *vrf-name*] *network mask* { *ipv4-address* | *interface* [*ipv4-address*] } [*distance*] [**tag** *tag*] [**permanent** | { **track** *object-number* | **arp** }] [**weight** *number*] [**description** *description-text*] [**disabled** | **enabled**] [**global**]

No static route is configured by default.

(4) Enter the BGP configuration mode.

router bgp *as-number*

BGP is disabled by default.

(5) Enter the BGP VRF address family configuration mode.

address-family ipv4 vrf *vrf-name*

No IPv4 VRF address family is configured by default.

(6) Redistribute static routes.

redistribute static

The route redistribution function is disabled by default.

1.3.11 Configuring the Label Distribution Mode for VPN Routes

1. Overview

Two label distribution modes are used in L3VPN applications: route-based and VRF-based label distribution. Route-based label distribution features a fast forwarding speed. A device only needs to query the ILM table to forward packets to the next hop. However, the ILM table needs to have a large capacity. VRF-based label distribution requires only one label distributed to each VRF instance, and all routes in the VRF instance share the label. This reduces the ILM table capacity. However, the forwarding speed is slow. This is because the system needs to look up the table twice in the forwarding process. It first looks up the ILM table to find the VRF instance where the packet is located, and then forwards the packet based on the destination IP address in the routing table of the VRF instance.

2. Restrictions and Guidelines

- When you modify the label distribution mode, the MP-BGP cancels all routes advertised in the VPN and re-advertises the routes.
- In VRF instance configuration mode, you can run the **alloc-label** command to modify the default label distribution mode. You can also choose different distribution modes for different VRF instances. **per-vrf** indicates that a label is distributed to all routes of a VRF instance. When advertising VPN routes, the MP-BGP uses the same label for all routes. **per-route** indicates that a label is distributed to each route of a VRF instance. When advertising VPN routes, the MP-BGP uses a different label for each route.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a VRF instance and enter the VRF instance configuration mode.

ip vrf *vrf-name*

No VRF instance is created by default.

(4) Configure the label distribution mode for VPN routes.

alloc-label { **per-vrf | per-route** }

An L3VPN adopts the VRF-based label distribution mode by default. When you modify the label distribution mode, the MP-BGP cancels all routes advertised in the VPN and re-advertises the routes.

1.3.12 Configuring the Import and Export Policies for VPN Routes

1. Overview

In most situations, you can define the import route-target attribute in VRF configuration mode to determine the routes to be imported into a VRF instance and define the export route-target attribute to determine the RTs to be carried in the routes. These configurations are valid to all routes. In certain application scenarios that require accurate control on the import and export of VPN routes, however, you need to adopt policies.

2. Restrictions and Guidelines

The rule defined by the **import map** command takes effect after the import extended community attributes defined in the VRF instance. That is, only after these routes match the extended community attributes defined by the **route-target import** command in the VRF instance, the VPN routes received from the remote device can be filtered again by rules defined by the **import map** command.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a VRF instance and enter the single-protocol VRF configuration mode.

ip vrf *vrf-name*

No VRF instance is created by default.

(4) Configure a policy for importing remote VPN routes to the local VPN routes based on the rules defined in the route map.

import map *routemap-name*

(5) Configure the extended group attributes that the local end distributes to remote VPN routes based on the rules defined in the route map.

export map *routemap-name*

1.3.13 Configuring Static L3VPN FTN and ILM Entries

1. Overview

In most situations, the MP-BGP distributes labels to private routes and the public LSP is generated by running the LDP on a public network. You can also configure a static LSP to distribute labels to private routes and set up private LSPs.

2. Restrictions and Guidelines

The configured static private FTN and ILM entries take effect only after the corresponding public LSP is set up. To set up a public LSP, refer to 1.3.4 Configuring an MPLS Network. You can set up a public LSP through LDP or configure it statically.

3. Procedure on PEs

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a static private FTN entry.

mpls static l3vpn-ftn *vrf-name* { *ipv4-address/mask-length* | *ipv6-address/prefix-length* } **out-label** *label* **remote-pe** *remote-pe-ipv4-addres*

No L3VPN FTN entry is configured by default.

If the egress of a forwarding equivalence class (FEC) is another PE, you must specify the private label and the egress PE. The address of the egress PE is then used to match the public LSP.

(4) Configure a static private FTN entry.

(IPv4 network)

mpls static l3vpn-ftn *vrf-name ipv4-address/mask-length* **local-forward nexthop** *interface-type interface-number nexthop-ipv4-address*

(IPv6 network)

mpls static l3vpn-ftn *vrf-name ipv6-address/prefix-length* **local-forward nexthop** *interface-type interface-number nexthop-ipv6-address*

No L3VPN FTN entry is configured by default.

If the egress of an FEC is the local PE, you must specify the outbound interface on the local PE and the next-hop address (the outbound interface and the next hop is generally in another VRF instance). You can use this command when the local PE has several VRF instances that belong to the same VPN.

(5) Configure an ILM entry for the L3VPN. You need to specify the incoming label, the outbound interface, and the next-hop address.

(IPv4 network)

mpls static ilm in-label *in-label* **forward-action pop-l3vpn-nexthop** *vrf-name* **nexthop** *interface-type interface-number nexthop-ipv4-address* **fec** *ipv4-address/mask-length*

(IPv6 network)

mpls static ilm in-label *in-label* **forward-action pop-l3vpn-nexthop** *vrf-name* **nexthop** *interface-type interface-number nexthop-ipv6-address* **fec** *ipv6-address/prefix-length*

No L3VPN ILM entry is configured by default.

1.4 Configuring the Inter-AS VPN Service Model – Option A

1.4.1 Overview

In Option A solution, ASBRs establish a VRF instance for each VPN that needs to traverse domains, and bind interfaces for these VRF instances. VRF instances between ASBRs exchange VPN routes by using these interfaces. With configuration in this section, you can create an MPLS L3VPN across multiple ASs.

1.4.2 Restrictions and Guidelines

- The Option A solution requires an ASBR to configure one interface (usually logical subinterface) for each inter-AS VPN and bind the interface to the inter-AS VPN. The number of bound interfaces should be at least equivalent to the number of inter-AS VPNs, and the VPNs need to be configured one after another on the ASBR. Therefore, the extensibility is poor. The subinterface creation for each VPN raises higher requirements for the ASBR. This solution is generally applicable to networks with few inter-AS VPNs.
- The LDP router ID must be 32 bits.
- The BGP router ID must be 32 bits.
- An ASBR needs to configure an interface for each VPN and bind the interface to the VPN.

1.4.3 Procedure

Configure Option A in the method similar to 1.3 Configuring Basic IPv4 MPLS L3VPN Functions.

1.5 Configuring the Inter-AS VPN Service Model – Option B (ASBRs Do Not Change the Next Hops of VPN Routes)

1.5.1 Overview

When an ASBR receives a VPN route sent from an ASBR in another AS and sends it to an MP-IBGP neighbor in the local AS, the ASBR does not change the next hop of the VPN route. This is called the Option B solution with the next hop unchanged. In this solution, the ASBR and PE in the local AS establish an MP-IBGP session to exchange VPN routes. An MP-EBGP session can also be established between two ASBRs in different ASs to directly exchange VPN routes. An ASBR does not change the next hop of a route received from an MP-EBGP neighbor when it sends the route to an MP-IBGP neighbor. Therefore, the route to the next hop (ASBR in another AS) must exist on the PE in the local AS. An ASBR can redistribute a route destined for the peer ASBR to the IGP domain in the local AS so that the address of the ASBR in another AS becomes reachable. LSPs can be established via LDP.

1.5.2 Configuration Tasks

Configuration of the inter-AS VPN service model Option B (VPN route next hop unchanged) includes the following tasks:

(1) Configuring Route Exchange Between PEs and CEs

(2) Configuring IGP and MPLS Signaling Protocol in an AS

(3) Configuring an ASBR to Cancel the Default RT Filtering Function

(4) Configuring PEs and ASBRs in the Same AS to Exchange VPN Routing Information

(5) Establishing an MP-EBGP Session Between ASBRs in Different ASs

(6) (Optional) Configuring Route Map Rules to Filter VPN Routes

(7) Configuring an IGP to Redistribute ASBR Routes of Another AS

1.5.3 Configuring Route Exchange Between PEs and CEs

The procedure is similar to "Configuring Route Exchange Between PEs and CEs" in 1.3 Configuring Basic IPv4 MPLS L3VPN Functions.

1.5.4 Configuring IGP and MPLS Signaling Protocol in an AS

The procedure is similar to 1.3.4 Configuring an MPLS Network.

1.5.5 Configuring an ASBR to Cancel the Default RT Filtering Function

1. Restrictions and Guidelines

By default, a PE rejects a VPN route sent by another PE (or ASBR) if the route is not imported by any VRF instance on the PE. To enable an ASBR to receive all VPN routes from other PEs (or ASBRs) no matter whether these routes are imported into a local VRF instance, you should disable this default RT filtering function on the ASBR.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable BGP and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(4) Disable RT filtering.

no bgp default route-target filter

The RT filtering function is enabled by default.

1.5.6 Configuring PEs and ASBRs in the Same AS to Exchange VPN Routing Information

The procedure is similar to 1.3.6 Configuring VPN Route Exchange Between PEs.

1.5.7 Establishing an MP-EBGP Session Between ASBRs in Different ASs

1. Overview

Establish a directly-connected single-hop MP-EBGP session between two inter-AS ASBRs to advertise VPN routes.

2. Restrictions and Guidelines

- You must run the **label-switching** command to enable labeled MPLS packet forwarding on the interfaces that connect two ASBRs so that the links between the ASBRs can forward MPLS packets.
- If the ASBRs do not use directly-connected addresses to establish an MP-EBGP session but use the loopback interface addresses with 32-bit mask as the source addresses to establish an MP-EBGP session, you must run the **neighbor ebgp-multihop** command to enable the multi-hop EBGP function. In addition, you must configure a static route on each ASBR to the loopback interface addresses on the peer and enable LDP or configure a static FTN entry (with an outgoing label 3, indicating that the ASBR is the penultimate hop).

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable BGP and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(4) Configure an EBGP session between ASBRs.

neighbor *asbr-address* **remote-as** *asbr-asn-number*

No BGP peer is configured by default.

(5) Enter the BGP VPN address family configuration mode.

address-family vpnv4

No VPNv4 address family is defined by default.

(6) Enable VPN route exchange with peers.

neighbor *asbr-address* **activate**

VPN route exchange is enabled in an IPv4 unicast address family by default.

1.5.8 Configuring Route Map Rules to Filter VPN Routes

1. Overview

In view of the AS security in actual applications, you can configure policies on ASBRs to send or receive only certain VPN routes. You can realize this purpose by filtering the RT extended community attributes of VPN routes. In addition, all VPN routes are saved because the default RT filtering function is disabled on the ASBRs. In this case, you can configure VPN route policies on the ASBRs to receive only inter-AS VPN routes sent from the local AS, lessening the capacity pressure of the ASBRs.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a rule for the extended community attribute list.

ip extcommunity-list standard [*extcommunity-name* | *extcommunity-number*] { **permit | deny** } **rt** *rt-value*

No standard extended community attribute list is configured by default.

(4) Create a route map rule and enter the route map configuration mode.

route-map *route-map-name* **permit** [*number*]

(5) Configure the RT matching rule for a route map.

match extcommunity [*extcommunity-name* | *extcommunity-number*]

No extended community attribute list is matched by default.

(6) Exit the route map configuration mode.

exit

(7) Enable BGP and enter the BGP configuration mode.

router bgp *as-number*

BGP is disabled by default.

(8) Enter the VPN address family configuration mode.

address-family vpnv4

No VPNv4 address family is defined by default.

(9) Filter the VPN routes received from ASBRs in another AS.

neighbor *peer-address* **route-map** *route-map-name* **in**

(10) Filter the VPN routes sent to ASBRs in another AS.

neighbor *peer-address* **route-map** *route-map-name* **out**

1.5.9 Configuring an IGP to Redistribute ASBR Routes of Another AS

1. Overview

Since an ASBR does not change the next hops of VPN routes sent to the IBGP peer, the next hop addresses of VPN routes learned by the PE in the local AS are the ASBR addresses in another AS. Therefore, you must configure the PE to learn the routes to the next hop address. For a single-hop directly-connected MP-EBGP session between two ASBRs where BGP is enabled to carry labels (through IPv4 routes or VPN routes), the MP-BGP automatically generates a host route with 32-bit mask and an FTN entry (with the outgoing label 3) to the peer on each ASBR. In this manner, the tunnel egress is not terminated on the local ASBR. Therefore, as long as the ASBRs redistribute the host route to the IGP in the local AS, the PEs can learn routes to the ASBR in the other AS.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable an IGP, for example, OSPF, RIP, or IS-IS.

router *igp*

(4) Redistribute routes to a directly-connected network segment.

redistribute connected subnets

1.6 Configuring Inter-AS VPN Service Model – Option B (ASBRs Change the Next Hops of VPN Routes)

1.6.1 Overview

When an ASBR receives a VPN route sent from an ASBR in another AS and then sends it to a PE in the local AS, the ASBR changes the next hop of the VPN route to the ASBR itself. This is called the Option B solution with the next hop changed. In this solution, a PE and an ASBR in the same AS establish an MP-IBGP session to exchange VPN routes and an MP-EBGP session can be established between the two ASBRs to exchange VPN routes. When an ASBR receives a VPN route from the other ASBR and advertises the VPN route to the MP-IBGP peer in the local AS, the ASBR changes the next hop of the VPN route to the ASBR itself.

1.6.2 Restrictions and Guidelines

1.6.3 Configuration Tasks

Configuration of the inter-AS VPN Option B service model (VPN route next hop changed) includes the following tasks:

(1) Configuring Route Exchange Between PEs and CEs

(2) Configuring IGP and MPLS Signaling Protocol in an AS

(3) Configuring an ASBR to Cancel the Default RT Filtering Function

(4) Establishing an MP-IBGP Session Between an ASBR and a PE and Changing the Next Hop Address to the ASBR Address

(5) Establishing an MP-EBGP Session Between ASBRs

(6) (Optional) Configuring Route Map Rules to Filter VPN Routes

1.6.4 Configuring Route Exchange Between PEs and CEs

The procedure is similar to "Configuring Route Exchange Between PEs and CEs" in 1.3 Configuring Basic IPv4 MPLS L3VPN Functions.

1.6.5 Configuring IGP and MPLS Signaling Protocol in an AS

The procedure is similar to 1.3.4 Configuring an MPLS Network.

1.6.6 Configuring an ASBR to Cancel the Default RT Filtering Function

By default, a PE rejects a VPN route sent by another PE (or ASBR) if the route is not imported by any VRF instance on the PE. To enable an ASBR to receive all VPN routes from other PEs (or ASBRs) no matter whether these routes are imported into a local VRF instance, you should disable this default RT filtering function on the ASBR.

The procedure is similar to 1.5.5 Configuring an ASBR to Cancel the Default RT Filtering Function.

1.6.7 Establishing an MP-IBGP Session Between an ASBR and a PE and Changing the Next Hop Address to the ASBR Address

1. Restrictions and Guidelines

By default, an ASBR does not change the next hops of the VPN routes received from an MP-EBGP peer when the ASBR sends the routes to the MP-IBGP peer. You can configure the ASBR to forcibly change the next hops of the VPN routes to the ASBR itself. In this manner, the PEs in the local AS are not required to learn the address of the peer ASBR. This is the major difference with solution 1 (next hop unchanged).

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable BGP and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(4) Establish an IBGP session with a PE.

neighbor *pe-address* **remote-as** *asn-num*

No BGP peer is configured by default.

(5) Specify the local loopback interface address as the source address to establish an IBGP session.

neighbor *pe-address* **update-source** *interface-type interface-number*

The optimal local interface is used as the outbound interface by default.

Generally, the loopback interface address is used as the source address.

(6) Enter the BGP VPN address family configuration mode.

address-family vpnv4

No VPNv4 address family is defined by default.

(7) Enable VPN route exchange with peers.

neighbor *pe-address* **activate**

(8) Configure an ASBR to change the next hops to its own address when sending VPN routes to the IBGP neighbor.

neighbor *pe-address* **next-hop-self**

1.6.8 Establishing an MP-EBGP Session Between ASBRs

The procedure is similar to 1.5.7 Establishing an MP-EBGP Session Between ASBRs in Different ASs.

1.6.9 Configuring Route Map Rules to Filter VPN Routes

The procedure is similar to 1.5.8 Configuring Route Map Rules to Filter VPN Routes.

1.7 Configuring Inter-AS VPN Service Model – Option C (Enabling Label Switching for IPv4 Routes Only with EBGP Neighbors)

1.7.1 Overview

In this solution, ASBRs need to run IGP (such as OSPF or RIP) to redistribute BGP routes so that each device in an AS has routes to PEs in another AS. In an AS, you can use the LDP to distribute labels for routes to PEs in another AS and set up LSPs. On the directly-connected ASBRs in two ASs, enable label switching for IPv4 routes. BGP serves as the MPLS signaling protocol to distribute labels for routes to PEs in another AS and set up inter-AS LSPs.

1.7.2 Configuration Tasks

Configuration of the inter-AS VPN service model – Option C (enabling label switching for IPv4 routes only between EBGP neighbors) includes the following tasks:

(1) Configuring Route Exchange Between PEs and CEs in the Same ASs

(2) Configuring IGP and MPLS Signaling Protocol in an AS

(3) Establishing an EBGP Session Between ASBRs to Distribute Labels to IPv4 Routes

(4) Configuring an ASBR to Redistribute PE Routes Learned from the EBGP Domain to the IGP Domain

(5) Configuring a Multi-Hop MP-EBGP Session

1.7.3 Configuring Route Exchange Between PEs and CEs in the Same ASs

The procedure is similar to "Configuring Route Exchange Between PEs and CEs" in 1.3 Configuring Basic IPv4 MPLS L3VPN Functions.

1.7.4 Configuring IGP and MPLS Signaling Protocol in an AS

The procedure is similar to 1.3.4 Configuring an MPLS Network.

1.7.5 Establishing an EBGP Session Between ASBRs to Distribute Labels to IPv4 Routes

1. Overview

Establish an EBGP session between inter-AS ASBRs and enable label distribution for IPv4 routes. To import PE routes to the BGP domain, run the **network** command in the BGP IPv4 address family mode or run the IGP route redistribution command. In view of the AS security in actual applications, you are generally required to configure IPv4 route distribution policies on ASBRs. By configuring route map rules, you can control the routes sent to neighbors and specify whether the routes carry labels. Similar control is available for receiving routes.

2. Restrictions and Guidelines

- You must run the **label-switching** command to enable labeled MPLS packet forwarding on the interfaces that connect two ASBRs so that the links between the ASBRs can forward MPLS packets.
- If the ASBRs do not use directly-connected addresses but use the loopback interface addresses with 32-bit mask as the source addresses to establish an MP-EBGP session, you must run the **neighbor ebgp-multihop** command to enable the multi-hop EBGP function. In addition, you must configure a static route on each ASBR to the loopback interface addresses on the peer and enable LDP or configure a static FTN entry (with an outgoing label 3, indicating that the ASBR is the penultimate hop).
- In actual applications, an ASBR is generally required to distribute labels only to PE routes that carry inter-AS VPN services. You can run the **set mpls-label** command in route map mode to achieve this purpose. Create a route map rule and run the **set mpls-label** command in route map configuration mode to distribute labels to routes and advertise only inter-AS PE routes to the peer ASBR. For details about configurations related to the routing policies, see *Configuring Routing Policies*.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable BGP and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(4) Establish an EBGP session with the ASBR in another AS.

neighbor *asbr-address* **remote-as** *asbr-asn-num*

No BGP peer is configured by default.

(5) Enter the BGP IPv4 address family configuration mode.

address-family ipv4

(6) Configure the ASBR to exchange labeled IPv4 routes with the ASBR peer in the other AS.

neighbor *asbr-address* **send-label**

Forwarding labeled MPLS packets is disabled by default.

(7) (Optional) Configure PE addresses to be imported into the BGP routing table in the local AS, that is, host routes to each PE in the AS.

network *pe-address* **mask** *mask*

(8) (Optional) Configure a route distribution policy to control the routes sent to neighbors by defining a route map rule.

neighbor *asbr-address* **route-map** *route-map-name* **out**

(9) (Optional) Configure a route distribution policy to receive only labeled routes by defining a route map rule.

neighbor *asbr-address* **route-map** *route-map-name* **in**

1.7.6 Configuring an ASBR to Redistribute PE Routes Learned from the EBGP Domain to the IGP Domain

1. Overview

When an ASBR learns a route to the PE in another AS from the peer ASBR and needs to inform other PEs in the local AS of the route and to set up an LSP to the PE in the other AS, the ASBR can redistribute routes learned from the EBGP domain to the IGP domain and enable the LDP to distribute labels to BGP routes.

2. Restrictions and Guidelines

You can run the **redistribute bgp subnets route-map** *routemap-name* command in IGP configuration mode to control routes learned from the EBGP domain that need to be redistributed to the IGP domain. You can also run the **advertise-labels for bgp-routes acl** *acl-name* command in LDP configuration mode to control the BGP routes for which labels are distributed.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the IGP configuration mode.

router *igp*

(4) Redistribute BGP routes. Route filtering by using route map rules is optional.

redistribute bgp subnets [**route-map** *routemap-name*]

(5) Exit the IGP configuration mode.

exit

(6) Enter the LDP configuration mode.

mpls router ldp

LDP is disabled by default.

(7) Configure the LDP router ID.

ldp router-id { *ipv4-address* | **interface** *interface-type interface-number* [**force**] }

The system router ID is used as the LDP router ID by default.

Generally, the loopback interface address is used as the router ID. If **force** is specified, the new router ID is forced to take effect immediately. Otherwise, the new router ID does not take effect immediately.

(8) Distribute labels to BGP routes. Route filtering by using ACL rules is optional.

advertise-labels for bgp-routes [**acl** *acl-name*]

By default, the LDP distributes labels only to IGP routes rather than BGP routes. To enable the LDP to distribute labels to BGP routes, you can run the **advertise-labels for bgp-routes** command.

1.7.7 Configuring a Multi-Hop MP-EBGP Session

1. Overview

Establish a multi-hop MP-EBGP session between a PE that needs inter-AS VPN services and a PE in another AS to exchange VPN routes.

2. Restrictions and Guidelines

In a multi-hop MP-EBGP session, IPv4 routes do not need to be exchanged or at least the routes of the two addresses used to set up the BGP session should not be exchanged. Otherwise, a PE has two routes to the PE in another AS. One route is advertised by the ASBR in the local AS, and the other is advertised by the multi-hop EBGP session. According to BGP specifications, an EBGP route has a higher priority over an IGBP route by default. In this case, the BGP preferentially chooses the route advertised by the multi-hop BGP session, and this results in flapping of routes on this PE to the PE in another AS and causes unreachable VPN routes.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable BGP and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(4) Establish a multi-hop EBGP session with a PE in another AS.

neighbor *ebgp-peer-address* **remote-as** *ebgp-asn-num*

No BGP peer is configured by default.

(5) Use the loopback interface address to establish a neighbor relationship with the EBGP peer.

neighbor *ebgp-peer-address* **update-source** *interface-type interface-number*

The optimal local interface is used as the outbound interface by default.

Generally, the loopback interface address is used as the source address.

(6) Configure multi-hop attributes.

neighbor *ebgp-peer-address* **ebgp-multihop**

(7) Enter the BGP VPN address family configuration mode.

address-family vpnv4

No VPNv4 address family is defined by default.

(8) Enable VPN route exchange with peers.

neighbor *ebgp-peer-address* **activate**

(9) Exit the BGP VPN address family configuration mode.

exit

(10) Enter the BGP IPv4 address family configuration mode.

address-family ipv4

(11) Disable the IPv4 route exchange function.

no neighbor *ebgp-peer-address* **activate**

1.8 Configuring the Inter-AS VPN Service Model – Option C (Enabling Label Switching for IPv4 Routes with EBGP and IBGP Neighbors)

1.8.1 Overview

In the Option C solution (enabling label switching for IPv4 routes only with EBGP neighbors), the IGP and LDP in one AS need to maintain the PE routes in another AS. That is, inter-AS PE routes should be advertised to each device in an AS. In view of the AS security in actual applications, the PE routes of another AS are generally not advertised to each device in the local AS. These routes need to be owned only by the BGP and therefore are transparent to the IGP and LDP in the local AS. To achieve this, you can enable label switching for IPv4 routes with EBGP and IBGP neighbors.

This solution differs from the Option C solution (enabling label switching for IPv4 routes only with EBGP neighbors) in that the IGP on an ASBR is not required to redistribute BGP routes, and the LDP is not required to distribute labels to BGP routes and only needs to set up LSPs in the local AS. However, you need to enable label switching for IPv4 routes with both IBGP and EBGP neighbors to set up inter-AS LSPs. In addition, the PEs are required to push three consecutive layers of labels.

1.8.2 Configuration Tasks

Configuration of the inter-AS VPN service model – Option C (enabling label switching for IPv4 routes with EBGP and IBGP neighbors) includes the following tasks:

(1) Configuring Route Exchange Between PEs and CEs in the Same ASs

(2) Configuring IGP and MPLS Signaling Protocol in an AS

(3) Establishing an IBGP Session Between a PE and an ASBR to Distribute Labels to IPv4 Routes

(4) Establishing an EBGP Session Between ASBRs to Distribute Labels to IPv4 Routes

(5) Configuring a Multi-Hop MP-EBGP Session

1.8.3 Configuring Route Exchange Between PEs and CEs in the Same ASs

The procedure is similar to "Configuring Route Exchange Between PEs and CEs" in 1.3 Configuring Basic IPv4 MPLS L3VPN Functions.

1.8.4 Configuring IGP and MPLS Signaling Protocol in an AS

The procedure is similar to 1.3.4 Configuring an MPLS Network.

1.8.5 Establishing an IBGP Session Between a PE and an ASBR to Distribute Labels to IPv4 Routes

1. Overview

This configuration procedure is the main difference between the inter-AS VPN Option C solution (enabling IPv4 route exchange between EBGP and IBGP neighbors) and the inter-AS VPN Option C solution (enabling IPv4 route exchange only between EBGP neighbors). The IBGP session between an ASBR and a PE is used to

transmit the PE routes of another AS, and the BGP distributes labels to the PE routes. The PE routes that are learned by EBGP from another AS are not redistributed to the IGP in the local AS.

2. Restrictions and Guidelines

Before you enable label switching for IPv4 routes for an IBGP session with an IBGP peer, you must run the **neighbor update-source** command to specify the source address of the IBGP session, and this source address must be the address of the loopback interface. Otherwise, the inter-AS LSP cannot be set up.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

config terminal

(3) Enable BGP and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(4) Establish an IBGP session with an ASBR (PE).

neighbor *peer-address* **remote-as** *asn-number*

No BGP peer is configured by default.

(5) Use the loopback interface address as the source address to establish the BGP session with an ASBR (PE) peer.

neighbor *peer-address* **update-source** *interface-type interface-number*

The optimal local interface is used as the outbound interface by default.

Generally, the loopback interface address is used as the source address.

(6) Enter the IPv4 address family configuration mode.

address-family ipv4

(7) Configure labeled IPv4 route exchange with an ASBR (PE) peer.

neighbor *peer-address* **send-label**

Forwarding labeled MPLS packets is disabled by default.

1.8.6 Establishing an EBGP Session Between ASBRs to Distribute Labels to IPv4 Routes

The procedure is similar to 1.7.5 Establishing an EBGP Session Between ASBRs to Distribute Labels to IPv4 Routes.

1.8.7 Configuring a Multi-Hop MP-EBGP Session

The procedure is similar to 1.7.7 Configuring a Multi-Hop MP-EBGP Session.

1.9 Configuring the Inter-AS VPN Service Model – Option C (Establishing a Multi-Hop MP-EBGP Session Between RRs)

1.9.1 Overview

In the traditional Option C solution, the inter-AS VPN sites should be connected in full mesh mode. The addition of a single VPN site requires the setup of MP-MBGP connections with the PEs in other ASs, hindering the expansion of VPN sites. To solve this problem, you can deploy an RR in each AS and establish multi-hop MP-EBGP sessions between the RRs to exchange VPN routes.

1.9.2 Configuration Tasks

Configuration of the inter-AS VPN service model – Option C (establishing a multi-hop MP-EBGP session between RRs) includes the following tasks:

(1) Configuring Route Exchange Between PEs and CEs

(2) Configuring IGP and MPLS Signaling Protocol in an AS

(3) Establishing an MP-IBGP Session Between an RR and a PE and Enabling Label Switching for IPv4 Routes

(4) Establishing an IBGP Session Between an RR and an ASBR and Enabling Label Switching for IPv4 Routes

(5) Establishing an EBGP Session Between ASBRs to Distribute Labels for IPv4 Routes

(6) Configuring a Multi-Hop MP-EBGP Session

1.9.3 Configuring Route Exchange Between PEs and CEs

The procedure is similar to "Configuring Route Exchange Between PEs and CEs" in 1.3 Configuring Basic IPv4 MPLS L3VPN Functions.

1.9.4 Configuring IGP and MPLS Signaling Protocol in an AS

The procedure is similar to 1.3.4 Configuring an MPLS Network.

1.9.5 Establishing an MP-IBGP Session Between an RR and a PE and Enabling Label Switching for IPv4 Routes

1. Overview

Establish an MP-IBGP session between a PE and an RR to exchange VPN routes and enable label switching for IPv4 routes in this session.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable BGP and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(4) Establish an IBGP session.

neighbor peer-address **remote-as** asn-number

No BGP peer is configured by default.

(5) Use the loopback interface address as the source address to establish an IBGP session.

neighbor *peer-address* **update-source** *interface-type interface-number*

The optimal local interface is used as the outbound interface by default.

Generally, the loopback interface address is used as the source address.

(6) Enter the IPv4 address family configuration mode.

address-family ipv4

(7) Enable IPv4 route exchange.

neighbor *peer-address* **activate**

(8) Enable label switching for IPv4 routes.

neighbor *peer-address* **send-label**

Forwarding labeled MPLS packets is disabled by default.

(9) On the RR, configure all PE peers as the IPv4 RR clients.

neighbor *peer-address* **route-reflector-client**

(10) Exit the IPv4 address family configuration mode.

exit

(11) Enter the VPN address family configuration mode.

address-family vpnv4

No VPNv4 address family is defined by default.

(12) Enable VPN route exchange with peers.

neighbor *peer-address* **activate**

(13) On the RR, configure all PE peers as the VPN RR clients.

neighbor *peer-address* **route-reflector-client**

1.9.6 Establishing an IBGP Session Between an RR and an ASBR and Enabling Label Switching for IPv4 Routes

1. Overview

Establish an MP-IBGP session between an ASBR and an RR to receive routes to the PEs in the local AS from the RR and send routes to the PEs in another AS to the RR. In addition, enable label switching for IPv4 routes in the session.

2. Restrictions and Guidelines

For the IBGP session between an RR and an ASBR, you are generally not required to set the ASBR as the RR client unless the ASBR also serves as a PE.

3. Procedure

(1) Enter the global configuration mode.

config terminal

(2) Enable BGP and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(3) Establish an IBGP session.

neighbor *peer-address* **remote-as** *asn-number*

No BGP peer is configured by default.

(4) Use the loopback interface address as the source address to establish an IBGP session.

neighbor *peer-address* **update-source** *interface-type interface-number*

The optimal local interface is used as the outbound interface by default.

Generally, the loopback interface address is used as the source address.

(5) Enter the IPv4 address family configuration mode.

address-family ipv4

(6) Enable IPv4 route exchange.

neighbor *peer-address* **activate**

(7) Enable label switching for IPv4 routes.

neighbor *peer-address* **send-label**

Forwarding labeled MPLS packets is disabled by default.

1.9.7 Establishing an EBGP Session Between ASBRs to Distribute Labels for IPv4 Routes

The procedure is similar to 1.7.5 Establishing an EBGP Session Between ASBRs to Distribute Labels to IPv4 Routes.

1.9.8 Configuring a Multi-Hop MP-EBGP Session

1. Overview

Establish a multi-hop MP-EBGP session between the RRs in two ASs to exchange inter-AS VPN routes. In addition, disable the transmission of IPv4 routing information for the session. The PE routes are advertised to another AS through an ASBR.

2. Restrictions and Guidelines

- When advertising a route to an EBGP peer, the device with EBGP enabled modifies the next hop of the route as its own address. Upon receipt of the VPN route, the PE in another AS considers the next hop of the route as the RR. As a result, all inter-AS VPN traffic is transmitted through the RR. This is not the optimal forwarding path and has high requirements on the forwarding performance of the RR. To avoid the preceding situation, you can run the **neighbor next-hop-unchanged** command in the VPNv4 address family mode to configure the ASBR not to change the next hop of a VPNv4 route sent to the BGP peer when you establish a multi-hop MP-EBGP session on the RR.
- In a multi-hop MP-EBGP session, IPv4 routes do not need to be exchanged or at least the routes of the two addresses used to establish the BGP session should not be exchanged. Otherwise, a PE has two routes to

a PE in another AS. One route is advertised by the ASBR in the local AS, and the other is advertised by the multi-hop EBGP session. According to BGP specifications, an EBGP route has a higher priority over an IGBP route by default. In this case, the BGP preferentially chooses the route advertised by the multi-hop BGP and this results in flapping of routes on this PE to the PE in another AS and causes unreachable VPN routes.

3. Procedure

(1) Enter the global configuration mode.

config terminal

(2) Enable BGP and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(3) Establish an EBGP session.

neighbor *rr-address* **remote-as** *ebgp-asn-number*

No BGP peer is configured by default.

(4) Use the loopback interface address as the source address to establish an EBGP session.

neighbor *rr-address* **update-source** *interface-type interface-number*

The optimal local interface is used as the outbound interface by default.

Generally, the loopback interface address is used as the source address.

(5) Configure multi-hop EBGP attributes.

neighbor *rr-address* **ebgp-multihop**

BGP connections can be established only with directly-connected EBGP peers by default.

(6) Enter the IPv4 address family configuration mode.

address-family ipv4

(7) Disable IPv4 route exchange for the session.

no neighbor *rr-address* **activate**

(8) Exit the IPv4 address family configuration mode.

exit

(9) Enter the VPN address family configuration mode.

address-family vpnv4

No VPNv4 address family is defined by default.

(10) Enable VPN route exchange with the RR in another AS.

neighbor *rr-address* **activate**

(11) (Optional) Configure the device not to change the next hop when advertising VPN routes to the peer.

neighbor *rr-address* **next-hop-unchanged**

The function is disabled by default. The device does not change the next hop when advertising routes to the IBGP peer.

1.10 Configuring OSPF VPN Extended Features

1.10.1 Overview

When OSPF is run in a VPN, run OSPF between PEs and CEs to simplify CE configuration and management.

1.10.2 Restrictions and Guidelines

The LDP router ID must be 32 bits.

1.10.3 Configuration Tasks

Configuration of OSPF VPN extended features includes the following tasks:

(1) Configuring the Domain ID

(2) Configuring the VPN Route Tag

(3) Configuring a Sham Link

(4) Configuring Loop Detection for a VRF-associated OSPF process

(5) Configuring Extended Community Attributes of VPN Routes

(6) Disabling Loop Detection Based on the DN Bit Carried in LSAs

(7) Disabling Loop Detection Based on the Route Tag Carried in LSAs

1.10.4 Configuring the Domain ID

1. Overview

A domain ID is used to identify the domain to which an OSPF process belongs. Generally, all OSPF processes associated with VRF instances in a VPN are configured with the same domain ID.

2. Restrictions and Guidelines

- A VRF-associated OSPF process can be configured with multiple domain IDs. However, there is only one primary domain ID, and the others are secondary domain IDs. The only primary domain ID is configured by running the **domain-id** *value* command, while secondary domain IDs are configured by running the **domain-id** *hex-value* **secondary** command. When OSPF routes are converted to VPN routes and advertised, the VPN routes contain only the primary domain ID.
- The primary and secondary domain IDs can be configured by running **domain-id** *ipv4-address* or **domain-id type** { **0005** | **0105** | **0205** | **8005** } **value**.
- Different VRF-associated OSPF processes can have the same domain ID. However, VRF-associated OSPF processes in the same VPN must be configured with the same domain ID to guarantee the correctness of route advertisement.

3. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Create an OSPF process and enter the OSPF configuration mode.

router ospf *process-id* [**vrf** *vrf-name*]

The OSPF routing process is disabled by default.

(3) Configure the domain ID of an OSPF process.

domain-id { *ipv4-address* [**secondary**] | **null** | **type** { **0005** | **0105** | **0205** | **8005** } **value** *hex-value* [**secondary**] }

The default domain ID of an OSPF process is **null**, and the type value is **0x0005**.

This command takes effect only to OSPF processes associated with VRF instances.

1.10.5 Configuring the VPN Route Tag

1. Overview

In L3VPN applications, if a VPN site connects to multiple PEs, the VPN routes learned by a PE through MP-BGP are advertised to the VPN site in type 5/7 LSAs. Such routes may also be learned by other PEs connecting to this VPN site and then advertised, hence causing loops. To avoid such loops, the same VPN route tag must be configured for VRF-associated OSPF processes connecting to the same VPN site on PEs. When a VRF-associated OSPF process sends a type 5/7 LSA to the VPN site, this LSA carries the VPN route tag. When other PEs receive such a type 5/7 LSA containing the VPN route tag and the route tag is the same as the route tag of the corresponding OSPF process, the LSA is not used for OSPF route calculation.

2. Restrictions and Guidelines

Generally, OSPF processes belonging to the same VPN must be configured with the same VPN route tag.

3. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Create an OSPF process and enter the OSPF configuration mode.

router ospf *process-id* [**vrf** *vrf-name*]

The OSPF routing process is disabled by default.

(3) Configure a VPN route tag for the OSPF process.

domain-tag *value*

The VPN route tag of an OSPF process is the AS number of the local BGP by default.

This command takes effect only to OSPF processes associated with VRF instances.

1.10.6 Configuring a Sham Link

1. Overview

A sham link is mainly used in a scenario where there is a backdoor link between VPN sites. If you expect to transmit VPN data still through the MPLS backbone network, you can establish a sham link between the VRF-associated OSPF processes of two PEs. Both OSPF processes can establish OSPF neighbors and distribute LSA packets through this sham link.

However, OSPF routes advertised through the sham link do not carry the VPN route tag and cannot be used for forwarding. Packets are still forwarded through BGP VPNv4 routes. In actual configuration, ensure that routes learned through the sham link are also learned through MP-BGP.

The source addresses used to establish the sham link must be redistributed to the BGP VPNv4 route but cannot participate in route calculation of the VRF-associated OSPF processes.

2. Restrictions and Guidelines

- The sham link configuration must be performed on two PEs. The link cannot be established if only one PE is configured.
- To establish a sham link between two PEs, the following conditions must be met:
  - The area IDs of the sham link configured on two PEs must be identical.
  - The <source address, destination address> of the sham link configured on one PE must be the same as the <destination address, source address> of the sham link configured on the other PE.
  - The source and destination addresses used to establish a sham link on the PEs must be 32-bit loopback addresses bound to VRF instances.

3. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Create an OSPF process and enter the OSPF configuration mode.

router ospf *process-id* [**vrf** *vrf-name*]

The OSPF routing process is disabled by default.

(3) Configure the area ID, source address, and destination address of a sham link.

area *area-id* **sham-link** *source-address destination-address* [**cost** *number*] [**dead-interval** *dead-interval*] [**hello-interval** *hello-interval*] [**retransmit-interval** *retransmit-interval*] [**transmit-delay** ***transmit-delay***] [**authentication** [**message-digest** | **null | key-chain** *kechain-name*]] [**authentication-key** [**0** | **7**] *key* | **message-digest-key** *key-id* [**md5** | **hmac-md5** | **hmac-sha256**] [**0** | **7**] *key*]

The sham link is disabled by default. A sham link is not authenticated by default.

This command takes effect only to OSPF processes associated with VRF instances.

1.10.7 Configuring Loop Detection for a VRF-associated OSPF process

1. Overview

In some application scenarios, the loop detection function of a VRF-associated OSPF process needs to be disabled. For example, when a VPN uses a multi-VPN-instance CE (MCE) to exchange VPN routes with a PE via OSPF, you must run the **capability vrf-lite** command on the MCE to disable the loop detection function of the VRF-associated OSPF process so that the VPN site can learn the routes of other VPN sites.

2. Restrictions and Guidelines

Before configuring loop detection, you must create a VRF instance.

3. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Create an OSPF process and enter the OSPF configuration mode.

router ospf *process-id* [**vrf** *vrf-name*]

The OSPF routing process is disabled by default.

(3) Enable the loop detection function for an OSPF process associated with a VRF instance.

capability vrf-lite [**auto**]

A VRF-associated OSPF process supports PE-CE OSPF extended features by default, which include LSA conversion based on the domain ID, DN bit, and VPN route tag. If you do not expect a VRF-associated OSPF process to support PE-CE OSPF extended features, run the **capability vrf-lite** command.

This command takes effect only to OSPF processes associated with VRF instances.

1.10.8 Configuring Extended Community Attributes of VPN Routes

1. Overview

When OSPF routes are redistributed to the BGP domain to form VPN routes, the extended community attributes of OSPF routes are carried, including Router-ID and Route-Type. You can manually configure the type of Router-ID and Route-type to be compatible with implementation of different vendors.

For example, some vendors support only the Router-ID type 0x0107. When interconnecting with such vendors, run the **extcommunity-type** command to set the Router-ID type to 0x0107.

Some vendors support only the Router-Type type 0x8000. When interconnecting with such vendors, run the **extcommunity-type** command to set the Router-Type type to 0x8000.

2. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Create an OSPF process and enter the OSPF configuration mode.

router ospf *process-id* [**vrf** *vrf-name*]

The OSPF routing process is disabled by default.

(3) Configure OSPF route extended community attributes Router-ID and Route-Type.

extcommunity-type { **router-id** { **0107 | 8001** } | **route-type** { **0306** | **8000** } }

The default Router-ID is **0x0107**, and the default Route-Type is **0x0306**.

This command takes effect only to OSPF processes associated with VRF instances.

1.10.9 Disabling Loop Detection Based on the DN Bit Carried in LSAs

1. Overview

In L3VPN CE dual-homing scenarios, route calculation based on the DN bit is suppressed between PEs to prevent loops. In some scenarios, PEs may be allowed to learn routes from each other without generating loops. In these scenarios, you can cancel DN bit check. When a PE connects to an MCE, the MCE needs to calculate routes advertised by the PE and does not check the DN bit. OSPF type 3/5/7 LSAs can carry the DN bit.

2. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Create an OSPF process and enter the OSPF configuration mode.

router ospf *process-id* [**vrf** *vrf-name*]

The OSPF routing process is disabled by default.

(3) Disable loop detection using the DN bit in LSAs.

disable-dn-bit-check [**summary| ase | nssa**]

Loop detection based on the DN bit carried in LSAs is enabled by default.

This command takes effect only to OSPF processes associated with VRF instances.

1.10.10 Disabling Loop Detection Based on the Route Tag Carried in LSAs

1. Overview

In L3VPN CE dual-homing scenarios, when a PE receives an LSA with a route tag same as that of its own, the PE does not use the route tag to calculate routes. In this way, loops can be prevented. In some scenarios, PEs may be allowed to learn routes from each other without generating loops. In these scenarios, you can set different route tags for different PEs or disable route tag check. When a PE connects to an MCE, the MCE needs to calculate routes advertised by the PE and does not check the route tag. OSPF type 5/7 LSAs can carry the route tag.

2. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Create an OSPF process and enter the OSPF configuration mode.

router ospf *process-id* [**vrf** *vrf-name*]

The OSPF routing process is disabled by default.

(3) Disable loop detection based on the route tag carried in LSAs.

disable-tag-check

Loop detection based on the route tag carried in LSAs is enabled by default.

This command takes effect only to OSPF processes associated with VRF instances.

1.11 IPv6 MPLS L3VPN Configuration Task Summary

IPv6 MPLS L3VPN configuration includes the following tasks:

(1) Configuring the 6VPE Service Model

(2) Configuring the 6PE Service Model

1.12 Configuring the 6VPE Service Model

1.12.1 Overview

The 6VPE technology uses IPv4 BGP/MPLS VPN on an IPv4 backbone network to provide VPN services for IPv6 networks.

1.12.2 Configuration Tasks

6VPE service model configuration includes the following tasks:

(1) Enabling IPv6 Forwarding

(2) Configuring a Public Network Tunnel

(3) Configuring the VRF Instance of a 6VPE Device

(4) Configuring the IPv6 Address of a 6VPE Device Under a VRF Instance

(5) Configuring a BGP Session Between 6VPE Devices

(6) Configuring a 6VPE Device to Distribute IPv6 Routes Under a VRF Instance

(7) Configuring Routes Between a CE and a 6VPE Device

1.12.3 Enabling IPv6 Forwarding

1. Overview

Because a 6VPE device needs to establish an IPv6 connection with a CE under a VRF instance, you need to enable the IPv6 forwarding capability of the 6VPE device.

2. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Enable IPv6 forwarding.

ipv6 unicast-routing

The IPv6 forwarding function is enabled by default.

1.12.4 Configuring a Public Network Tunnel

1. Overview

On a public network, an LSP must be set up to carry users' service traffic. To run MPLS on the backbone network, you must run LDP on the Ps and PEs to establish public tunnels. This means that you have to configure LDP on MPLS devices and enable MPLS forwarding on each interface.

2. Restrictions and Guidelines

Currently, LDP supports only IPv4 public networks and does not support IPv6 public networks.

3. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Enable MPLS forwarding globally.

mpls ip

MPLS forwarding is disabled globally by default.

To implement MPLS forwarding on a device, enable MPLS forwarding globally first.

(3) Enable LDP and enter the MPLS route configuration mode.

mpls router ldp

LDP is disabled by default.

(4) Configure the LDP router ID.

ldp router-id { *ipv4-address* | **interface** *interface-type interface-number* [**force**] }

The system router ID is used as the LDP router ID by default.

Generally, the loopback interface address is used as the router ID. If **force** is specified, the new router ID is forced to take effect immediately. Otherwise, the new router ID does not take effect immediately.

(5) Exit the MPLS route configuration mode.

exit

(6) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(7) Set an IP address.

ip address *ipv4-address mask-length*

No IP address is configured for an interface by default.

(8) Enable labeled MPLS packet forwarding on the public interface.

label-switching

Forwarding labeled MPLS packets is disabled on an interface by default.

(9) Enable LDP on an interface.

mpls ip

LDP is disabled on an interface by default.

1.12.5 Configuring the VRF Instance of a 6VPE Device

(1) Enter the global configuration mode.

configure terminal

(2) Create a multiprotocol VRF instance and enter the VRF instance configuration mode.

vrf definition *vrf-name*

vrf-name cannot exceed 31 characters.

(3) Configure the RD value.

rd *rd-value*

(4) Enable the VRF instance to support the IPv6 address family and enter the VRF instance IPv6 address family submode.

address-family ipv6

The IPv6 address family is disabled by default.

(5) Configure the RT value.

route-target { **both** | **export** | **import** } *rt-value*

(6) Exit the VRF instance address family configuration submode.

exit-address-family

1.12.6 Configuring the IPv6 Address of a 6VPE Device Under a VRF Instance

1. Restrictions and Guidelines

- A PE can forward IPv6 packets only after the **ipv6 enable** command is configured to enable IPv6 forwarding for a private interface on the PE.
- To save IPv6 addresses, you can use an automatically generated link-local address instead of a global IPv6 address for the interface on a PE used to connect to a CE.

2. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(3) Associate an interface with a VRF instance.

vrf forwarding *vrf_name*

(4) Enable IPv6 forwarding on the interface.

ipv6 enable

(5) (Optional) Configure the IPv6 address of the interface.

ipv6 address *ipv6-address/prefix-length*

1.12.7 Configuring a BGP Session Between 6VPE Devices

(1) Enter the global configuration mode.

configure terminal

(2) Create a BGP domain and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(3) Configure a BGP session.

neighbor *ipv4-address* **remote-as** *asn-number*

No BGP peer is configured by default.

(4) Use an interface address as the source address to establish a BGP session.

neighbor *ipv4-address* **update-source** *interface-type interface-number*

The optimal local interface is used as the outbound interface by default.

Generally, the loopback interface address is used as the source address.

(5) Enter the IPv6 address family configuration mode.

address-family vpnv6 unicast

(6) Activate IPv6 route exchange in the BGP session.

neighbor *ipv4-address* **activate**

(7) Exit the VPNv6 unicast address family configuration mode.

exit-address-family

1.12.8 Configuring a 6VPE Device to Distribute IPv6 Routes Under a VRF Instance

(1) Enter the global configuration mode.

configure terminal

(2) Create a BGP domain and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(3) Enter the IPv6 unicast address family configuration mode under a VRF instance.

address-family ipv6 unicast vrf *vrf-name*

The IPv6 unicast address family configuration mode is used by default.

(4) (Optional) Establish a BGP session with a CE.

neighbor *ipv6-address* **remote-as** *ce-asn-num*

No BGP peer is configured by default.

(5) (Optional) Configure IPv6 prefixes in the local AS that need to be imported to the BGP routing table.

network *ipv6-prefix*

(6) (Optional) Import network information in direct or static routes to BGP.

redistribute { **connected** | **static** } [**route-map** *map-tag*]

(7) Exit the IPv6 unicast address family configuration mode under the VRF instance.

exit-address-family

(8) Enter the scope configuration mode.

scope vrf *vrf-name*

(9) Enter the IPv6 unicast address family configuration mode under a VRF instance.

address-family ipv6 unicast

The IPv6 unicast address family configuration mode is used by default.

(10) (Optional) Establish a BGP session with a CE.

neighbor *ipv6-address* **remote-as** *ce-asn-num*

No BGP peer is configured by default.

(11) (Optional) Configure IPv6 prefixes in the local AS that need to be imported to the BGP routing table.

network *ipv6-prefix*

(12) (Optional) Import network information in direct routes to BGP.

redistribute { **connected** | **static** } [**route-map** *map-tag*]

1.12.9 Configuring Routes Between a CE and a 6VPE Device

Routes between a CE and a 6VPE device can be IPv6 static or dynamic routes. When IPv6 dynamic routes are used, BGP routes of the 6VPE device and dynamic routes between the 6VPE and CE need to be imported to each other.

For details about IPv6 dynamic route configuration, see *Configuring RIPng*, *Configuring OSPFv3*, *Configuring IS-IS*, and *Configuring BGP*.

1.13 Configuring the 6PE Service Model

1.13.1 Overview

Network SPs use existing IPv4 MPLS backbone networks to provide access services (non-VPN services) for scattered IPv6 networks in case of IPv6 islands.

The 6VPE technology uses IPv4 BGP/MPLS VPN on an IPv4 backbone network to provide VPN services for IPv6 networks.

1.13.2 Configuration Tasks

6PE service model configuration includes the following tasks:

(1) Enabling IPv6 Forwarding for a 6PE Device

(2) Configuring a Public Network Tunnel

(3) Configuring the IPv6 Address of a 6PE Device

(4) Configuring a BGP Session Between 6PE Devices

(5) Configuring Routes Between a CE and a 6VPE Device

1.13.3 Enabling IPv6 Forwarding for a 6PE Device

1. Overview

Because a 6PE device needs to establish an IPv6 connection with a CE, you need to enable the IPv6 forwarding capability of the 6PE device.

2. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Enable IPv6 forwarding.

ipv6 unicast-routing

The IPv6 forwarding function is enabled by default.

1.13.4 Configuring a Public Network Tunnel

1. Overview

On a public network, an LSP must be set up to carry users' service traffic. To run MPLS on the backbone network, you must run LDP on the Ps and PEs to establish public tunnels. This means that you have to configure LDP on MPLS devices and enable MPLS forwarding on each interface.

2. Restrictions and Guidelines

Currently, LDP supports only IPv4 public networks and does not support IPv6 public networks.

3. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Enable MPLS forwarding globally.

mpls ip

MPLS forwarding is disabled globally by default.

To implement MPLS forwarding on a device, enable MPLS forwarding globally first.

(3) Enable LDP and enter the LDP configuration mode.

mpls router ldp

LDP is disabled by default.

(4) Configure the LDP router ID.

ldp router-id { *ipv4-address* | **interface** *interface-type interface-number* [**force**] }

The system router ID is used as the LDP router ID by default.

Generally, the loopback interface address is used as the router ID. If **force** is specified, the new router ID is forced to take effect immediately. Otherwise, the new router ID does not take effect immediately.

(5) Return to the global configuration mode.

exit

(6) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(7) Configure an IP address for the interface.

ip address *ipv4-address mask-length*

No IP address is configured for an interface by default.

(8) Enable labeled MPLS packet forwarding on the public interface.

label-switching

Forwarding labeled MPLS packets is disabled on an interface by default.

(9) Enable LDP on the interface.

mpls ip

LDP is disabled on an interface by default.

1.13.5 Configuring the IPv6 Address of a 6PE Device

1. Overview

Configure an IPv6 address for the interface on the 6PE device used to connect to a CE.

2. Restrictions and Guidelines

To save IPv6 addresses, you can use an automatically generated link-local address instead of a global IPv6 address for the interface on a PE used to connect to a CE.

3. Procedure

(1) Enter the global configuration mode.

configure terminal

(2) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(3) Enable IPv6 forwarding on the interface.

ipv6 enable

(4) Configure an IPv6 address for the interface.

ipv6 address *ipv6-address/prefix-length*

1.13.6 Configuring a BGP Session Between 6PE Devices

(1) Enter the global configuration mode.

configure terminal

(2) Create a BGP domain and enter the BGP configuration mode.

router bgp *asn-number*

BGP is disabled by default.

(3) Configure a BGP session.

neighbor *ipv4-address* **remote-as** *asn-number*

No BGP peer is configured by default.

Currently, a 6PE device only supports BGP sessions using IPv4 addresses.

(4) Use an interface address as the source address to establish an MP-IBGP session.

neighbor *ipv4-address* **update-source** *interface-type interface-number*

The optimal local interface is used as the outbound interface by default.

Generally, the loopback interface address is used as the source address.

(5) Enter the IPv6 address family configuration mode.

address-family ipv6 unicast

The IPv6 unicast address family configuration mode is used by default.

(6) Activate IPv6 route exchange in the BGP session.

neighbor *ipv4-address* **activate**

(7) Activate labeled IPv6 route exchange in the BGP session.

neighbor *ipv4-address* **send-label**

Forwarding labeled MPLS packets is disabled by default.

1.13.7 Configuring Routes Between a CE and a 6VPE Device

Routes between a CE and a 6PE device can be IPv6 static or dynamic routes. When IPv6 dynamic routes are used, BGP4+ routes of the 6PE device and dynamic routes between the 6PE and CE need to be imported to each other.

For details about IPv6 dynamic route configuration, see *Configuring RIPng*, *Configuring OSPFv3*, *Configuring IS-IS*, and *Configuring BGP*.

1.14 Monitoring

Run the **clear** commands to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

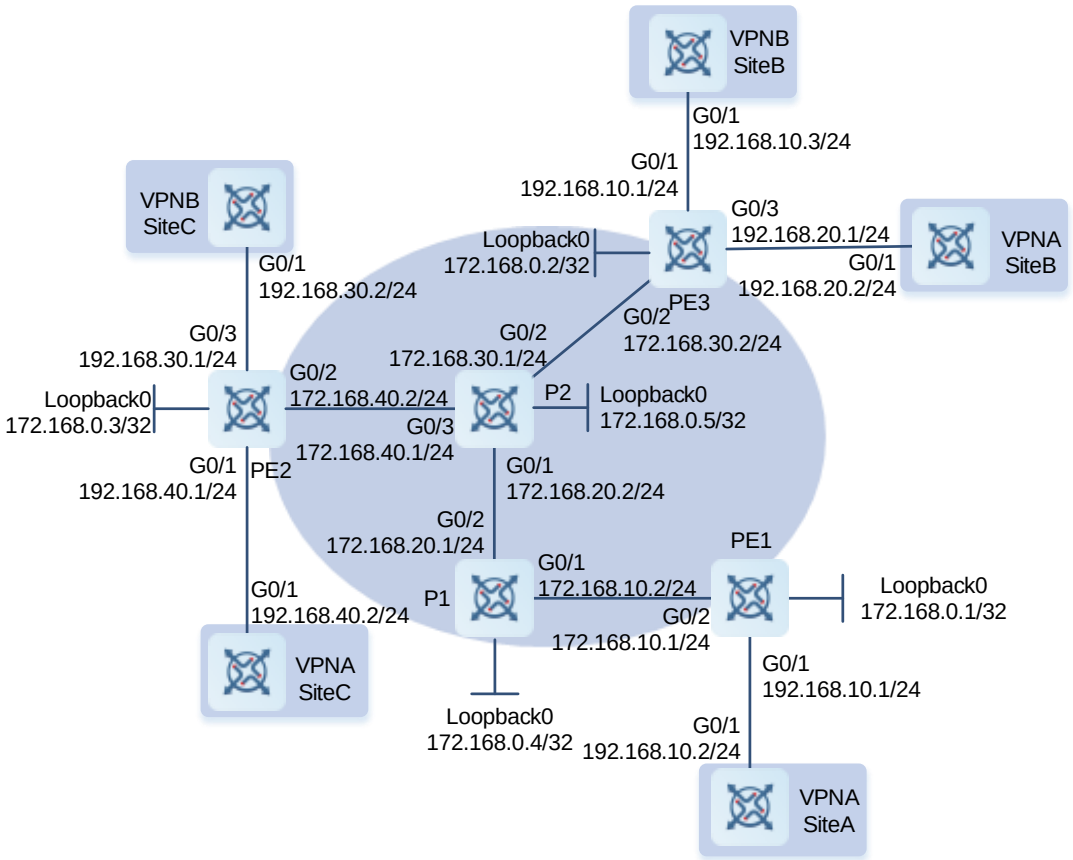
Table 1-1 MPLS L3VPN Monitoring

Command	Purpose
clear bgp vpnv4 unicast { * | *as-number* | *peer-address* } [**soft**] [**in** | **out**]	Resets the VPNv4 unicast address family of BGP.
clear bgp vpnv4 unicast dampening [*ipv4-address* [*mask-length*]]	Clears VPNv4 route flapping information and restores suppressed VPNv4 routes.
clear bgp vpnv4 unicast external [**soft**] [**in** | **out**]	Resets all EBGP connections of the VPNv4 address family.
clear bgp vpnv4 unicast flap-statistics [*ipv4-address* [*mask-length*]]	Clears route flapping statistics of the VPNv4 address family.
clear bgp vpnv4 unicast peer-group *peer-group-name* [**soft**] [**in** | **out**]	Resets VPNv4 address families of all members in a BGP peer group.
clear bgp vpnv6 unicast { * | *as-number* | *peer-address* } [**soft**] [**in** | **out**]	Resets the VPNv6 unicast address family of BGP.
clear bgp vpnv6 unicast dampening	Clears VPNv6 route flapping information and restores suppressed VPNv6 routes.
clear bgp vpnv6 unicast external [**soft**] [**in** | **out**]	Resets all EBGP connections of the VPNv6 address family.
clear bgp vpnv6 unicast flap-statistics	Clears route flapping statistics of the VPNv6 address family.
clear bgp vpnv6 unicast peer-group *peer-group-name* [**soft**] [**in** | **out**]	Resets VPNv6 address families of all members in a BGP peer group.
clear ip bgp vrf *vrf-name* { * | *address* | *as-num* } [**soft**] [**in** | **out**]	Resets the BGP session of a VRF instance.
show bgp ipv4 unicast labels	Displays IPv4 routing information with the MPLS label learned and sent by BGP.
show bgp ipv6 unicast labels	Displays IPv6 routing information with the MPLS label learned and sent by BGP.
show bgp vpnv4 unicast all [*network* | **neighbor** [*peer-address*] | **summary** | **label**]	Displays all VPNv4 routing information or neighbor information learned and sent by BGP.
show bgp vpnv4 unicast vrf *vrf-name* [*network* | **summary** | **label**]	Displays VPNv4 routing information or neighbor information learned and sent by BGP under a VRF instance.

Command	Purpose
show bgp vpnv4 unicast rd *rd-value* [*network* | **summary** | **label**]	Displays VPNv4 routing information or neighbor information learned and sent by BGP under an RD.
show bgp vpnv6 unicast all [*network* | **neighbor** [*peer-address*] | **summary** | **label**]	Displays VPNv6 routing information or neighbor information learned and sent by BGP.
show bgp vpnv6 unicast vrf *vrf-name* [*network* | **summary** | **label**]	Displays VPNv6 routing information or neighbor information learned and sent by BGP under a VRF instance.
show bgp vpnv6 unicast rd *rd-value* [*network* | **summary** | **label**]	Displays VPNv6 routing information or neighbor information learned and sent by BGP under an RD.
show ip extcommunity-list [*extcommunity-list-num* | *extcommunity-list-name*]	Displays configurations of an extended community attribute list.
show ip ospf [*process-id*] **sham-links** [**area** *area-id*]	Displays OSPF sham link information.
show ip vrf [**brief** | **detail** | **interfaces**] [*vrf-name*]	Displays configured single-protocol VRF instance information.
show vrf brief [*vrf-name*]	Displays the brief VRF instance information (including single-protocol and multiprotocol VRF instances).
show vrf ipv4 [*vrf-name*]	Displays brief IPv4 address family information of VRF instances (including single-protocol and multiprotocol VRF instances)
show vrf ipv6 [*vrf-name*]	Displays brief IPv6 address family information of a multiprotocol VRF instance.
show vrf detail [*vrf-name*]	Displays detailed VRF instance information (including single-protocol VRF instances and multi-protocol VRF instances).
show mpls forwarding-table	Displays L3VPN forwarding entries.
debug ip bgp mpls	Debugs BGP MPLS.
debug mpls	Debugs MPLS entry internal processing.
debug mpls msg [**send** | **recv**]	Debugs MPLS messages.

1.15 IPv4 MPLS L3VPN Configuration Examples

1.15.1 Configuring Basic IPv4 MPLS L3VPN Functions (Intranet)



1. Requirements

There are two VPNs: VPNA and VPNB. VPNA has user sites at SiteA, SiteB, and SiteC, VPNB has user sites at SiteB and SiteC, and VPNA SiteA and VPNB SiteB have address overlapping. The requirements are as follows:

- Users at different sites of VPNA can communicate with each other.
- Users at different sites of VPNB can communicate with each other.
- Users in VPNA and VPNB cannot communicate with each other.

2. Topology

Figure 1-15 Configuring Basic IPv4 MPLS L3VPN Functions (Intranet)

3. Notes

- Configure interface IP addresses and OSPF on MPLS backbone network nodes to ensure communication between them.
- Enable MPLS forwarding and LDP and establish LDP LSPs on MPLS backbone network nodes.
- Configure VPN routing instances, define RD and RT values, and associate VRF instances with interfaces on PEs.

- Configure MP-IBGP neighbors on PEs to exchange VPN routing information.
- Establish EBGP sessions between different VPN sites and PEs to exchange VPN routing information.

4. Procedure

(1) Configure interface IP addresses and OSPF on MPLS backbone network nodes to ensure communication between them.

Configure PE1.

```
PE1> enable
PE1# configure terminal
PE1(config)# interface loopback 0
PE1(config-if-Loopback 0)# ip address 172.168.0.1 255.255.255.255
PE1(config-if-Loopback 0)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# no switchport
PE1(config-if-GigabitEthernet 0/2)# ip address 172.168.10.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/2)# exit
PE1(config)# router ospf 10
PE1(config-router)# network 172.168.0.1 0.0.0.0 area 0
PE1(config-router)# network 172.168.10.0 0.0.0.255 area 0
PE1(config-router)# exit
```

Configure P1.

```
P1> enable
P1# configure terminal
P1(config)# interface loopback 0
P1(config-if-Loopback 0)# ip address 172.168.0.4 255.255.255.255
P1(config-if-Loopback 0)# exit
P1(config)# interface gigabitethernet 0/1
P1(config-if-GigabitEthernet 0/1)# no switchport
P1(config-if-GigabitEthernet 0/1)# ip address 172.168.10.2 255.255.255.0
P1(config-if-GigabitEthernet 0/1)# exit
P1(config)# interface gigabitethernet 0/2
P1(config-if-GigabitEthernet 0/2)# no switchport
P1(config-if-GigabitEthernet 0/2)# ip address 172.168.20.1 255.255.255.0
P1(config-if-GigabitEthernet 0/2)# exit
P1(config)# router ospf 10
P1(config-router)# network 172.168.0.4 0.0.0.0 area 0
P1(config-router)# network 172.168.10.0 0.0.0.255 area 0
P1(config-router)# network 172.168.20.0 0.0.0.255 area 0
P1(config-router)# exit
```

Configure P2.

```
P2> enable
P2# configure terminal
P2(config)# interface loopback 0
P2(config-if-Loopback 0)# ip address 172.168.0.5 255.255.255.255
```

```
P2(config-if-Loopback 0)# exit
P2(config)# interface gigabitethernet 0/1
P2(config-if-GigabitEthernet 0/1)# no switchport
P2(config-if-GigabitEthernet 0/1)# ip address 172.168.20.2 255.255.255.0
P2(config-if-GigabitEthernet 0/1)# exit
P2(config)# interface gigabitethernet 0/2
P2(config-if-GigabitEthernet 0/2)# no switchport
P2(config-if-GigabitEthernet 0/2)# ip address 172.168.30.1 255.255.255.0
P2(config-if-GigabitEthernet 0/2)# exit
P2(config)# interface gigabitethernet 0/3
P2(config-if-GigabitEthernet 0/3)# no switchport
P2(config-if-GigabitEthernet 0/3)# ip address 172.168.40.1 255.255.255.0
P2(config-if-GigabitEthernet 0/3)# exit
P2(config)# router ospf 10
P2(config-router)# network 172.168.0.5 0.0.0.0 area 0
P2(config-router)# network 172.168.20.0 0.0.0.255 area 0
P2(config-router)# network 172.168.30.0 0.0.0.255 area 0
P2(config-router)# network 172.168.40.0 0.0.0.255 area 0
P2(config-router)# exit
```

Configure PE2.

```
PE2> enable
PE2# configure terminal
PE2(config)# interface loopback 0
PE2(config-if-Loopback 0)# ip address 172.168.0.3 255.255.255.255
PE2(config-if-Loopback 0)# exit
PE2(config)# interface gigabitethernet 0/2
PE2(config-if-GigabitEthernet 0/2)# no switchport
PE2(config-if-GigabitEthernet 0/2)# ip address 172.168.40.2 255.255.255.0
PE2(config-if-GigabitEthernet 0/2)# exit
PE2(config)# router ospf 10
PE2(config-router)# network 172.168.0.3 0.0.0.0 area 0
PE2(config-router)# network 172.168.40.0 0.0.0.255 area 0
PE2(config-router)# exit
```

Configure PE3.

```
PE3> enable
PE3# configure terminal
PE3(config)# interface loopback 0
PE3(config-if-Loopback 0)# ip address 172.168.0.2 255.255.255.255
PE3(config-if-Loopback 0)# exit
PE3(config)# interface gigabitethernet 0/2
PE3(config-if-GigabitEthernet 0/2)# no switchport
PE3(config-if-GigabitEthernet 0/2)# ip address 172.168.30.2 255.255.255.0
PE3(config-if-GigabitEthernet 0/2)# exit
PE3(config)# router ospf 10
PE3(config-router)# network 172.168.0.2 0.0.0.0 area 0
```

```
PE3(config-router)# network 172.168.30.0 0.0.0.255 area 0
PE3(config-router)# exit
```

(2) Enable MPLS forwarding and LDP and establish LDP LSPs on MPLS backbone network nodes.

Configure PE1.

```
PE1(config)# mpls ip
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# label-switching
PE1(config-if-GigabitEthernet 0/2)# mpls ip

PE3(config-if-GigabitEthernet 0/2)# exit
```

(3) Configure VPN routing instances, define RD and RT values, and associate VRF instances with interfaces on PEs.

Configure PE1.

```
PE1(config)# ip vrf VPNA
PE1(config-vrf)# rd 1:100
PE1(config-vrf)# route-target both 1:100
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# no switchport
PE1(config-if-GigabitEthernet 0/1)# ip vrf forwarding VPNA
PE1(config-if-GigabitEthernet 0/1)# ip address 192.168.10.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/1)# exit
```

Configure PE2.

```
PE2(config)# ip vrf VPNA
PE2(config-vrf)# rd 1:100
PE2(config-vrf)# route-target both 1:100
PE2(config-vrf)# exit
PE2(config)# ip vrf VPNB
PE2(config-vrf)# rd 1:200
PE2(config-vrf)# route-target both 1:200
PE2(config-vrf)# exit
PE2(config)# interface gigabitethernet 0/1
PE2(config-if-GigabitEthernet 0/1)# no switchport
PE2(config-if-GigabitEthernet 0/1)# ip vrf forwarding VPNA
PE2(config-if-GigabitEthernet 0/1)# ip address 192.168.40.1 255.255.255.0
PE2(config-if-GigabitEthernet 0/1)# exit
PE2(config)# interface gigabitethernet 0/3
PE2(config-if-GigabitEthernet 0/3)# no switchport
```

```
PE2(config-if-GigabitEthernet 0/3)# ip vrf forwarding VPNB
PE2(config-if-GigabitEthernet 0/3)# ip address 192.168.30.1 255.255.255.0
PE2(config-if-GigabitEthernet 0/3)# exit
```

Configure PE3.

```
PE3(config)# ip vrf VPNA
PE3(config-vrf)# rd 1:100
PE3(config-vrf)# route-target both 1:100
PE3(config-vrf)# exit
PE3(config)# ip vrf VPNB
PE3(config-vrf)# rd 1:200
PE3(config-vrf)# route-target both 1:200
PE3(config-vrf)# exit
PE3(config)# interface gigabitethernet 0/1
PE3(config-if-GigabitEthernet 0/1)# no switchport
PE3(config-if-GigabitEthernet 0/1)# ip vrf forwarding VPNB
PE3(config-if-GigabitEthernet 0/1)# ip address 192.168.10.1 255.255.255.0
PE3(config-if-GigabitEthernet 0/1)# exit
PE3(config)# interface gigabitethernet 0/3
PE3(config-if-GigabitEthernet 0/3)# no switchport
PE3(config-if-GigabitEthernet 0/3)# ip vrf forwarding VPNA
PE3(config-if-GigabitEthernet 0/3)# ip address 192.168.20.1 255.255.255.0
PE3(config-if-GigabitEthernet 0/3)# exit
```

(4) Configure MP-IBGP neighbors on PEs to exchange VPN routing information.

Configure PE1.

```
PE1(config)# router bgp 1
PE1(config-router)# neighbor 172.168.0.2 remote-as 1
PE1(config-router)# neighbor 172.168.0.2 update-source loopback 0
PE1(config-router)# neighbor 172.168.0.3 remote-as 1
PE1(config-router)# neighbor 172.168.0.3 update-source loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 172.168.0.2 activate
PE1(config-router-af)# neighbor 172.168.0.3 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit
```

Configure PE2.

```
PE2(config)# router bgp 1
PE2(config-router)# neighbor 172.168.0.1 remote-as 1
PE2(config-router)# neighbor 172.168.0.1 update-source loopback 0
PE2(config-router)# neighbor 172.168.0.2 remote-as 1
PE2(config-router)# neighbor 172.168.0.2 update-source loopback 0
PE2(config-router)# address-family vpnv4
PE2(config-router-af)# neighbor 172.168.0.1 activate
PE2(config-router-af)# neighbor 172.168.0.2 activate
PE2(config-router-af)# exit-address-family
```

```
PE2(config-router)# exit
```

Configure PE3.

```
PE3(config)# router bgp 1
PE3(config-router)# neighbor 172.168.0.1 remote-as 1
PE3(config-router)# neighbor 172.168.0.1 update-source loopback 0
PE3(config-router)# neighbor 172.168.0.3 remote-as 1
PE3(config-router)# neighbor 172.168.0.3 update-source loopback 0
PE3(config-router)# address-family vpnv4
PE3(config-router-af)# neighbor 172.168.0.1 activate
PE3(config-router-af)# neighbor 172.168.0.3 activate
PE3(config-router-af)# exit-address-family
PE3(config-router)# exit
```

(5) Establish EBGP sessions between different VPN sites and PEs to exchange VPN routing information.

Configure PE1.

```
PE1(config)# router bgp 1
PE1(config-router)# address-family ipv4 vrf VPNA
PE1(config-router-af)# neighbor 192.168.10.2 remote-as 65001
PE1(config-router-af)# neighbor 192.168.10.2 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# end
```

Configure PE2.

```
PE2(config)# router bgp 1
PE2(config-router)# address-family ipv4 vrf VPNA
PE2(config-router-af)# neighbor 192.168.40.2 remote-as 65003
PE2(config-router-af)# neighbor 192.168.40.2 activate
PE2(config-router-af)# exit-address-family
PE2(config-router)# address-family ipv4 vrf VPNB
PE2(config-router-af)# neighbor 192.168.30.2 remote-as 65005
PE2(config-router-af)# neighbor 192.168.30.2 activate
PE2(config-router-af)# exit-address-family
PE2(config-router)# end
```

Configure PE3.

```
PE3(config)# router bgp 1
PE3(config-router)# address-family ipv4 vrf VPNA
PE3(config-router-af)# neighbor 192.168.20.2 remote-as 65002
PE3(config-router-af)# neighbor 192.168.20.2 activate
PE3(config-router-af)# exit-address-family
PE3(config-router)# address-family ipv4 vrf VPNB
PE3(config-router-af)# neighbor 192.168.10.3 remote-as 65004
PE3(config-router-af)# neighbor 192.168.10.3 activate
PE3(config-router-af)# exit-address-family
PE3(config-router)# end
```

VPNA SiteA configuration

```
VPNA-SITEA> enable
VPNA-SITEA# configure terminal
VPNA-SITEA(config)# interface gigabitethernet 0/1
VPNA-SITEA(config-if-GigabitEthernet 0/1)# no switchport
VPNA-SITEA(config-if-GigabitEthernet 0/1) ip address 192.168.10.2 255.255.255.0
VPNA-SITEA(config-if-GigabitEthernet 0/1) exit
VPNA-SITEA(config)# router bgp 65001
VPNA-SITEA(config-router)# neighbor 192.168.10.1 remote-as 1
VPNA-SITEA(config-router)# neighbor 192.168.10.1 activate
VPNA-SITEA(config-router)# end
```

VPNA SiteB configuration

```
VPNA-SITEB> enable
VPNA-SITEB# configure terminal
VPNA-SITEB(config)# interface gigabitethernet 0/1
VPNA-SITEB(config-if-GigabitEthernet 0/1)# no switchport
VPNA-SITEB(config-if-GigabitEthernet 0/1) ip address 192.168.20.2 255.255.255.0
VPNA-SITEB(config-if-GigabitEthernet 0/1) exit
VPNA-SITEB(config)# router bgp 65002
VPNA-SITEB(config-router)# neighbor 192.168.20.1 remote-as 1
VPNA-SITEB(config-router)# neighbor 192.168.20.1 activate
VPNA-SITEB(config-router)# end
```

VPNA SiteC configuration

```
VPNA-SITEC> enable
VPNA-SITEC# configure terminal
VPNA-SITEC(config)# interface gigabitethernet 0/1
VPNA-SITEC(config-if-GigabitEthernet 0/1)# no switchport
VPNA-SITEC(config-if-GigabitEthernet 0/1) ip address 192.168.40.2 255.255.255.0
VPNA-SITEC(config-if-GigabitEthernet 0/1) exit
VPNA-SITEC(config)# router bgp 65003
VPNA-SITEC(config-router)# neighbor 192.168.40.1 remote-as 1
VPNA-SITEC(config-router)# neighbor 192.168.40.1 activate
VPNA-SITEC(config-router)# end
```

VPNB SiteB configuration

```
VPNB-SITEB> enable
VPNB-SITEB# configure terminal
VPNB-SITEB(config)# interface gigabitethernet 0/1
VPNB-SITEB(config-if-GigabitEthernet 0/1)# no switchport
VPNB-SITEB(config-if-GigabitEthernet 0/1)# ip address 192.168.10.3 255.255.255.0
VPNB-SITEB(config-if-GigabitEthernet 0/1)# exit
VPNB-SITEB(config)# router bgp 65004
VPNB-SITEB(config-router)# neighbor 192.168.10.1 remote-as 1
VPNB-SITEB(config-router)# neighbor 192.168.10.1 activate
VPNB-SITEB(config-router)# end
```

VPNB SiteC configuration

```
VPNB-SITEC> enable
VPNB-SITEC# configure terminal
VPNB-SITEC(config)# interface gigabitethernet 0/1
VPNB-SITEC(config-if-GigabitEthernet 0/1)# no switchport

```

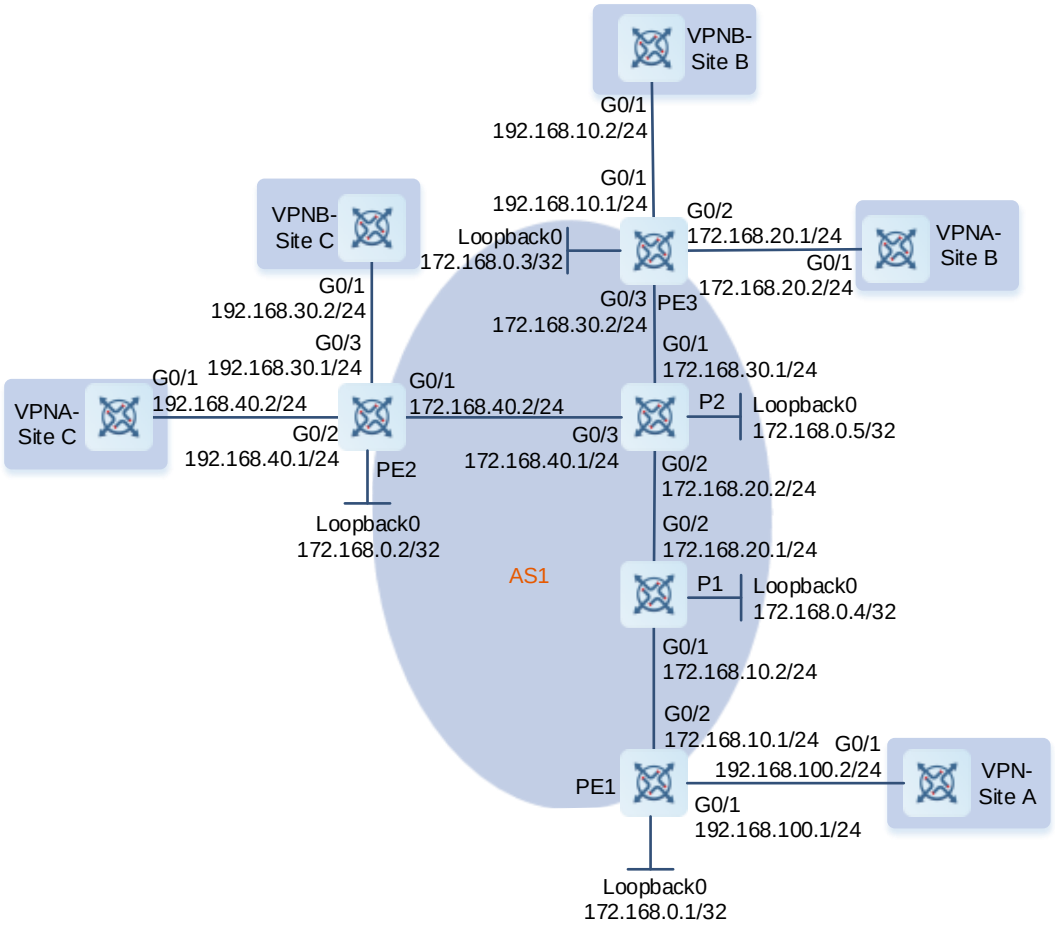
6. Verification

After the configuration is completed, run the **ping** command to detect the connectivity between sites.

- Verify that PE1 can ping PE2, PE3, P1, P2, and VPNA SiteA.
- Verify that PE2 can ping PE1, PE3, P1, P2, VPNA SiteC, and VPNB SiteC.
- Verify that PE3 can ping PE1, PE2, P1, P2, VPNA SiteB, and VPNB SiteB.
- Verify that VPNA SiteA can ping VPNA SiteB and VPNA SiteC and cannot ping VPNB SiteB or VPNB SiteC.
- Verify that VPNA SiteB can ping VPNA SiteA and VPNA SiteC and cannot ping VPNB SiteB or VPNB SiteC.
- Verify that VPNA SiteC can ping VPNA SiteA and VPNA SiteB and cannot ping VPNB SiteB or VPNB SiteC.
- Verify that VPNB SiteB can ping VPNB SiteC and cannot ping VPNA SiteA, VPNA SiteB, or VPNA SiteC.
- Verify that VPNB SiteC can ping VPNB SiteB and cannot ping VPNA SiteA, VPNA SiteB, or VPNA SiteC.
- Verify that P1 can ping PE1, PE2, PE3, and P2 but cannot ping VPN sites.
- Verify that P2 can ping PE1, PE2, PE3, and P1 but cannot ping VPN sites.

7. Common Errors

The router ID is not 32 bits. As a result, the LDP session or BGP neighbor relationship fails to be established.



1.15.2 Configuring Basic IPv4 MPLS L3VPN Functions (Extranet)

1. Requirements

There are two VPNs: VPNA and VPNB. It is required that users within a VPN can communicate with each other, users in different VPNs cannot communicate with each other, and the two VPNs can access shared resources. As shown in Figure 1-16, VPNA and VPNB sites can access resources of VPN SiteA.

2. Topology

Figure 1-16 Configuring Basic IPv4 MPLS L3VPN Functions (Extranet)

3. Notes

- Configure interface IP addresses and OSPF on MPLS backbone network nodes to ensure communication between them.
- Enable MPLS forwarding and LDP and establish LDP LSPs on MPLS backbone network nodes.
- Configure VPN routing instances, define RD and RT values, and associate VRF instances with interfaces on PEs.
- Configure MP-IBGP neighbors on PEs to exchange VPN routing information.
- Configure OSPF between different VPN sites and PEs to exchange VPN routing information.

4. Procedure

(1) Configure interface IP addresses and OSPF on MPLS backbone network nodes to ensure communication between them.

Configure PE1.

```
PE1> enable
PE1# configure terminal
```

```
PE1(config)# interface loopback 0
PE1(config-if-Loopback 0)# ip address 172.168.0.1 255.255.255.255
PE1(config-if-Loopback 0)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# no switchport
PE1(config-if-GigabitEthernet 0/2)# ip address 172.168.10.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/2)# exit
PE1(config)# router ospf 1
PE1(config-router)# network 172.168.0.1 0.0.0.0 area 0
PE1(config-router)# network 172.168.10.0 0.0.0.255 area 0
PE1(config-router)# exit
```

Configure P1.

```
P1> enable
P1# configure terminal
P1(config)# interface loopback 0
P1(config-if-Loopback 0)# ip address 172.168.0.4 255.255.255.255
P1(config-if-Loopback 0)# exit
P1(config)# interface gigabitethernet 0/1
P1(config-if-GigabitEthernet 0/1)# no switchport
P1(config-if-GigabitEthernet 0/1)# ip address 172.168.10.2 255.255.255.0
P1(config-if-GigabitEthernet 0/1)# exit
P1(config)# interface gigabitethernet 0/2
P1(config-if-GigabitEthernet 0/2)# no switchport
P1(config-if-GigabitEthernet 0/2)# ip address 172.168.20.1 255.255.255.0
P1(config-if-GigabitEthernet 0/2)# exit
P1(config)# router ospf 1
P1(config-router)# network 172.168.0.4 0.0.0.0 area 0
P1(config-router)# network 172.168.10.0 0.0.0.255 area 0
P1(config-router)# network 172.168.20.0 0.0.0.255 area 0
P1(config-router)# exit
```

Configure P2.

```
P2> enable
P2# configure terminal
P2(config)# interface loopback 0
P2(config-if-Loopback 0)# ip address 172.168.0.5 255.255.255.255
P2(config-if-Loopback 0)# exit
P2(config)# interface gigabitethernet 0/1
P2(config-if-GigabitEthernet 0/1)# no switchport
P2(config-if-GigabitEthernet 0/1)# ip address 172.168.30.1 255.255.255.0
P2(config-if-GigabitEthernet 0/1)# exit
P2(config)# interface gigabitethernet 0/2
P2(config-if-GigabitEthernet 0/2)# no switchport
P2(config-if-GigabitEthernet 0/2)# ip address 172.168.20.2 255.255.255.0
P2(config-if-GigabitEthernet 0/2)# exit
P2(config)# interface gigabitethernet 0/3
```

```
P2(config-if-GigabitEthernet 0/3)# no switchport
P2(config-if-GigabitEthernet 0/3)# ip address 172.168.40.1 255.255.255.0
P2(config-if-GigabitEthernet 0/3)# exit
P2(config)# router ospf 1
P2(config-router)# network 172.168.0.5 0.0.0.0 area 0
P2(config-router)# network 172.168.20.0 0.0.0.255 area 0
P2(config-router)# network 172.168.30.0 0.0.0.255 area 0
P2(config-router)# network 172.168.40.0 0.0.0.255 area 0
P2(config-router)# exit
```

Configure PE2.

```
PE2> enable
PE2# configure terminal
PE2(config)# interface loopback 0
PE2(config-if-Loopback 0)# ip address 172.168.0.2 255.255.255.255
PE2(config-if-Loopback 0)# exit
PE2(config)# interface gigabitethernet 0/1
PE2(config-if-GigabitEthernet 0/1)# no switchport
PE2(config-if-GigabitEthernet 0/1)# ip address 172.168.40.2 255.255.255.0
PE2(config-if-GigabitEthernet 0/1)# exit
PE2(config)# router ospf 1
PE2(config-router)# network 172.168.0.2 0.0.0.0 area 0
PE2(config-router)# network 172.168.40.0 0.0.0.255 area 0
PE2(config-router)# exit
```

Configure PE3.

```
PE3> enable
PE3# configure terminal
PE3(config)# interface loopback 0
PE3(config-if-Loopback 0)# ip address 172.168.0.3 255.255.255.255
PE3(config-if-Loopback 0)# exit
PE3(config)# interface gigabitethernet 0/3
PE3(config-if-GigabitEthernet 0/3)# no switchport
PE3(config-if-GigabitEthernet 0/3)# ip address 172.168.30.2 255.255.255.0
PE3(config-if-GigabitEthernet 0/3)# exit
PE3(config)# router ospf 1
PE3(config-router)# network 172.168.0.3 0.0.0.0 area 0
PE3(config-router)# network 172.168.30.0 0.0.0.255 area 0
PE3(config-router)# exit
```

(2) Enable MPLS forwarding and LDP and establish LDP LSPs on MPLS backbone network nodes.

Configure PE1.

```
PE1(config)# mpls ip
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
PE1(config)# interface gigabitethernet 0/2
```

```
PE1(config-if-GigabitEthernet 0/2)# label-switching
PE1(config-if-GigabitEthernet 0/2)# mpls ip
PE1(config-if-GigabitEthernet 0/2)# exit
```

Configure P1.

```
P1(config)# mpls ip
P1(config)# mpls router ldp
P1(config-mpls-router)# ldp router-id interface loopback 0 force
P1(config-mpls-router)# exit
P1(config)# interface gigabitethernet 0/1
P1(config-if-GigabitEthernet 0/1)# label-switching
P1(config-if-GigabitEthernet 0/1)# mpls ip
P1(config-if-GigabitEthernet 0/1)# exit
P1(config)# interface gigabitethernet 0/2
P1(config-if-GigabitEthernet 0/2)# label-switching
P1(config-if-GigabitEthernet 0/2)# mpls ip
P1(config-if-GigabitEthernet 0/2)# exit
```

Configure P2.

```
P2(config)# mpls ip
P2(config)# mpls router ldp
P2(config-mpls-router)# ldp router-id interface loopback 0 force
P2(config-mpls-router)# exit
P2(config)# interface gigabitethernet 0/1
P2(config-if-GigabitEthernet 0/1)# label-switching
P2(config-if-GigabitEthernet 0/1)# mpls ip
P2(config-if-GigabitEthernet 0/1)# exit
P2(config)# interface gigabitethernet 0/2
P2(config-if-GigabitEthernet 0/2)# label-switching
P2(config-if-GigabitEthernet 0/2)# mpls ip
P2(config-if-GigabitEthernet 0/2)# exit
P2(config)# interface gigabitethernet 0/3
P2(config-if-GigabitEthernet 0/3)# label-switching
P2(config-if-GigabitEthernet 0/3)# mpls ip
P2(config-if-GigabitEthernet 0/3)# exit
```

Configure PE2.

```
PE2(config)# mpls ip
PE2(config)# mpls router ldp
PE2(config-mpls-router)# ldp router-id interface loopback 0 force
PE2(config-mpls-router)# exit
PE2(config)# interface gigabitethernet 0/1
PE2(config-if-GigabitEthernet 0/1)# label-switching
PE2(config-if-GigabitEthernet 0/1)# mpls ip
PE2(config-if-GigabitEthernet 0/1)# exit
```

Configure PE3.

```
PE3(config)# mpls ip
```

```
PE3(config)# mpls router ldp
PE3(config-mpls-router)# ldp router-id interface loopback 0 force
PE3(config-mpls-router)# exit
PE3(config)# interface gigabitethernet 0/3
PE3(config-if-GigabitEthernet 0/3)# label-switching
PE3(config-if-GigabitEthernet 0/3)# mpls ip
PE3(config-if-GigabitEthernet 0/3)# exit
```

(3) Configure VPN routing instances, define RD and RT values, and associate VRF instances with interfaces on PEs.

Configure PE1.

```
PE1(config)# ip vrf VPN_EXTRA
PE1(config-vrf)# rd 1:100
PE1(config-vrf)# route-target both 1:100
PE1(config-vrf)# route-target both 1:200
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# no switchport
PE1(config-if-GigabitEthernet 0/1)# ip vrf forwarding VPN_EXTRA
PE1(config-if-GigabitEthernet 0/1)# ip address 192.168.100.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/1)# exit
```

Configure PE2.

```
PE2(config)# ip vrf VPNA
PE2(config-vrf)# rd 1:100
PE2(config-vrf)# route-target both 1:100
PE2(config-vrf)# exit
PE2(config)# ip vrf VPNB
PE2(config-vrf)# rd 1:200
PE2(config-vrf)# route-target both 1:200
PE2(config-vrf)# exit
PE2(config)# interface gigabitethernet 0/2
PE2(config-if-GigabitEthernet 0/2)# no switchport
PE2(config-if-GigabitEthernet 0/2)# ip vrf forwarding VPNA
PE2(config-if-GigabitEthernet 0/2)# ip address 192.168.40.1 255.255.255.0
PE2(config-if-GigabitEthernet 0/2)# exit
PE2(config)# interface gigabitethernet 0/3
PE2(config-if-GigabitEthernet 0/3)# no switchport
PE2(config-if-GigabitEthernet 0/3)# ip vrf forwarding VPNB
PE2(config-if-GigabitEthernet 0/3)# ip address 192.168.30.1 255.255.255.0
PE2(config-if-GigabitEthernet 0/3)# exit
```

Configure PE3.

```
PE3(config)# ip vrf VPNA
PE3(config-vrf)# rd 1:100
PE3(config-vrf)# route-target both 1:100
PE3(config-vrf)# exit
```

```
PE3(config)# ip vrf VPNB
PE3(config-vrf)# rd 1:200
PE3(config-vrf)# route-target both 1:200
PE3(config-vrf)# exit
PE3(config)# interface gigabitethernet 0/1
PE3(config-if-GigabitEthernet 0/1)# no switchport
PE3(config-if-GigabitEthernet 0/1)# ip vrf forwarding VPNB
PE3(config-if-GigabitEthernet 0/1)# ip address 192.168.10.1 255.255.255.0
PE3(config-if-GigabitEthernet 0/1)# exit
PE3(config)# interface gigabitethernet 0/2
PE3(config-if-GigabitEthernet 0/2)# ip vrf forwarding VPNA
PE3(config-if-GigabitEthernet 0/2)# ip address 192.168.20.1 255.255.255.0
PE3(config-if-GigabitEthernet 0/2)# exit
```

(4) Configure MP-IBGP neighbors on PEs to exchange VPN routing information.

Configure PE1.

```
PE1(config)# router bgp 1
PE1(config-router)# neighbor 172.168.0.2 remote-as 1
PE1(config-router)# neighbor 172.168.0.2 update-source loopback 0
PE1(config-router)# neighbor 172.168.0.3 remote-as 1
PE1(config-router)# neighbor 172.168.0.3 update-source loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 172.168.0.2 activate
PE1(config-router-af)# neighbor 172.168.0.3 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit
```

Configure PE2.

```
PE2(config)# router bgp 1
PE2(config-router)# neighbor 172.168.0.1 remote-as 1
PE2(config-router)# neighbor 172.168.0.1 update-source loopback 0
PE2(config-router)# neighbor 172.168.0.3 remote-as 1
PE2(config-router)# neighbor 172.168.0.3 update-source loopback 0
PE2(config-router)# address-family vpnv4
PE2(config-router-af)# neighbor 172.168.0.1 activate
PE2(config-router-af)# neighbor 172.168.0.3 activate
PE2(config-router-af)# exit-address-family
PE2(config-router)# exit
```

Configure PE3.

```
PE3(config)# router bgp 1
PE3(config-router)# neighbor 172.168.0.1 remote-as 1
PE3(config-router)# neighbor 172.168.0.1 update-source loopback 0
PE3(config-router)# neighbor 172.168.0.2 remote-as 1
PE3(config-router)# neighbor 172.168.0.2 update-source loopback 0
PE3(config-router)# address-family vpnv4
PE3(config-router-af)# neighbor 172.168.0.1 activate
```

```
PE3(config-router-af)# neighbor 172.168.0.2 activate
PE3(config-router-af)# exit-address-family
PE3(config-router)# exit
```

(5) Configure OSPF between different VPN sites and PEs to exchange VPN routing information.

Configure PE1.

```
PE1(config)# router ospf 10 vrf VPN_EXTRA
PE1(config-router)# network 192.168.100.0 0.0.0.255 area 0
PE1(config-router)# redistribute bgp subnets
PE1(config-router)# exit
PE1(config)# router bgp 1
PE1(config-router)# address-family ipv4 vrf VPN_EXTRA
PE1(config-router-af)# redistribute ospf 10
PE1(config-router-af)# exit-address-family
PE1(config-router)# end
```

Configure PE2.

```
PE2(config)# router ospf 10 vrf VPNA
PE2(config-router)# network 192.168.40.0 0.0.0.255 area 0
PE2(config-router)# redistribute bgp subnets
PE2(config-router)# exit
PE2(config)# router ospf 20 vrf VPNB
PE2(config-router)# network 192.168.30.0 0.0.0.255 area 0
PE2(config-router)# redistribute bgp subnets
PE2(config-router)# exit
PE2(config)# router bgp 1
PE2(config-router)# address-family ipv4 vrf VPNA
PE2(config-router-af)# redistribute ospf 10
PE2(config-router-af)# exit-address-family
PE2(config-router)# address-family ipv4 vrf VPNB
PE2(config-router-af)# redistribute ospf 20
PE2(config-router-af)# exit-address-family
PE2(config-router)# end
```

Configure PE3.

```
PE3(config)# router ospf 10 vrf VPNA
PE3(config-router)# network 192.168.20.0 0.0.0.255 area 0
PE3(config-router)# redistribute bgp subnets
PE3(config-router)# exit
PE3(config)# router ospf 20 vrf VPNB
PE3(config-router)# network 192.168.10.0 0.0.0.255 area 0
PE3(config-router)# redistribute bgp subnets
PE3(config-router)# exit
PE3(config)# router bgp 1
PE3(config-router)# address-family ipv4 vrf VPNA
PE3(config-router-af)# redistribute ospf 10
PE3(config-router-af)# exit
```

```
PE3(config-router)# address-family ipv4 vrf VPNB
PE3(config-router-af)# redistribute ospf 20
PE3(config-router-af)# exit-address-family
PE3(config-router)# end
```

VPN SiteA configuration

```
VPN-SITEA> enable
VPN-SITEA# configure terminal
VPN-SITEA(config)# interface gigabitethernet 0/1
VPN-SITEA(config-if-GigabitEthernet 0/1)# no switchport
VPN-SITEA(config-if-GigabitEthernet 0/1)# ip address 192.168.100.2 255.255.255.0
VPN-SITEA(config-if-GigabitEthernet 0/1)# exit
VPN-SITEA(config)# router ospf 10
VPN-SITEA(config-router)# network 192.168.100.0 0.0.0.255 area 0
VPN-SITEA(config-router)# end
```

VPNA SiteB configuration

```
VPNA-SITEB> enable
VPNA-SITEB# configure terminal
VPNA-SITEB(config)# interface gigabitethernet 0/1
VPNA-SITEA(config-if-GigabitEthernet 0/1)# no switchport
VPNA-SITEB(config-if-GigabitEthernet 0/1)# ip address 192.168.20.2 255.255.255.0
VPNA-SITEB(config-if-GigabitEthernet 0/1)# exit
VPNA-SITEB(config)# router ospf 10
VPNA-SITEB(config-router)# network 192.168.20.0 0.0.0.255 area 0
VPNA-SITEB(config-router)# end
```

VPNB SiteB configuration

```
VPNB-SITEB> enable
VPNB-SITEB# configure terminal
VPNB-SITEB(config)# interface gigabitethernet 0/1
VPNB-SITEA(config-if-GigabitEthernet 0/1)# no switchport
VPNB-SITEB(config-if-GigabitEthernet 0/1)# ip address 192.168.10.2 255.255.255.0
VPNB-SITEB(config-if-GigabitEthernet 0/1)# exit
VPNB-SITEB(config)# router ospf 10
VPNB-SITEB(config-router)# network 192.168.10.0 0.0.0.255 area 0
VPNB-SITEB(config-router)# end
```

VPNA SiteC configuration

```
VPNA-SITEC> enable
VPNA-SITEC# configure terminal
VPNA-SITEC(config)# interface gigabitethernet 0/1
VPNA-SITEC(config-if-GigabitEthernet 0/1)# no switchport
VPNA-SITEC(config-if-GigabitEthernet 0/1)# ip address 192.168.40.2 255.255.255.0
VPNA-SITEC(config-if-GigabitEthernet 0/1)# exit
VPNA-SITEC(config)# router ospf 10
VPNA-SITEC(config-router)# network 192.168.40.0 0.0.0.255 area 0
VPNA-SITEC(config-router)# end
```

VPNB SiteC configuration

```
VPNB-SITEC> enable
VPNB-SITEC# configure terminal
VPNB-SITEC(config)# interface gigabitethernet 0/1
VPNB-SITEC(config-if-GigabitEthernet 0/1)# no switchport
VPNB-SITEC(config-if-GigabitEthernet 0/1)# ip address 192.168.30.2 255.255.255.0
VPNB-SITEC(config-if-GigabitEthernet 0/1)# exit
VPNB-SITEC(config)# router ospf 10
VPNB-SITEC(config-router)# network 192.168.30.0 0.0.0.255 area 0
VPNB-SITEC(config-router)# end
```

```

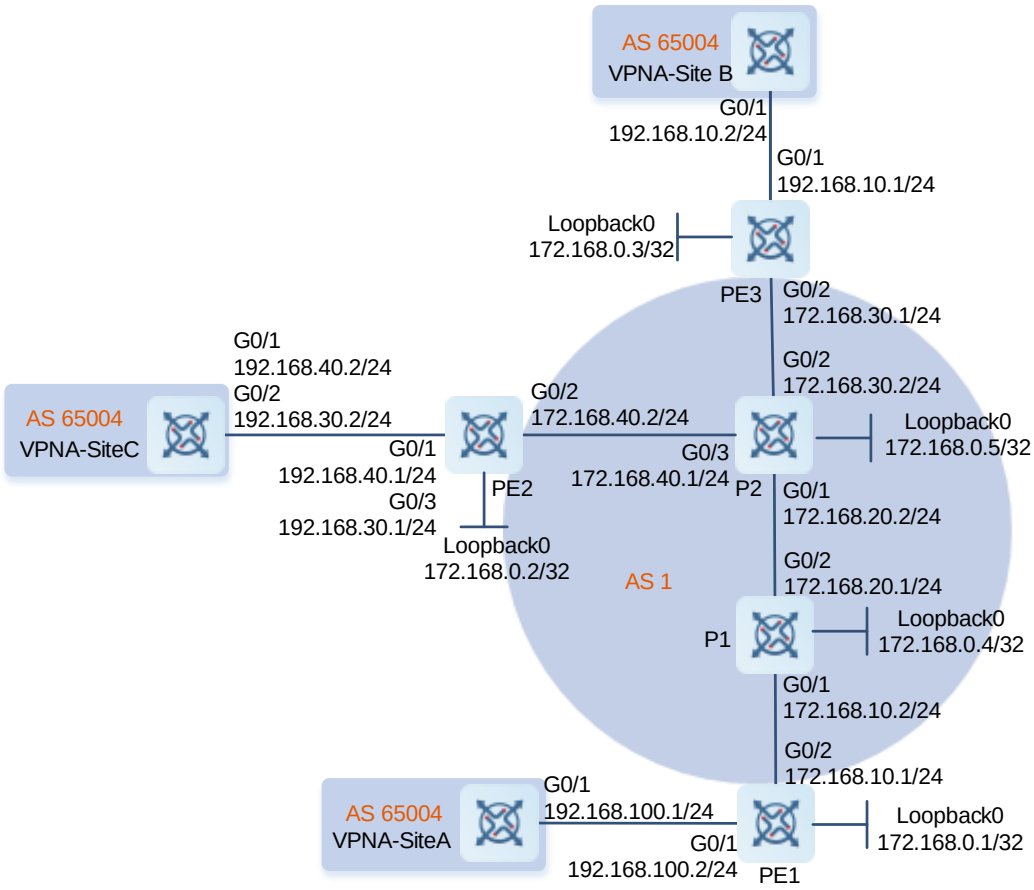
6. Verification

After the configuration is completed, run the **ping** command to detect the connectivity between sites.

- Verify that PE1 can ping PE2, PE3, P1, P2, and VPN SiteA.
- Verify that PE2 can ping PE1, PE3, P1, P2, VPNA SiteC, and VPNB SiteC.
- Verify that PE3 can ping PE1, PE2, P1, P2, VPNA SiteB, and VPNB SiteB.
- Verify that P1 can ping PE1, PE2, PE3, and P2.
- Verify that P2 can ping PE1, PE2, PE3, and P1.
- Verify that VPN SiteA can ping VPNA SiteB, VPNA SiteC, VPNB SiteB, and VPNB SiteC.
- Verify that VPNA SiteB can ping VPN SiteA and VPNA SiteC and cannot ping VPNB SiteB or VPNB SiteC.
- Verify that VPNA SiteC can ping VPN SiteA and VPNA SiteB and cannot ping VPNB SiteB or VPNB SiteC.
- Verify that VPNB SiteB can ping VPN SiteA and VPNB SiteC and cannot ping VPNA SiteB or VPNA SiteC.
- Verify that VPNB SiteC can ping VPN SiteA and VPNB SiteB and cannot ping VPNA SiteB or VPNA SiteC.

7. Common Errors

The router ID is not 32 bits. As a result, the LDP session or BGP neighbor relationship fails to be established.



1.15.3 Configuring Basic IPv4 MPLS L3VPN Functions (Hub-and-Spoke)

1. Requirements

Data in a VPN cannot be exchanged directly and needs to be forwarded through a unified control center, and only the control center knows all resources in a VPN. Users in a VPN can obtain resources in the VPN only through the control center. As shown in Figure 1-17, VPNA Site A can access resources in VPNA SiteB only through VPNA SiteC.

2. Topology

Figure 1-17 Configuring Basic IPv4 MPLS L3VPN Functions (Hub-and-Spoke)

3. Notes

- Configure interface IP addresses and OSPF on MPLS backbone network nodes to ensure communication between them.
- Enable MPLS forwarding and LDP and establish LDP LSPs on MPLS backbone network nodes.
- Configure VPN routing instance spoke1 on PE1, instances from-spoke and from-hub on PE2, and instance spoke2 on PE3, define RD and RT values, and associate VRF instances with interfaces.

- Configure MP-IBGP neighbors on PEs to exchange VPN routing information.
- Establish EBGP sessions between VPN sites and PEs to exchange VPN routing information.

4. Procedure

(1) Configure interface IP addresses and OSPF on MPLS backbone network nodes to ensure communication between them.

Configure PE1.

```
PE1> enable
PE1# configure terminal
PE1(config)# interface loopback 0
PE1(config-if-Loopback 0)# ip address 172.168.0.1 255.255.255.255
PE1(config-if-Loopback 0)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# no switchport
PE1(config-if-GigabitEthernet 0/2)# ip address 172.168.10.1 255.255.255.0
PE1(config)# router ospf 10
PE1(config-router)# network 172.168.0.1 0.0.0.0 area 0
PE1(config-router)# network 172.168.10.0 0.0.0.255 area 0
PE1(config-router)# exit
```

Configure P1.

```
P1> enable
P1# configure terminal
P1(config)# interface loopback 0
P1(config-if-Loopback 0)# ip address 172.168.0.4 255.255.255.255
P1(config-if-Loopback 0)# exit
P1(config)# interface gigabitethernet 0/1
P1(config-if-GigabitEthernet 0/1)# no switchport
P1(config-if-GigabitEthernet 0/1)# ip address 172.168.10.2 255.255.255.0
P1(config-if-GigabitEthernet 0/1)# exit
P1(config)# interface gigabitethernet 0/2
P1(config-if-GigabitEthernet 0/2)# no switchport
P1(config-if-GigabitEthernet 0/2)# ip address 172.168.20.1 255.255.255.0
P1(config-if-GigabitEthernet 0/2)# exit
P1(config)# router ospf 1
P1(config-router)# network 172.168.0.4 0.0.0.0 area 0
P1(config-router)# network 172.168.10.0 0.0.0.255 area 0
P1(config-router)# network 172.168.20.0 0.0.0.255 area 0
P1(config-router)# exit
```

Configure P2.

```
P2> enable
P2# configure terminal
P2(config)# interface loopback 0
P2(config-if-Loopback 0)# ip address 172.168.0.5 255.255.255.255
P2(config-if-Loopback 0)# exit
```

```
P2(config)# interface gigabitethernet 0/1
P2(config-if-GigabitEthernet 0/1)# no switchport
P2(config-if-GigabitEthernet 0/1)# ip address 172.168.20.2 255.255.255.0
P2(config-if-GigabitEthernet 0/1)# exit
P2(config)# interface gigabitethernet 0/2
P2(config-if-GigabitEthernet 0/2)# no switchport
P2(config-if-GigabitEthernet 0/2)# ip address 172.168.30.1 255.255.255.0
P2(config-if-GigabitEthernet 0/2)# exit
P2(config)# interface gigabitethernet 0/3
P2(config-if-GigabitEthernet 0/3)# no switchport
P2(config-if-GigabitEthernet 0/3)# ip address 172.168.40.1 255.255.255.0
P2(config-if-GigabitEthernet 0/3)# exit
P2(config)# router ospf 1
P2(config-router)# network 172.168.0.5 0.0.0.0 area 0
P2(config-router)# network 172.168.20.0 0.0.0.255 area 0
P2(config-router)# network 172.168.30.0 0.0.0.255 area 0
P2(config-router)# network 172.168.40.0 0.0.0.255 area 0
P2(config-router)# exit
```

Configure PE2.

```
PE2> enable
PE2# configure terminal
PE2(config)# interface loopback 0
PE2(config-if-Loopback 0)# ip address 172.168.0.2 255.255.255.255
PE2(config-if-Loopback 0)# exit
PE2(config)# interface gigabitethernet 0/2
PE2(config-if-GigabitEthernet 0/2)# no switchport
PE2(config-if-GigabitEthernet 0/2)# ip address 172.168.40.2 255.255.255.0
PE2(config-if-GigabitEthernet 0/2)# exit
PE2(config)# router ospf 10
PE2(config-router)# network 172.168.0.2 0.0.0.0 area 0
PE2(config-router)# network 172.168.40.0 0.0.0.255 area 0
PE2(config-router)# exit
```

Configure PE3.

```
PE3> enable
PE3# configure terminal
PE3(config)# interface loopback 0
PE3(config-if-Loopback 0)# ip address 172.168.0.3 255.255.255.255
PE3(config-if-Loopback 0)# exit
PE3(config)# interface gigabitethernet 0/2
PE3(config-if-GigabitEthernet 0/2)# no switchport
PE3(config-if-GigabitEthernet 0/2)# ip address 172.168.30.2 255.255.255.0
PE3(config-if-GigabitEthernet 0/2)# exit
PE3(config)# router ospf 10
PE3(config-router)# network 172.168.0.3 0.0.0.0 area 0
PE3(config-router)# network 172.168.30.0 0.0.0.255 area 0
```

```
PE3(config-router)# exit
```

(2) Enable MPLS forwarding and LDP and establish LDP LSPs on MPLS backbone network nodes.

Configure PE1.

```
PE1(config)# mpls ip
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# label-switching
PE1(config-if-GigabitEthernet 0/2)# mpls ip
PE1(config-if-GigabitEthernet 0/2)# exit
```

Configure P1.

```
P1(config)# mpls ip
P1(config)# mpls router ldp
P1(config-mpls-router)# ldp router-id interface loopback 0 force
P1(config-mpls-router)# exit
P1(config)# interface gigabitethernet 0/1
P1(config-if-GigabitEthernet 0/1)# label-switching
P1(config-if-GigabitEthernet 0/1)# mpls ip
P1(config-if-GigabitEthernet 0/1)# exit
P1(config)# interface gigabitethernet 0/2
P1(config-if-GigabitEthernet 0/2)# label-switching
P1(config-if-GigabitEthernet 0/2)# mpls ip
P1(config-if-GigabitEthernet 0/2)# exit
```

Configure P2.

```
P2(config)# mpls ip
P2(config)# mpls router ldp
P2(config-mpls-router)# ldp router-id interface loopback 0 force
P2(config-mpls-router)# exit
P2(config)# interface gigabitethernet 0/1
P2(config-if-GigabitEthernet 0/1)# label-switching
P2(config-if-GigabitEthernet 0/1)# mpls ip
P2(config-if-GigabitEthernet 0/1)# exit
P2(config)# interface gigabitethernet 0/2
P2(config-if-GigabitEthernet 0/2)# label-switching
P2(config-if-GigabitEthernet 0/2)# mpls ip
P2(config-if-GigabitEthernet 0/2)# exit
P2(config)# interface gigabitethernet 0/3
P2(config-if-GigabitEthernet 0/3)# label-switching
P2(config-if-GigabitEthernet 0/3)# mpls ip
P2(config-if-GigabitEthernet 0/3)# exit
```

Configure PE2.

```
PE2(config)# mpls ip
PE2(config)# mpls router ldp
```

```
PE2(config-mpls-router)# ldp router-id interface loopback 0 force
PE2(config-mpls-router)# exit
PE2(config)# interface gigabitethernet 0/2
PE2(config-if-GigabitEthernet 0/2)# label-switching
PE2(config-if-GigabitEthernet 0/2)# mpls ip
PE2(config-if-GigabitEthernet 0/2)# exit
```

Configure PE3.

```
PE3(config)# mpls ip
PE3(config)# mpls router ldp
PE3(config-mpls-router)# ldp router-id interface loopback 0 force
PE3(config-mpls-router)# exit
PE3(config)# interface gigabitethernet 0/2
PE3(config-if-GigabitEthernet 0/2)# label-switching
PE3(config-if-GigabitEthernet 0/2)# mpls ip
PE3(config-if-GigabitEthernet 0/2)# exit
```

(3) Configure VPN routing instances, define RD and RT values, and associate VRF instances with interfaces on PEs.

Configure PE1.

```
PE1(config)# ip vrf spoke1
PE1(config-vrf)# rd 1:100
PE1(config-vrf)# route-target export 1:200
PE1(config-vrf)# route-target import 1:100
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# no switchport
PE1(config-if-GigabitEthernet 0/1)# ip vrf forwarding spoke1
PE1(config-if-GigabitEthernet 0/1)# ip address 192.168.100.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/1)# exit
```

Configure PE2.

```
PE2(config)# ip vrf from-spoke
PE2(config-vrf)# rd 1:100
PE2(config-vrf)# route-target import 1:300
PE2(config-vrf)# route-target import 1:200
PE2(config-vrf)# exit
PE2(config)# ip vrf from-hub
PE2(config-vrf)# rd 1:200
PE2(config-vrf)# route-target export 1:100
PE2(config-vrf)# exit
PE2(config)# interface gigabitethernet 0/1
PE2(config-if-GigabitEthernet 0/1)# no switchport
PE2(config-if-GigabitEthernet 0/1)# ip vrf forwarding from-hub
PE2(config-if-GigabitEthernet 0/1)# ip address 192.168.40.1 255.255.255.0
PE2(config-if-GigabitEthernet 0/1)# exit
PE2(config)# interface gigabitethernet 0/3
```

```
PE2(config-if-GigabitEthernet 0/3)# no switchport
PE2(config-if-GigabitEthernet 0/3)# ip vrf forwarding from-spoke
PE2(config-if-GigabitEthernet 0/3)# ip address 192.168.30.1 255.255.255.0
PE2(config-if-GigabitEthernet 0/3)# exit
```

Configure PE3.

```
PE3(config)# ip vrf spoke2
PE3(config-vrf)# rd 1:100
PE3(config-vrf)# route-target export 1:300
PE3(config-vrf)# route-target import 1:100
PE3(config-vrf)# exit
PE3# configure terminal
PE3(config)# interface gigabitethernet 0/1
PE3(config-if-GigabitEthernet 0/1)# no switchport
PE3(config-if-GigabitEthernet 0/1)# ip vrf forwarding spoke2
PE3(config-if-GigabitEthernet 0/1)# ip address 192.168.10.1 255.255.255.0
PE3(config-if-GigabitEthernet 0/1)# exit
```

(4) Configure MP-IBGP neighbors on PEs to exchange VPN routing information.

Configure PE1.

```
PE1(config)# router bgp 1
PE1(config-router)# neighbor 172.168.0.2 remote-as 1
PE1(config-router)# neighbor 172.168.0.2 update-source loopback 0
PE1(config-router)# neighbor 172.168.0.3 remote-as 1
PE1(config-router)# neighbor 172.168.0.3 update-source loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 172.168.0.2 activate
PE1(config-router-af)# neighbor 172.168.0.2 allowas-in
PE1(config-router-af)# neighbor 172.168.0.3 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit
```

Configure PE2.

```
PE2(config)# router bgp 1
PE2(config-router)# neighbor 172.168.0.1 remote-as 1
PE2(config-router)# neighbor 172.168.0.1 update-source loopback 0
PE2(config-router)# neighbor 172.168.0.3 remote-as 1
PE2(config-router)# neighbor 172.168.0.3 update-source loopback 0
PE2(config-router)# address-family vpnv4
PE2(config-router-af)# neighbor 172.168.0.1 activate
PE2(config-router-af)# neighbor 172.168.0.3 activate
PE2(config-router-af)# exit-address-family
PE2(config-router)# exit
```

Configure PE3.

```
PE3(config)# router bgp 1
PE3(config-router)# neighbor 172.168.0.1 remote-as 1
PE3(config-router)# neighbor 172.168.0.1 update-source loopback 0
```

```
PE3(config-router)# neighbor 172.168.0.2 remote-as 1
PE3(config-router)# neighbor 172.168.0.2 update-source loopback 0
PE3(config-router)# address-family vpnv4
PE3(config-router-af)# neighbor 172.168.0.1 activate
PE3(config-router-af)# neighbor 172.168.0.2 activate
PE3(config-router-af)# neighbor 172.168.0.2 allowas-in
PE3(config-router-af)# exit-address-family
PE3(config-router)# exit
```

(5) Establish EBGP sessions between VPN sites and PEs to exchange VPN routing information.

Configure PE1.

```
PE1(config)# router bgp 1
PE1(config-router)# address-family ipv4 vrf spoke1
PE1(config-router-af)# neighbor 192.168.100.2 remote-as 65004
PE1(config-router-af)# neighbor 192.168.100.2 activate
PE1(config-router-af)# neighbor 192.168.100.2 as-override
PE1(config-router-af)# exit-address-family
PE1(config-router)# end
```

Configure PE2.

```
PE2(config)# router bgp 1
PE2(config-router)# address-family ipv4 vrf from-spoke
PE2(config-router-af)# neighbor 192.168.30.2 remote-as 65004
PE2(config-router-af)# neighbor 192.168.30.2 activate
PE2(config-router-af)# neighbor 192.168.30.2 as-override
PE2(config-router-af)# exit-address-family
PE2(config-router)# address-family ipv4 vrf from-hub
PE2(config-router-af)# neighbor 192.168.40.2 remote-as 65004
PE2(config-router-af)# neighbor 192.168.40.2 activate
PE2(config-router-af)# neighbor 192.168.40.2 allows-in
PE2(config-router-af)# exit-address-family
PE2(config-router)# end
```

Configure PE3.

```
PE3(config)# router bgp 1
PE3(config-router)# address-family ipv4 vrf spoke2
PE3(config-router-af)# neighbor 192.168.10.2 remote-as 65004
PE3(config-router-af)# neighbor 192.168.10.2 activate
PE3(config-router-af)# neighbor 192.168.10.2 as-override
PE3(config-router-af)# exit-address-family
PE3(config-router)# end
```

VPNA SiteA configuration

```
VPNA-SITEA> enable
VPNA-SITEA# configure terminal
VPNA-SITEA(config)# interface gigabitethernet 0/1
VPNA-SITEA(config-if-GigabitEthernet 0/1)# ip address 192.168.100.2 255.255.255.0
VPNA-SITEA(config-if-GigabitEthernet 0/1)# exit
```

```
VPNA-SITEA(config)# router bgp 65004
VPNA-SITEA(config-router)# neighbor 192.168.100.1 remote-as 1
VPNA-SITEA(config-router)# neighbor 192.168.100.1 activate
VPNA-SITEA(config-router)# end
```

VPNA SiteB configuration

```
VPNA-SITEB> enable
VPNA-SITEB# configure terminal
VPNA-SITEB(config)# interface gigabitethernet 0/1
VPNA-SITEB(config-if-GigabitEthernet 0/1)# ip address 192.168.10.2 255.255.255.0
VPNA-SITEB(config-if-GigabitEthernet 0/1)# exit
VPNA-SITEB(config)# router bgp 65004
VPNA-SITEB(config-router)# neighbor 192.168.10.1 remote-as 1
VPNA-SITEB(config-router)# neighbor 192.168.10.1 activate
VPNA-SITEB(config-router)# end
```

VPNA SiteC configuration

```
VPNA-SITEC> enable
VPNA-SITEC# configure terminal
VPNA-SITEC(config)# interface gigabitethernet 0/1
VPNA-SITEC(config-if-GigabitEthernet 0/1)# ip address 192.168.40.2 255.255.255.0
VPNA-SITEC(config-if-GigabitEthernet 0/1)# exit
VPNA-SITEC(config)# interface gigabitethernet 0/2
VPNA-SITEC(config-if-GigabitEthernet 0/2)# ip address 192.168.30.2 255.255.255.0
VPNA-SITEC(config-if-GigabitEthernet 0/2)# exit
VPNA-SITEC(config)# router bgp 65004
VPNA-SITEC(config-router)# neighbor 192.168.30.1 remote-as 1
VPNA-SITEC(config-router)# neighbor 192.168.30.1 activate
VPNA-SITEC(config-router)# neighbor 192.168.40.1 remote-as 1
VPNA-SITEC(config-router)# neighbor 192.168.40.1 activate
VPNA-SITEC(config-router)# end
```

5. Configuration Files

- PE1 configuration file

```
hostname PE1
!
ip vrf spoke1
 rd 1:100
 route-target export 1:200
 route-target import 1:100
!
mpls ip
!
interface GigabitEthernet 0/1

  exit-address-family
!
```

6. Verification

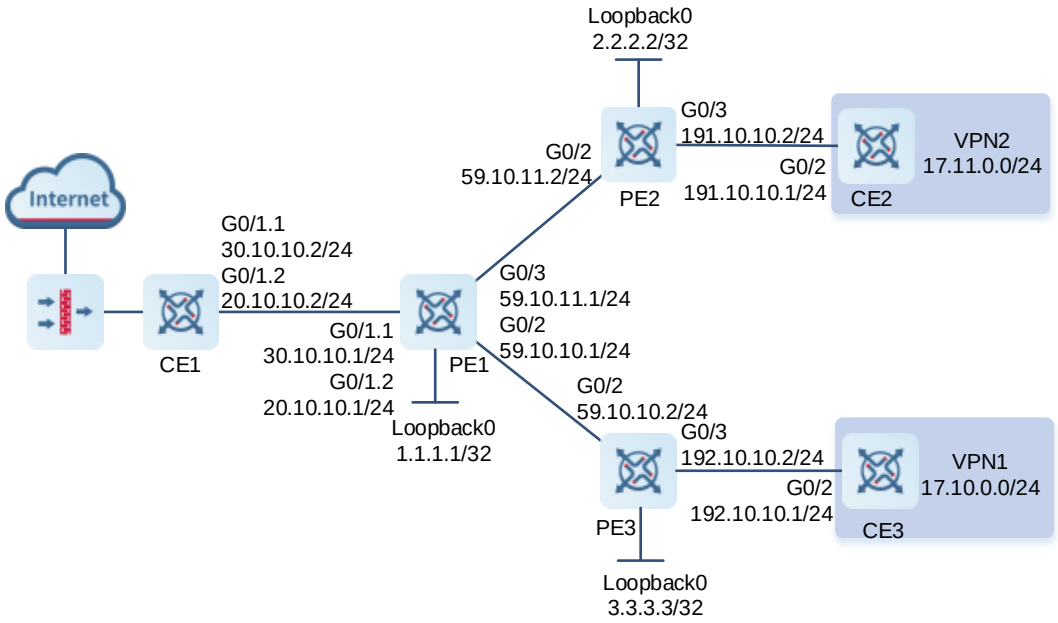
After the configuration is completed, run the **ping** command to detect the connectivity between sites and run the **traceroute** command to trace bypassing devices.

- Verify that PE1 can ping PE2 and PE3.
- Verify that PE2 can ping PE1 and PE3.
- Verify that PE3 can ping PE1 and PE2.
- Verify that VPNA SiteA can ping VPNA SiteB, and traffic from VPNA SiteA to VPNA SiteB passes through VPNA SiteC.
- Verify that VPNA SiteB can ping VPNA SiteA, and traffic from VPNA SiteB to VPNA SiteA passes through VPNA SiteC.
- Verify that VPNA SiteC can ping VPNA SiteA and VPNA SiteB.

7. Common Errors

The router ID is not 32 bits. As a result, the LDP session or BGP neighbor relationship fails to be established.

1.15.4 Configuring Basic IPv4 MPLS L3VPN Functions (Unified Egress for Centralized Internet Access Control)



1. Requirements

VPNs cannot access each other, and these VPNs access the Internet through a unified device. VPN1 and VPN2 access the Internet through PE1. However, VPN1 and VPN2 cannot access each other.

When the centralized control mode is utilized and newly added VPN sites need to access the Internet through the unified egress, you only need to add filtering rules on the egress CE without changing configurations of other VPN sites. This ensures good extensibility. The disadvantage is that traffic to be isolated can be discarded only after reaching the egress CE, wasting network bandwidth.

2. Topology

Figure 1-18 Configuring Basic IPv4 MPLS L3VPN Functions (Unified Internet Access Egress and Centralized Control)

3. Notes

- On PE2, configure a loopback interface, create VRF instance VPN1, define RD and RT values, and associate the VRF instance with the corresponding interface. Use OSPF to exchange routes with CE2, and establish IBGP neighbor relationship with PE1 to distribute IP routes. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On CE2, configure an IP address for the interface used to connect to PE2, and use OSPF to exchange routes with PE2.
- On PE3, configure a loopback interface, create VRF instance VPN2, set the export and import RT values of VPN2 to 1 and 200, define RD and RT values, and associate the VRF instance with the corresponding interface. Use OSPF to exchange routes with CE3, and establish IBGP neighbor relationship with PE1 to distribute IP routes. Configure the backbone network MPLS signaling, enable MPLS on the public interface,

and configure the backbone network routing protocol.

- On PE1, configure a loopback interface, create a trunk interface, create VRF instance vrf_out, define RD and RT values, and associate the VRF instance with the corresponding interface. Configure a default route to the Internet, create VRF instance vrf_in, define RD and RT values, and associate the VRF instance with the corresponding interface. Use EBGP to exchange routes with CE1, establish IBGP neighbor relationship with PE2 and PE3, and configure the route exchange function for VRF instance vrf_out. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On CE1, create a Layer 3 subinterface, configure the EBGP neighbor relationship with PE1, and create an ACL rule on Layer 3 subinterface GigabitEthernet0/1.1.

Caution

For connection between PE1 and CE1, this example uses switch virtual interface (SVI) and 802.1Q subinterface configurations, which are not supported by some devices. PE1 and CE1 can be connected through any two links (physical or logical links) only if two route adjacencies are formed between them. Users can select a suitable connection method based on actual requirements.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on PEs and CEs are similar. The following shows how to configure OSPF neighbors on PE1.

```
PE1> enable
PE1# configure terminal
PE1(config)# router ospf 1
PE1(config-router)# network 59.10.11.0 0.0.0.255 area 0
PE1(config-router)# network 59.10.10.0 0.0.0.255 area 0
PE1(config-router)# network 1.1.1.1 0.0.0.0 area 0
PE1(config-router)# exit
```

(3) Configure basic MPLS functions.

Configurations on PEs are similar. The following shows how to configure basic MPLS functions on PE1.

```
PE1(config-router)# exit
PE1(config)# mpls ip
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
PE1(config)# interface gigabitethernet 0/3
PE1(config-if-GigabitEthernet 0/3)# ip address 59.10.11.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/3)# label-switching
PE1(config-if-GigabitEthernet 0/3)# mpls ip
PE1(config-if-GigabitEthernet 0/3)# exit
PE1(config)# interface gigabitethernet 0/2
```

```
PE1(config-if-GigabitEthernet 0/2)# ip address 59.10.10.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/2)# label-switching
PE1(config-if-GigabitEthernet 0/2)# mpls ip
PE1(config-if-GigabitEthernet 0/2)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following uses PE1 as an example.

```
PE1(config)# ip vrf vrf_in
PE1(config-vrf)# rd 1:400
PE1(config-vrf)# route-target import 1:100
PE1(config-vrf)# route-target import 1:200
PE1(config-vrf)# exit
PE1(config)# ip vrf vrf_out
PE1(config-vrf)# rd 1:300
PE1(config-vrf)# route-target export 1:100
PE1(config-vrf)# route-target export 1:200
PE1(config-vrf)# exit
PE1(config)# interface vlan 10
PE1(config-if-Vlan 10)# ip vrf forwarding vrf_in
PE1(config-if-Vlan 10)# ip address 30.10.10.1 255.255.255.0
PE1(config-if-Vlan 10)# exit
PE1(config)# interface vlan 20
PE1(config-if-Vlan 20)# ip vrf forwarding vrf_out
PE1(config-if-Vlan 20)# ip address 20.10.10.1 255.255.255.0
PE1(config-if-Vlan 20)# exit
```

(5) Configure BGP neighbors to advertise VPN routes.

PE1 establishes EBGP neighbor relationship with CE1.

```
PE1(config)# router bgp 1
PE1(config-router)# address-family ipv4 vrf vrf_in
PE1(config-router-af)# neighbor 30.10.10.2 remote-as 100
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit
```

CE1 establishes EBGP neighbor relationship with PE1.

```
CE1(config)# router bgp 100
CE1(config-router)# neighbor 30.10.10.1 remote-as 1
CE1(config-router)# exit
```

PE1 establishes IBGP neighbor relationship with PE2 and PE3 to advertise VPN routes.

```
PE1(config)# router bgp 1
PE1(config-router)# neighbor 2.2.2.2 remote-as 1
PE1(config-router)# neighbor 2.2.2.2 update-source loopback 0
PE1(config-router)# neighbor 3.3.3.3 remote-as 1
PE1(config-router)# neighbor 3.3.3.3 update-source loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 2.2.2.2 activate
PE1(config-router-af)# neighbor 3.3.3.3 activate
```

```
PE1(config-router-af)# exit-address-family
PE1(config-router)# address-family ipv4 vrf vrf_out
PE1(config-router-af)# default-information originate
PE1(config-router-af)# redistribute static
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit
```

5. Verification

(1) After the configuration is completed, run the **show ip route** command to display existing routes.

PE1 verification result

```
PE1# show ip route vrf vrf_out
Routing Table: vrf_out

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is 20.10.10.2 to network 0.0.0.0
S*   0.0.0.0/0 [1/0] via 20.10.10.2, VLAN 20
C    20.10.10.0/24 is directly connected, VLAN 20
C    20.10.10.1/32 is local host.

PE1# show ip route vrf vrf_in
Routing Table: vrf_in

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is 20.10.10.2 to network 0.0.0.0

B    192.10.10.0/24 [20/0] via 30.10.10.1, 00:33:19
```

CE2 verification result

```
CE2# show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is 191.10.10.2 to network 0.0.0.0
O*E2 0.0.0.0/0 [110/1] via 191.10.10.2, 00:08:11, GigabitEthernet 0/2
C    17.11.0.0/24 is directly connected, Loopback 0
C    17.11.0.1/32 is local host.
C    191.10.10.0/24 is directly connected, GigabitEthernet 0/2
C    191.10.10.1/32 is local host.
```

CE3 verification result

```
CE3# show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is 192.10.10.2 to network 0.0.0.0
```

```
O*E2 0.0.0.0/0 [110/1] via 192.10.10.2, 00:31:48, GigabitEthernet 0/2
C    17.10.0.0/24 is directly connected, Loopback 0
C    17.10.0.1/32 is local host.
C    192.10.10.0/24 is directly connected, GigabitEthernet 0/2
C    192.10.10.1/32 is local host.
```

(2) After the configuration is completed, run the **ping** command to detect the connectivity between sites.

- Verify that PE2 can ping PE1 and PE3.
- Verify that CE2 can ping CE1 but cannot ping CE3.
- Verify that PE3 can ping PE1 and PE2.
- Verify that CE3 can ping CE1 but cannot ping CE2.
- Verify that PE1 can ping PE2 and PE3.
- Verify that CE1 can ping CE2 and CE3.

6. Configuration Files

```

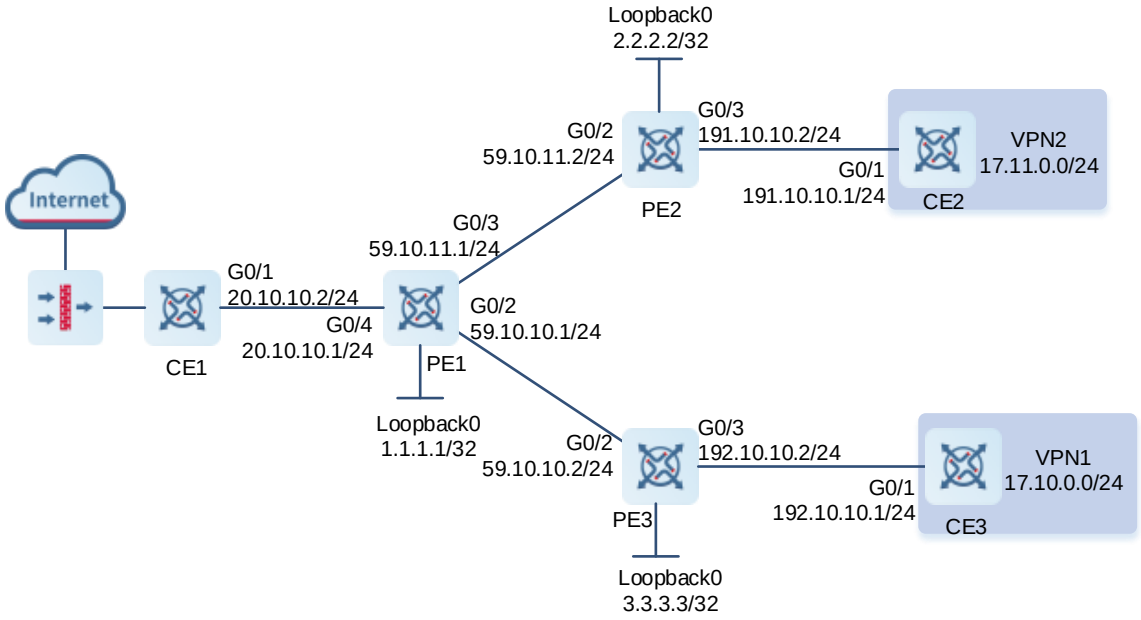
7. Common Errors

The router ID is not 32 bits. As a result, the LDP session or BGP neighbor relationship fails to be established.

1.15.5 Configuring Basic IPv4 MPLS L3VPN Functions (Unified Internet Access Egress and Distributed Control)



1. Requirements

VPNs cannot access each other, and these VPNs access the Internet through a unified device. VPN1 and VPN2 access the Internet through PE1. However, VPN1 and VPN2 cannot access each other.

When the distributed control mode is utilized and newly added VPN sites need to access the Internet through the unified egress, you need to add filtering rules for CEs in each VPN site that accesses the Internet through the unified egress. This results in poor extensibility. The advantage is that traffic to be isolated can be discarded at CEs of VPN sites, saving network bandwidth.

2. Topology

Figure 1-19 Configuring Basic IPv4 MPLS L3VPN Functions (Unified Internet Access Egress and Distributed Control)

3. Notes

- On PE1, configure a loopback interface, create VRF instance vrf_net, define RD and RT values, and associate the VRF instance with the corresponding interface. Configure a default route to the Internet, use EBGP to exchange routes with CE1, establish IBGP neighbor relationship with PE2 and PE3, and configure the route exchange function of VRF instance vrf_net. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On CE1, establish EBGP neighbor relationship with PE1.
- On PE2, configure a loopback interface, create VRF instance VPN1, define RD and RT values, and associate the VRF instance with the corresponding interface. Use OSPF to exchange routes with CE2, and establish IBGP neighbor relationship with PE1 to distribute IP routes. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On CE2, create ACL rules and apply the ACL rules to Layer 3 subinterfaces. Configure route exchange with PE2 and configure a default static route.
- On PE3, configure a loopback interface, create VRF instance VPN2, set the export and import RT values of VPN2 to 1 and 200, define RD and RT values, and associate the VRF instance with the corresponding interface. Use OSPF to exchange routes with CE3, and establish IBGP neighbor relationship with PE1 to distribute IP routes. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On CE3, create ACL rules and apply the ACL rules to Layer 3 subinterfaces. Configure route exchange with PE3 and configure a default static route.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on PEs and CEs are similar. The following shows how to configure OSPF neighbors on PE1.

```
PE1> enable
PE1# configure terminal
PE1(config)# router ospf 1
PE1(config-router)# network 59.10.11.0 0.0.0.255 area 0
PE1(config-router)# network 59.10.10.0 0.0.0.255 area 0
PE1(config-router)# network 1.1.1.1 0.0.0.0 area 0
```

(3) Configure basic MPLS functions.

Configurations on PEs are similar. The following shows how to configure basic MPLS functions on PE1.

```
PE1(config)# mpls ip
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
PE1(config)# interface gigabitethernet 0/3
PE1(config-if-GigabitEthernet 0/3)# ip address 59.10.11.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/3)# label-switching
PE1(config-if-GigabitEthernet 0/3)# mpls ip
PE1(config-if-GigabitEthernet 0/3)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# ip address 59.10.10.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/2)# label-switching
PE1(config-if-GigabitEthernet 0/2)# mpls ip
PE1(config-if-GigabitEthernet 0/2)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following uses PE1 as an example.

```
PE1(config)# ip vrf vrf_net
PE1(config-vrf)# rd 1:300
PE1(config-vrf)# route-target import 1:100
PE1(config-vrf)# route-target import 1:200
PE1(config-vrf)# route-target export 1:100
PE1(config-vrf)# route-target export 1:200
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/4
PE1(config-if-GigabitEthernet 0/4)# no switchport
PE1(config-if-GigabitEthernet 0/4)# ip vrf forwarding vrf_net
PE1(config-if-GigabitEthernet 0/4)# ip address 20.10.10.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/4)# exit
```

(5) Configure BGP neighbors to advertise VPN routes.

PE1 establishes EBGP neighbor relationship with CE1 to advertise VPN routes.

```
PE1(config)# router bgp 1
PE1(config-router)# address-family ipv4 vrf vrf_net
PE1(config-router-af)# neighbor 20.10.10.2 remote-as 100
PE1(config-router-af)# default-information originate
PE1(config-router-af)# redistribute static
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit
```

CE1 establishes EBGP neighbor relationship with PE1.

```
CE1(config)# router bgp 100
CE1(config-router)# neighbor 20.10.10.1 remote-as 1
CE1(config-router)# exit
```

PE1 establishes IBGP neighbor relationship with PE2 and PE3.

```
PE1(config)# router bgp 1
PE1(config-router)# neighbor 2.2.2.2 remote-as 1
PE1(config-router)# neighbor 2.2.2.2 update-source loopback 0
PE1(config-router)# neighbor 3.3.3.3 remote-as 1
PE1(config-router)# neighbor 3.3.3.3 update-source loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 2.2.2.2 activate
PE1(config-router-af)# neighbor 3.3.3.3 activate
```

Configure CE1.

```
CE1> enable
CE1(config)# interface gigabitethernet 0/1
CE1(config-if-GigabitEthernet 0/1)# ip address 20.10.10.2 255.255.255.0
CE1(config-if-GigabitEthernet 0/1)# exit
CE1(config)# router bgp 100
CE1(config-router)# neighbor 20.10.10.1 remote-as 1
```

Configure PE1.

```
PE1> enable
PE1# configure terminal
PE1(config)# interface loopback 0
PE1(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
PE1(config-if-Loopback 0)# exit
PE1(config)# ip vrf vrf_net
PE1(config-vrf)# rd 1:300
PE1(config-vrf)# route-target import 1:100
PE1(config-vrf)# route-target import 1:200
PE1(config-vrf)# route-target export 1:100
PE1(config-vrf)# route-target export 1:200
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/4
PE1(config-if-GigabitEthernet 0/4)# no switchport
PE1(config-if-GigabitEthernet 0/4)# ip vrf forwarding vrf_net
PE1(config-if-GigabitEthernet 0/4)# ip address 20.10.10.1 255.255.255.0
```

```
PE1(config-if-GigabitEthernet 0/4)# exit
PE1(config)#ip route vrf vrf_net 0.0.0.0 0.0.0.0 GigabitEthernet 0/4 20.10.10.2
PE1(config)# router bgp 1
PE1(config-router)# address-family ipv4 vrf vrf_net
PE1(config-router-af)# neighbor 20.10.10.2 remote-as 100
PE1(config-router-af)# exit-address-family
PE1(config-router)# neighbor 2.2.2.2 remote-as 1
PE1(config-router)# neighbor 2.2.2.2 update-source loopback 0
PE1(config-router)# neighbor 3.3.3.3 remote-as 1
PE1(config-router)# neighbor 3.3.3.3 update-source loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 2.2.2.2 activate
PE1(config-router-af)# neighbor 3.3.3.3 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# address-family ipv4 vrf vrf_net
PE1(config-router-af)# default-information originate
PE1(config-router-af)# redistribute static
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit

Gateway of last resort is no set
C    1.1.1.1/32 is local host.
O    2.2.2.2/32 [110/1] via 59.10.11.2, 03:59:18, GigabitEthernet 0/3
O    3.3.3.3/32 [110/1] via 59.10.10.2, 03:46:02, GigabitEthernet 0/2
C    59.10.10.0/24 is directly connected, GigabitEthernet 0/3
C    59.10.10.1/32 is local host.
C    59.10.11.0/24 is directly connected, GigabitEthernet 0/2
C    59.10.11.1/32 is local host.
```

(2) After the configuration is completed, run the **ping** command to detect the connectivity between sites.

- Verify that PE1 can ping PE2 and PE3.
- Verify that CE1 can ping CE2 and CE3.
- Verify that PE2 can ping PE1 and PE3.
- Verify that CE2 can ping CE1 but cannot ping CE3.
- Verify that PE3 can ping PE1 and PE2.
- Verify that CE3 can ping CE1 but cannot ping CE2.

6. Configuration Files

```

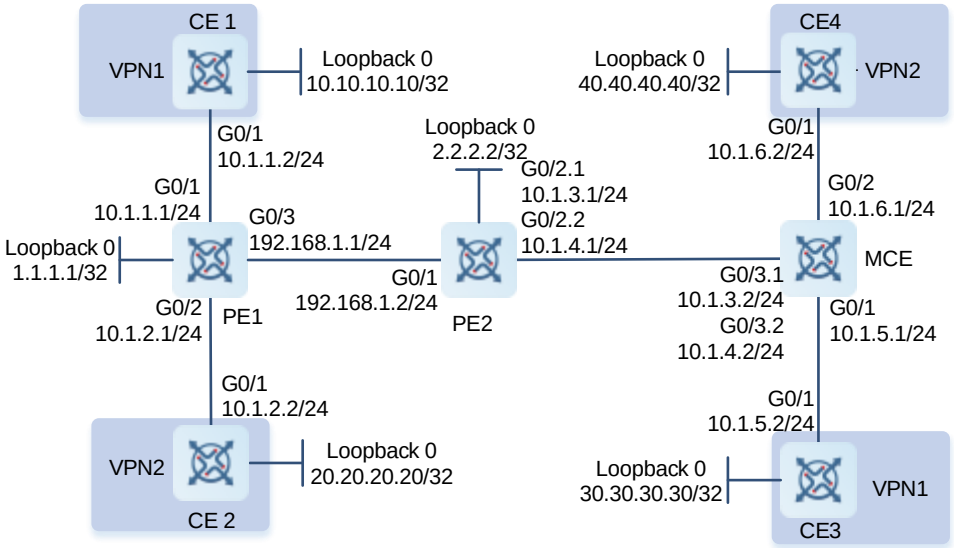
7. Common Errors

The router ID is not 32 bits. As a result, the LDP session or BGP neighbor relationship fails to be established.



1.15.6 Configuring Basic IPv4 MPLS L3VPN Functions (MCE-based Hierarchal VPNs)

1. Requirements

Use the MCE networking method to change the original MPLS L3VPN network to a hierarchal network. The MCE saves only routes of the connected VPN site and default routes distributed by PE2 instead of routes of all VPN sites. Therefore, the capacity and performance requirements on the MCE are low. However, PE1 and PE2 need to save all VPN routes. Therefore, the capacity and performance requirements on PE1 and PE2 are high.

2. Topology

Figure 1-20 Configuring Basic IPv4 MPLS L3VPN Functions (MCE-based Hierarchal VPNs)

3. Notes

- Configure the MPLS network: configure interface addresses and OSPF on PE1 and PE2 and configure the MPLS function.

- Configure the MPLS L3VPN: configure access from CEs to PEs on PE1, PE2, CE1, and CE2 and configure MP-IBGP on PE1 and PE2.
- Configure the MCE and connected CEs.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on all devices are similar. The following shows how to configure OSPF neighbors on PE1.

```
PE1> enable
PE1# configure terminal
PE1(config)# router ospf 1
PE1(config-router)# network 1.1.1.1 0.0.0.0 area 0
PE1(config-router)# network 192.168.1.0 0.0.0.255 area 0
PE1(config-router)# exit
```

(3) Configure basic MPLS functions.

Configurations on PEs are similar. The following shows how to configure basic MPLS functions on PE1.

```
PE1(config)# mpls ip
PE1(config)# interface gigabitethernet 0/3
PE1(config-if-GigabitEthernet 0/3)# mpls ip
PE1(config-if-GigabitEthernet 0/3)# label-switching
PE1(config-if-GigabitEthernet 0/3)# exit
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following uses PE1 as an example.

```
PE1(config)# ip vrf VPN1
PE1(config-vrf)# rd 100:1
PE1(config-vrf)# route-target both 100:1
PE1(config-vrf)# exit
PE1(config)# ip vrf VPN2
PE1(config-vrf)# rd 100:2
PE1(config-vrf)# route-target both 100:2
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# ip vrf forwarding VPN1
PE1(config-if-GigabitEthernet 0/1)# ip address 10.1.1.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/1)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# ip vrf forwarding VPN2
PE1(config-if-GigabitEthernet 0/2)# ip address 10.1.2.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/2)# exit
```

(5) Configure VPN routes.

Configurations on PEs and MCEs are similar. The following shows how to configure VPN routes on PE1.

```
PE1(config)# router ospf 10 vrf VPN1
PE1(config-router)# network 10.1.1.0 0.0.0.255 area 0
PE1(config-router)# redistribute bgp subnets
PE1(config-router)# exit
PE1(config)# router ospf 20 vrf VPN2
PE1(config-router)# network 10.1.2.0 0.0.0.255 area 0
PE1(config-router)# redistribute bgp subnets
PE1(config-router)# exit
```

(6) Configure BGP neighbors to advertise VPN routes.

Configurations on PE1 and PE2 are similar. The following shows how to configure IBGP neighbors on PE1.

```
PE1(config)# router bgp 100
PE1(config-router)# neighbor 2.2.2.2 remote-as 100
PE1(config-router)# neighbor 2.2.2.2 update-source loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 2.2.2.2 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# address-family ipv4 vrf VPN1
PE1(config-router-af)# redistribute ospf 10
PE1(config-router-af)# exit-address-family
PE1(config-router)# address-family ipv4 vrf VPN2
PE1(config-router-af)# redistribute ospf 20
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit
```

(7) Configure a default route.

Configure a default route on PE2.

```
PE2(config)# ip route vrf VPN1 0.0.0.0 0.0.0.0 null 0
PE2(config)# ip route vrf VPN2 0.0.0.0 0.0.0.0 null 0
```

5. Verification

(1) After the configuration is completed, run the **show ip route** command to display VPN routes.

MCE verification result

```
MCE# show ip route vrf VPN1
Routing Table: VPN1

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is 10.1.3.1 to network 0.0.0.0
O*E2 0.0.0.0/0 [110/1] via 10.1.3.1, 00:38:35, GigabitEthernet 0/3.1
```

```
C    10.1.3.0/24 is directly connected, GigabitEthernet 0/3.1
C    10.1.3.2/32 is local host.
C    10.1.5.0/24 is directly connected, GigabitEthernet 0/1
C    10.1.5.0/42 is local host.
O    30.30.30.30/32 [110/1] via 10.1.5.2, 00:40:05, GigabitEthernet 0/1

MCE# show ip route vrf VPN2
Routing Table: VPN2

Codes:  C - connected, S - static, R - RIP, B - BGP
        O - OSPF, IA - OSPF inter area
        N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
        E1 - OSPF external type 1, E2 - OSPF external type 2
        i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
        ia - IS-IS inter area, * - candidate default

Gateway of last resort is 10.1.4.1 to network 0.0.0.0
O*E2 0.0.0.0/0 [110/1] via 10.1.4.1, 00:38:35, GigabitEthernet 0/3.2
C    10.1.4.0/24 is directly connected, GigabitEthernet 0/3.2
C    10.1.4.2/32 is local host.
C    10.1.6.0/24 is directly connected, GigabitEthernet 0/2
C    10.1.6.0/42 is local host.
O    40.40.40.40/32 [110/1] via 10.1.6.2, 00:40:07, GigabitEthernet 0/2
```

(2) Devices in the same VPN site can ping each other, and devices in different VPN sites cannot ping each other.

CE3 verification result

```
CE3# ping 10.10.10.10 source 30.30.30.30
Sending 5, 100-byte ICMP Echoes to 10.10.10.10, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 0/20/20 ms

CE3#ping 20.20.20.20 source 30.30.30.30
Sending 5, 100-byte ICMP Echoes to 20.20.20.20, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5)
```

CE4 verification result

```
CE4# ping 20.20.20.20 source 40.40.40.40
Sending 5, 100-byte ICMP Echoes to 20.20.20.20, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 0/20/20 ms

CE3#ping 10.10.10.10 source 40.40.40.40
```

```
Sending 5, 100-byte ICMP Echoes to 10.10.10.10, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5)
```

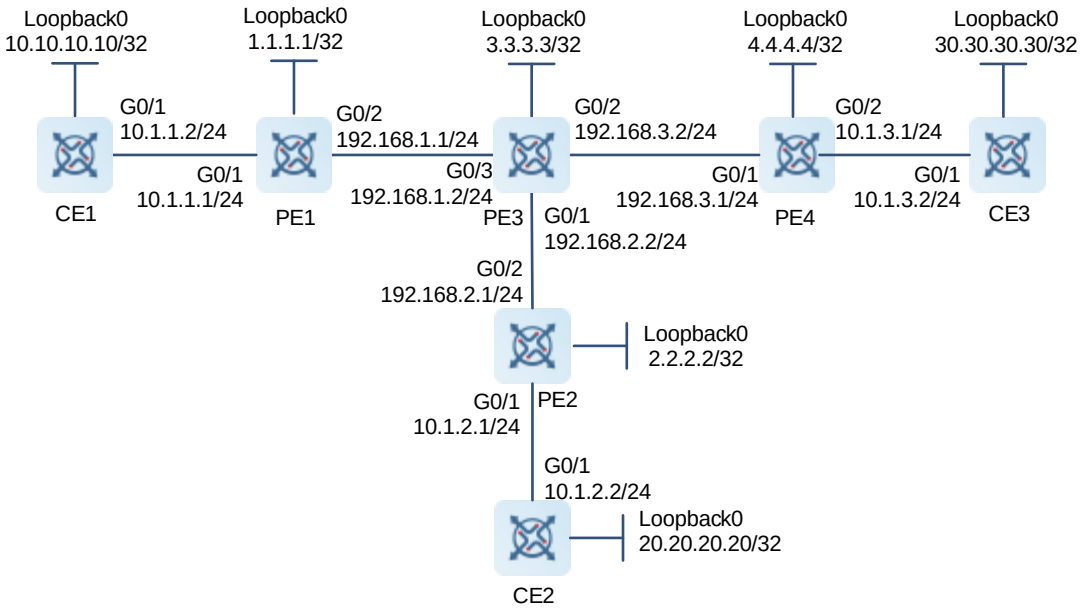
7. Common Errors

The router ID is not 32 bits. As a result, the LDP session or BGP neighbor relationship fails to be established.



1.15.7 Configuring Basic IPv4 MPLS L3VPN Functions (Hierarchal VPNs Based on BGP Routing Policies)

1. Requirements

Use BGP routing policies to change the original MPLS L3VPN network to a hierarchal network. Figure 1-21 shows the topology. PE1 and PE2 are lower-layer PEs and do not save all VPN routes. They save only routes of associated VPN sites and default routes advertised by the upper-layer PE. PE3 and PE4 are upper-layer PEs and need to save all VPN routes, and PE3 is the upper-layer PE of PE1 and PE2.

2. Topology

Figure 1-21 Configuring Basic IPv4 MPLS L3VPN Functions (Hierarchal VPNs Based on BGP Routing Policies)

3. Notes

- Configure the MPLS network: configure interface addresses, OSPF, and the MPLS function on PE1, PE2, PE3, and PE4.

- Configure the MPLS L3VPN: configure a VRF instance on RR PE3, configure MP-IBGP on PE1, PE2, PE3, and PE4, and configure access from CEs to PEs.
- Configure routing policies on PE3 to advertise VPN routes only to PE1 and PE2.
- Configure default VPN routes on PE3 and advertise them to PE1 and PE2 but not to PE4.
- Configure the VRF-associated OSPF instance to advertise default routes on PE1 and PE2.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on all devices are similar. The following shows how to configure OSPF neighbors on PE1.

```
PE1> enable
PE1# configure terminal
PE1(config)# router ospf 1
PE1(config-router)# network 1.1.1.1 0.0.0.0 area 0
PE1(config-router)# network 192.168.1.0 0.0.0.255 area 0
PE1(config-router)# exit
```

(3) Configure basic MPLS functions.

Configurations on PEs are similar. The following shows how to configure basic MPLS functions on PE1.

```
PE1(config)# mpls ip
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# mpls ip
PE1(config-if-GigabitEthernet 0/2)# label-switching
PE1(config-if-GigabitEthernet 0/2)# exit
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following uses PE1 as an example.

```
PE1(config)# ip vrf VPN1
PE1(config-vrf)# rd 100:1
PE1(config-vrf)# route-target both 100:1
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# ip vrf forwarding VPN1
PE1(config-if-GigabitEthernet 0/1)# ip address 10.1.1.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/1)# exit
```

(5) Configure VPN routes.

Configurations on PEs are similar. The following shows how to configure VPN routes on PE1.

```
PE1(config)# router ospf 10 vrf VPN1
PE1(config-router)# network 10.1.1.0 0.0.0.255 area 0
PE1(config-router)# redistribute bgp subnets
PE1(config-router)# default-information originate
```

```
PE1(config-router)# exit
```

(6) Configure BGP neighbors to advertise VPN routes.

Configurations on PE1 and PE2 are similar. The following shows how to configure IBGP neighbors on PE1.

```
PE1(config)# router bgp 100
PE1(config-router)# neighbor 3.3.3.3 remote-as 100
PE1(config-router)# neighbor 3.3.3.3 update-source loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 3.3.3.3 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# address-family ipv4 vrf VPN1
PE1(config-router-af)# redistribute ospf 10
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit
```

5. Verification

(1) After the configuration is completed, run the **show ip route** command to display VPN routes.

PE1 verification result

```
PE1# show ip route vrf VPN1
Routing Table: VPN1

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is 3.3.3.3 to network 0.0.0.0
B*   0.0.0.0/0 [200/0] via 3.3.3.3, 00:00:09
C    10.1.1.0/24 is directly connected, GigabitEthernet 0/1
C    10.1.1.1/32 is local host.
O    10.10.10.10/32 [110/2] via 10.1.1.2, 01:36:19, GigabitEthernet 0/1
```

PE3 verification result

```
PE3# show ip route vrf VPN1
Routing Table: VPN1

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is 0.0.0.0 to network 0.0.0.0
```

```
S*   0.0.0.0/0 is directly connected, Null 0
B    10.1.1.0/24 [200/1] via 1.1.1.1, 01:54:23
B    10.1.2.0/24 [200/1] via 2.2.2.2, 01:54:27
B    10.1.3.0/24 [200/1] via 4.4.4.4, 01:54:29
B    10.10.10.10/32 [200/1] via 1.1.1.1, 01:54:23
B    20.20.20.20/32 [200/2] via 2.2.2.2, 01:54:27
B    30.30.30.30/32 [200/1] via 4.4.4.4, 01:54:29
```

(2) VPN sites can ping each other.

CE1 verification result

```
CE1# ping 20.20.20.20 source 10.10.10.10
Sending 5, 100-byte ICMP Echoes to 20.20.20.20, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/10/20 ms
CE1# ping 30.30.30.30 source 10.10.10.10
Sending 5, 100-byte ICMP Echoes to 30.30.30.30, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/10/20 ms
```

CE2 verification result

```
CE2# ping 10.10.10.10 source 20.20.20.20
Sending 5, 100-byte ICMP Echoes to 10.10.10.10, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/10/20 ms
CE2# ping 30.30.30.30 source 20.20.20.20
Sending 5, 100-byte ICMP Echoes to 30.30.30.30, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/10/20 ms
```

CE3 verification result

```
CE3# ping 10.10.10.10 source 30.30.30.30
Sending 5, 100-byte ICMP Echoes to 10.10.10.10, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/10/20 ms
CE3# ping 20.20.20.20 source 30.30.30.30.
Sending 5, 100-byte ICMP Echoes to 20.20.20.20, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/10/20 ms
```

6. Configuration Files

CE1 configuration file

```
hostname CE1
```

```
!

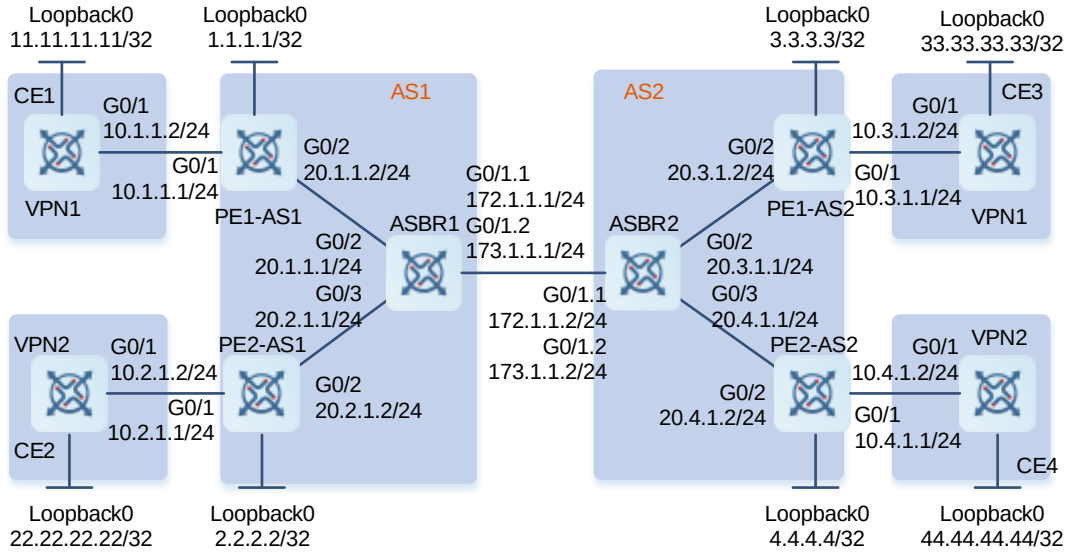
7. Common Errors

The router ID is not 32 bits. As a result, the LDP session or BGP neighbor relationship fails to be established.



1.15.8 Configuring Inter-AS VPN Service Model – Option A

1. Requirements

In networks with few inter-AS VPNs, implement the Option A solution to provide inter-AS BGP/MPLS VPN services. An ASBR establishes a VRF instance for each VPN that needs to traverse domains and binds interfaces for these VRF instances. VRF instances between ASBRs exchange VPN routes by using these interfaces.

2. Topology

Figure 1-22 Inter-AS VPN in VRF-to-VRF Mode

3. Notes

The Option A solution requires an ASBR to configure an interface (usually logical subinterface) for each inter-AS VPN and bind the interface to the inter-AS VPN. The number of bound interfaces should be at least equivalent to the number of inter-AS VPNs and the VPNs need to be configured one after another on the ASBR.

- The LDP router ID must be 32 bits.
- The BGP router ID must be 32 bits.
- An ASBR needs to configure an interface for each VPN and bind the interface to the VPN.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on PE-ASs and ASBRs are similar. The following shows how to configure OSPF neighbors on PE1-AS1.

```
PE1-AS1> enable
PE1-AS1# configure terminal
PE1-AS1(config)# router ospf 1
PE1-AS1(config-router)# router-id 1.1.1.1
PE1-AS1(config-router)# network 1.1.1.1 0.0.0.0 area 0
PE1-AS1(config-router)# network 20.1.1.0 0.0.0.255 area 0
```

(3) Configure basic MPLS functions.

Configurations on PE-ASs and ASBRs are similar. The following shows how to configure basic MPLS functions on PE1-AS1.

```
PE1-AS1(config)# mpls ip
PE1-AS1(config)# mpls router ldp
PE1-AS1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1-AS1(config-mpls-router)# exit
PE1-AS1(config)# interface gigabitethernet 0/2
PE1-AS1(config-if-GigabitEthernet 0/2)# label-switching
PE1-AS1(config-if-GigabitEthernet 0/2)# mpls ip
PE1-AS1(config-if-GigabitEthernet 0/2)# exit
```

(4) Create a VPN and perform association.

Configurations on PEs and ASBRs are similar. The following shows how to create a VPN on PE1.

```
PE1-AS1(config)# ip vrf VPN1
PE1-AS1(config-vrf)# rd 1:101
PE1-AS1(config-vrf)# route-target both 1:100
PE1-AS1(config-vrf)# exit
PE1-AS1(config)# interface gigabitethernet 0/1
PE1-AS1(config-if-GigabitEthernet 0/1)# ip vrf forwarding VPN1
PE1-AS1(config-if-GigabitEthernet 0/1)# ip address 10.1.1.1 255.255.255.0
PE1-AS1(config-if-GigabitEthernet 0/1)# exit
```

Create a VPN on the ASBR. ASBR1 is used as an example.

```
ASBR1(config)# ip vrf VPN1
ASBR1(config-vrf)# rd 301:1
ASBR1(config-vrf)# route-target both 100:1
ASBR1(config-vrf)# exit
ASBR1(config)# ip vrf VPN2
ASBR1(config-vrf)# rd 401:1
ASBR1(config-vrf)# route-target both 200:1
ASBR1(config-vrf)# exit
ASBR1(config)# interface gigabitethernet 0/1.1
ASBR1(config-if-GigabitEthernet 0/1)# encapsulation dot1Q 1
ASBR1(config-if-GigabitEthernet 0/1)# ip vrf forwarding VPN1
ASBR1(config-if-GigabitEthernet 0/1)# ip address 172.1.1.1 255.255.255.0
ASBR1(config-if-GigabitEthernet 0/1)# exit
ASBR1(config)# interface gigabitethernet 0/1.2
```

```
ASBR1(config-if-GigabitEthernet 0/1)# encapsulation dot1Q 2
ASBR1(config-if-GigabitEthernet 0/1)# ip vrf forwarding VPN2
ASBR1(config-if-GigabitEthernet 0/1)# ip address 173.1.1.1 255.255.255.0
ASBR1(config-if-GigabitEthernet 0/1)# exit
```

(5) Configure BGP neighbors to advertise VPN routes.

Configurations on PEs and CEs are similar. The following shows how to establish EBGP neighbor relationship on PE1 and CE1.

PEs establish EBGP neighbor relationship with CEs to advertise VPN routes.

```
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router)# address-family ipv4 vrf VPN1
PE1-AS1(config-router-af)# neighbor 10.1.1.2 remote-as 65001
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# exit
```

CEs establish EBGP neighbor relationship with PEs to advertise VPN routes.

```
CE1> enable
CE1# configure terminal
CE1(config)# router bgp 65001
CE1(config-router)# neighbor 10.1.1.1 remote-as 1
CE1(config-router)# address-family ipv4
CE1(config-router-af)# neighbor 10.1.1.1 activate
CE1(config-router-af)# network 11.11.11.11 mask 255.255.255.255
CE1(config-router-af)# exit-address-family
CE1(config-router)# exit
```

Configurations on PEs and ASBRs are similar. The following shows how to establish EBGP neighbor relationship on PE1 and ASBR1.

PEs establish IBGP neighbor relationship with ASBRs.

```
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router)# neighbor 5.5.5.5 remote-as 1
PE1-AS1(config-router)# neighbor 5.5.5.5 update-source Loopback 0
PE1-AS1(config-router)# address-family ipv4
PE1-AS1(config-router-af)# no neighbor 5.5.5.5 activate
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# address-family vpnv4 unicast
PE1-AS1(config-router-af)# neighbor 5.5.5.5 activate
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# exit
```

ASBRs establish IBGP neighbor relationship with PEs.

```
ASBR1> enable
ASBR1# configure terminal
ASBR1(config)# router bgp 1
ASBR1(config-router)# neighbor 1.1.1.1 remote-as 1
ASBR1(config-router)# neighbor 1.1.1.1 update-source Loopback 0
ASBR1(config-router)# neighbor 2.2.2.2 remote-as 1
```

```
ASBR1(config-router)# neighbor 2.2.2.2 update-source Loopback 0
ASBR1(config-router)# address-family ipv4
ASBR1(config-router-af)# neighbor 1.1.1.1 activate
ASBR1(config-router-af)# neighbor 2.2.2.2 activate
ASBR1(config-router-af)#  exit-address-family
ASBR1(config-router)# address-family vpnv4 unicast
ASBR1(config-router-af)# neighbor 1.1.1.1 activate
ASBR1(config-router-af)# neighbor 2.2.2.2 activate
ASBR1(config-router-af)# exit-address-family
ASBR1(config-router)# exit
```

ASBRs establish EBGP neighbor relationship with each other. The following shows how to establish EBGP neighbor relationship on ASBR1.

```
ASBR1> enable
ASBR1# configure terminal
ASBR1(config)# router bgp 1
ASBR1(config-router)# address-family ipv4 vrf VPN1
ASBR1(config-router-af)# neighbor 172.1.1.2 remote-as 2
ASBR1(config-router-af)# neighbor 172.1.1.2 activate
ASBR1(config-router-af)# exit-address-family
ASBR1(config-router)#address-family ipv4 vrf VPN2
ASBR1(config-router-af)#  neighbor 173.1.1.2 remote-as 2
ASBR1(config-router-af)#  neighbor 173.1.1.2 activate
ASBR1(config-router-af)# exit-address-family
ASBR1(config-router)# exit
```

5. Verification

Verify that CE1 can ping CE3 but cannot ping CE2 or CE4.

```
CE1# ping 33.33.33.33 source 11.11.11.11
Sending 5, 100-byte ICMP Echoes to 33.33.33.33, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 10/10/10 ms

CE1#ping 22.22.22.22 source 11.11.11.11
Sending 5, 100-byte ICMP Echoes to 22.22.22.22, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5)

CE1#ping 44.44.44.44 source 11.11.11.11
Sending 5, 100-byte ICMP Echoes to 44.44.44.44, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5)
```

6. Configuration Files

CE1 configuration file

```
hostname CE1
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.1.1.2 255.255.255.0
!
interface Loopback 0
 ip address 11.11.11.11 255.255.255.255
!
router bgp 65001
 neighbor 10.1.1.1 remote-as 1
 !
 address-family ipv4
  network 11.11.11.11 mask 255.255.255.255

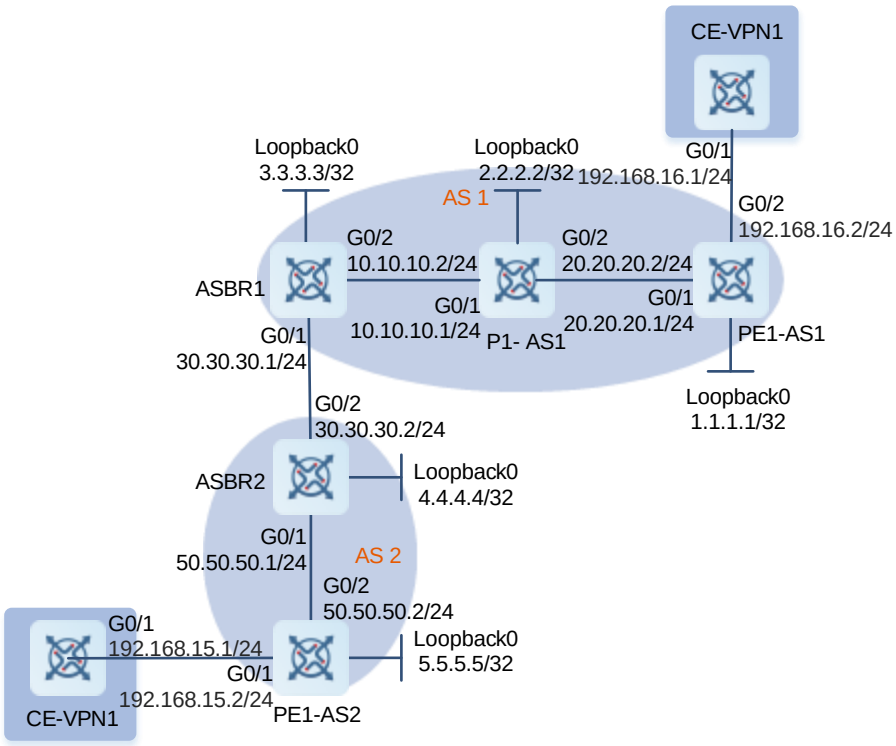
7. Common Errors

The **ip vrf forwarding** command is not used to bind a VRF instance for an interface. As a result, no routing protocol is run between a PE and a CE. When the **show ip route vrf** command is run on the PE, no CE route is found.



1.15.9 Configuring Inter-AS VPN Service Model – Option B (Next Hop Unchanged)

1. Requirements

A VPN has sites in two different ASs and requires the VPN sites in these two ASs to access each other.

2. Topology

Figure 1-23 Configuring Inter-AS VPN Service Model – Option B (Next Hop Unchanged)

3. Notes

- On PE1-AS1, configure a loopback interface, create VRF instance VPN1, define RD and RT values, and associate the VRF instance with the corresponding interface. Configure the BGP, establish an MP-IBGP session with ASBR1, and configure a CE neighbor using EBGP. Configure the backbone network MPLS

signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.

- On PE1-AS2, configure a loopback interface, create VRF instance VPN1, define RD and RT values, and associate the VRF instance with the corresponding interface. Configure the BGP, establish an MP-IBGP session with ASBR2, and configure a CE neighbor using EBGP. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On P1-AS1, configure a loopback interface, configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On ASBR1, configure a loopback interface, configure BGP, disable the RT filtering function of BGP, and establish neighbor relationship with P1-AS1 and ASBR2. Configure MPLS signaling and enable MPLS on the public network interface, run OSPF on the backbone network to transmit routing information, and redistribute routes of directly-connected network segments. Configure an IP address for the interface used to connect to ASBR2 and enable labeled packet forwarding on the interface.
- On ASBR2, configure a loopback interface, configure the BGP, disable the RT filtering function of BGP, and establish neighbor relationship with PE1-AS2 and ASBR1. Configure MPLS signaling and enable MPLS on the public network interface, run OSPF on the backbone network to transmit routing information, and redistribute routes of directly-connected network segments. Configure an IP address for the interface used to connect to ASBR1 and enable labeled packet forwarding on the interface.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on PEs, Ps, and ASBRs are similar. The following shows how to configure OSPF neighbors on PE1-AS1.

```
PE1-AS1> enable
PE1-AS1# configure terminal
PE1-AS1(config)# router ospf 10
PE1-AS1(config-router)# network 20.20.20.0 0.0.0.255 area 0
PE1-AS1(config-router)# network 1.1.1.1 0.0.0.0 area 0
PE1-AS1(config-router)# end
```

(3) Configure basic MPLS functions.

Configurations on PEs, Ps, and ASBRs are similar. The following shows how to configure basic MPLS functions on PE1-AS1.

```
PE1-AS1(config)# mpls ip
PE1-AS1(config)# mpls router ldp
PE1-AS1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1-AS1(config-mpls-router)# exit
PE1-AS1(config)# interface gigabitethernet 0/1
PE1-AS1(config-if-GigabitEthernet 0/1)# label-switching
PE1-AS1(config-if-GigabitEthernet 0/1)# mpls ip
PE1-AS1(config-if-GigabitEthernet 0/1)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following shows how to create a VPN on PE1-AS1.

```
PE1-AS1(config)# ip vrf VPN1
PE1-AS1(config-vrf)# rd 1:100
PE1-AS1(config-vrf)# route-target both 1:100
PE1-AS1(config-vrf)# exit
PE1-AS1(config)# interface gigabitethernet 0/2
PE1-AS1(config-if-GigabitEthernet 0/2)# ip vrf forwarding VPN1
PE1-AS1(config-if-GigabitEthernet 0/2)# ip address 192.168.16.2 255.255.255.0
PE1-AS1(config-if-GigabitEthernet 0/2)# exit
```

(5) Configure BGP neighbors to advertise VPN routes.

PE1-AS1 establishes EBGP neighbor relationship with CE1-VPN1.

```
PE1-AS1> enable
PE1-AS1# configure terminal
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router)# address-family ipv4 vrf VPN1
PE1-AS1(config-router-af)# neighbor 192.168.16.1 remote-as 65001
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# exit
```

CE1-VPN1 establishes EBGP neighbor relationship with PE1-AS1 to advertise VPN routes.

```
CE1-VPN1> enable
CE1-VPN1# configure terminal
CE1-VPN1(config)# router bgp 65001
CE1-VPN1(config-router)# neighbor 192.168.16.2 remote-as 1
CE1-VPN1(config-router)# address-family ipv4
CE1-VPN1(config-router-af)# neighbor 192.168.16.2 activate
CE1-VPN1(config-router-af)# network 10.10.10.10 mask 255.255.255.255
CE1-VPN1(config-router-af)# exit-address-family
CE1-VPN1(config-router)# exit
```

PE-ASs establish IBGP neighbor relationship with ASBRs.

```
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router)# neighbor 3.3.3.3 remote-as 1
PE1-AS1(config-router)# neighbor 3.3.3.3 update-source loopback 0
PE1-AS1(config-router)# address-family vpnv4
PE1-AS1(config-router-af)# neighbor 3.3.3.3 activate
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)#
```

ASBRs establish IBGP neighbor relationship with PE-ASs.

```
ASBR1> enable
ASBR1# configure terminal
ASBR1(config)# router bgp 1
ASBR1(config-router)# neighbor 1.1.1.1 remote-as 1
ASBR1(config-router)# neighbor 1.1.1.1 update-source loopback 0
ASBR1(config-router)# no bgp default route-target filter
ASBR1(config-router)# address-family vpnv4
ASBR1(config-router-af)# neighbor 1.1.1.1 activate
```

```
ASBR1(config-router-af)# exit-address-family
ASBR1(config-router)# exit
```

ASBRs establish EBGP neighbor relationship with PE-ASs. The following example configures EBGP neighbor relationship for ASBR1.

```
ASBR1(config)# router bgp 1
ASBR1(config-router)# neighbor 30.30.30.2 remote-as 2
ASBR1(config-router)# address-family vpnv4 unicast
ASBR1(config-router-af)# neighbor 30.30.30.2 activate
ASBR1(config-router-af)# exit-address-family
ASBR1(config-router)# exit
```

Configure egress proxy for host routes on ASBR. The following example configures egress proxy for host routes on ASBR 1.

```
ASBR1(config)# mpls router ldp
ASBR1(config-mpls-router)# egress-proxy for host
```

5. Verification

(1) After the configuration is complete, verify that devices at the same VPN site can communicate with each other, and devices in different VPNs cannot communicate with each other.

PE1-AS1 verification result

```
PE1-AS1# show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
C    1.1.1.1/32 is local host.
O    2.2.2.2/32 [110/1] via 20.20.20.2, 02:33:49, GigabitEthernet 0/1
O    3.3.3.3/32 [110/2] via 20.20.20.2, 02:31:30, GigabitEthernet 0/1
O    10.10.10.0/24 [110/2] via 20.20.20.2, 02:32:15, GigabitEthernet 0/1
C    20.20.20.0/24 is directly connected, GigabitEthernet 0/0
C    20.20.20.1/32 is local host.
O E2 30.30.30.0/24 [110/20] via 20.20.20.2, 00:39:24, GigabitEthernet 0/1
O E2 30.30.30.2/32 [110/20] via 20.20.20.2, 00:39:21, GigabitEthernet 0/1

PE1-AS1# ping 3.3.3.3
Sending 5, 100-byte ICMP Echoes to 3.3.3.3, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms

PE1-AS1# ping 4.4.4.4
```

```
Sending 5, 100-byte ICMP Echoes to 4.4.4.4, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5)

PE1-AS1# ping 5.5.5.5
Sending 5, 100-byte ICMP Echoes to 5.5.5.5, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5)
```

PE1-AS2 verification result

```
PE1-AS2# show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
O    4.4.4.4/32 [110/1] via 50.50.50.1, 00:40:56, GigabitEthernet 0/1

!
```

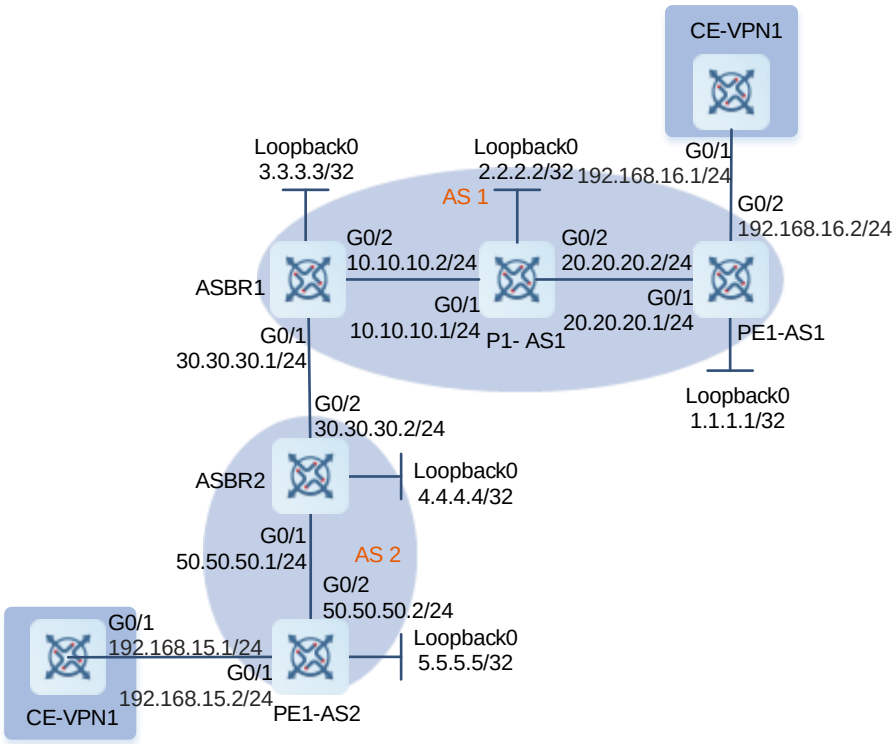
7. Common Errors

- An LDP session fails to be established.
- The RT filtering function of BGP is enabled.
- The **redistribute connecter subnets** command is not used to redistribute routes of the directly-connected subnet to OSPF. As a result, the CE and VPN1 site cannot ping each other.



1.15.10 Configuring Inter-AS VPN Service Model – Option B (Next Hop Changed)

1. Requirements

A VPN has sites in two different ASs and requires the VPN sites in these two ASs to access each other.

2. Topology

Figure 1-24 Configuring Inter-AS VPN Service Model – Option B (Next Hop Changed)

3. Notes

- On PE1-AS1, configure a loopback interface, create VRF instance VPN1, define RD and RT values, and associate the VRF instance with the corresponding interface. Configure the BGP, establish an MP-IBGP session with ASBR1, and configure a CE neighbor using EBGP. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On PE1-AS2, configure a loopback interface, create VRF instance VPN1, define RD and RT values, and associate the VRF instance with the corresponding interface. Configure the BGP, establish an MP-IBGP session with ASBR2, and configure a CE neighbor using EBGP. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On P1-AS1, configure a loopback interface, configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On ASBR1, configure a loopback interface, configure the BGP, disable the RT filtering function of BGP, and establish neighbor relationship with PE1-AS1 and ASBR2. Configure MPLS signaling and enable MPLS on the public network interface, run OSPF on the backbone network to transmit routing information, and redistribute routes of directly-connected network segments. Configure an IP address for the interface used to connect to ASBR2 and enable labeled packet forwarding on the interface. Configure the ASBR to modify the next hop as its own address when sending VPN routes to an IBGP neighbor.
- On ASBR2, configure a loopback interface, configure the BGP, disable the RT filtering function of BGP, and establish neighbor relationship with PE1-AS2 and ASBR1. Configure MPLS signaling and enable MPLS on the public network interface, run OSPF on the backbone network to transmit routing information, and redistribute routes of directly-connected network segments. Configure an IP address for the interface used to connect to ASBR2 and enable labeled packet forwarding on the interface. Configure the ASBR to modify the next hop as its own address when sending VPN routes to an IBGP neighbor.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on PEs, Ps, and ASBRs are similar. The following shows how to configure OSPF neighbors on PE1-AS1.

```
PE1-AS1> enable
PE1-AS1# configure terminal
PE1-AS1(config)# router ospf 10
PE1-AS1(config-router)# network 20.20.20.0 0.0.0.255 area 0
PE1-AS1(config-router)# network 1.1.1.1 0.0.0.0 area 0
PE1-AS1(config-router)# end
```

(3) Configure basic MPLS functions.

Configurations on PEs, Ps, and ASBRs are similar. The following shows how to configure basic MPLS functions on PE1-AS1.

```
PE1-AS1(config)# mpls ip
PE1-AS1(config)# mpls router ldp
PE1-AS1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1-AS1(config-mpls-router)# exit
```

```
PE1-AS1(config)# interface gigabitethernet 0/1
PE1-AS1(config-if-GigabitEthernet 0/1)# ip address 20.20.20.1 255.255.255.0
PE1-AS1(config-if-GigabitEthernet 0/1)# label-switching
PE1-AS1(config-if-GigabitEthernet 0/1)# mpls ip
PE1-AS1(config-if-GigabitEthernet 0/1)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following shows how to create a VPN on PE1-AS1.

```
PE1-AS1(config)# ip vrf VPN1
PE1-AS1(config-vrf)# rd 1:100
PE1-AS1(config-vrf)# route-target both 1:100
PE1-AS1(config-vrf)# exit
PE1-AS1(config)# interface gigabitethernet 0/2
PE1-AS1(config-if-GigabitEthernet 0/2)# ip vrf forwarding VPN1
PE1-AS1(config-if-GigabitEthernet 0/2)# ip address 192.168.16.2 255.255.255.0
PE1-AS1(config-if-GigabitEthernet 0/2)# exit
```

(5) Configure BGP neighbors to advertise VPN routes.

PE1-AS1 establishes EBGP neighbor relationship with CE1-VPN1.

```
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router-af)# address-family ipv4 vrf VPN1
PE1-AS1(config-router-af)# neighbor 192.168.16.1 remote-as 65001
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# exit
```

CE1-VPN1 establishes EBGP neighbor relationship with PE1-AS1 to advertise VPN routes.

```
CE1-VPN1> enable
CE1-VPN1# configure terminal
CE1-VPN1(config)# router bgp 65001
CE1-VPN1(config-router)# neighbor 192.168.16.2 remote-as 1
CE1-VPN1(config-router)# address-family ipv4
CE1-VPN1(config-router-af)# neighbor 192.168.16.2 activate
CE1-VPN1(config-router-af)# network 10.10.10.10 mask 255.255.255.255
CE1-VPN1(config-router-af)# exit-address-family
CE1-VPN1(config-router)# exit
```

PE_ASs establish IBGP neighbor relationship with ASBRs.

```
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router)# neighbor 3.3.3.3 remote-as 1
PE1-AS1(config-router)# neighbor 3.3.3.3 update-source loopback 0
PE1-AS1(config-router)# address-family vpnv4
PE1-AS1(config-router-af)# neighbor 3.3.3.3 activate
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# exit
```

ASBRs establish IBGP neighbor relationship with PE-ASs.

```
ASBR1> enable
ASBR1# configure terminal
```

```
ASBR1(config)# router bgp 1
ASBR1(config-router)# neighbor 1.1.1.1 remote-as 1
ASBR1(config-router)# neighbor 1.1.1.1 update-source loopback 0
ASBR1(config-router)# no bgp default route-target filter
ASBR1(config-router)# address-family vpnv4
ASBR1(config-router-af)# neighbor 1.1.1.1 activate
ASBR1(config-router-af)# neighbor 1.1.1.1 next-hop-self
ASBR1(config-router-af)# exit-address-family
ASBR1(config-router)# exit
```

ASBRs establish EBGP neighbor relationship with each other. The following shows how to establish EBGP neighbor relationship on ASBR1.

```
ASBR1(config)# router bgp 1
ASBR1(config-router)# neighbor 30.30.30.2 remote-as 2
ASBR1(config-router)# address-family vpnv4 unicast
ASBR1(config-router-af)# neighbor 30.30.30.2 activate
ASBR1(config-router-af)# exit-address-family
ASBR1(config-router)# exit
```

Configure egress proxy for host routes on ASBR. The following example configures egress proxy for host routes on ASBR 1.

```
ASBR1(config)# mpls router ldp
ASBR1(config-mpls-router)# egress-proxy for host
```

5. Verification

(1) After the configuration is completed, verify that devices at the same VPN site can communicate with each other and devices at different VPN sites cannot communicate with each other.

PE1-AS1 verification result

```
PE1-AS1# show ip route

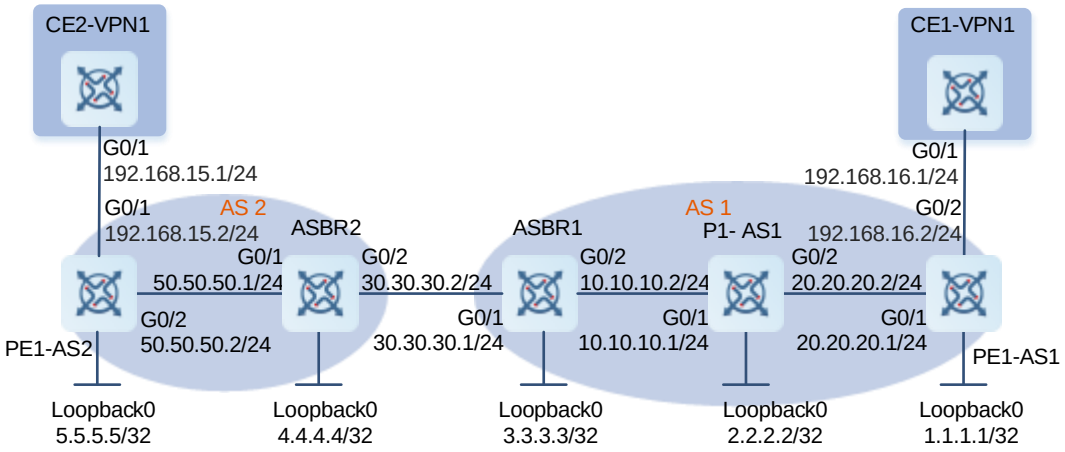
7. Common Errors

- An LDP session fails to be established.
- The RT filtering function of BGP is enabled.
- When distributing VPN routes to IBGP neighbors, an ASBR does not configure itself as the next hop. As a result, the CE and VPN1 cannot ping each other.



1.15.11 Configuring Inter-AS VPN Service Model – Option C (Enabling Label Switching for IPv4 Routes with EBGP Neighbors)

1. Requirements

A VPN has sites in two different ASs and requires the VPN sites in these two ASs to access each other.

2. Topology

Figure 1-25 Configuring Inter-AS VPN Service Model – Option C (Enabling Label Switching for IPv4 Routes with EBGP Neighbors)

3. Notes

- On PE1-AS1, configure a loopback interface, create VRF instance VPN1, define RD and RT values, and associate the VRF instance with the corresponding interface. Configure a multi-hop MP-EBGP session, disable IPv4 route exchange in the multi-hop EBGP session, and configure CE neighbors using EBGP. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On PE1-AS2, configure a loopback interface, create VRF instance VPN1, define RD and RT values, and associate the VRF instance with the corresponding interface. Configure a multi-hop MP-EBGP session, disable IPv4 route exchange in the multi-hop EBGP session, and configure CE neighbors using EBGP. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On P1-AS1, configure a loopback interface, configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On ASBR1, configure a loopback interface and configure an ACL rule to distribute or set labels only for routes that meet specific conditions. Establish an EBGP session with ASBR2 and configure a route-map rule to configure labels for PE routes that meet conditions, and statically configure PE routes in the local AS. The route-map rule is optional, and application of a route-map rule enables the BGP to distribute labels only to specific routes. Configure MPLS and use an ACL rule to distribute labels only to specific BGP routes. The ACL rule is optional, and application of an ACL rule can reduce unnecessary route entries. Configure a backbone network routing protocol and redistribute only BGP routes that meet the route-map rule. The route-map rule is optional, and application of a route-map rule can reduce unnecessary route entries. Configure an IP address for the interface used to connect to ASBR2 and enable labeled packet forwarding on the interface.
- On ASBR2, configure a loopback interface and configure an ACL rule to distribute or set labels only for routes that meet specific conditions. Establish an EBGP session with ASBR1 and configure a route-map rule to configure labels for PE routes that meet conditions, and statically configure PE routes in the local AS. The route-map rule is optional, and application of a route-map rule enables the BGP to distribute labels only to specific routes. Configure MPLS and use an ACL rule to distribute labels only to specific BGP routes. The ACL rule is optional, and application of an ACL rule can reduce unnecessary route entries. Configure a backbone network routing protocol and redistribute only BGP routes that meet the route-map rule. The route-map rule is optional, and application of a route-map rule can reduce unnecessary route entries. Configure an IP address for the interface used to connect to ASBR1 and enable labeled packet forwarding on the interface.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on PEs, Ps, and ASBRs are similar. The following shows how to configure OSPF neighbors on PE1-AS1.

```
PE1-AS1(config)# router ospf 10
PE1-AS1(config-router)# network 20.20.20.0 0.0.0.255 area 0
PE1-AS1(config-router)# network 1.1.1.1 0.0.0.0 area 0
PE1-AS1(config-router)# exit
```

(3) Configure basic MPLS functions.

Configurations on PEs, Ps, and ASBRs are similar. The following shows how to configure basic MPLS functions on PE1-AS1.

```
PE1-AS1(config)# mpls ip
PE1-AS1(config)# mpls router ldp
PE1-AS1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1-AS1(config-mpls-router)# exit
PE1-AS1(config)# interface gigabitethernet 0/1
PE1-AS1(config-if-GigabitEthernet 0/1)# ip address 20.20.20.1 255.255.255.0
PE1-AS1(config-if-GigabitEthernet 0/1)# label-switching
PE1-AS1(config-if-GigabitEthernet 0/1)# mpls ip
PE1-AS1(config-if-GigabitEthernet 0/1)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following shows how to create a VPN on PE1-AS1.

```
PE1-AS1(config)# ip vrf VPN1
PE1-AS1(config-vrf)# rd 1:100
PE1-AS1(config-vrf)# route-target both 1:100
PE1-AS1(config-vrf)# exit
PE1-AS1(config)# interface gigabitethernet 0/2
PE1-AS1(config-if-GigabitEthernet 0/2)# ip vrf forwarding VPN1
PE1-AS1(config-if-GigabitEthernet 0/2)# ip address 192.168.16.2 255.255.255.0
PE1-AS1(config-if-GigabitEthernet 0/2)# exit
```

(5) Configure BGP neighbors to advertise VPN routes.

PE1-AS1 establishes EBGP neighbor relationship with CE1-VPN1.

```
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router)# address-family ipv4 vrf VPN1
PE1-AS1(config-router-af)# neighbor 192.168.16.1 remote-as 65001
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# exit
```

CE1-VPN1 establishes EBGP neighbor relationship with PE1-AS1 to advertise VPN routes.

```
CE1-VPN1(config)# router bgp 65001
CE1-VPN1(config-router)# neighbor 192.168.16.2 remote-as 1
CE1-VPN1(config-router)# address-family ipv4
CE1-VPN1(config-router-af)# neighbor 192.168.16.2 activate
CE1-VPN1(config-router-af)# network 10.10.10.10 mask 255.255.255.255
CE1-VPN1(config-router-af)# exit-address-family
CE1-VPN1(config-router)# exit
```

PE-ASs establish EBGP neighbor relationship with each other. The following shows how to establish EBGP neighbor relationship on PE1-AS1.

```
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router)# neighbor 5.5.5.5 remote-as 2
PE1-AS1(config-router)# neighbor 5.5.5.5 update-source loopback 0
PE1-AS1(config-router)# neighbor 5.5.5.5 ebgp-multihop
```

```
PE1-AS1(config-router)# address-family ipv4
PE1-AS1(config-router-af)# no neighbor 5.5.5.5 activate
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# address-family vpnv4 unicast
PE1-AS1(config-router-af)# neighbor 5.5.5.5 activate
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# exit
```

ASBR1 establishes EBGP neighbor relationship with ASBR2 and redistributes BGP routes. The following shows how to establish EBGP neighbor relationship between ASBR1 and ASBR2.

```
ASBR1(config)# ip access-list extended 101
ASBR1(config-ext-nacl)# permit ip host 1.1.1.1 any
ASBR1(config-ext-nacl)# exit
ASBR1(config)# ip access-list extended 102
ASBR1(config-ext-nacl)# permit ip host 5.5.5.5 any
ASBR1(config-ext-nacl)# exit
ASBR1(config)# route-map set-mpls permit
ASBR1(config-route-map)# match ip address 101
ASBR1(config-route-map)# set mpls-label
ASBR1(config-route-map)# exit
ASBR1(config)# route-map external-pe-route permit
ASBR1(config-route-map)# match ip address 102
ASBR1(config-route-map)# exit
ASBR1(config)# router bgp 1
ASBR1(config-router)# neighbor 30.30.30.2 remote-as 2
ASBR1(config-router)# address-family ipv4
ASBR1(config-router-af)# neighbor 30.30.30.2 activate
ASBR1(config-router-af)# neighbor 30.30.30.2 send-label
ASBR1(config-router-af)# neighbor 30.30.30.2 route-map set-mpls out
ASBR1(config-router-af)# exit-address-family
ASBR1(config-router)# exit
ASBR1(config)# router ospf 10
ASBR1(config-router)# redistribute bgp route-map external-pe-route subnets
ASBR1(config-router)# network 3.3.3.3 0.0.0.0 area 0
ASBR1(config-router)# network 10.10.10.0 0.0.0.255 area 0
ASBR1(config-router)# exit
```

5. Verification

(1) After the configuration is completed, verify that devices at different sites of a VPN can communicate with each other.

PE1-AS1 verification result

```
PE1-AS1# show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
        O - OSPF, IA - OSPF inter area
        N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
```

```
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set

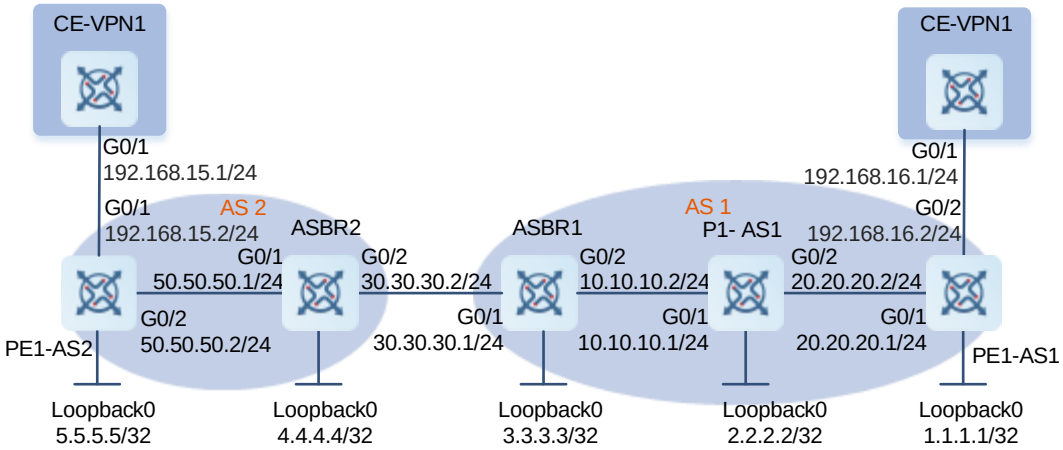
7. Common Errors

- When a multi-hop MP-EBGP session is configured, IPv4 route exchange is not disabled for the multi-hop EBGP session.
- ASBRs are not configured to use LDP to distribute labels to BGP routes. As a result, VPN sites cannot interconnect with each other.



1.15.12 Configuring Inter-AS Service Model – Option C (Enabling Label Switching for IPv4 Routes with EBGP and IBGP Neighbors)

1. Requirements

A VPN has sites in two different ASs and requires the VPN sites in these two ASs to access each other.

2. Topology

Figure 1-26 Configuring Inter-AS Service Model – Option C (Enabling Label Switching for IPv4 Routes with EBGP and IBGP Neighbors)

3. Notes

- On PE1-AS1, configure a loopback interface, create VRF instance VPN1, define RD and RT values, and associate the VRF instance with the corresponding interface. Establish a multi-hop MP-EBGP session and disable IPv4 route exchange for the multi-hop EBGP session. Establish an IBGP session with ASBR1, enable label switching for IPv4 routes, and configure CE neighbors using EBGP. Configure the backbone

network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.

- On PE1-AS2, configure a loopback interface, create VRF instance VPN1, define RD and RT values, and associate the VRF instance with the corresponding interface. Establish a multi-hop MP-EBGP session and disable IPv4 route exchange for the multi-hop MP-EBGP session. Establish an IBGP session with ASBR2, enable label switching for IPv4 routes, and configure CE neighbors using EBGP. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On P1-AS1, configure a loopback interface, configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- On ASBR1, configure a loopback interface and configure an ACL rule to distribute or set labels only for routes that meet specific conditions. Establish an EBGP session with ASBR2 and configure a route-map rule to configure labels for PE routes that meet conditions, and statically configure PE routes in the local AS. The route-map rule is optional, and application of a route-map rule enables the BGP to distribute labels only to specific routes. Configure MPLS signaling, enable MPLS on an interface, and run OSPF on the backbone network to transmit routing information. Configure an IP address for the interface used to connect to ASBR2 and enable labeled packet forwarding on the interface.
- On ASBR2, configure a loopback interface and configure an ACL rule to distribute or set labels only for routes that meet specific conditions. Establish an EBGP session with ASBR1, configure a route-map rule to configure labels for PE routes that meet conditions, and statically configure PE routes in the local AS. The route-map rule is optional, and application of a route-map rule to enable the BGP to distribute labels only to specific routes. Configure MPLS signaling, enable MPLS on an interface, and run OSPF on the backbone network to transmit routing information. Configure an IP address for the interface used to connect to ASBR1 and enable labeled packet forwarding on the interface.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on PEs, Ps, and ASBRs are similar. The following shows how to configure OSPF neighbors on PE1-AS1.

```
PE1-AS1> enable
PE1-AS1# configure terminal
PE1-AS1(config)# router ospf 10
PE1-AS1(config-router)# network 20.20.20.0 0.0.0.255 area 0
PE1-AS1(config-router)# network 1.1.1.1 0.0.0.0 area 0
PE1-AS1(config-router)# end
```

(3) Configure basic MPLS functions.

Configurations on PEs, Ps, and ASBRs are similar. The following shows how to configure basic MPLS functions on PE1-AS1.

```
PE1-AS1(config)# mpls ip
PE1-AS1(config)# mpls router ldp
PE1-AS1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1-AS1(config-mpls-router)# exit
```

```
PE1-AS1(config)# interface gigabitethernet 0/1
PE1-AS1(config-if-GigabitEthernet 0/1)# ip address 20.20.20.1 255.255.255.0
PE1-AS1(config-if-GigabitEthernet 0/1)# label-switching
PE1-AS1(config-if-GigabitEthernet 0/1)# mpls ip
PE1-AS1(config-if-GigabitEthernet 0/1)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following shows how to create a VPN on PE1-AS1.

```
PE1-AS1(config)# ip vrf VPN1
PE1-AS1(config-vrf)# rd 1:100
PE1-AS1(config-vrf)# route-target both 1:100
PE1-AS1(config-vrf)# exit
PE1-AS1(config)# interface gigabitethernet 0/2
PE1-AS1(config-if-GigabitEthernet 0/2)# ip vrf forwarding VPN1
PE1-AS1(config-if-GigabitEthernet 0/2)# ip address 192.168.16.2 255.255.255.0
PE1-AS1(config-if-GigabitEthernet 0/2)# exit
```

(5) Configure BGP neighbors to advertise VPN routes.

PE1-AS1 establishes EBGP neighbor relationship with CE1-VPN1.

```
PE1-AS1(config)# router bgp 1
PE1-AS1(config)# address-family ipv4 vrf VPN1
PE1-AS1(config-router-af)# neighbor 192.168.16.1 remote-as 65001
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router-af)# exit
```

CE1-VPN1 establishes EBGP neighbor relationship with PE1-AS1 to advertise VPN routes.

```
CE1-VPN1(config)# router bgp 65001
CE1-VPN1(config-router)# neighbor 192.168.16.2 remote-as 1
CE1-VPN1(config-router)# address-family ipv4
CE1-VPN1(config-router-af)# neighbor 192.168.16.2 activate
CE1-VPN1(config-router-af)# network 10.10.10.10 mask 255.255.255.255
CE1-VPN1(config-router-af)# exit-address-family
CE1-VPN1(config-router)# exit
```

PE1-AS1 establishes IBGP neighbor relationship with ASBR1.

```
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router)# neighbor 3.3.3.3 remote-as 1
PE1-AS1(config-router)# neighbor 3.3.3.3 update-source loopback 0
PE1-AS1(config-router)# address-family ipv4
PE1-AS1(config-router-af)# neighbor 3.3.3.3 activate
PE1-AS1(config-router-af)# neighbor 3.3.3.3 send-label
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router-af)# exit
```

ASBR1 establishes IBGP neighbor relationship with PE1-AS1.

```
ASBR1(config)# router bgp 1
ASBR1(config-router)# neighbor 1.1.1.1 remote-as 1
ASBR1(config-router)# neighbor 1.1.1.1 update-source loopback 0
```

```
ASBR1(config-router)# address-family ipv4
ASBR1(config-router-af)# neighbor 1.1.1.1 send-label
ASBR1(config-router-af)# neighbor 1.1.1.1 route-map external-mpls-route out
ASBR1(config-router-af)# network 1.1.1.1 mask 255.255.255.255
ASBR1(config-router-af)# exit-address-family
ASBR1(config-router)# exit
```

PE-ASs establish EBGP neighbor relationship with each other.

```
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router)# neighbor 5.5.5.5 remote-as 2
PE1-AS1(config-router)# neighbor 5.5.5.5 update-source loopback 0
PE1-AS1(config-router)# neighbor 5.5.5.5 ebgp-multihop
PE1-AS1(config-router)# address-family ipv4
PE1-AS1(config-router-af)# no neighbor 5.5.5.5 activate
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# address-family vpnv4 unicast
PE1-AS1(config-router-af)# neighbor 5.5.5.5 activate
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# exit
```

5. Verification

(1) After the configuration is completed, verify that devices at different VPN sites can communicate with each other.

PE1-AS1 verification result

```
PE1-AS1# show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
C    1.1.1.1/32 is local host.
O    2.2.2.2/32 [110/1] via 20.20.20.2, 01:04:47, GigabitEthernet 0/1
O    3.3.3.3/32 [110/2] via 20.20.20.2, 01:03:26, GigabitEthernet 0/1
O E2 5.5.5.5/32 [110/1] via 20.20.20.2, 00:50:44, GigabitEthernet 0/1

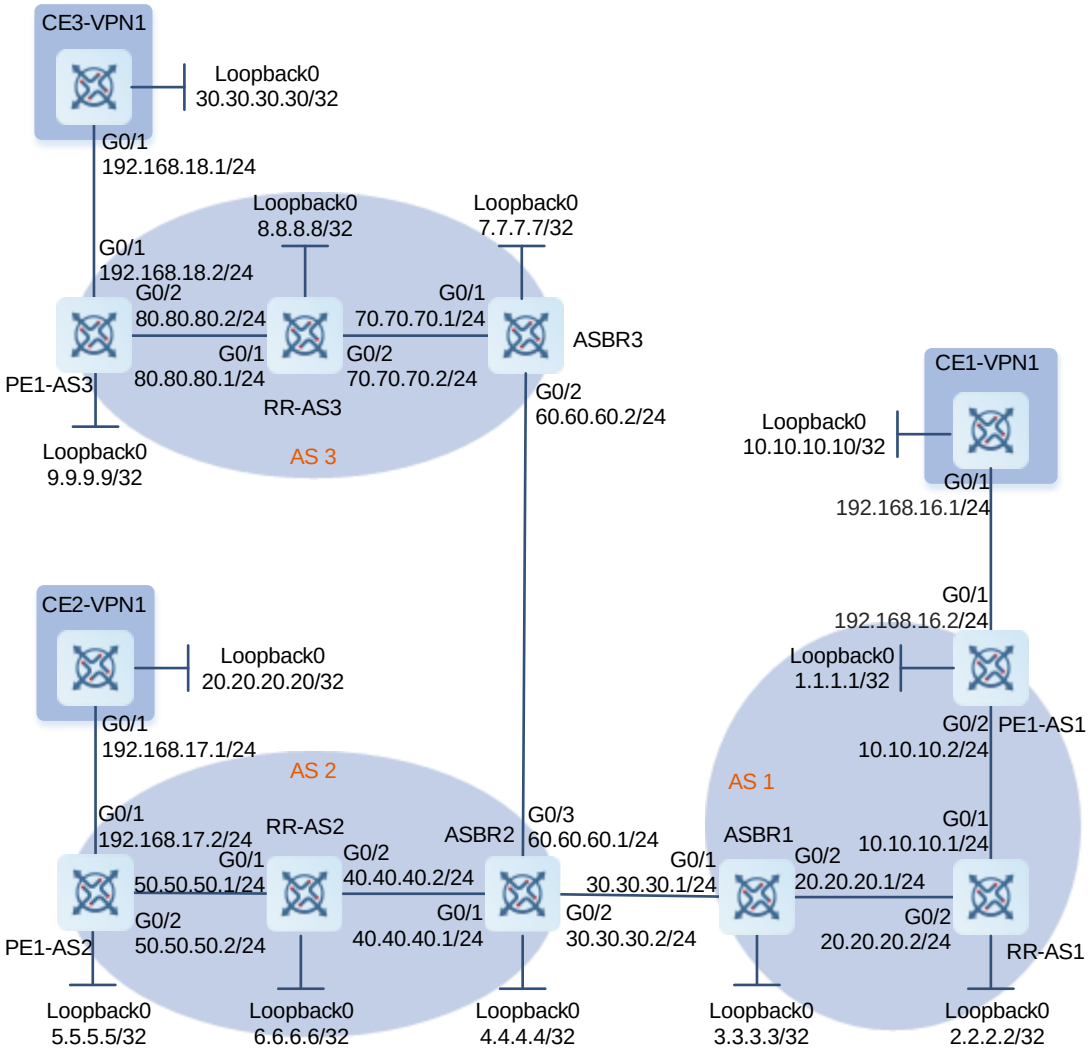
7. Common Errors

- When a multi-hop MP-EBGP session is configured, IPv4 route exchange is not disabled for the multi-hop EBGP session.
- Label switching for IPv4 routes is not configured between IBGP neighbors. As a result, VPN sites cannot interconnect with each other.



1.15.13 Configuring Inter-AS VPN Service Model – Option C (RR Deployment)

1. Requirements

Two Option C implementation solutions are provided. If sites of a VPN are deployed in different ASs, the common Option C implementation solution is adopted. As shown in Figure 1-27, sites of a VPN are deployed in three different ASs. To ensure reachability of these VPN sites, BGP connections need to be established between inter-AS PEs. Each time a new VPN site is added, the new VPN site needs to establish BGP connections with other VPN sites, which restricts the application of the common Option C solution. To solve the preceding extensibility problem, you can deploy an RR in each AS and establish multi-hop MP-EBGP connections between RRs to exchange inter-AS VPN routes. In addition, establish MP-IBGP sessions between PEs and RRs in the same AS.

2. Topology

Figure 1-27 Configuring Inter-AS VPN Service Model – Option C (RR Deployment)

3. Notes

- On PE1-AS1, configure a loopback interface, create VRF instance VPN1, define RD and RT values, and associate the VRF instance with the corresponding interface. Establish an MP-IBGP session with the RR, enable label switching for IPv4 routes, and configure CE neighbors using EBGP. Configurations on PE1-AS2 and PE1-AS3 are similar to that on PE1-AS1.
- On RR-AS1, configure a loopback interface, establish an MP-IBGP session with PE1-AS1, specify PE1-AS1 as an RR client, and enable label switching for IPv4 routes. Establish MP-EBGP sessions with other RRs and do not change the next hop of VPN routes exchanged with the RRs, disable IPv4 route exchange with the RRs, and establish an IBGP session with the ASBR1. Enable label switching for IPv4 routes, configure MPLS, and run OSPF in the backbone network to transmit routing information. Configurations on RR-AS2 and RR-AS3 are similar to that on RR-AS1.
- On ASBR1, configure a loopback interface and configure an ACL rule and a route-map rule. Establish EBGP sessions with ASBR2, enable label switching for IPv4 routes, and configure a route-map rule to configure

labels for PE routes that meet conditions. The route-map rule is optional, and application of a route-map rule enables the BGP to distribute labels only to specific routes. Establish IBGP sessions with RRs, enable label switching for IPv4 routes, configure a route-map rule to configure labels for inter-AS PE routes that meet conditions. Statically configure PE routes in the local AS. Configure MPLS signaling, enable MPLS on an interface, and run OSPF on the backbone network to transmit routing information. Configure an IP address for the interface used to connect to other ASBRs and enable labeled packet forwarding on the interface. Configurations on ASBR2 and ASBR3 are similar to that on ASBR1.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on PE-ASs, RR-ASs, and ASBRs are similar. The following shows how to configure OSPF neighbors on PE1-AS1.

```
PE1-AS1> enable
PE1-AS1# configure terminal
PE1-AS1(config)# router ospf 10
PE1-AS1(config-router)# router-id 1.1.1.1
PE1-AS1(config-router)# network 1.1.1.1 0.0.0.0 area 0
PE1-AS1(config-router)# network 10.10.10.0 0.0.0.255 area 0
PE1-AS1(config-router)# exit
```

(3) Configure basic MPLS functions.

Configurations on PE-ASs, RR-ASs, and ASBRs are similar. The following shows how to configure basic MPLS functions on PE1-AS1.

```
PE1-AS1(config)# mpls ip
PE1-AS1(config)# mpls router ldp
PE1-AS1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1-AS1(config-mpls-router)# exit
PE1-AS1(config)# interface gigabitethernet 0/2
PE1-AS1(config-if-GigabitEthernet 0/2)# label-switching
PE1-AS1(config-if-GigabitEthernet 0/2)# mpls ip
PE1-AS1(config-if-GigabitEthernet 0/2)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following shows how to create a VPN on PE1-AS1.

```
PE1-AS1(config)# ip vrf VPN1
PE1-AS1(config-vrf)# rd 1:100
PE1-AS1(config-vrf)# route-target both 1:100
PE1-AS1(config-vrf)# exit
PE1-AS1(config)# interface gigabitethernet 0/1
PE1-AS1(config-if-GigabitEthernet 0/1)# ip vrf forwarding VPN1
PE1-AS1(config-if-GigabitEthernet 0/1)# ip address 192.168.16.2 255.255.255.0
PE1-AS1(config-if-GigabitEthernet 0/1)# exit
```

(5) Configure BGP neighbors to advertise VPN routes.

PE1-AS1 establishes EBGP neighbor relationship with CE1-VPN1.

```
PE1-AS1> enable
PE1-AS1# configure terminal
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router)# address-family ipv4 vrf VPN1
PE1-AS1(config-router-af)# neighbor 192.168.16.1 remote-as 65001
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# exit
```

PE1-AS1 establishes IBGP neighbor relationship with RR-AS1.

```
PE1-AS1(config)# router bgp 1
PE1-AS1(config-router)# neighbor 2.2.2.2 remote-as 1
PE1-AS1(config-router)# neighbor 2.2.2.2 update-source loopback 0
PE1-AS1(config-router)# address-family vpnv4 unicast
PE1-AS1(config-router-af)# neighbor 2.2.2.2 activate
PE1-AS1(config-router-af)# exit
PE1-AS1(config-router)# address-family ipv4
PE1-AS1(config-router-af)# neighbor 2.2.2.2 activate
PE1-AS1(config-router-af)# neighbor 2.2.2.2 send-label
PE1-AS1(config-router-af)# exit-address-family
PE1-AS1(config-router)# exit
```

RR-AS1 establishes IBGP neighbor relationship with ASBR1.

```
RR-AS1> enable
RR-AS1# configure terminal
RR-AS1(config)# router bgp 1
RR-AS1(config-router)# neighbor 3.3.3.3 remote-as 1
RR-AS1(config-router)# neighbor 3.3.3.3 update-source loopback 0
RR-AS1(config-router)# address-family ipv4
RR-AS1(config-router-af)# neighbor 3.3.3.3 activate
RR-AS1(config-router-af)# neighbor 3.3.3.3 send-label
RR-AS1(config-router-af)# exit-address-family
RR-AS1(config-router)# exit
```

RR-ASs establish EBGP neighbor relationship with each other.

```
RR-AS1(config)# router bgp 1
RR-AS1(config-router)# neighbor 6.6.6.6 remote-as 2
RR-AS1(config-router)# neighbor 6.6.6.6 update-source loopback 0
RR-AS1(config-router)# neighbor 6.6.6.6 ebgp-multihop
RR-AS1(config-router)# neighbor 8.8.8.8 remote-as 3
RR-AS1(config-router)# neighbor 8.8.8.8 update-source loopback 0
RR-AS1(config-router)# neighbor 8.8.8.8 ebgp-multihop
RR-AS1(config-router)# address-family ipv4
RR-AS1(config-router-af)# no neighbor 6.6.6.6 activate
RR-AS1(config-router-af)# no neighbor 8.8.8.8 activate
RR-AS1(config-router-af)# exit-address-family
RR-AS1(config-router)# address-family vpnv4 unicast
RR-AS1(config-router-af)# neighbor 6.6.6.6 activate
RR-AS1(config-router-af)# neighbor 6.6.6.6 next-hop-unchanged
```

```
RR-AS1(config-router-af)# neighbor 8.8.8.8 activate
RR-AS1(config-router-af)# neighbor 8.8.8.8 next-hop-unchanged
RR-AS1(config-router-af)# exit-address-family
RR-AS1(config-router)# exit
```

ASBRs establish EBGP neighbor relationship with each other.

```
ASBR1(config)# router bgp 1
ASBR1(config-router)# neighbor 30.30.30.2 remote-as 2
ASBR1(config-router)# address-family ipv4
ASBR1(config-router-af)# neighbor 30.30.30.2 send-label
ASBR1(config-router-af)# network 1.1.1.1 mask 255.255.255.255
ASBR1(config-router-af)# exit-address-family
ASBR1(config-router)# exit
```

5. Verification

(1) Run the **show bgp vpnv4 unicast all** command on RR-AS1, RR-AS2, and RR-AS3 to verify that entries of 11.11.11.11 and 22.22.22.22 exist.

```
RR-AS1#show bgp vpnv4 unicast all
BGP table version is 40, local router ID is 2.2.2.2
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
              S Stale, b - backup entry
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network          Next Hop            Metric     LocPrf     Weight Path

*>i11.11.11.11/32   1.1.1.1                  0        100          0 65001 i
*> 22.22.22.22/32   5.5.5.5                  0                     0 2 65002 i
```

Total number of prefixes 2

(2) Different sites of the same VPN can interconnect with each other.

PE1-AS1 verification result

```
Assume that the loopback interfaces of the peer CEs are 20.20.20.20 and 30.30.30.30.
The local CE can ping 20.20.20.20.
The local CE can ping 30.30.30.30.
Ping operation to 5.5.5.5 fails.
Ping operation to 5.5.5.5 source 1.1.1.1 is successful.
Ping operation to 9.9.9.9 fails.
Ping operation to 9.9.9.9 source 1.1.1.1 is successful.
```

PE1-AS2 verification result

```
Assume that the loopback interfaces of the peer CEs are 10.10.10.10 and 30.30.30.30.
The local CE can ping 10.10.10.10
The local CE can ping 30.30.30.30.
Ping operation to 1.1.1.1 fails.
Ping operation to 1.1.1.1 source 5.5.5.5 is successful.
Ping operation to 9.9.9.9 fails.
Ping operation to 9.9.9.9 source 5.5.5.5 is successful.
```

PE1-AS3 verification result

```
Assume that the loopback interfaces of the peer CEs are 10.10.10.10 and 20.20.20.20.
The local CE can ping 10.10.10.10
The local CE can ping 20.20.20.20.
Ping operation to 1.1.1.1 fails.
Ping operation to 1.1.1.1 source 9.9.9.9 is successful.
Ping operation to 5.5.5.5 fails.
Ping operation to 5.5.5.5 source 9.9.9.9 is successful.
```

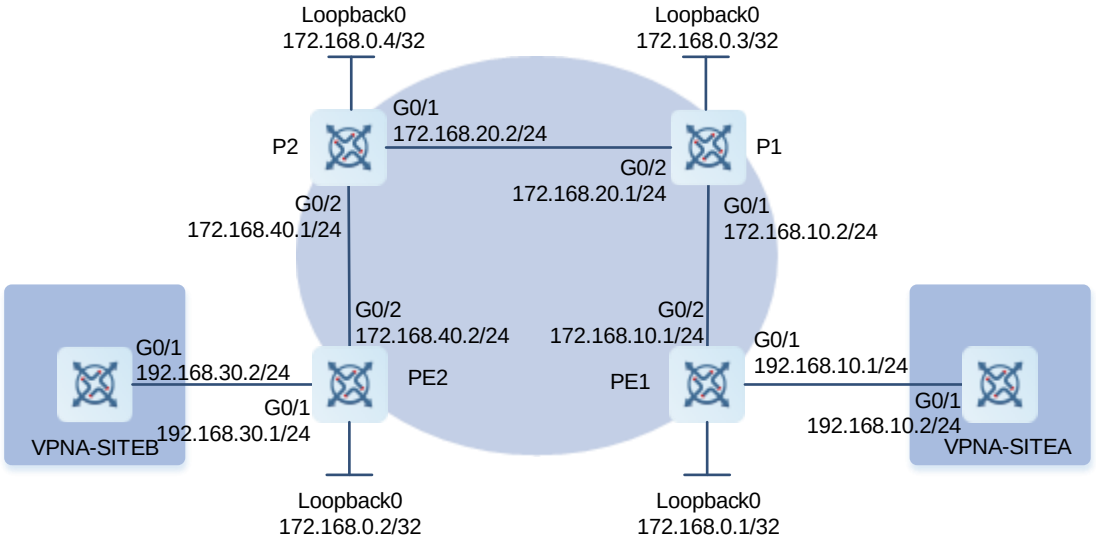
7. Common Errors

- When a multi-hop MP-EBGP session is configured between RRs, IPv4 route exchange is not disabled for the multi-hop MP-EBGP session.
- When VPN routes are exchanged through a multi-hop MP-EBGP session, next hop unchanged is not configured. As a result, VPN sites cannot interconnect with each other.



1.15.14 Configuring OSPF VPN Extended Features (Domain ID)

1. Requirements

Two different sites of a customer exchange VPN routes through the MPLS backbone network, and these sites access PEs using OSPF. It is required that after OSPF routing information is exchanged through the MPLS backbone network, OSPF routes of the original sites can be restored to the maximum.

2. Topology

Figure 1-28 Configuring OSPF VPN Extended Features (Domain ID)

3. Notes

- Configure OSPF between PEs and CEs on SiteA and SiteB.
- On PE1, configure a loopback interface, create VRF instance VPNA, define RD and RT values, and associate the VRF instance with the interface connected to CE1. Configure the BGP, establish an MP-IBGP session with PE2, exchange routes with the CE using OSPF, and set the domain ID of the OSPF process to 10. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol. Configurations on PE2 are similar to that on PE1.
- Configure the backbone network MPLS signaling on P1 and P2, enable MPLS on the interface, and configure the backbone network routing protocol.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on all devices are similar. The following shows how to configure OSPF neighbors on a PE.

```
PE1> enable
PE1# configure terminal
PE1(config)# router ospf 1
PE1(config-router)# network 172.168.10.0 0.0.0.255 area 0
```

```
PE1(config-router)# network 172.168.0.1 0.0.0.0 area 0
PE1(config-router)# exit
```

(3) Configure basic MPLS functions.

Configurations on PEs and Ps are similar. The following shows how to configure basic MPLS functions on PE1.

```
PE1(config)# mpls ip
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-GigabitEthernet 0/2)# ip address 172.168.10.1 255.255.255.0
PE1(config-GigabitEthernet 0/2)# label-switching
PE1(config-GigabitEthernet 0/2)# mpls ip
PE1(config-GigabitEthernet 0/2)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following uses PE1 as an example.

```
PE1(config)# ip vrf VPNA
PE1(config-vrf)# rd 1:100
PE1(config-vrf)# route-target both 1:100
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-GigabitEthernet 0/1)# ip vrf forwarding VPNA
PE1(config-GigabitEthernet 0/1)# ip address 192.168.10.1 255.255.255.0
PE1(config-GigabitEthernet 0/1)# exit
```

(5) Configure VPN routes.

Configurations on PE1 and PE2 are similar. The following shows how to configure VPN routes on PE1.

```
PE1(config)# router ospf 10 vrf VPNA
PE1(config-router)# network 192.168.10.0 0.0.0.255 area 0
PE1(config-router)# redistribute bgp subnets
PE1(config-router)# domain-id 10.10.10.10
PE1(config-router)# exit
```

(6) Configure BGP neighbors to advertise VPN routes.

A PE configures IBGP neighbors to advertise VPN routes.

```
PE1(config)# router bgp 1
PE1(config-router)# neighbor 172.168.0.2 remote-as 1
PE1(config-router)# neighbor 172.168.0.2 update-source loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 172.168.0.2 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# address-family ipv4 vrf VPNA
PE1(config-router-af)# redistribute ospf 10
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit
```

5. Verification

(1) After the configuration is completed, run the **show ip route** command to display routes of VPN A Site A and VPNA SiteB.

VPNA SiteB verification result

```
VPNA-SITEB# show ip route
Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
O IA    192.168.10.0/24 [110/2] via 192.168.30.1, 00:00:36, GigabitEthernet 0/1
C      192.168.30.0/24 is directly connected, GigabitEthernet 0/1
```

PE2 verification result

```
PE2# show ip route vrf VPNA
Routing Table: VPNA

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set

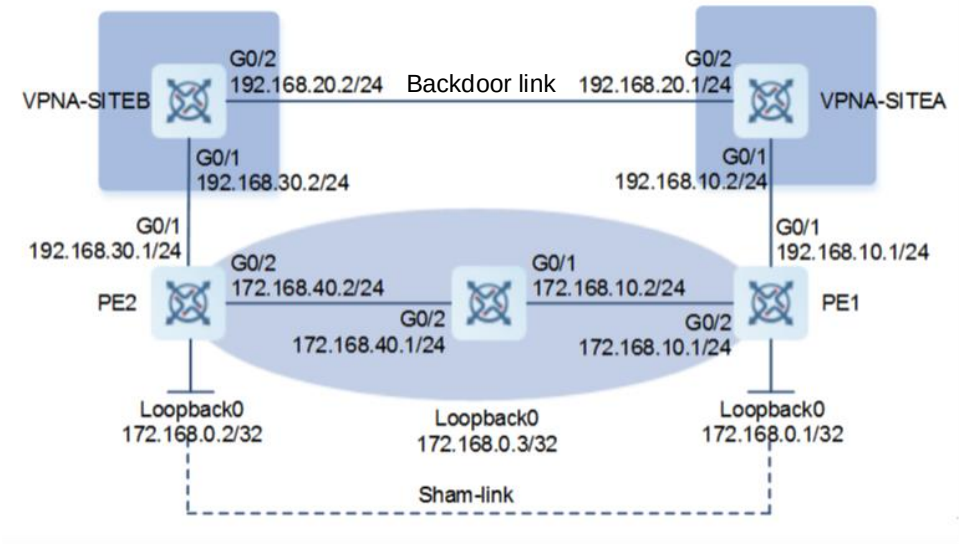
7. Common Errors

The router ID is not 32 bits. As a result, an LDP session fails to be established.



1.15.15 Configuring OSPF VPN Extended Features (Sham Link)

1. Requirements

Two sites of a customer exchange VPN routes through the MPLS backbone network. A backdoor link is established between the two sites. When the MPLS backbone network is faulty, the two sites can exchange information through the backdoor link.

2. Topology

Figure 1-29 Configuring OSPF VPN Extended Features (Sham Link)

3. Notes

- On VPNA SiteA, configure OSPF run with PE1 and VPNA SiteB. VPNA SiteA and VPNA SiteB run OSPF through the backdoor link. Configure the OSPF cost value of interface G0/2.
- On VPNA SiteB, configure OSPF run with PE2 and VPNA SiteA. VPNA SiteB and VPNA SiteA run OSPF through the backdoor link. Configure the OSPF cost value of the interfaces.
- On PE1, configure a loopback interface, create VRF instance VPNA, define RD and RT values, and associate the VRF instance with the corresponding interface. Configure a loopback interface for the VRF instance to establish a sham link. Configure the BGP, establish an MP-IBGP session with PE2, exchange

routes with VPNA SiteA using OSPF, and establish a sham link with the OSPF process on PE2. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.

- On PE2, configure a loopback interface, create VRF instance VPNA, define RD and RT values, and associate the VRF instance with the corresponding interface. Configure a loopback interface for the VRF instance to establish a sham link. Configure the BGP, establish an MP-IBGP session with PE1, exchange VPN routes with VPNA SiteB using OSPF, and establish a sham link with the OSPF process on PE1. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol.
- Configure the backbone network MPLS signaling on P1, enable MPLS on the interface, and configure the backbone network routing protocol.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on PEs and Ps are similar. The following shows how to configure OSPF neighbors on a PE.

```
PE1> enable
PE1# configure terminal
PE1(config)# router ospf 1
PE1(config-router)# network 172.168.10.0 0.0.0.255 area 0
PE1(config-router)# network 172.168.0.1 0.0.0.0 area 0
PE1(config-router)# end
```

Configurations on VPNA SiteA and VPNA SiteB are similar. The following shows how to configure OSPF neighbors on VPNA SiteA.

```
VPNA-SITEA> enable
VPNA-SITEA# configure terminal
VPNA-SITEA(config)# router ospf 10
VPNA-SITEA(config-router)# network 192.168.10.0 255.255.255.0 area 0
VPNA-SITEA(config-router)# network 192.168.20.0 255.255.255.0 area 0
VPNA-SITEA(config-router)# exit
VPNA-SITEA(config)# interface gigabitethernet 0/1
VPNA-SITEA(config-GigabitEthernet 0/1)# ip address 192.168.10.2 255.255.255.0
VPNA-SITEA(config-GigabitEthernet 0/1)# ip ospf cost 1
VPNA-SITEA(config)# interface gigabitethernet 0/2
VPNA-SITEA(config-GigabitEthernet 0/2)# ip address 192.168.20.1 255.255.255.0
VPNA-SITEA(config-GigabitEthernet 0/2)# ip ospf cost 200
```

(3) Configure basic MPLS functions.

Configurations on PEs and Ps are similar. The following shows how to configure basic MPLS functions on PE1.

```
PE1(config)# mpls ip
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
```

```
PE1(config)# interface gigabitethernet 0/2
PE1(config-GigabitEthernet 0/2)# ip address 172.168.10.1 255.255.255.0
PE1(config-GigabitEthernet 0/2)# label-switching
PE1(config-GigabitEthernet 0/2)# mpls ip
PE1(config-GigabitEthernet 0/2)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following uses PE1 as an example.

```
PE1(config)# ip vrf VPNA
PE1(config-vrf)# rd 1:100
PE1(config-vrf)# route-target both 1:100
PE1(config-vrf)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-GigabitEthernet 0/1)# ip vrf forwarding VPNA
PE1(config-GigabitEthernet 0/1)# ip address 192.168.10.1 255.255.255.0
PE1(config-GigabitEthernet 0/1)# exit
PE1(config)# interface loopback 10
PE1(config-Loopback 10)# ip vrf forwarding VPNA
PE1(config-Loopback 10)# ip address 192.168.0.1 255.255.255.255
PE1(config-Loopback 10)# exit
```

(5) Configure VPN routes.

Configurations on PEs are similar. The following shows how to configure VPN routes on PE1.

```
PE1(config)# router ospf 10 vrf VPNA
PE1(config-router)# network 192.168.10.0 255.255.255.0 area 0
PE1(config-router)# redistribute bgp subnets
PE1(config-router)# area 0 sham-link 192.168.0.1 192.168.0.2
PE1(config-router)# exit
```

(6) Configure BGP neighbors to advertise VPN routes.

A PE configures IBGP neighbors to advertise VPN routes.

```
PE1(config)# router bgp 1
PE1(config-router)# neighbor 172.168.0.2 remote-as 1
PE1(config-router)# neighbor 172.168.0.2 update-source loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 172.168.0.2 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# address-family ipv4 vrf VPNA
PE1(config-router-af)# redistribute ospf 10
PE1(config-router-af)# redistribute connected
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit
```

5. Verification

(1) After the configuration is completed, verify that an OSPF sham link exists on the PE.

PE1 verification result

```
PE1# show ip ospf 10 sham-links
Sham Link SLINK0 to address 192.168.0.2 is up
  Area 0.0.0.0 source address 192.168.0.1, Cost: 1
  Output interface is GigabitEthernet 0/2
  Nexthop address 172.16.40.2
  Transmit Delay is 1 sec, State Point-To-Point,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:01
    Adjacency state Full

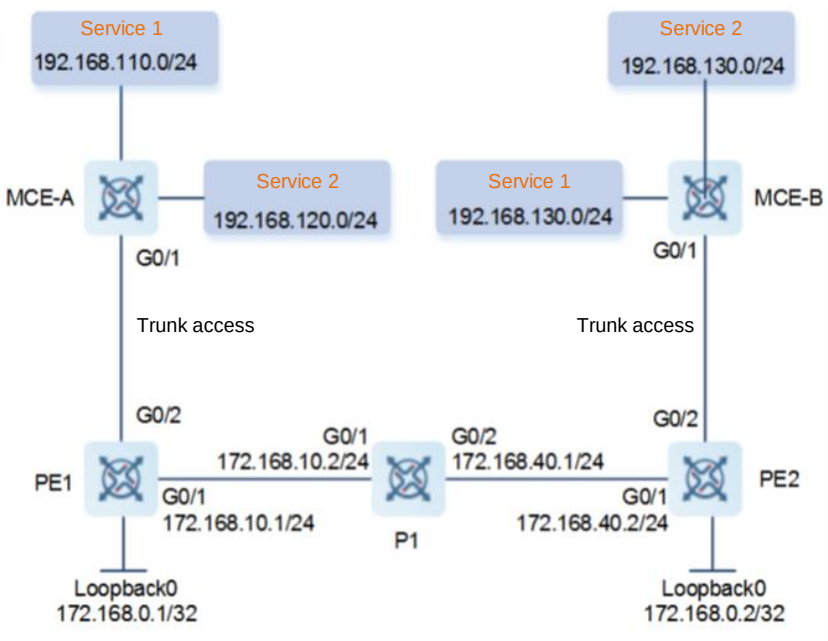
7. Common Errors

The router ID is not 32 bits. As a result, an LDP session fails to be established.



1.15.16 Configuring OSPF VPN Extended Features (Multiple OSPF Instances on the MCE)

1. Requirements

A customer site has multiple different services. Traffic for the same service can be exchanged across MPLS backbone networks, and traffic of different services is isolated.

2. Topology

Figure 1-30 Configuring OSPF VPN Extended Features (Multiple OSPF Instances on the MCE)

3. Notes

- On MCE-A, configure a trunk link between PE1 and CE1, configure two VRF instances that represent two different services and bind them to corresponding interfaces, and configure OSPF. Configurations of MCE-B are similar to that on MCE-A.
- On PE1, configure a loopback interface, configure a trunk link between PE1 and CE1, create two VRF instances VPN1 and VPN2 that correspond to different services, associate VRF instances with the interface used to connect to CE1. Configure the BGP, establish an MP-IBGP session with PE2, and exchange routes with CE1 using OSPF. Configure the backbone network MPLS signaling, enable MPLS on the public interface, and configure the backbone network routing protocol. Configurations on PE2 are similar to that on PE1.
- Configure the backbone network MPLS signaling on P1, enable MPLS on the interface, and configure the backbone network routing protocol.

Note

For the connection between PE1 and CE1, this example uses SVI and 802.1Q subinterface configurations, which are not supported bysome devices. PE1 and CE1 can be connected through any two links (physical or

logical links) only if two route adjacencies are formed between them. Users can select a suitable connection method based on actual requirements.

4. Procedure

(1) Configure IP addresses for all device interfaces (omitted).

(2) Configure OSPF neighbors to ensure reachable unicast routes.

Configurations on PEs are similar. The following shows how to configure OSPF neighbors on a PE.

```
PE1(config)# router ospf 1
PE1(config-router)# network 172.168.10.0 0.0.0.255 area 0
PE1(config-router)# network 172.168.0.1 0.0.0.0 area 0
```

(3) Configure basic MPLS functions.

Configurations on PEs and Ps are similar. The following shows how to configure basic MPLS functions on PE1.

```
PE1(config)# mpls ip
PE1(config)# mpls router ldp
PE1(config-mpls-router)# ldp router-id interface loopback 0 force
PE1(config-mpls-router)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# ip address 172.168.10.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/1)# label-switching
PE1(config-if-GigabitEthernet 0/1)# mpls ip
PE1(config-if-GigabitEthernet 0/1)# exit
```

(4) Create a VRF instance and a VLAN and associate them.

Configurations on PEs are similar. The following uses PE1 as an example.

```
PE1(config)# ip vrf VPN1
PE1(config-vrf)# rd 1:100
PE1(config-vrf)# route-target both 1:100
PE1(config-vrf)# exit
PE1(config)# ip vrf VPN2
PE1(config-vrf)# rd 1:200
PE1(config-vrf)# route-target both 1:200
PE1(config-vrf)# exit
PE1(config)# vlan 10
PE1(config)# interface vlan 10
PE1(config-if-Vlan 10)# ip vrf forwarding VPN1
PE1(config-if-Vlan 10)# ip address 192.168.10.1 255.255.255.0
PE1(config-if-Vlan 10)# exit
PE1(config)# vlan 20
PE1(config)# interface vlan 20
PE1(config-if-Vlan 20)# ip vrf forwarding VPN1
PE1(config-if-Vlan 20)# ip address 192.168.20.1 255.255.255.0
```

Configurations on MCEs are similar. The following shows how to create a VPN on MCE-A.

```
MCE-A> enable
MCE-A# configure terminal
MCE-A(config)# ip vrf VPN1
MCE-A(config-vrf)# exit
MCE-A(config)# ip vrf VPN2
MCE-A(config-vrf)# exit
MCE-A(config)# vlan 10
MCE-A(config)# interface vlan 10
MCE-A(config-if-Vlan 10)# ip vrf forwarding VPN1
MCE-A(config-if-Vlan 10)# ip address 192.168.10.2 255.255.255.0
MCE-A(config-if-Vlan 10)# exit
MCE-A(config)# vlan 20
MCE-A(config)# interface vlan 20
MCE-A(config-if-Vlan 20)# ip vrf forwarding VPN2
MCE-A(config-if-Vlan 20)# ip address 192.168.20.2 255.255.255.0
MCE-A(config-if-Vlan 20)# exit
```

(5) Configure VPN routes.

Configurations on PEs are similar. The following shows how to configure VPN routes on PE1.

```
PE1(config)# router ospf 10 vrf VPN1
PE1(config-router)# network 192.168.10.0 0.0.0.255 area 0
PE1(config-router)# redistribute bgp subnets
PE1(config-router)# exit
PE1(config)# router ospf 20 vrf VPN2
PE1(config-router)# network 192.168.20.0 0.0.0.255 area 0
PE1(config-router)# redistribute bgp subnets
PE1(config-router)# exit
```

Configurations on MCEs are similar. The following shows how to configure VPN routes on MCE-A.

```
MCE-A(config)# router ospf 10 vrf VPN1
MCE-A(config-router)# network 192.168.10.0 0.0.0.255 area 0
MCE-A(config-router)# capability vrf-lite
MCE-A(config-router)# exit
MCE-A(config)# router ospf 20 vrf VPN2
MCE-A(config-router)# network 192.168.20.0 0.0.0.255 area 0
MCE-A(config-router)# capability vrf-lite
```

(6) Configure BGP neighbors to advertise VPN routes.

A PE configures IBGP neighbors to advertise VPN routes.

```
PE1(config)# router bgp 1
PE1(config-router)# neighbor 172.168.0.2 remote-as 1
PE1(config-router)# neighbor 172.168.0.2 update-source loopback 0
PE1(config-router)# address-family vpnv4
PE1(config-router-af)# neighbor 172.168.0.2 activate
PE1(config-router-af)# exit-address-family
PE1(config-router)# address-family ipv4 vrf VPN1
PE1(config-router-af)# redistribute ospf 10
```

```
PE1(config-router-af)# redistribute connected
PE1(config-router-af)# exit-address-family
PE1(config-router)# address-family ipv4 vrf VPN2
PE1(config-router-af)# redistribute ospf 20
PE1(config-router-af)# redistribute connected
PE1(config-router-af)# exit-address-family
PE1(config-router)# exit
```

5. Verification

(1) After the configuration is completed, run the **show ip route vrf** command on MCE-A and MCE-B to display the private network routing table.

MCE-A verification result

```
MCE-A# show ip route vrf VPN1
Routing Table: VPN1

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2

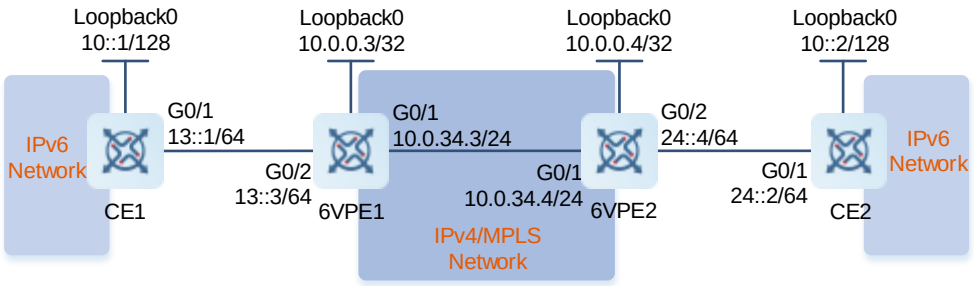
7. Common Errors

The router ID is not 32 bits. As a result, an LDP session fails to be established.

1.16 IPv6 MPLS L3VPN Configuration Examples



1.16.1 Configuring the 6VPE Service Model

1. Requirements

A company has branches in Fuzhou and Beijing and implements communication between the branches through an ISP. The two branches use IPv6 communication internally, and the ISP's network is an IPv4 MPLS network. The company requires that the branches can communicate with each other, VPN connections are used inside branches, and branches do not communicate with external ISPs.

2. Topology

Figure 1-31 Configuring the 6VPE Service Model

3. Notes

- On 6VPE1 and 6VPE2, configure interface IP addresses and OSPF to ensure that the routes between them are reachable and enable IPv6 forwarding.
- On 6VPE1 and 6VPE2, configure public network tunnels.
- On 6VPE1 and 6VPE2, create VRF instances.
- Configure the IPv6 addresses and routes of 6VPE1 and 6VPE2 under VRF instances.
- Establish a BGP session between 6VPE1 and 6VPE2.
- Configure 6VPE1 and 6VPE2 to redistribute IPv6 routes with CE1 and CE2 under VRF instances.
- On CE1 and CE2, enable IPv6 forwarding and configure the IPv6 addresses and static routes.

4. Procedure

(1) On 6VPE1 and 6VPE2, configure interface IP addresses and OSPF to ensure that the routes between them are reachable and enable IPv6 forwarding.

Configure 6VPE1.

```
6VPE1> enable
6VPE1# configure terminal
6VPE1(config)# interface gigabitethernet 0/1
6VPE1(config-if-GigabitEthernet 0/1)# no switchport
6VPE1(config-if-GigabitEthernet 0/1)# ip address 10.0.34.3 255.255.255.0
6VPE1(config-if-GigabitEthernet 0/1)# exit
6VPE1(config)# interface loopback 0
6VPE1(config-if-Loopback 0)# ip address 10.0.0.3 255.255.255.255
6VPE1(config-if-Loopback 0)# exit
6VPE1(config)# router ospf 1
6VPE1(config-router)# network 10.0.0.3 0.0.0.0 area 0
6VPE1(config-router)# network 10.0.34.0 0.0.0.255 area 0
6VPE1(config-router)# exit
6VPE1(config)# ipv6 unicast-routing
```

Configure 6VPE2.

```
6VPE2> enable
```

```
6VPE2# configure terminal
6VPE2(config)# interface gigabitethernet 0/1
6VPE2(config-if-GigabitEthernet 0/1)# no switchport
6VPE2(config-if-GigabitEthernet 0/1)# ip address 10.0.34.4 255.255.255.0
6VPE2(config-if-GigabitEthernet 0/1)# exit
6VPE2(config)# interface loopback 0
6VPE2(config-if-Loopback 0)# ip address 10.0.0.4 255.255.255.255
6VPE2(config-if-Loopback 0)# exit
6VPE2(config)# router ospf 1
6VPE2(config-router)# network 10.0.0.4 0.0.0.0 area 0
6VPE2(config-router)# network 10.0.34.0 0.0.0.255 area 0
6VPE2(config-router)# exit
6VPE2(config)# ipv6 unicast-routing
```

(2) On 6VPE1 and 6VPE2, configure public network tunnels.

Configure 6VPE1.

```
6VPE1(config)# mpls ip
6VPE1(config)# mpls router ldp
6VPE1(config-mpls-router)# ldp router-id interface loopback 0 force
6VPE1(config-mpls-router)# exit
6VPE1(config)# interface gigabitethernet 0/1
6VPE1(config-if-GigabitEthernet 0/1)# label-switching
6VPE1(config-if-GigabitEthernet 0/1)# mpls ip
6VPE1(config-if-GigabitEthernet 0/1)# exit
```

Configure 6VPE2.

```
6VPE2(config)# mpls ip
6VPE2(config)# mpls router ldp
6VPE2(config-mpls-router)# ldp router-id interface loopback 0 force
6VPE2(config-mpls-router)# exit
6VPE2(config)# interface gigabitethernet 0/1
6VPE2(config-if-GigabitEthernet 0/1)# label-switching
6VPE2(config-if-GigabitEthernet 0/1)# mpls ip
6VPE2(config-if-GigabitEthernet 0/1)# exit
```

(3) On 6VPE1 and 6VPE2, create VRF instances.

Configure 6VPE1.

```
6VPE1(config)# vrf definition vrf1
6VPE1(config-vrf)# rd 34:34
6VPE1(config-vrf)# address-family ipv6
6VPE1(config-vrf-af)# route-target export 34:34
6VPE1(config-vrf-af)# route-target import 34:34
6VPE1(config-vrf-af)# exit-address-family
6VPE1(config-vrf)# exit
```

Configure 6VPE2.

```
6VPE2(config)# vrf definition vrf1
6VPE2(config-vrf)# rd 34:34
```

```
6VPE2(config-vrf)# address-family ipv6
6VPE2(config-vrf-af)# route-target export 34:34
6VPE2(config-vrf-af)# route-target import 34:34
6VPE2(config-vrf-af)# exit-address-family
6VPE2(config-vrf-af)# exit
```

(4) Configure the IPv6 addresses and routes of 6VPE1 and 6VPE2 under VRF instances.

Configure 6VPE1.

```
6VPE1(config)# interface gigabitethernet 0/2
6VPE1(config-if-GigabitEthernet 0/2)# vrf forwarding vrf1
6VPE1(config-if-GigabitEthernet 0/2)# ipv6 enable
6VPE1(config-if-GigabitEthernet 0/2)# ipv6 address 13::3/64
6VPE1(config-if-GigabitEthernet 0/2)# exit
6VPE1(config)# ipv6 route vrf vrf1 10::1/128 13::1
```

Configure 6VPE2.

```
6VPE2(config)# interface gigabitethernet 0/2
6VPE2(config-if-GigabitEthernet 0/2)# vrf forwarding vrf1
6VPE2(config-if-GigabitEthernet 0/2)# ipv6 enable
6VPE2(config-if-GigabitEthernet 0/2)# ipv6 address 24::4/64
6VPE2(config-if-GigabitEthernet 0/2)# exit
6VPE2(config)# ipv6 route vrf vrf1 10::2/128 24::2
```

(5) Establish a BGP session between 6VPE1 and 6VPE2.

Configure 6VPE1.

```
6VPE1(config)# router bgp 34
6VPE1(config-router)# neighbor 10.0.0.4 remote-as 34
6VPE1(config-router)# neighbor 10.0.0.4 update-source loopback 0
6VPE1(config-router)# address-family vpnv6 unicast
6VPE1(config-router-af)# neighbor 10.0.0.4 activate
6VPE1(config-router-af)# exit-address-family
```

Configure 6VPE2.

```
6VPE2(config)# router bgp 34
6VPE2(config-router)# neighbor 10.0.0.3 remote-as 34
6VPE2(config-router)# neighbor 10.0.0.3 update-source loopback 0
6VPE2(config-router)# address-family vpnv6 unicast
6VPE2(config-router-af)# neighbor 10.0.0.3 activate
6VPE2(config-router-af)# exit-address-family
```

(6) Configure 6VPE1 and 6VPE2 to distribute IPv6 routes under VRF instances.

Configure 6VPE1.

```
6VPE1(config-router)# address-family ipv6 unicast vrf vrf1
6VPE1(config-router-af)# redistribute static
```

Configure 6VPE2.

```
6VPE2(config-router)# address-family ipv6 vrf vrf1
6VPE2(config-router-af)# redistribute static
```

(7) On CE1 and CE2, enable IPv6 forwarding and configure the IPv6 addresses and static routes.

Configure CE1.

```
CE1> enable
CE1# configure terminal
CE1(config)# ipv6 unicast-routing
CE1(config)# interface loopback 0
CE1(config-if-Loopback 0)# ipv6 enable
CE1(config-if-Loopback 0)# ipv6 address 10::1/128
CE1(config-if-Loopback 0)# exit
CE1(config)# interface gigabitethernet 0/1
CE1(config-if-GigabitEthernet 0/1)# ipv6 enable
CE1(config-if-GigabitEthernet 0/1)# ipv6 address 13::1/64
CE1(config-if-GigabitEthernet 0/1)# exit
CE1(config)# ipv6 route ::/0 13::3
CE1(config)# exit
```

Configure CE2.

```
CE2> enable
CE2# configure terminal
CE2(config)# ipv6 unicast-routing
CE2(config)# interface loopback 0
CE2(config-if-Loopback 0)# ipv6 enable
CE2(config-if-Loopback 0)# ipv6 address 10::2/128
CE2(config-if-Loopback 0)# exit
CE2(config)# interface gigabitethernet 0/1
CE2(config-if-GigabitEthernet 0/1)# ipv6 enable
CE2(config-if-GigabitEthernet 0/1)# ipv6 address 24::2/64
CE2(config-if-GigabitEthernet 0/1)# exit
CE2(config)# ipv6 route ::/0 24::4
CE2(config)# exit
```

5. Verification

On CE1, run the **show ipv6 route** command to display the routing table.

```
CE1# show ipv6 route
IPv6 routing table name - Default - 9 entries
Codes:  C - Connected, L - Local, S - Static
       R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       IA - Inter area, EV - BGP EVPN, N - Nd to host

S     ::/0 [1/0] via 13::3
              (recursive via 13::3, GigabitEthernet 0/1)
LC    10::1/128 via Loopback 0, local host
C     13::/64 via GigabitEthernet 0/1, directly connected
```

```
L     13::1/128 via GigabitEthernet 0/1, local host
C     FE80::/10 via ::1, Null0
C     FE80::/64 via Loopback 0, directly connected
L     FE80::274:9CFF:FEEE:53CB/128 via Loopback 0, local host
C     FE80::/64 via GigabitEthernet 0/1, directly connected
L     FE80::274:9CFF:FEEE:53CB/128 via GigabitEthernet 0/1, local host
```

On CE2, run the **show ipv6 route** command to displaythe routing table.

```
CE2# show ipv6 route
IPv6 routing table name - Default - 9 entries
Codes:  C - Connected, L - Local, S - Static
       R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       IA - Inter area, EV - BGP EVPN, N - Nd to host

S     ::/0 [1/0] via 24::4
              (recursive via 24::4, GigabitEthernet 0/1)
LC    10::2/128 via Loopback 0, local host
C     24::/64 via GigabitEthernet 0/1, directly connected
L     24::2/128 via GigabitEthernet 0/1, local host
C     FE80::/10 via ::1, Null0
C     FE80::/64 via GigabitEthernet 0/1, directly connected
L     FE80::274:9CFF:FEC8:E27B/128 via GigabitEthernet 0/1, local host
C     FE80::/64 via Loopback 0, directly connected
L     FE80::274:9CFF:FEC8:E27B/128 via Loopback 0, local host
```

On 6VPE1, run the **show ipv6 route vrf vrf1** command to displaythe private network routing table.

```
6VPE1# show ipv6 route vrf vrf1
IPv6 routing table name - vrf1 - 7 entries
Codes:  C - Connected, L - Local, S - Static
       R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       IA - Inter area, EV - BGP EVPN, N - Nd to host

S     10::1/128 [1/0] via 13::1
              (recursive via 13::1, GigabitEthernet 0/2)
B     10::2/128 [200/0] via ::FFFF:10.0.0.4, IPv6-mpls
C     13::/64 via GigabitEthernet 0/2, directly connected
L     13::3/128 via GigabitEthernet 0/2, local host
C     FE80::/10 via ::1, Null0
C     FE80::/64 via GigabitEthernet 0/2, directly connected
L     FE80::274:9CFF:FEEE:F49F/128 via GigabitEthernet 0/2, local host
```

On 6VPE2, run the **show ipv6 route vrf vrf1** command to displaythe private network routing table.

```
6VPE2# show ipv6 route vrf vrf1
IPv6 routing table name - vrf1 - 7 entries
Codes:  C - Connected, L - Local, S - Static
       R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       IA - Inter area, EV - BGP EVPN, N - Nd to host

B     10::1/128 [200/0] via ::FFFF:10.0.0.3, IPv6-mpls

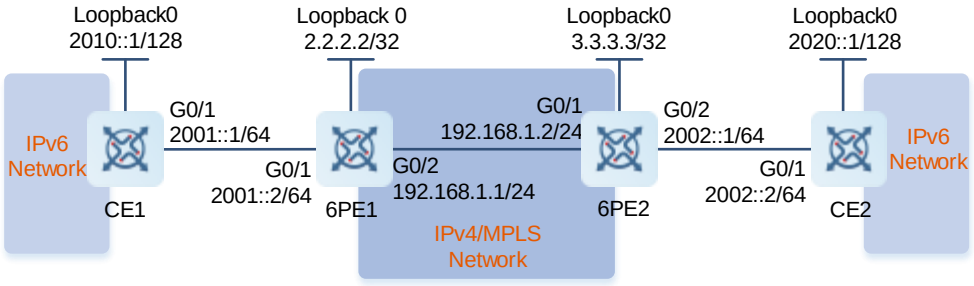
7. Common Errors

IPv6 forwarding is not enabled. As a result, IPv6 VPN forwarding fails.



1.16.2 Configuring the 6PE Service Model

1. Requirements

A company has branches in Fuzhou and Beijing and implements communication between the branches through an ISP. The two branches use IPv6 communication internally, and the ISP's network is an IPv4 MPLS network. The company wants to access ISPs in IPv6 method without modifying IPv6 communication between branches.

2. Topology

Figure 1-32 Configuring the 6PE Service Model

3. Notes

- On 6PE1 and 6PE2, configure the interface IP addresses and OSPF to ensure that the routes between them are reachable.
- On 6PE1 and 6PE2, configure public network tunnels.
- On 6PE1 and 6PE2, enable IPv6 forwarding and configure the IPv6 addresses and OSPFv3.
- Establish a BGP session between 6PE1 and 6PE2 and redistribute the IPv6 routes between 6PE1 and CE1 and between 6PE2 and CE2.
- On CE1 and CE2, enable IPv6 forwarding and configure IPv6 addresses and OSPFv3 routes.

4. Procedure

(1) On 6PE1 and 6PE2, configure the interface IP addresses and OSPF to ensure that the routes between them are reachable.

Configure 6PE1.

```
6PE1> enable
6PE1# configure terminal
6PE1(config)# interface loopback 0
6PE1(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
6PE1(config-if-Loopback 0)# exit
6PE1(config)# interface gigabitethernet 0/2
6PE1(config-if-GigabitEthernet 0/2)# no switchport
6PE1(config-if-GigabitEthernet 0/2)# ip address 192.168.1.1 255.255.255.0
6PE1(config-if-GigabitEthernet 0/2)# exit
6PE1(config)# router ospf 1
6PE1(config-router)# network 192.168.1.0 0.0.0.255 area 0
6PE1(config-router)# network 2.2.2.2 0.0.0.0 area 0
6PE1(config-router)# exit
```

Configure 6PE2.

```
6PE2> enable
6PE2# configure terminal
6PE2(config)# interface loopback 0
6PE2(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
6PE2(config-if-Loopback 0)# exit
6PE2(config)# interface gigabitethernet 0/1
6PE2(config-if-GigabitEthernet 0/1)# no switchport
6PE2(config-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
6PE2(config-if-GigabitEthernet 0/1)# exit
6PE2(config)# router ospf 1
6PE2(config-router)# network 192.168.1.0 0.0.0.255 area 0
6PE2(config-router)# network 3.3.3.3 0.0.0.0 area 0
6PE2(config-router)# exit
```

(2) On 6PE1 and 6PE2, configure public network tunnels.

Configure 6PE1.

```
6PE1(config)# mpls ip
6PE1(config)# mpls router ldp
6PE1(config-mpls-router)# ldp router-id interface loopback 0 force
6PE1(config-mpls-router)# exit
6PE1(config)# interface gigabitethernet 0/2
6PE1(config-if-GigabitEthernet 0/2)# label-switching
6PE1(config-if-GigabitEthernet 0/2)# mpls ip
6PE1(config-if-GigabitEthernet 0/2)# exit
```

Configure 6PE2.

```
6PE2(config)# mpls ip
```

```
6PE2(config)# mpls router ldp
6PE2(config-mpls-router)# ldp router-id interface loopback 0 force
6PE2(config-mpls-router)# exit
6PE2(config)# interface gigabitethernet 0/1
6PE2(config-if-GigabitEthernet 0/1)# label-switching
6PE2(config-if-GigabitEthernet 0/1)# mpls ip
6PE2(config-if-GigabitEthernet 0/1)# exit
```

(3) On 6PE1 and 6PE2, enable IPv6 forwarding and configure IPv6 addresses and OSPFv3 routes.

Configure 6PE1.

```
6PE1(config)# ipv6 unicast-routing
6PE1(config)# ipv6 router ospf 10
6PE1(config-router)# router-id 2.2.2.2
Change router-id and update OSPFv3 process! [yes/no]:yes
6PE1(config-router)# exit
6PE1(config)# interface gigabitethernet 0/1
6PE1(config-if-GigabitEthernet 0/1)# no switchport
6PE1(config-if-GigabitEthernet 0/1)# ipv6 enable
6PE1(config-if-GigabitEthernet 0/1)# ipv6 address 2001::2/64
6PE1(config-if-GigabitEthernet 0/1)# ipv6 ospf 10 area 0
6PE1(config-if-GigabitEthernet 0/1)# exit
```

Configure 6PE2.

```
6PE2(config)# ipv6 unicast-routing
6PE2(config)# ipv6 router ospf 10
6PE2(config-router)# router-id 3.3.3.3
Change router-id and update OSPFv3 process! [yes/no]:yes
6PE2(config-router)# exit
6PE2(config)# interface gigabitethernet 0/2
6PE2(config-if-GigabitEthernet 0/2)# no switchport
6PE2(config-if-GigabitEthernet 0/2)# ipv6 enable
6PE2(config-if-GigabitEthernet 0/2)# ipv6 address 2002::1/64
6PE2(config-if-GigabitEthernet 0/2)# ipv6 ospf 10 area 0
6PE2(config-if-GigabitEthernet 0/2)# exit
```

(4) Establish a BGP session between 6PE1 and 6PE2 and redistribute the IPv6 routes between 6PE1 and CE1 and between 6PE2 and CE2.

Configure 6PE1.

```
6PE1(config)# router bgp 100
6PE1(config-router)# neighbor 3.3.3.3 remote-as 100
6PE1(config-router)# neighbor 3.3.3.3 update-source loopback 0
6PE1(config-router)# address-family ipv6 unicast
6PE1(config-router-af)# neighbor 3.3.3.3 activate
6PE1(config-router-af)# neighbor 3.3.3.3 send-label
6PE1(config-router-af)# redistribute ospf 10
6PE1(config-router-af)# exit
6PE1(config-router)# exit
```

```
6PE1(config)# ipv6 router ospf 10
6PE1(config-router)# redistribute bgp
6PE1(config-router)# end
```

Configure 6PE2.

```
6PE2(config)# router bgp 100
6PE2(config-router)# neighbor 2.2.2.2 remote-as 100
6PE2(config-router)# neighbor 2.2.2.2 update-source loopback 0
6PE2(config-router)# address-family ipv6 unicast
6PE2(config-router-af)# neighbor 2.2.2.2 activate
6PE2(config-router-af)# neighbor 2.2.2.2 send-label
6PE2(config-router-af)# redistribute ospf 10
6PE2(config-router-af)# exit
6PE2(config-router)# exit
6PE2(config)# ipv6 router ospf 10
6PE2(config-router)# redistribute bgp
6PE2(config-router)# end
```

(5) On CE1 and CE2, enable IPv6 forwarding and configure IPv6 addresses and OSPFv3 routes.

Configure CE1.

```
CE1> enable
CE1# configure terminal
CE1(config)# ipv6 unicast-routing
CE1(config)# ipv6 router ospf 1
CE1(config-router)# router-id 1.1.1.1
Change router-id and update OSPFv3 process! [yes/no]:yes
CE1(config-router)# exit
CE1(config)# interface loopback 0
CE1(config-if-Loopback 0)# ipv6 enable
CE1(config-if-Loopback 0)# ipv6 address 2010::1/128
CE1(config-if-Loopback 0)# ipv6 ospf 1 area 0
CE1(config-if-Loopback 0)# exit
CE1(config)# interface gigabitethernet 0/1
CE1(config-if-GigabitEthernet 0/1)# no switchport
CE1(config-if-GigabitEthernet 0/1)# ipv6 enable
CE1(config-if-GigabitEthernet 0/1)# ipv6 address 2001::1/64
CE1(config-if-GigabitEthernet 0/1)# ipv6 ospf 1 area 0
CE1(config-if-GigabitEthernet 0/1)# end
```

Configure CE2.

```
CE2> enable
CE2# configure terminal
CE2(config)# ipv6 unicast-routing
CE2(config)# ipv6 router ospf 1
CE2(config-router)# router-id 4.4.4.4
Change router-id and update OSPFv3 process! [yes/no]:yes
CE2(config)# interface loopback 0
```

```
CE2(config-if-Loopback 0)# ipv6 enable
CE2(config-if-Loopback 0)# ipv6 address 2020::1/128
CE2(config-if-Loopback 0)# ipv6 ospf 1 area 0
CE2(config-if-Loopback 0)# exit
CE2(config)# interface gigabitethernet 0/1
CE2(config-if-GigabitEthernet 0/1)# no switchport
CE2(config-if-GigabitEthernet 0/1)# ipv6 enable
CE2(config-if-GigabitEthernet 0/1)# ipv6 address 2002::2/64
CE2(config-if-GigabitEthernet 0/1)# ipv6 ospf 1 area 0
CE2(config-if-GigabitEthernet 0/1)# end
```

5. Verification

After the configuration is completed, run the **show ipv6 route** command to display IPv6 route entries.

CE1 verification result

```
CE1# show ipv6 route
IPv6 routing table name - Default - 10 entries
Codes:  C - Connected, L - Local, S - Static
       R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       IA - Inter area, EV - BGP EVPN, N - Nd to host

C     2001::/64 via GigabitEthernet 0/1, directly connected
L     2001::1/128 via GigabitEthernet 0/1, local host
O  E2  2002::/64 [110/1] via FE80::250:56FF:FEB0:59C, GigabitEthernet 0/1
LC    2010::1/128 via Loopback 0, local host
O  E2  2020::1/128 [110/1] via FE80::250:56FF:FEB0:59C, GigabitEthernet 0/1
C     FE80::/10 via ::1, Null0

1 Configuring IPsec

1.1 Introduction

1.1.1 Overview

Internet Protocol version 4 (IPv4) is the most widely used network protocol. However, security is not taken into consideration in the design of this protocol. Malicious users can forge addresses of IP packets, tamper with packet content, retransmit the same IP packets repeatedly, and intercept and check packet content at will, which brings many security risks to networks.

IP Security (IPsec) is an L3 tunnel encryption protocol formulated by the Internet Engineering Task Force (IETF). It provides high-quality, interoperable, and cryptography-based security guarantee for data transmitted over networks. Communication parties use IPsec to encrypt and authenticate data sources at the IP layer, in a bid to ensure communication security. IPsec provides the following security services:

- Data confidentiality: An IPsec sender encrypts packets before sending them over a network.
- Data integrity: An IPsec receiver authenticates packets sent by a sender to ensure that data is not tampered with during transmission.
- Data source authentication: An IPsec receiver authenticates an IPsec sender.
- Anti-replay: An IPsec receiver can detect and reject outdated or duplicate packets.

1.1.2 Basic Concepts

1. Security Association

IPsec provides secure communication between two endpoints, which are called IPsec peers.

Security associations (SAs) are the foundation and essence of IPsec. An SA is an agreement on certain elements between communication peers, such as the protocol to be used (Authentication Header (AH), Encapsulating Security Payload (ESP), or both), protocol encapsulation mode (transport mode or tunnel mode), encryption algorithm (Data Encryption Standard (DES), Triple DES (3DES), or Advanced Encryption Standard (AES)), authentication algorithm (secure hash algorithm (SHA) or message digest algorithm 5 (MD5)), shared keys used to protect data in a specific flow, and key lifetime.

An SA is unidirectional but communication between two peers is bidirectional. At least one SA is needed to protect the data flow in each direction. Therefore, at least two SAs are required for secure communication between two peers. If two peers use both AH and ESP for secure communication, each peer constructs an independent SA for each protocol.

An SA is uniquely identified by a triplet, which contains the security parameter index (SPI), destination IP address, and security protocol number (AH or ESP). An SPI is a 32-bit value that uniquely identifies an SA and is transmitted in the AH and ESP headers.

SAs can be generated via manual configuration and automatic IKE negotiation.

- Manual configuration: You need to run commands to configure all information about an SA. This mode is independent of IKE but you need to update keys periodically to ensure security. The manual mode is applicable to small-sized static networking environments.

- IKE automatic negotiation: An SA is automatically generated and maintained by IKE. The configuration is simpler and this mode is more scalable than the manual mode. IKE automatic negotiation is applicable to large-sized dynamic networking environments.

Manually configured SAs never age whereas SAs automatically negotiated by IKE are valid in their lifetime. There are two types of lifetime:

- Time-based lifetime: Defines the duration from the establishment to expiration of an SA.
- Traffic-based lifetime: Defines the maximum traffic that can be processed by an SA.

You can configure both time-based and traffic-based SA lifetime. An SA will expire once its lifetime reaches the specified time or traffic. Before an SA expires, IKE negotiates and establishes a new SA for IPsec to ensure that the new SA is ready before the expiration of the old SA. The old SA is still used to protect communication before the new SA is successfully negotiated. The new SA is used to protect communication immediately after it is successfully negotiated.

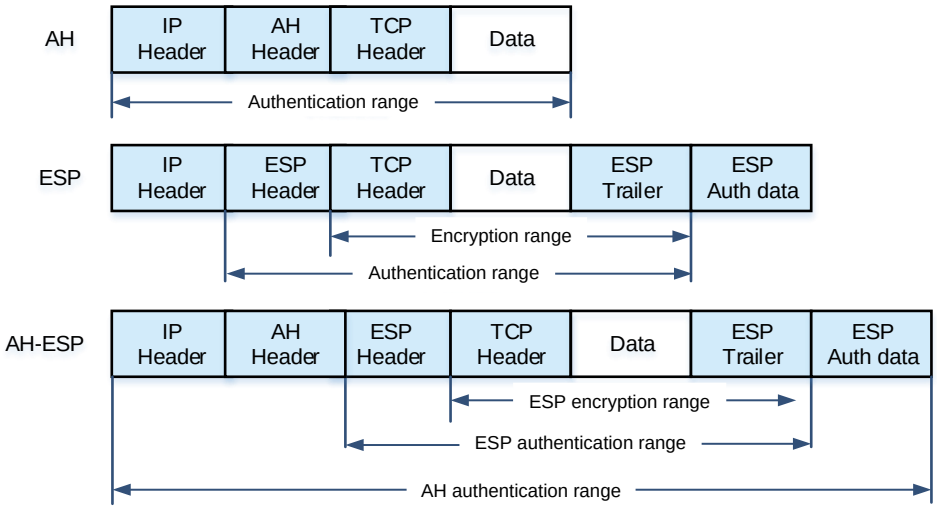
2. Security Protocols

IPsec implements security services by using the following two protocols:

- AH: The protocol number is 51. This protocol provides data source authentication, data integrity verification, and packet replay prevention. Available authentication algorithms include MD5 and Secure Hash Algorithm 1 (SHA-1). AH ensures the integrity and authenticity of data packets, and prevents hackers from intercepting data packets or inserting forged data packets into the network.
- ESP: The protocol number is 50. Different from AH, ESP encrypts user data to be protected and then encapsulates the data into IP packets to ensure data confidentiality. Common encryption algorithms include DES, 3DES, and AES. In addition, you can use the MD5 or SHA-1 algorithm to ensure packet integrity and authenticity.

Table 1-1 Comparison Between AH and ESP

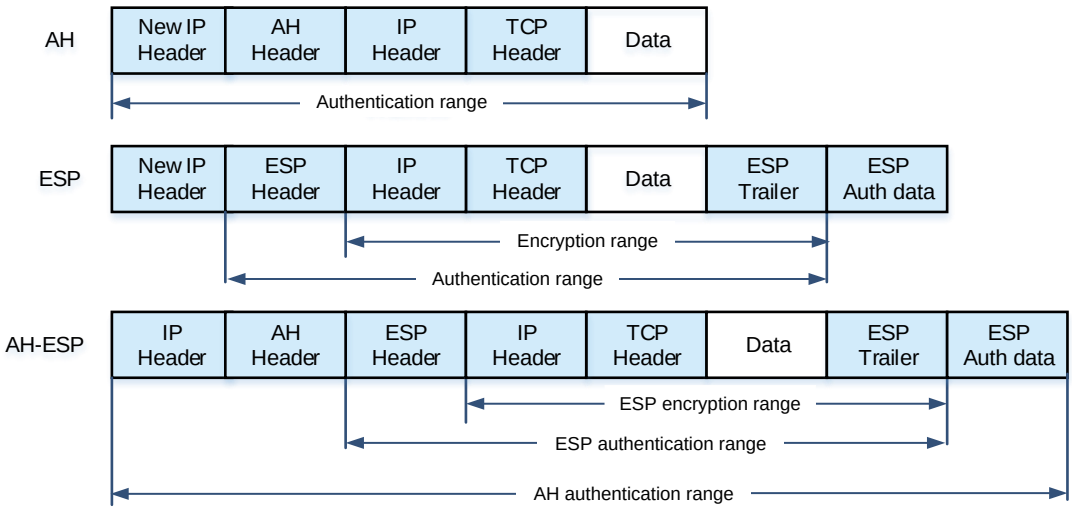
Security Service	AH	ESP
Data confidentiality	Not supported	Supported
Data integrity	Supported (entire IP packet)	Supported (excluding the IP header)
Data source authentication	Supported	Supported
Anti-replay	Supported	Supported



AH and ESP can be used independently or in combination. The device supports the combination of AH and ESP as follows: The device encapsulates packets through ESP and then uses AH to encapsulate packets. If you use AH first and then ESP, the length of a data packet will be changed due to the header, trailer, and padding fields of ESP. However, AH authenticates the entire IP data packet, and an authentication failure is caused.

3. Encapsulation Mode

IPsec supports two work modes:



- Transport mode: The AH or ESP header and ESP-encrypted user data are placed after the original IP packet header. The transport mode is typically applied in the communication between two hosts.

Figure 1-1 Packet Encapsulation in Transport Mode

- Tunnel mode: The AH or ESP header and ESP-encrypted user data are encapsulated into a new IP packet. The tunnel mode is typically applied in the communication between two security gateways.

Figure 1-2 Packet Encapsulation in Tunnel Mode

4. Authentication Algorithm

The authentication algorithm is mainly implemented using a hash function. The hash function can accept the input of messages of any length and output a message digest of a fixed length. IPsec peers compute digests separately. If the two digests are the same, a packet is intact and not tampered with. IPsec uses the following authentication algorithms:

- MD5: Generates a 128-bit message digest based on an input message of any length.
- SHA-1: Generates a 160-bit message digest based on an input message with the bit length less than the 64th power of 2.

- SHA2-256: Generates a 256-bit message digest based on an input message with the bit length less than the 64th power of 2.
- SHA2-384: Generates a 384-bit message digest based on an input message with the bit length less than the 128th power of 2.
- SHA2-512: Generates a 512-bit message digest based on an input message with the bit length less than the 128th power of 2.
- SM3: Generates a 256-bit message digest based on an input message with the bit length less than the 64th power of 2.

A longer message digest indicates higher security and slower computation.

5. Encryption Algorithm

IPsec adopts encryption algorithms using symmetric keys, and encrypts and decrypts data with the same key. Currently, IPsec on the device supports three encryption algorithms:

- DES: Encrypts 64-bit plaintext by using a 56-bit key.
- 3DES: Encrypts plaintext by using three 56-bit DES keys.
- AES: Encrypts plaintext by using a 128-bit, 192-bit, or 256-bit key.

1.1.3 IPsec Tunnel

You can configure a static tunnel policy on the CLI to create a common manual tunnel. In the establishment of a tunnel via IKE negotiation, an IKE-encrypted tunnel is established through IKE and then an IPsec tunnel is negotiated through the IKE tunnel. The IKE tunnel and IPsec tunnel are independent of each other. If the IKE tunnel is deleted, the IPsec tunnel still exists. Likewise, the IKE tunnel can exist independently after the IPsec tunnel is deleted. Therefore, IPsec tunnel-related control takes effect only on IPsec tunnels.

1.1.4 Protocols and Standards

- RFC 2401: Security Architecture for the Internet Protocol. S. Kent, R. Atkinson. November 1998. (Format: TXT=168162 bytes) (Obsoletes RFC 1825) (Obsoleted by RFC 4301) (Updated by RFC 3168) (Status: PROPOSED STANDARD)
- RFC 2402: IP Authentication Header. S. Kent, R. Atkinson. November 1998. (Format: TXT=52831 bytes) (Obsoletes RFC 1826) (Obsoleted by RFC 4302, RFC 4305) (Status: PROPOSED STANDARD)
- RFC 2403: The Use of HMAC-MD5-96 within ESP and AH. C. Madson, R. Glenn. November 1998. (Format: TXT=13578 bytes) (Status: PROPOSED STANDARD)
- RFC 2404: The Use of HMAC-SHA-1-96 within ESP and AH. C. Madson, R. Glenn. November 1998. (Format: TXT=13089 bytes) (Status: PROPOSED STANDARD)
- RFC 2405: The ESP DES-CBC Cipher Algorithm With Explicit IV. C. Madson, N. Doraswamy. November 1998. (Format: TXT=20208 bytes) (Status: PROPOSED STANDARD)
- RFC 2406: IP Encapsulating Security Payload (ESP). S. Kent, R. Atkinson. November 1998. (Format: TXT=54202 bytes) (Obsoletes RFC 1827) (Obsoleted by RFC 4303, RFC 4305) (Status: PROPOSED STANDARD)
- RFC 3948: UDP Encapsulation of IPsec ESP Packets. A. Huttunen, B. Swander, V. Volpe, L. DiBurro, M. Stenberg. January 2005. (Format: TXT=30366bytes) (Status: PROPOSED STANDARD)

1.2 Configuring an IPsec Tunnel for Routing Protocol Authentication

1.2.1 Overview

IPsec authentication is used to authenticate sending and receiving of routing protocol packets to prevent attacks on the device from forged routing protocol packets.

1.2.2 Restrictions and Guidelines

- One IPsec proposal can be applied to multiple IPsec SAs.
- One IPsec SA can be applied to multiple routing protocols.

1.2.3 Configuration Task Summary

IPsec tunnel configuration for routing protocol authentication includes the following tasks:

(1) Configuring an IPsec proposal

(2) Configuring an IPsec SA

(3) Applying the IPsec SA to a routing protocol

1.2.4 Configuring an IPsec Proposal

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Define an IPsec proposal for IPsec SA and enter the IPsec proposal configuration mode.

ipsec proposal proposal-name

The IPsec proposal for IPsec SA is not defined by default.

(4) Configure an encapsulation mode.

encapsulation-mode { transport | tunnel }

No encapsulation mode is configured by default.

(5) Configure a security protocol.

transform { ah | ah-esp | esp }

No security protocol is configured by default.

(6) (Optional) Configure an authentication algorithm for the AH protocol.

ah authentication-algorithm { **md5 | sha1 | sha2-256 | sha2-384 | sha2-512 | sm3** }

No authentication algorithm is configured for the AH protocol by default.

(7) (Optional) Configure an authentication algorithm for the ESP protocol.

esp authentication-algorithm { **md5 | sha1 | sha2-256 | sha2-384 | sha2-512 | sm3** }

No authentication algorithm is configured for the ESP protocol by default.

(8) (Optional) Configure an encryption algorithm for the ESP protocol.

esp encryption-algorithm { **3des | aes-128 | aes-192 | aes-256 | des** }

No encryption algorithm is configured for the ESP protocol by default.

1.2.5 Configuring an IPsec SA

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an IPsec SA and enter the IPsec SA configuration mode.

ipsec sa *sa-name*

No IPsec SA is created by default.

(4) Configure an IPsec proposal for the IPsec SA.

proposal *proposal-name*

No IPsec proposal is configured for the IPsec SA by default.

(5) Configure a security parameter index (SPI) for the IPsec SA.

sa spi { **ah** *spi* | **esp** *spi* }

No SPI is configured by default.

(6) (Optional) Configure an authentication key in hexadecimal notation.

sa authentication-hex { **ah** [**0** | **7**] *hex-key* | **esp** [**0** | **7**] *hex-key* }

No authentication key in hexadecimal notation is configured by default.

(7) (Optional) Configure an authentication key string.

sa string-key { **ah** [**0** | **7**] *string-key* | **esp** [**0** | **7**] *string-key* }

No authentication key string is configured by default.

(8) (Optional) Configure an encryption key in hexadecimal notation.

sa encryption-hex esp [**0** | **7**] *encryption-key*

No encryption key in hexadecimal notation is configured by default.

1.2.6 Applying the IPsec SA to a Routing Protocol

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Associate SA authentication with an interface.

ipv6 ospf ipsec sa { **disable** | *sa-name* } [**instance** *instance-id*]

No interface is associated with SA authentication by default.

1.3 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Run the **clear** command to clear information.

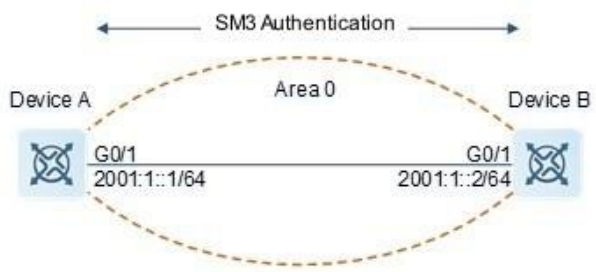
Caution

- The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.
- Running the **clear** command may lose vital information and thus interrupt services.

Table 1-2 IPsec Monitoring

Command	Purpose
show ipsec manual sa [*sa-name*]	Displays information about a configured IPsec SA.
show ipsec proposal [*proposal-name*]	Displays information about a configured IPsec proposal.

1.4 Configuration Examples



1.4.1 Configuring an IPsec Tunnel for Routing Protocol Authentication

1. Requirements

The customer wants to use SM3 authentication for OSPFv3.

2. Topology

Figure 1-3 Configuring an IPsec Tunnel for Routing Protocol Authentication

3. Notes

- Enable IPv6 on all device interfaces.
- Configure basic OSPFv3 features on all devices.
- Configure OSPFv3 IPsec authentication on all device interfaces.

4. Procedure

(4) Configure Device A.

Start an OSPFv3 process and configure a router ID.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# ipv6 router ospf 1
DeviceA(config-router)# router-id 1.1.1.1
DeviceA(config-router)# exit
```

Configure an IPsec proposal.

```
DeviceA(config)# ipsec proposal proposal111
DeviceA(config-ipsec-proposal)# encapsulation-mode transport
DeviceA(config-ipsec-proposal)# transform ah
DeviceA(config-ipsec-proposal)# ah authentication-algorithm sm3
DeviceA(config-ipsec-proposal)# exit
```

Configure an IPsec SA.

```
DeviceA(config)# ipsec sa sa1
DeviceA(config-ipsec-sa)# proposal proposal111
DeviceA(config-ipsec-sa)# sa spi ah 256
DeviceA(config-ipsec-sa)# sa authentication-hex ah
0123456789012345678901234567890123456789012345678901234567890abcd
DeviceA(config-ipsec-sa1)# exit
```

Configure an IP address for an interface and configure OSPFv3 on the interface.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1) ipv6 enable
```

```
DeviceA(config-if-GigabitEthernet 0/1) ipv6 address 2001:1::1/64
DeviceA(config-if-GigabitEthernet 0/1) ipv6 ospf 1 area 0
```

Apply the IPsec SA to the routing protocol.

```
DeviceA(config-if-GigabitEthernet 0/1)# ipv6 ospf ipsec sa sa1
```

(5) Configure Device B.

Start an OSPFv3 process and configure a router ID.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ipv6 router ospf 1
DeviceB(config-router)# router-id 2.2.2.2
DeviceB(config-router)# exit
```

Configure an IPsec proposal.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ipsec proposal proposal111
DeviceB(config-ipsec-proposal)# encapsulation-mode transport
DeviceB(config-ipsec-proposal)# transform ah
DeviceB(config-ipsec-proposal)# ah authentication-algorithm sm3
DeviceB(config-ipsec-proposal)# exit
```

Configure an IPsec SA.

```
DeviceB(config)# ipsec sa sa1
DeviceB(config-ipsec-sa)# proposal proposal111
DeviceB(config-ipsec-sa)# sa spi ah 256
DeviceB(config-ipsec-sa)# sa authentication-hex ah
0123456789012345678901234567890123456789012345678901234567890123456789abcd
DeviceB(config-ipsec-sa)# exit
```

Configure an IP address for an interface and configure OSPFv3 on the interface.

```
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1) ipv6 enable
DeviceB(config-if-GigabitEthernet 0/1) ipv6 address 2001:1::2/64
DeviceB(config-if-GigabitEthernet 0/1) ipv6 ospf 1 area 0
```

Apply the IPsec SA to the routing protocol.

```
DeviceB(config-if-GigabitEthernet 0/1)# ipv6 ospf ipsec sa sa1
```

5. Verification

Check information about the configured IPsec SA.

```
DeviceA# show ipsec manual sa sa1
ip security association name sa1(len 3), ref 0
  id: 2048(Activated)
  proposal name: proposal111
    encapsulation mode: transport
    transform: ah
    AH protocol: authentication sm3
```

```
   ESP protocol: authentication none, encryption none
  AH setting:
   AH spi: 256 (0x100)
   AH string-key:
   AH authentication hex key:
$10$181$huzuRca9EbwlWTHlMox5plYAfxdN7KC/5vaqeafY8QOjiAr0XjqBD3l6qBal1f6VzI95hKUGD
/VdZFd96drCwQ==$
  ESP setting:
   ESP spi: 0 (0x0)
   ESP string-key:
   ESP encryption hex key:
   ESP authentication hex key:
```

Check whether the OSPF neighbor status is correct on Device A.

```
DeviceA# show ipv6 ospf neighbor
OSPFv3 Process (1), 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State       BFD State     Dead Time   Instance ID   Interface
2.2.2.2          1   Full/DR     -           00:00:38    0           GigabitEthernet
0/1
```

Check whether the OSPF neighbor status is correct on Device B.

```
DeviceB# show ipv6 ospf neighbor
OSPFv3 Process (1), 1 Neighbors, 1 is Full:
Neighbor ID     Pri   State       BFD State      Dead Time   Instance ID   Interface
1.1.1.1          1   Full/BDR    -            00:00:38    0
GigabitEthernet 0/1
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ipsec proposal proposal111
 encapsulation-mode transport
 transform ah
 ah authentication-algorithm sm3
!
ipsec sa sa1
 proposal proposal111
 sa spi ah 256
 sa authentication-hex ah 7

1 Configuring ACL

1.1 Introduction

1.1.1 Overview

The access control list (ACL) is also called access list or packet filtering in some documents. An ACL defines a series of "permit" or "deny" rule statements, and applies these rules to a device to control the data packets entering/leaving the device, so as to improve the security of network devices.

Configuring ACL can guarantee network security, reliability, and stability, for example:

- Preventing packet attacks: An ACL can be configured to deny the attacks launched using the Internet Protocol (IP), Transmission Control Protocol (TCP), or Internet Control Message Protocol (ICMP) packets.
- Controlling network access: An ACL can be configured to restrict users to some services, for example, users are allowed to access only the WWW and email services, but not allowed to access other services such as telnet; some users are allowed to access services only within a given time period, or only certain hosts are allowed to access the network.
- Controlling network traffic: An ACL can be used together with quality of service (QoS) to guarantee prioritized services for some important data flows. For QoS configuration, see *Configuring QoS*.

1.1.2 Principles

1. Basic Concepts

- ACL

  ACLs are classified into basic ACLs and dynamic ACLs.

  Users can select a basic ACL or a dynamic ACL as needed. In general, a basic ACL can meet security requirements. However, attackers may counterfeit source addresses by using some software to spoof devices and access the network. Before users access the network, the dynamic ACL requires them to pass identity authentication, which makes it hard for attackers to access the network. Therefore, the dynamic ACL can be used in some sensitive areas to ensure network security.

Note

Spoofing devices by counterfeiting source addresses, namely, spoofing, is an inherent problem of all ACLs. Spoofing also occur on the dynamic ACL: Attackers may fake users' addresses to access the network during the effective access period after the users pass the identity authentication. This problem can be solved in two ways. One is to set shorter idle time of user access. The other is to use the IP Security (IPSec) encryption protocol to encrypt the network data, and ensure that all the data is encrypted when the data is transmitted to a device.

The ACL is generally configured on the following network devices:

- A device between an internal network and an external network (such as the Internet)
- A device at the boundary of two networks

- A device connecting to a control port

- ACE

  An access control entry (ACE) is a statement containing the "permit" or "deny" action and filtering rules. Each ACE has a sequence number, which is automatically allocated by the device or manually configured. An ACL contains one or more ACEs. The ACL identifies and filters packets by using ACEs.

  The sequence of ACEs in an ACL determines the matching priority of the ACEs in the ACL. When processing packets, a network device performs rule matching in the ascending order of ACE sequence numbers. When finding a matched ACE, the network device stops matching subsequent ACEs.

  For example, create ACE 10 to deny all data flows.

```
10 deny ip any any
20 permit tcp 192.168.12.0 0.0.0.255 eq telnet any
```

  Since ACE 10 denies all the IP packets, the telnet packet from the host in the 192.168.12.0/24 network is denied even if it matches ACE 20. The reason is that, after finding that the packet matches the first ACE 10, the device stops matching the packet with the subsequent ACE 20.

  Here is another example: Create ACE 10 to permit all IPv6 data flows to pass through.

```
10 permit ipv6 any any
20 deny ipv6 host 200::1 any
```

  Since ACE 10 permits all IPv6 packets to pass through, the IPv6 packet sent from the host with IP address 200::1 can pass through even if it matches ACE 20. The reason is that, after finding that the packet matches the first ACE, the device stops matching the packet with the subsequent ACE 20.

- Step

  When the device automatically allocates sequence numbers to ACEs, the difference between two adjacent ACE sequence numbers is called a step. For example, if the step is set to 5, the device automatically allocates sequence numbers to ACEs in the ascending order of 5, 10, 15.... See the example below.

```
5 deny ip any any
10 permit tcp 192.168.12.0 0.0.0.255 eq telnet any
```

  After the step is changed, the ACE sequence numbers will be automatically rearranged based on the new step value. For example, when the step is changed to 10, the original ACE sequence numbers are changed from 5, 10, and 15 to 5, 15, and 25.

  A new ACE can be inserted between two ACEs by changing the step. For example, four ACEs are created, and the ACEs are manually numbered 1, 2, 3, and 4 in turn. To insert a new ACE after ACE 1, first change the step to 2 (then, the sequence numbers of the original four ACEs automatically change to 1, 3, 5, and 7), and then insert a manually configured ACE with sequence number 2.

- Filter field template

  Filter fields mean the fields used to identify and classify packets when an ACE is generated. A filter field template is a combination of such fields. An ACE identifies Ethernet packets by some fields in them, including:

- Layer2 fields:
  - 48-bit source MAC address (the 48-bit source MAC address must be matched completely)
  - 48-bit destination MAC address (the 48-bit destination MAC address must be matched completely)

- 16-bit Layer2 type field

- Layer3 fields:
  - Source IP address field (all the source IP address values can be matched or a subnet can be used to define a type of flow)
  - Destination IP address field (all the destination IP address values can be matched or a subnet can be used to define a type of flow)
  - Protocol type field
- Layer4 fields:
  - You can define a TCP source port, destination port, or both for matching; you can also define the range of the source port or destination port for matching.
  - You can define a User Datagram Protocol (UDP) source port, destination port, or both for matching; you can also define the range of the source port or destination port for matching.

  For example, you can create an ACE to identify and classify packets based on their destination IP address field. You can also create another ACE to identify and classify packets based on their source IP address field and UDP source port field. These two ACEs use different filter field templates.
- Rules

  Rules refer to the values of fields in an ACE filter field template. For example, an ACE reads as follows:

  ```
  10 permit tcp host 192.168.12.2 any eq telnet
  ```

  In this ACE, the filter field template is a collection of the following fields: source IP address field, destination IP address field, IP protocol field, and TCP destination port field. The corresponding values (namely, rules) are as follows: The source IP address is Host 192.168.12.2, the destination IP address is Any (namely, all the hosts), the IP protocol is TCP, and the TCP destination port is Telnet. See Figure 1-1.
- Action

  Action is specified in ACE. The actions include permit and deny. Permit means that the traffic matching the rules can pass, and deny means that the traffic matching the rules is rejected.

Figure 1-1 Analysis of ACE: permit tcp host 192.168.12.2 any eq telnet

Note

- A filter field template can be a collection of Layer3 fields and Layer4 fields, or a collection of multiple Layer2 fields. However, the filter field templates of the standard and extended ACLs cannot be a collection of Layer2 and Layer3 fields, or Layer2 and Layer4 fields, or Layer2, Layer3, and Layer4 fields. To use a collection of Layer2, Layer3, and Layer4 fields, you can use an expert extended ACL.
- If a destination MAC address is configured for matching in MAC extended and expert ACLs and such ACLs are applied in the outbound direction of an SVI, the ACEs containing the destination MAC address can be configured but fail to take effect. If you configure a destination IP address for matching in the IP extended and expert ACLs but the destination IP address is not within the subnet IP address range of the associated SVI, the configured ACLs do not take effect. For example, if VLAN 1 has an IP address 192.168.64.1 255.255.255.0 and an IP extended ACL is created, with the ACE deny udp any 192.168.65.1 0.0.0.255 eq 255, this ACL does not take effect when it is applied to the egress of VLAN 1. The cause is that the destination IP address is not within the subnet IP address range of VLAN 1. If the ACE is deny udp any 192.168.64.1 0.0.0.255 eq 255, the ACL takes effect because the destination IP address complies with the requirements.
- When an expert ACL is configured and applied to the outbound direction of a port, if some ACEs in the ACL contain Layer3 matching information (such as IP address and Layer4 port), the non-IP packets received by the port cannot be subjected to the permit and deny ACEs of the ACL.

Specification

- The outbound ACL acting on the physical port and Layer3 aggregation port (AP) only supports matching well-known packets (unicast and multicast), but does not support matching unknown unicast packets, that is, the outbound ACL configured on a port does not take effect for the unknown packets or broadcast packets.
- When the input ACL, IEEE 802.1x, global IP and MAC address binding, port security, and IP source guard are all configured, the permit and default deny ACEs do not take effect but other deny ACEs take effect normally.
- When the input ACL and QoS are configured, the permit ACE does not take effect, but other deny ACEs take effect normally; the default deny ACE takes effect after the QoS entry.
- If an ACE is added to an ACL after the ACL is applied to the inbound direction of multiple SVIs, and the device is restarted after the configuration is saved, the ACLs configured on several SVIs may fail to take effect due to the hardware capacity causes.

2. IP ACL

IP ACL implements refined control over the IPv4 packets entering/leaving the device. You can deny or permit specific IPv4 packets destined to a network according to the actual needs, so as to control the access of IP users to network resources.

You can define a series of access rules in an IP ACL, and apply the ACL to the inbound or outbound direction of a port. You can also apply an IP ACL globally. When IPv4 packets enter or leave a device, the device determines whether to forward or block them by judging whether they match the rules.

To configure an IP ACL on a device, you must specify a unique name or number for each ACL to uniquely identify the ACL.

IP ACLs are classified into IP standard ACLs and IP extended ACLs. Table 1-1 lists the ranges of numbers that can be used for IP standard ACLs and IP extended ACLs.

Table 1-1 Number Ranges for IP Standard ACLs and IP Extended ACLs

Type	Number Range	Matching Field
IP standard ACL	1 to 99, 1300 to 1999	Source IP address
IP extended ACL	100 to 199, 2000 to 2699	● Source IP address ● Destination IP address ● IP protocol number ● Layer4 source port ID or ICMP type ● Layer4 destination port ID or ICMP code

The IP standard ACL controls the forwarding or blocking of packets based on the source IP address. The IP extended ACL controls the forwarding or blocking of packets by combining the matching fields in the table above.

A single ACL can use multiple independent ACL statements to define multiple rules, and all the statements use the same number or name so that the statements are bound to the same ACL.

Note

The ICMP code matching field in ACL rules is invalid for the ICMP packets with ICMP type 3. If the code field for matching ICMP packets is configured in an ACL rule, when ACL matching is performed on the ICMP packets with type 3 on the routers, the matching result may be different from the expected result.

One rule statement of denying all data flows is hidden at the end of each IP ACL. If a packet fails to match any rules, it will be denied. For example:

```
access-list 1 permit host 192.168.4.12
```

This ACL only permits the packets with source host address 192.168.4.12 to pass through, and denies the packets of the other hosts. The reason is that this ACL contains a rule statement at its end as follows:

```
access-list 1 deny any
```

Here is another example:

```
access-list 1 deny host 192.168.4.12
```

If an ACL contains the above statement only, the packets of all the hosts are denied wen passing through the port.

Caution

When defining an ACL, you must consider the route update packets. The rule statement of denying all data flows at the end of the ACL may result in blocking of all the route update packets.

3. MAC Extended ACL

The MAC extended ACL implements refined control over the packets entering/leaving the device based on the Layer2 information of the packets. You can deny or permit specific Layer2 packets destined to a network according to the actual needs, so as to protect network resources against attacks or control the access of users to network resources.

You can define a series of access rules in a MAC extended ACL, and apply the ACL to the inbound or outbound direction of a port. When packets enter or leave a device, the device determines whether to forward or block them by judging whether they match the rules.

To configure a MAC extended ACL on a device, you must specify a unique name or number for each ACL to uniquely identify the ACL. Table 1-2 lists the range of numbers for the MAC extended ACLs.

Table 1-2 Number Range for MAC Extended ACLs

Type	Number Range	Matching Field
MAC extended ACL	700 to 799	● Source MAC address ● Destination MAC address ● Ethernet protocol type

The MAC extended ACL controls the forwarding or blocking of packets based on the source or destination MAC address and the Ethernet type of packets.

A single MAC extended ACL can use multiple independent ACL statements to define multiple rules, and all the statements use the same number or name so that the statements are bound to the same ACL.

Note

If a MAC extended ACL rule does not specify IPv6 packets, that is, the Ethernet type field is not defined or the defined Ethernet type field value is not 0x86dd, then the MAC extended ACL is not used to match IPv6 packets. If you need to match IPv6 packets, define an IPv6 ACL.

One rule statement of denying all data flows is hidden at the end of each MAC extended ACL. If a packet fails to match any rules, it will be denied. For example:

```
access-list 700 permit host 00d0.f800.0001 any
```

This ACL permits only the packets sent from the host with MAC address 00d0.f800.0001 to pass through, and denies the packets from all the other hosts. The reason is that this ACL contains a rule statement at its end as follows:

```
access-list 700 deny any any
```

4. Expert Extended ACL

An expert extended ACL implements refined control over the packets entering/leaving a device based on the Layer2 and Layer3 information of the packets. The expert extended ACL can be regarded as a combination and enhancement of the IP ACL and MAC extended ACL. An expert extended ACL can contain IP ACL rules and MAC extended ACL rules, and specify VLAN IDs for packet matching.

You can define a series of access rules in an expert extended ACL, and apply the ACL to the inbound or outbound direction of a port. When packets enter or leave a device, the device determines whether to forward or block them by judging whether they match the access rules.

To configure an expert extended ACL on a device, you must specify a unique name or number for each ACL to uniquely identify the ACL. Table 1-3 lists the range of numbers that can be used for expert extended ACLs.

Table 1-3 Number Range for Expert Extended ACLs

Type	Number Range	Matching Field
Expert extended ACL	2700 to 2899	● Source IP address ● Destination IP address ● IP protocol number ● Layer4 source port ID or ICMP type ● Layer4 destination port ID or ICMP code ● Source MAC address ● Destination MAC address ● Ethernet protocol type ● VLAN ID

The expert extended ACL controls the forwarding or blocking of packets by combining the matching fields in the table above.

A single expert extended ACL can use multiple independent ACL statements to define multiple rules, and all the statements must use the same number or name so that the statements are bound to the same ACL.

Note

If an expert extended ACL rule does not specify IPv6 packets, that is, the Ethernet type field is not defined or the defined Ethernet type field is not 0x86dd, then the expert extended ACL does not match IPv6 packets. If you need to match IPv6 packets, define an IPv6 ACL.

One rule statement of denying all data flows is hidden at the end of each expert extended ACL. If a packet fails to match any rules, it will be denied. For example:

```
access-list 2700 permit 0x0806 any any any any any
```

This ACL only permits the packets with Ethernet type 0x0806 (namely, ARP) to pass through, and denies the packets of the other types. The reason is that this ACL contains a rule statement at its end as follows:

```
access-list 2700 deny any any any any
```

5. IPv6 ACL

The IPv6 ACL implements refined control over the IPv6 packets entering/leaving a device. You can deny or permit specific IPv6 packets destined to a network according to the actual needs, so as to control the access of IPv6 users to network resources.

You can define a series of access rules in an IPv6 ACL, and apply the ACL to the inbound or outbound direction of a port. When IPv6 packets enter or leave a device, the device determines whether to forward or block them by judging whether they match the rules.

To configure an ACL on a device, you must specify a unique name for the ACL of a protocol.

One rule statement of denying all IPv6 data flows is hidden at the end of each IPv6 ACL. If a packet fails to match any rules, it is denied. For example:

```
ipv6 access-list ipv6_acl
 10 permit ipv6 host 200::1 any
```

This ACL only permits the IPv6 packets coming from source host 200::1 to pass through, and denies the IPv6 packets from all the other hosts. The reason is that this ACL contains a rule statement at its end as follows:

```
deny ipv6 any any
```

6. ACL80

ACL80 is the expert advanced ACL, also known as user-defined ACL. ACL80 supports matching the specified bytes in the first 80 bytes of a packet by bit.

There are three elements in ACL80 matching: matching field content, matching field mask, and the start position (that is, the offset) of matching. The bits of the matching field content map to those of the matching field mask. The matching field content specifies the field value to be matched, and the matching field mask specifies whether the corresponding bits need to be matched. When a bit needs to be matched, the corresponding bit in the matching field mask must be set to **1**. If a bit in a matching field mask is set to **0**, the corresponding bit in the matching field content will not be matched regardless of the bit value in the matching field content. For example:

```
10 permit 00d0f8123456 ffffffffffff 0
20 deny 00d0f8154321 ffffffffffff 6
```

In ACE 10, the matching field content is 00d0f8123456, the matching field mask is ffffffffffff, and the offset is 0. This rule indicates that, if the destination MAC address of a packet is 00d0f8123456, the packet is permitted to be forwarded.

In ACE 20, the matching field content is 00d0f8154321, the matching field mask is ffffffffffff, and the offset is 6. This rule indicates that, if the source MAC address of a packet is 00d0f8154321, the packet is blocked.

You need to deeply understand the Layer2 data frame structure so as to use the user-defined ACL correctly. Figure 1-2 shows the first 64 bytes of an Layer2 data frame. In the figure, each letter represents one hexadecimal number and every two letters represent one byte.

Figure 1-2 First 64 Bytes of a Layer2 Data Frame

AA	AA	AA	AA	AA	AA	BB	BB	BB	BB	BB	BB	CC	CC	DD	DD
DD	DD	EE	FF	GG	HH	HH	HH	II	II	JJ	KK	LL	LL	MM	MM
NN	NN	OO	PP	QQ	QQ	RR	RR	RR	RR	SS	SS	SS	SS	TT	TT
UU	UU	VV	VV	VV	VV	ww	ww	ww	ww	XY	ZZ	aa	aa	bb	bb

Table 1-4 lists the meaning and offset value of each letter.

Table 1-4 Meanings and Offset Values of Letters

Letter	Description	Offset	Letter	Description	Offset
A	Destination MAC address	0	O	TTL field	34
B	Source MAC address	6	P	Protocol number	35
C	VLAN tag field	12	Q	IP checksum	36
D	Data frame length field	16	R	Source IP address	38
E	Destination service access point (DSAP) field	18	S	Destination IP address	42
F	Source service access point (SSAP) field	19	T	TCP source port	46
G	Control field	20	U	TCP destination port	48
H	Org code field	21	V	Serial number	50
I	Encapsulated data type	24	W	Acknowledgment field	54
J	IP version No.	26	XY	IP header length and reserved bits	58
K	ToS field	27	Z	Reserved bits and flags bits	59
L	IP packet length	28	a	Windows size field	60
M	ID	30	b	Others	62
N	Flags field	32			

The offset of each field in the table is their offset in the IEEE 802.3 data frame containing the SNAP+Tag fields. The user-defined ACL extracts specific fields from the first 80 bytes of a data frame according to offsets listed in Table 1-5, and then compare the fields with the matching field masks so as to determine the matching field content. For example, if you permit all TCP packets to be forwarded, you can set the matching field content to **06**, the matching field mask to **ff**, and the offset to **35**. Create ACE 10 as follows:

```
10 permit 06 ff 35
```

Apply the ACL to the inbound or outbound direction of a port. When a packet enters or leaves a device, ACL80 extracts the content of the TCP protocol number field from the data frame, and then compares the content with the matching field content to find out all the matched TCP packets for forwarding.

7. Redirect ACL

Redirect ACL enables a device to redirect the packets matching the rules to a specified port for forwarding. Or the device obtains and analyzes the packets in specified ports.

Redirect ACL binds an ACL on an input port and specifies an output port. When the input interface receives a packet, it queries ACL rules bound to the port one by one. If the packet conforms to the characteristics described in a rule, it is forwarded from the output port specified by the policy.

8. Global Security ACL

The global security ACL function can prevent the internal access to illegal websites or prevent viruses from entering the internal network of the enterprise. There are various virus packets in the network, and the identification characteristics of virus packets are the same or similar on each port. A port-based security ACL is often configured to filter out packets that comply with some characteristics (such as forged TCP attack packets) and prevent virus packets. You can create an ACL, add ACEs that match the characteristics of various virus packets, and apply the ACL to each port of a device to filter out virus packets.

When the port-based security ACL is used in the attack-defense scenarios such as virus filtering, there are much inconvenience.

- Ports must be configured one by one. Duplicate configuration, poor operating performance, and excessive consumption of ACL resources can occur.
- The access control function of the security ACL is weakened. Because the security ACL is used for virus filtering, the basic functions of the security ACL including restricting route updates and restricting network access become unavailable.

The global security ACL can be used for global anti-virus deployment and defense without affecting the port-based security ACL. A global security ACL can take effect on all the Layer2 ports after one command is configured.

When both the global security ACL and port-based security ACL are configured, they take effect at the same time. The packets that match rules in the global security ACL will be directly filtered out as virus packets, and the packets that fail to match the rules of the global security ACL are still controlled by the port-based security ACL. To exempt some ports from the control of the global security ACL, disable the global security ACL function on these ports. When the global, port-based, and VLAN-based security ACLs are applied at the same time, the priorities are global > interface. That is, the global security ACL is matched first, and then the security ACL of the interface is matched. The security ACL of the VLAN is independently matched.

To avoid misconfiguration of the global security ACL, the global security ACL disabling function is provided. If you disable the global security ACL function and then configure a global security ACL, the system prompts a configuration failure. If you have configured a global security ACL and then disable the global security ACL function, the system deletes all the current global security ACLs and displays a log prompt.

9. Security Channel

In some application scenarios, the packets complying with certain characteristics must bypass the check of access control application. For example, before the IEEE 802.1x authentication, users must be allowed to log in to the specified resource site and download the IEEE 802.1x authentication client. This can be achieved through the security channel.

A security channel is also an ACL, which can be configured globally or on ports.

When entering a device port, a packet is first checked by the security channel. If the packet meets the matching conditions of the security channel, it bypasses the access control such as port security, Web authentication, IEEE 802.1x, and IP-MAC binding check, and directly enters the device. The security channel applied globally takes effect for all the non-excluded ports.

10. SVI Router ACL

An ACL applied to an SVI (namely, SVI ACL) takes effect for both the packets forwarded on Layer2 in a VLAN and the inter-VLAN routed packets. As a result, different users in the same VLAN cannot make normal

communication. The SVI router ACL function enables the ACL applied to an SVI to take effect only for the inter-VLAN routed packets.

The SVI router ACL function is disabled by default. The SVI ACL takes effect for the inter-VLAN Layer3 forwarded packets and the intra-VLAN packets forwarded by bridges. After the SVI router ACL function is enabled, the SVI ACL is effective only for the inter-VLAN Layer3 forwarded packets.

11. Packet Matching Logging

The packet matching logging is used to monitor the running status of ACL rules and provide necessary information for routine network maintenance and network optimization.

To better grasp the running status of ACL in the device, when adding ACEs, you can decide whether to specify the packet matching logging option as needed. If this option is specified, the matching logs are output when ACEs match packets. ACL prints log information based on ACE, that is, the device periodically prints the ACEs that match packets and the number of matched packets. See the example below:

```
*Sep  9 16:23:06: %ACL-6-MATCH: ACL 100 ACE 10 permit icmp any any, match 71
packets.
```

To reasonably control the quantity and frequency of log output, ACL allows configuring the log output interval.

Caution

- An ACL rule with the log option uses more hardware resources. If all the configured rules have the log option, the hardware policy capacity of the device is halved.
- The default output interval of packet matching logs is 0 minutes, that is, no ACL matching log is output. After specifying the log option when configuring ACL rules, you also need to configure the output interval, otherwise no matching log is output.
- For a rule with the log option, if no packet matches the rule within the specified time interval, no packet matching log related to the rule is output; if a packet matches the rule within the specified time interval, the packet matching log related to the rule is output after the time interval expires. The number of matched packets is the total number of packets matching the rule within the time interval, that is, the number of matched packets from the last log output to the current log output.

12. Packet Matching Counting

For the needs of network management, you may want to know whether an ACL rule matches packets and the number of matched packets. ACL provides the rule-based packet matching counting function. You can enable or disable the packet matching counting function for all the rules in an ACL. When a packet matches a rule, the corresponding matching count increases accordingly. You can run the statistics clearing command for an ACL to clear the packet matching counts of all rules in the ACL and start new counting.

Caution

Enabling the packet matching counting function of ACL requires more hardware entries, and in extreme cases, halves the available hardware policy capacity of the device.

13. ACL Effective Time Range

If you need to control some flows within a specified time range, for example, disable chat tools during working hours, you can configure effective time ranges for ACEs to control the pass-through time of flows. The time ranges are classified into absolute time ranges and periodic time ranges.

An absolute time range indicates the time range from the specified start time to the end time. This time range does not occur cyclically nor has a period, for example, "12:00:00 on January 1, 2000 to 12:00:00 on January 1, 2001".

A periodic time range indicates a periodic time interval, for example, "8:00 on each Monday to 17:00 on each Friday".

For details about the time range configuration, see *Configuring Time Range* in **Configuration Guide** > **Device Management**.

14. Fragmented Packet Matching Mode

The fragmented packet matching mode enables ACL to control fragmented packets more finely.

IP packets may be fragmented during network transmission. When a packet is fragmented, only the first fragment carries Layer4 information, such as the TCP or UDP port ID, ICMP type, and ICMP code. Other fragmented packets do not carry the Layer4 information. In the default fragmented packet matching mode, if an ACL rule carries the fragment flag, only the non-first fragments are matched; if an ACL rule does not carry the fragment flag, all the packets, including the first fragment and all the subsequent fragmented packets, are matched. In addition to the default fragmented packet matching mode, another new fragmented packet matching method is provided. You can switch between the modes on a specified ACL as needed. In the new fragmented packet matching mode, when an ACL rule does not carry the fragment flag, if a packet is fragmented, the first fragment will be matched with all the user-defined matching fields in the rule (including the Layer3 and Layer4 information) and non-first fragments will be matched only with non-Layer4 information in the rule.

Specification

The fragmented packet matching mode can be switched only in the IP extended ACL and expert extended ACL.

15. Global Control Plane Security ACL

In some application scenarios, an ACL needs to be bound to restrict the source IP host to processing the initial packets in a TCP handshake, instead of conducting restriction after a TCP connection is established. The global control plane security ACL filters packets only through software. It not only reduces the hardware resource consumption but also meets the requirement for processing the initial TCP packets. If you apply a security ACL globally by running a control plane application command, the ACL takes effect on software only.

The global control plane security ACL takes effect on all Layer2 ports. ACEs are not applied to hardware but only to software, which reduces the hardware resource consumption. During a TCP handshake, the software ACL checks initial TCP packets and filters out the TCP packets that match the ACL.

Note

- The global control plane security ACL is effective to software-based filtering and can be applied only to the inbound direction.
- The global control plane security ACL is not limited by the configuration of global ACL excluded ports. After the excluded ports are configured, the global control plane security ACL remains effective on the excluded ports.
- The global control plane security ACL takes effect on both Layer2 ports and Layer3 ports. That is, it can take effect on the following types of ports: access port, trunk port, hybrid port, Layer 3 Ethernet port, Layer 2 or Layer 3 aggregation port. It does not take effect on the SVIs or member ports of aggregation ports.

- The global control plane security ACL can be associated only with the IP standard ACL.

1.2 Restrictions and Guidelines

- An ACL can contain no rules. When no rules are configured in an ACL, one rule statement of denying all data flows is hidden in the ACL to prohibit all IPv4 packets from entering the device.
- To make some ACL rules take effect at specified time or expire at specified time, for example, make an ACL effective within some time ranges in a week, configure an ACL rule with the **time-range** option.
- When configuring ACLs with time-range options, you need to configure the time range. For details about time range configurations, see *Configuring Time Range* in **Configuration Guide** > **Device Management.**
- During the actual network maintenance, if many ACLs or rules are configured, but no remark is configured for these ACLs or rules, it is difficult to distinguish the purposes of these ACLs or rules. Configuring remarks for ACLs or rules can help you understand the purpose of the ACLs.
  - Run the **access-list list-remark** or **list-remark** command to add a remark to an ACL. The configuration effect of the two commands is the same, and the command configured later takes effect.
  - Run the **access-list remark** or **remark** command to add a remark to an ACE. The configuration effect of the two commands is the same, and the command configured later takes effect. If the parameter *sequence-number* is specified, the remark is added to the specified ACE. If *sequence-number* is not specified, the remark is added to the last ACE.
- The ACL can be configured on access, convergence, or core devices, depending on user distribution. The ACL takes effect only on the configured device, and does not affect the other devices in the network.
- When you switch the fragmented packet matching mode, the ACL fails for a short period of time.
- In a new fragmented packet matching mode, if an ACL rule does not carry a fragment flag and the matching action is permit, such an ACL rule occupies more hardware entry resources, and, in extreme cases, halves the capacity of hardware policy entries. If such an ACE is configured to filter established TCP packets, more hardware policy entry resources will be occupied.
- In a new fragmented packet matching mode, if an ACL rule does not carry a fragment flag and needs to match the Layer 4 information of packets, when the matching action is permit, the ACL rule checks the Layer 3 and Layer 4 information of the first fragment, and checks only the Layer 3 information of the non-first fragments.
- When the matching action is deny, the ACL rule checks only the first fragment, but does not check the non-first fragments.
- In a new fragmented packet matching mode, if an ACL rule carries a fragment flag, no matter whether the matching action of the ACL rule is permit or deny, the ACL rule checks only the non-first fragments.

1.3 Configuration Task Summary

ACL configuration tasks are as follows.

(1) To configure an ACL, select at least one of the following tasks to configure:

- Configuring an IP Standard ACL
  - Creating an IP Standard ACL (Global Configuration Mode)

- Creating an IP Standard ACL (IP Standard ACL Configuration Mode)
- Configuring an IP Extended ACL
  - Creating an IP Extended ACL (Global Configuration Mode)
  - Creating an IP Extended ACL (IP Extended ACL Configuration Mode)
- Configuring a MAC Extended ACL
  - Creating a MAC Extended ACL (Global Configuration Mode)
  - Creating a MAC Extended ACL (MAC Extended ACL Configuration Mode)
- Configuring an Expert Extended ACL
  - Creating an Expert Extended ACL (Global Configuration Mode)
  - Creating an Expert Extended ACL (Expert Extended ACL Configuration Mode)
- Configuring an IPv6 ACL
- Configuring an Expert Advanced ACL (ACL80)

(2) Applying an ACL

- Applying an ACL Globally
- Applying an ACL to an Interface
- Configuring a Redirect ACL

(3) Configuring a Global Security ACL

(4) Configuring a Security Channel

(5) Configuring an SVI Router ACL

(6) Synchronizing All ACEs from Software to Hardware

1.4 Configuring an IP Standard ACL

1.4.1 Overview

This section describes how to configure an IP standard ACL to control the IPv4 packets entering/leaving a device. In this way, users' access to network resources can be controlled by only checking the source IP addresses of packets.

1.4.2 Restrictions and Guidelines

- Configuring an ACL rule with the **log** option consumes more hardware resources. If all the configured rules have the **log** option, the hardware policy capacity of the device is halved.
- The default output interval of packet matching logs is 0 minutes, that is, no ACL matching log is output. After specifying the **log** option when configuring ACL rules, you also need to configure an output interval; otherwise no matching log is output.
- For a rule with the **log** option, if no packet is matched within the specified time interval, no packet matching log related to the rule is output; if a packet is matched within the specified time interval, the packet matching log related to the rule is output after the time interval expires. The number of matched packets is the total number of packets matching the rule within the time interval, that is, the number of matched packets from the last log output to the current log output.

1.4.3 Configuration Tasks

IP standard ACL configuration includes the following tasks:

- Creating an IP Standard ACL (Global Configuration Mode)
- Creating an IP Standard ACL (IP Standard ACL Configuration Mode)

1.4.4 Creating an IP Standard ACL (Global Configuration Mode)

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an IP standard ACL and rules.

access-list *acl-number* { **deny** | **permit** } { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *time-range-name*] [**log**]

No IP standard ACL or rule is configured by default.

(4) (Optional) Configure an update interval for packet matching logs.

ip access-list log-update interval *time-value*

The default update interval is 0 minutes. That is, no ACL matching log is output.

(5) (Optional) Configure a remark for the ACL.

access-list *acl-number* **list-remark** *text*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for rules in the IP standard ACE.

access-list *acl-number* [*sequence-number*] **remark** *text*

No remark is configured for ACE rules by default.

(7) (Optional) Enable the packet matching counting function of an IP standard ACL.

ip access-list counter { *acl-name* | *acl-number* }

The packet matching counting function of an IP standard ACL is disabled by default.

(8) (Optional) Configure a new fragmented packet matching mode of an IP standard ACL.

ip access-list new-fragment-mode { *acl-name* | *acl-number* }

No new fragmented packet matching mode is configured for an IP standard ACL by default.

(9) (Optional) Configure a step for rule sequence numbers in the IP standard ACL.

ip access-list resequence { *acl-name* | *acl-number* } *start-value step-value*

Both the start value and step of an IP standard ACL rule sequence numbers are 10 by default.

1.4.5 Creating an IP Standard ACL (IP Standard ACL Configuration Mode)

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an IP standard ACL and enter the IP standard ACL configuration mode.

ip access-list standard { *acl-name* | *acl-number* }

No IP standard ACL is configured by default.

(4) Configure an ACL rule.

[*sequence-number*] { **deny** | **permit** } { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *time-range-name*] [**log**]

There is an ACL rule of deny type in an IP standard ACL by default.

(5) (Optional) Configure a remark for the ACL.

list-remark *text*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for rules in the IP standard ACE.

[*sequence-number*] **remark** *text*

No remark is configured for ACL rules by default.

1.5 Configuring an IP Extended ACL

1.5.1 Overview

This section describes how to configure an IP extended ACL to control the IPv4 packets entering/leaving a device. In this way, IP users' access to network resources can be controlled by checking the source IP addresses, destination IP addresses, protocol numbers, and source or destination TCP/UDP port numbers of packets.

1.5.2 Restrictions and Guidelines

- Configuring an ACL rule with the **log** option consumes more hardware resources. If all the configured rules have the **log** option, the hardware policy capacity of the device is halved.
- The default output interval of packet matching logs is 0 minutes, that is, no ACL matching log is output. After specifying the **log** option when configuring ACL rules, you also need to configure an output interval; otherwise no matching log is output.
- For a rule with the **log** option, if no packet is matched within the specified time interval, no packet matching log related to the rule is output; if a packet is matched within the specified time interval, the packet matching log related to the rule is output after the time interval expires. The number of matched packets is the total number of packets matching the rule within the time interval, that is, the number of matched packets from the last log output to the current log output.

1.5.3 Configuration Tasks

IP extended ACL configuration includes the following tasks:

- Creating an IP Extended ACL (Global Configuration Mode)
- Creating an IP Extended ACL (IP Extended ACL Configuration Mode)

1.5.4 Creating an IP Extended ACL (Global Configuration Mode)

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an IP extended ACL and its rules.

access-list *acl-number* { **deny** | **permit** } *protocol* { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**range** *lower upper*] [**time-range** *time-range-name*] [**log**]

No IP extended ACL or rule is configured by default.

Note

The commands for adding a rule of deny type to IP extended ACLs that specify some important protocols in the protocol field are as follows.

- The Internet Control Message Protocol (ICMP) field is selected.

  access-list *acl-number* { **deny** | **permit** } **icmp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**time-range** *time-range-name*] [**log**]

- The Transmission Control Protocol (TCP) field is selected.

  access-list *acl-number* { **deny** | **permit** } **tcp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**established** | **match-all** *tcp-flag* | **tcp-flag** *tcp-flag-value tcp-flag-mask*] [**time-range** *time-range-name*] [**log**]

- The User Datagram Protocol (UDP) field is selected.

  access-list *acl-number* { **deny** | **permit** } **udp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**time-range** *time-range-name*] [**log**]

(4) (Optional) Configure an update interval for packet matching logs.

ip access-list log-update interval *time-value*

The default update interval is 0 minutes. That is, no ACL matching log is output.

(5) (Optional) Configure a remark for the IP extended ACL.

access-list *acl-number* **list-remark** *comment text*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for rules in the IP extended ACL.

access-list *acl-number* **remark** *text*

No remark is configured for ACL rules by default.

(7) (Optional) Enable the packet matching counting function of an IP extended ACL.

ip access-list counter { *acl-name* | *acl-number* }

The packet matching counting function of an IP extended ACL is disabled by default.

(8) (Optional) Configure a new fragmented packet matching mode of an expert extended ACL.

expert access-list new-fragment-mode { *acl-name* | *acl-number* }

No new fragmented packet matching mode is configured for an expert extended ACL by default.

(9) (Optional) Configure the start value and the step for rule sequence numbers in the IP extended ACL.

ip access-list resequence { *acl-name* | *acl-number* } *start-value step-value*

Both the start value and step of IP extended ACL rule sequence numbers are 10 by default.

1.5.5 Creating an IP Extended ACL (IP Extended ACL Configuration Mode)

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a IP extended ACL and enter the IP extended ACL configuration mode.

ip access-list extended { *acl-name* | *acl-number* }

No IP extended ACL is configured by default.

(4) Configure an ACL rule.

[*sequence-number*] { **deny** | **permit** } *protocol* { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**time-range** *time-range-name*] [**log**]

There is an ACL rule of deny type in an IP extended ACL by default.

Note

The commands for adding a rule of deny type to IP extended ACLs that specify some important protocols in the protocol field are as follows.

- The Internet Control Message Protocol (ICMP) field is selected.
  [*sequence-number*] { **deny** | **permit** } **icmp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**time-range** *time-range-name*] [**log**]

- The Transmission Control Protocol (TCP) field is selected.
  [*sequence-number*]{ **deny** | **permit** } **tcp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**established** | **match-all** *tcp-flag* | **tcp-flag** *tcp-flag-value tcp-flag-mask*] [**time-range** *time-range-name*] [**log**]
- The User Datagram Protocol (UDP) field is selected.
  [*sequence-number*]{ **deny** | **permit** } **udp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**time-range** *time-range-name*] [**log**]

(5) (Optional) Configure a remark for the ACL.

list-remark *text*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for rules in the IP standard ACE.

[*sequence-number*] **remark** *text*

No remark is configured for ACL rules by default.

1.6 Configuring a MAC Extended ACL

1.6.1 Overview

This section describes how to create and apply a MAC extended ACL to control the Layer2 packets entering/leaving a port. You can deny or permit specific Layer2 packets destined to a network so as to control the access of users to network resources based on the Layer2 packet headers.

1.6.2 Restrictions and Guidelines

- If a device needs to control users' access to network resources based on the Layer2 packet information (such as the MAC addresses of users' PCs), you can configure a MAC extended ACL.

1.6.3 Configuration Tasks

MAC extended ACL configuration includes the following tasks:

- Creating a MAC Extended ACL (Global Configuration Mode)
- Creating a MAC Extended ACL (MAC Extended ACL Configuration Mode)

1.6.4 Creating a MAC Extended ACL (Global Configuration Mode)

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a MAC extended ACL and its rules.

access-list *acl-number* { **deny** | **permit** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [*ethernet-type* | **cos** [*cos-value*] [**inner** *cos-value*]] * [**time-range** *time-range-name*]

No MAC extended ACL or rule is configured by default.

(4) (Optional) Configure a remark for the ACL.

access-list *acl-number* **list-remark** *text*

No remark is configured for an ACL by default.

(5) (Optional) Configure remarks for ACL rules.

access-list *acl-number* [*sequence-number*] **remark** *text*

No remark is configured for ACL rules by default.

(6) (Optional) Enable the packet matching counting function of a MAC extended ACL.

mac access-list counter { *acl-name* | *acl-number* }

The packet matching counting function of a MAC extended ACL is disabled by default.

(7) (Optional) Configure the start value and the step for rule sequence numbers in the MAC extended ACL.

mac access-list resequence { *acl-name* | *acl-number* } *start-value step-value*

Both the start value and step of MAC extended ACL rule sequence numbers are 10 by default.

1.6.5 Creating a MAC Extended ACL (MAC Extended ACL Configuration Mode)

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a MAC extended ACL and enter the MAC extended ACL configuration mode.

mac access-list extended { *acl-name* | *acl-number* }

No MAC extended ACL is configured by default.

(4) Configure an ACL rule.

[*sequence-number*] { **deny** | **permit** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [*ethernet-type* | **cos** [*cos-value*] [**inner** *cos-value*]] * [**time-range** *time-range-name*]

There is an ACL rule of deny type in a MAC extended ACL by default.

(5) (Optional) Configure a remark for the ACL.

list-remark *text*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for rules in the IP standard ACE.

[*sequence-number*] **remark** *text*

No remark is configured for ACL rules by default.

1.7 Configuring an Expert Extended ACL

1.7.1 Overview

This section describes how to create and apply an expert extended ACL to control the packets entering/leaving the port. You can deny or permit specific packets destined to a network.

1.7.2 Restrictions and Guidelines

- If you need to control network resource access of users based on IP ACL rules, MAC extended ACL rules, and VLANs, configure an expert extended ACL.

1.7.3 Configuration Tasks

Expert extended ACL configuration includes the following tasks:

- Creating an Expert Extended ACL (Global Configuration Mode)
- Creating an Expert Extended ACL (Expert Extended ACL Configuration Mode)_Ref54855268

1.7.4 Creating an Expert Extended ACL (Global Configuration Mode)

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an expert extended ACL and its rules.

access-list *acl-number* { **deny** | **permit** } [*protocol* | [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]]] [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source*-mac-*address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**time-range** *time-range-name*]

No expert extended ACL or rule is configured by default.

Note

The commands for creating expert extended ACLs that specify some important protocols in the protocol field are as follows.

- The Internet Control Message Protocol (ICMP) field is selected.

  access-list *acl-number* { **deny** | **permit** } **icmp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [{ **precedence** *precedence* | **tos** *tos* }* | **dscp** *dscp*] [**fragment**] [**time-range** *time-range-name*]

- The Transmission Control Protocol (TCP) field is selected.

  access-list *acl-number* { **deny** | **permit** } **tcp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } [**eq** port | **gt** port | **lt** port | **neq** port | **range** lower upper] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [**eq** port | **gt** port | **lt** port | **neq** port | **range** lower upper] [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**established** | **match-all** *tcp-flag* | **tcp-flag** *tcp-flag-value tcp-flag-mask*] [**time-range** *time-range-name*]

- The User Datagram Protocol (UDP) field is selected.

  access-list *acl-number* { **deny** | **permit** } **udp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-*ipv4*-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } [**eq** port | **gt** port | **lt** port | **neq** port | **range** lower upper] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [**eq** port | **gt** port | **lt** port | **neq** port | **range** lower upper] [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**range** *lower upper*] [**time-range** *time-range-name*]

- The ARP field is selected.

  access-list *acl-number* { **deny** | **permit** } **arp** [**cos** { *cos-value* [[**cos**] **inner** *cos-value*] | **inner** *cos-value* [**cos** *cos-value*] }] [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [**time-range** *time-range-name*]

(4) (Optional) Configure a remark for the ACL.

access-list *acl-number* **list-remark** *text*

(5) (Optional) Configure remarks for ACE rules.

access-list *acl-number* [*sequence-number*] **remark** *comment*

No remark is configured for ACE rules by default.

(6) (Optional) Enable statistics collection for expert ACL packet matching.

expert access-list counter { *acl-name* | *acl-number* }

(7) (Optional) Configure the start value and the step for rule sequence numbers in the expert extended ACL.

expert access-list resequence { *acl-name* | *acl-number* } *start-value step-value*

Both the start value and step of an expert ACL rule sequence numbers are 10 by default.

1.7.5 Creating an Expert Extended ACL (Expert Extended ACL Configuration Mode)

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an expert extended ACL and enter the expert extended ACL configuration mode..

expert access-list extended { *acl-number* | *acl-name* }

(4) Configure an ACL rule.

[*sequence-number*] { **deny** | **permit** } [*protocol* | [*ethernet-type* | **cos** [*cos-value*] [**inner** *cos-value*]] *] [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**time-range** *time-range-name*]

There is an ACL rule of deny type in an expert extended ACL by default.

Note

The commands for creating expert extended ACLs that specify some important protocols in the protocol field are as follows:

- The Ethernet type field or **cos** field is selected.

  [*sequence-number*] { **deny** | **permit** } { *ethernet-type* | **cos** [*cos-value*] [**inner** *cos-value*] } * [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [**time-range** *time-range-name*]

- The protocol field is selected.

  [*sequence-number*] { **deny** | **permit** } *protocol* [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**time-range** *time-range-name*]

- The Internet Control Message Protocol (ICMP) field is selected.

  [*sequence-number*] { **deny** | **permit** } **icmp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**time-range** *time-range-name*]

- The Transmission Control Protocol (TCP) field is selected.

  [*sequence-number*] { **deny** | **permit** } **tcp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**established** | **match-all** *tcp-flag* | **tcp-flag** *tcp-flag-value tcp-flag-mask*] [**time-range** *time-range-name*]

- The User Datagram Protocol (UDP) field is selected.

  [*sequence-number*] { **deny** | **permit** } **udp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host**

source-mac-address | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [{ **precedence** *precedence* | **tos** *tos* } * | **dscp** *dscp*] [**fragment**] [**time-range** *time-range-name*]

- The Address Resolution Protocol (ARP) field is selected.

  [*sequence-number*] { **deny** | **permit** } **arp** [**cos** { *cos-value* [[**cos**] **inner** *cos-value*] | **inner** *cos-value* [**cos** *cos-value*] }] [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [**time-range** *time-range-name*]

(5) (Optional) Configure a remark for the ACL.

list-remark *text*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for rules in the IP standard ACE.

[*sequence-number*] **remark** *text*

No remark is configured for ACL rules by default.

1.8 Configuring an IPv6 ACL

1.8.1 Overview

This section describes how to create and apply an IPv6 ACL to control the IPv6 packets entering/leaving the port. You can deny or permit specific IPv6 packets destined to a network so as to control the access of IPv6 users to network resources.

1.8.2 Restrictions and Guidelines

- To control IPv6 users' access to network resources, configure an IPv6 ACL.
- You cannot specify the name of an IPv6 ACL but its number.
- Configuring an ACL rule with the **log** option consumes more hardware resources. If all the configured rules have the **log** option, the hardware policy capacity of the device is halved.
- The default output interval of packet matching logs is 0 minutes, that is, no ACL matching log is output. After specifying the **log** option when configuring ACL rules, you also need to configure an output interval; otherwise no matching log is output.
- For a rule with the **log** option, if no packet is matched within the specified time interval, no packet matching log related to the rule is output; if a packet is matched within the specified time interval, the packet matching log related to the rule is output after the time interval expires. The number of matched packets is the total number of packets matching the rule within the time interval, that is, the number of matched packets from the last log output to the current log output.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an IPv6 ACL and enter the IPv6 ACL configuration mode.

ipv6 access-list *acl-name*

No IPv6 ACL is configured by default.

(4) Configure IPv6 ACL rules.

[*sequence-number*] { **deny** | **permit** } [*protocol* { *source-ipv6-prefix/prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } { *destination-ipv6-prefix/prefix-length* | *destination-ipv6-address destination-ipv6-mask* | host *destination-ipv6-address* | **any** }] [**cos** *cos-value* [**inner** *cos-value*]] [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination-mac-address* | *destination-mac-address destination-mac-wildcard* }] [**dscp** *dscp* | **flow-label** *flow-label* | **fragment** | [**established** | **match-all** *tcp-flag* | **tcp-flag** *tcp-flag-value tcp-flag-mask*]] * [**time-range** *time-range-name*] [**log**] [**VID** [*vlan-id*] [**inner** *vlan-id*]] [**log**]

There is an ACL rule of deny type in an IPv6 ACL by default.

Note

The commands for adding a rule of deny type to IPv6 extended ACLs that specify some important protocols in the protocol field are as follows.

- The Internet Control Message Protocol (ICMP) field is selected.

  [*sequence-number*] { **deny** | **permit** } **icmp** { *source-ipv6-prefix/prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } { *destination-ipv6-prefix/prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** } [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination-mac-address* | *destination-mac-address destination-mac-wildcard* }] [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [**dscp** *dscp* | **flow-label** *flow-label* | **fragment**] * [**time-range** *time-range-name*] [**log**] [**VID** [*vlan-id*] [**inner** *vlan-id*]]

- The Transmission Control Protocol (TCP) field is selected.

  [*sequence-number*] { **deny** | **permit** } **tcp** { *source-ipv6-prefix/prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv6-prefix/prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination-mac-address* | *destination-mac-address destination-mac-wildcard* }] [**dscp** *dscp* | **flow-label** *flow-label* | **fragment** | [**established** | **match-all** *tcp-flag* | **tcp-flag** *tcp-flag-value tcp-flag-mask*]] * [**time-range** *time-range-name*] [**log**] [**VID** [*vlan-id*] [**inner** *vlan-id*]]

- The User Datagram Protocol (UDP) field is selected.

  [*sequence-number*] { **deny** | **permit** } **udp** { *source-ipv6-prefix/prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv6-prefix/prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host**

destination-ipv6-address | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination-mac-address* | *destination-mac-address destination-mac-wildcard* }] [**dscp** *dscp* | **flow-label** *flow-label* | **fragment**] * [**time-range** *time-range-name*] [**log**] [**VID** [*vlan-id*] [**inner** *vlan-id*]]

(5) (Optional) Configure a remark for the ACL.

list-remark *text*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for ACL rules.

[*sequence-number*] **remark** *text*

No remark is configured for ACL rules by default.

(7) Return to the global configuration mode.

exit

(8) (Optional) Configure an update interval of packet matching logs.

ipv6 access-list log-update interval *time*

The default update interval of packet matching logs is 0 minutes, that is, no ACL matching log is output.

(9) (Optional) Enable the packet matching counting function of an IPv6 ACL.

ipv6 access-list counter *acl-name*

The packet matching counting function of an IPv6 ACL is disabled by default.

(10) (Optional) Configure the start value and the step for rule sequence numbers in the IPv6 extended ACL.

ipv6 access-list resequence *acl-name start-value step-value*

Both the start value and step of an IPv6 ACL rule sequence numbers are 10 by default.

1.9 Configuring an Expert Advanced ACL (ACL80)

1.9.1 Overview

When the fixed matching fields of the IP standard ACL, IP extended ACL, MAC extended ACL, expert extended ACL, and IPv6 ACL all fail to meet requirements, you can configure an expert advanced ACL (ACL80) to define the packet fields to be matched.

1.9.2 Restrictions and Guidelines

- An ACL80 supports matching Ethernet II packets, IEEE 802.2 LLC SNAP packets, and IEEE 802.2 packets. If the values of the DSAP field to the Control field to be matched are AAAA03, IEEE 802.2 SNAP packets are matched. If the values of the DSAP field to the Control field to be matched are E0E003, IEEE 802.2 LLC packets are matched. If an ACL80 tries to match Ethernet II packets, you cannot set the values of the DSAP field to the Control field.
- Due to hardware, currently ACL80 cannot implement random byte matching for the first 80 bytes of packets, but only supports matching the fields of the destination MAC address, source MAC address, VLAN ID, ETYPE, IP protocol number, source IPv4 address, destination IPv4 address, source port, destination port, ICMP_TYPE, ICMP_CODE, and PPPOE_IPTYPE in packets.
- When an ACL80 matches IP, ARP, and other information, the encapsulated data type and data type mask

need to be configured first, that is, the field with offset 24 needs to be configured first, and the mask needs to be set to all Fs. For example, to allow the packets with the source IP address 192.168.1.2 to pass through, run the **permit 0800 FFFF 24 C0A80102 FFFFFFFF 38** command.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an expert advanced ACL and enter the expert advanced ACL configuration mode.

expert access-list advanced *acl-name*

No expert advanced ACL is configured by default.

(4) (Optional) Configure rules in the expert advanced ACL.

[*sequence-number*] { **deny** | **permit** } *hex hex-mask offset*

No expert advanced ACL is configured.

(5) (Optional) Configure a remark for the ACL.

list-remark *text*

No remark is configured for an ACL by default.

(6) (Optional) Configure remarks for ACE rules.

[*sequence-number*] **remark** *text*

No remark is configured for ACE rules by default.

1.10 Applying an ACL

1.10.1 Overview

Apply an ACL to control the packets entering/leaving a device. In this way, specific packets destined to a network are denied or permitted in order to control users' access to network resources.

1.10.2 Restrictions and Guidelines

- Configuring the **in** or **out** option indicates that the ACL takes effect for the packets entering the device or those forwarded by the device.
- Configure the **counter-only** option to count the packets with some characteristics. The counting function takes effect only for permit rules but not for deny rules in an ACL.
- After an ACL is used as a **counter-only** ACL, the counting function cannot be globally enabled for the ACL, and the ACL cannot be applied globally or on ports as a common ACL. That is, ACLs with the same *acl-number* or *acl-name* cannot be used as a **counter-only** ACL and a common ACL at the same time.
- After the ACL packet statistics collection is enabled, you can view the ACL configuration by running the **show access-lists** command, which includes the ACE configuration, ACE-based packet matching count, and ACL-based packet matching count. The ACL-based packet matching count only supports the statistics of packets denied by ACL.

- If the **control-plane** option is configured, the ACL is effective for software only so as to save hardware resources.
- If the **forward-plane** option is configured, the ACL is effective for hardware only.
- If the **forward-control-plane** option is configured, the ACL is effective for both software and hardware.

1.10.3 Configuration Tasks

Applying an ACL includes the following tasks:

- Applying an ACL Globally
- Applying an ACL to an Interface

1.10.4 Applying an ACL Globally

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Apply an ACL globally. Select at least one of the following tasks to configure.

- Apply an IP standard ACL globally.

  ip access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **forward-control-plane** | **forward-plane**]

  No IP standard ACL is applied globally by default.

- Apply an IP extended ACL globally.

  ip access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **forward-control-plane** | **forward-plane**]

  No IP extended ACL is applied globally by default.

- Apply a MAC extended ACL globally.

  mac access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **forward-control-plane** | **forward-plane**]

  No MAC extended ACL is applied globally by default.

- Apply an expert extended ACL globally.

  expert access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **forward-control-plane** | **forward-plane**]

  No expert extended ACL is applied globally by default.

- Apply an IPv6 ACL globally.

  ipv6 traffic-filter *acl-name* { **in** | **out** } { **control-plane** | **forward-control-plane** | **forward-plane** }

  No IPv6 ACL is applied globally by default.

- Apply the expert advanced ACL (ACL80) globally.

  expert access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **forward-control-plane** | **forward-plane**]

The expert advanced ACL (ACL80) is not applied globally by default.

1.10.5 Applying an ACL to an Interface

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode, VLAN configuration mode.

- Enter the Layer 2 interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the VLAN interface configuration mode.

  interface vlan *vlan-id*

- Enter the VLAN configuration mode.

  vlan *vlan-id*

(4) Apply an ACL to an interface. Select at least one of the following tasks to configure.

- Apply an IP standard ACL.

  ip access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane**]

  No IP standard ACL is applied to an interface by default.

- Apply an IP extended ACL.

  ip access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane**]

  No IP extended ACL is applied by default.

- Apply a MAC extended ACL.

  mac access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | forward-**plane**]

  No MAC extended ACL is applied by default.

- Apply an expert extended ACL.

  expert access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane**]

  No expert extended ACL is applied by default.

- Apply an IPv6 ACL.

  ipv6 traffic-filter *acl-name* { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane**]

  No IPv6 ACL is applied to an interface by default.

- Apply an expert advanced ACL.

  expert access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane**]

  No expert advanced ACL is applied by default.

1.11 Configuring a Redirect ACL

1.11.1 Overview

This section describes how to configure the ACL-based redirection function on a specified port, to redirect the matched packets entering the port to a specified port for forwarding.

1.11.2 Restrictions and Guidelines

- You can configure the ACL-based redirection function on an access, aggregation, or core device based on the distribution of users. The configuration takes effect only on the local device, but does not affect other devices in the network.
- The redirect ACL function can be configured on an Layer2 Ethernet interface and an Layer2 aggregate interface only.
- The packet to be redirected must be an Layer2 forwarded packet (that is, if a packet is forwarded from VLAN 2 to VLAN 3, it cannot be redirected), and the destination port of redirection must be in the same VLAN as the source port.
- If no rule is configured in an ACL, the ACL-based redirection function is unavailable.

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(4) Configure a redirect ACL on an interface.

redirect destination interface *interface-type interface-number* **acl** { *acl-name* | *acl-number* } **in**

No redirect ACL is configured on a port by default.

1.12 Configuring a Global Security ACL

1.12.1 Overview

Configuring the global security ACL function can prevent internal access to illegal websites or stop viruses from entering the internal network of an enterprise. In addition, you can configure excluded ports of the global security ACL to permit some special departments in an enterprise to access some external websites.

1.12.2 Restrictions and Guidelines

- If no rule is configured in an ACL, the global security ACL function is unavailable.
- Since the global security ACL is mainly used for virus filtering, among the ACEs in a global security ACL, only the deny ACEs take effect, and the permit ACEs do take effect.
- Different from a security ACL applied to a port, a global security ACL has no default rule of denying all entries, that is, the packets not matching the rules in a global security ACL can pass through.
- Global security ACLs can be associated only with IP standard ACLs, IP extended ACLs, MAC extended ACLs, and expert extended ACLs.
- A global security ACL takes effect on both Layer 2 and Layer 3 interfaces. That is, the ACL takes effect on the following interfaces: access ports, trunk ports, hybrid ports, Layer 2 Ethernet interfaces, Layer 3 Ethernet interfaces, Layer 2 link aggregations and Layer 3 link aggregations. The ACL does not take effect on an SVI.
- You can disable the global security ACL function on a physical port, Layer 2 link aggregation or Layer 3 link aggregation. You cannot disable the global security ACL function on a member port of a link aggregation.
- You can configure a global security ACL on an access, aggregation, or core device based on the distribution of users. The configuration takes effect only on the local device, but does not affect other devices in the network.
- Disable the global security ACL function to forbid configuring global security ACLs.
- Configuring a port as an excluded port disables the global security ACL on the port.

1.12.3 Prerequisite

You must configure an ACL first to enable the global security ACL function.

1.12.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Disable the global security ACL function.

global access-group disable

The global security ACL function is enabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.
  interface aggregateport *interface-number*

No global security ACL is configured by default.

(5) (Optional) Enable a global security ACL on the port.

global access-group

A port is an excluded port of a global security ACL by default.

(6) (Optional) Enable a global IP security ACL on the port.

global ip access-group

A port is an excluded port of a global IP security ACL by default.

1.13 Configuring a Security Channel

1.13.1 Overview

The security channel function enables the packets conforming to the security channel rules to bypass the access control related services. For example, IEEE 802.1x access control is enabled on a port of the uplink device connected to a user host, and a security channel can be configured to permit the user to log in to a site to download the authentication client before 802.1x authentication.

1.13.2 Restrictions and Guidelines

- If no rule is configured in an ACL, the security channel function is unavailable.
- The deny action in an ACL applied to a security channel does not take effect, and there is no rule statement of denying all data flows hidden at the end. If a packet does not meet the matching conditions of a security channel, it goes through the check of access control according to the process.
- You can set up to eight excluded ports for a global security channel, and no port-based security channel can be configured on the excluded ports of the global security channel.
- When both the port-based authentication migration mode and a security channel are used, the security channel does not take effect.
- You cannot set an IPv6 ACL as a security channel.
- To make a security channel take effect on a port, configure the security channel on the specified port only; to make a security channel globally, configure a security channel in global configuration mode. You must configure one of the two tasks.
- If you have configured a global security channel but want to disable the security channel on some ports, configure these ports as excluded ports of the global security channel.
- You can configure the security channel function on an access, aggregation, or core device based on the distribution of users. The configuration takes effect only on the local device, but does not affect other devices in the network.

1.13.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a global security channel.

security global access-group { **acl-name** | **acl-number** }

No global security channel is configured by default.

Choose either global security channel or interface security channel to configure.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.
  interface aggregateport *interface-number*

- Enter the SVI configuration mode.
  interface vlan *interface-number*

(5) (Optional) Configure a security channel for a port.

security access-group { *acl-name* | *acl-number* }

No security channel is configured on a port by default.

Choose either global security channel or interface security channel to configure.

(6) (Optional) Configure a port as an excluded port of the security channel.

security uplink enable

No port is configured as an excluded port of a security channel by default.

1.14 Configuring an SVI Router ACL

1.14.1 Overview

The SVI router ACL function can be configured to enable the ACL applied to an SVI to take effect only for the inter-VLAN routed packets.

1.14.2 Prerequisite

To implement this function, first configure an ACL.

1.14.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an SVI router ACL.

svi router-acls enable

1.15 Synchronizing All ACEs from Software to Hardware

1.15.1 Overview

When the entry capacity of the device software is greater than that supported by the hardware, no ACE can be added. When the entry capacity of the device software drops below that supported by the hardware, the ACEs that fail to be added before will not be added again. This command can be used to refresh the configuration to trigger the re-adding of ACEs, thus synchronizing ACEs from software to hardware.

1.15.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Synchronize all ACEs from software to hardware.

acl ref synchronize all

1.16 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

Caution

Running the **clear** commands may interrupt services due to loss of important information.

Run the **debug** command to output debugging information.

Caution

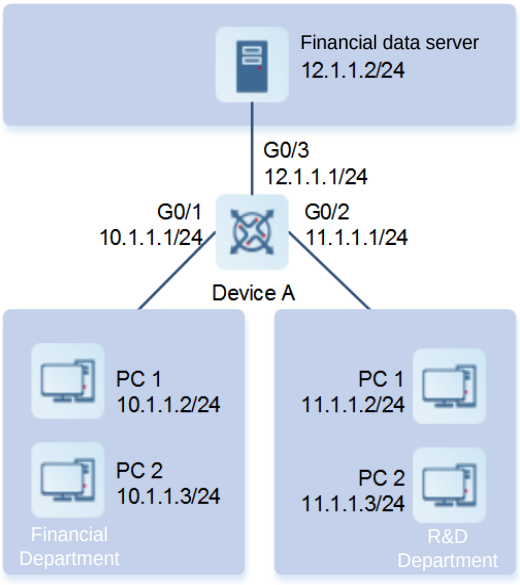
The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-5 ACL Monitoring

Command	Purpose
show access-lists [*acl-name* | *acl-number*] [**summary**]	Displays a basic ACL.

Command	Purpose
show redirect [**interface** *interface-type interface-number*]	Displays the redirection entries bound to a specified port. If no port is specified, the redirection entries bound to all the ports are displayed.
show access-group [**interface** *interface-type interface-number* | **vlan** *vlan-id*]	Displays the configuration of an ACL applied to a port.
.show ip access-group [**interface** *interface-type interface-number* | **vlan** *vlan-id*]	Displays the configuration of an IP standard ACL and an extended ACL applied to a port.
show mac access-group [**interface** *interface-type interface-number* | **vlan** *vlan-id*]	Displays the configuration of a MAC extended ACL applied to a port.
show expert access-group [**interface** *interface-type interface-number* | **vlan** *vlan-id*]	Displays the configuration of an expert extended ACL applied to a port.
show ipv6 traffic-filter [**interface** *interface-type interface-number* | **vlan** *vlan-id*]	Displays the configuration of an IPv6 ACL applied to a port.
show acl res [**dev** *dev-number* [**slot** *slot-number*]]	Displays information about all ternary content-addressable memory (TCAMs) or a specified TCAM.
show acl capability [**more**]	Displays device capability.
show svi router-acls state	Checks whether an ACL applied to an SVI takes effect on Layer2 and L packets.
show acl res detail [**dev** *dev-num* [**slot** *slot-num*]]	Displays usage details about all TCAMs or a specified TCAM.
clear acl res	Clears historical peak information of TCAM resource usage.
clear counters access-list [*acl-name* | *acl-number*]	Clears the number of packets matching an ACE.
clear access-list counters [*acl-name* | *acl-number*]	Clears the number of packets matching an ACL rules.
debug acl acld event	Debugs the ACL running process.
debug acl acld client-show	Displays ACL client information.

1.17 Examples



1.17.1 Configuring an IP Standard ACL

1. Requirements

An IP standard ACL needs to be configured to prevent the departments other than the financial department from accessing the financial data server.

2. Topology

Figure 1-3 Topology of Configuring IP Standard ACL

3. Notes

- Configure an IP standard ACL on device A and add access rules.
- Apply the IP standard ACL to the outbound direction of the port connected to the financial data server on device A.

4. Procedure

(1) Configure an IP standard ACL and add access rules.

On device A, configure an IP standard ACL and add access rules.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# ip access-list standard 1
DeviceA(config-std-nacl)# permit 10.1.1.0 0.0.0.255
DeviceA(config-std-nacl)# deny 11.1.1.1 0.0.0.255
DeviceA(config-std-nacl)# exit
```

(2) Apply the IP standard ACL to a port.

On device A, apply the IP standard ACL to the outbound direction of the port connected to the financial data server.

```
DeviceA(config)# interface gigabitethernet 0/3
DeviceA(config-if-GigabitEthernet 0/3)# ip access-group 1 out
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA# show access-lists

ip access-list standard 1
10 permit 10.1.1.0 0.0.0.255
20 deny 11.1.1.0 0.0.0.255

DeviceA# show access-group
ip access-group 1 out
Applied On interface GigabitEthernet 0/3
```

Ping the financial data server from a PC of the R&D department and confirm that the ping operation fails.

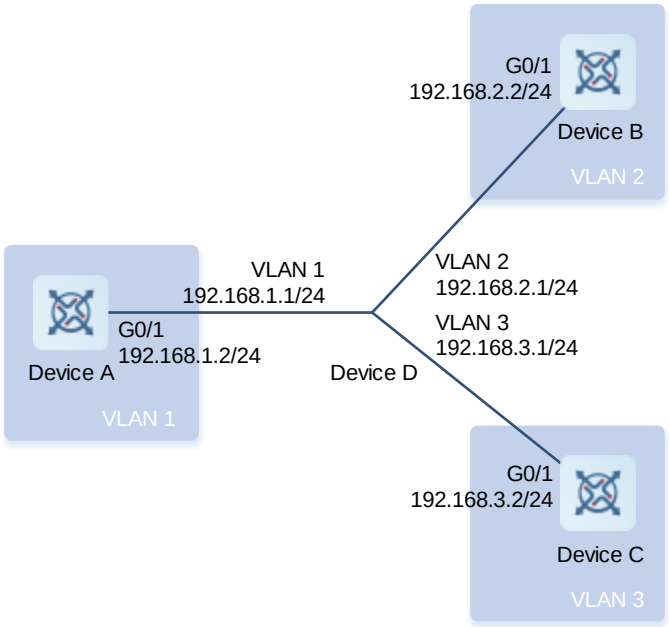
Ping the financial data server from a PC of the financial department and confirm that the ping operation succeeds.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
ip access-list standard 1
 10 permit 10.1.1.0 0.0.0.255
 20 deny 11.1.1.0 0.0.0.255
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
 no switchport
 ip address 11.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/3
 no switchport
 ip access-group 1 out
 ip address 12.1.1.1 255.255.255.0
!
```

1.17.2 Configuring an IP Extended ACL



1. Requirements

Device A (VLAN 1), device B (VLAN 2), and device C (VLAN 3) are directly connected to device 4, which functions as the gateway of all the hosts. Requirement 1: The ping operation fails between VLAN 2 and VLAN 3, but succeeds between VLAN 1 and VLAN 2, and between VLAN 1 and VLAN 3. Requirement 2: The DHCP packets of VLAN 1 and VLAN 2 are unreachable to each other, but the communication using other protocols is

normal. Requirement 3: The host in VLAN 1 cannot to access VLAN 3 through telnet or SSH, but the communication using other protocols is normal.

2. Topology

Figure 1-4 Topology of Configuring IP Extended ACL Application Scenario

3. Notes

- On device D, configure an IP extended ACL and add an access rule of filtering out packets received by UDP port 67 or 68 to meet requirement 2. On device C, configure an IP extended ACL and add an access rule of filtering out packets received by ACL ports 23 and 22 to meet requirement 3.
- On device A, apply the IP extended ACL to VLAN 1 interface, VLAN 2 interface, and VLAN 3 interface. On device C, apply the IP extended ACL to interface GigabitEthernet 0/1 that is connected to Device D.

4. Procedure

(1) Configure IP addresses for all the device ports (omitted).

(2) Configure an IP extended ACL and add access rules.

On device D, configure an IP extended ACL and add access rules.

```
DeviceD> enable
DeviceD# configure terminal
DeviceD(config)# ip access-list extended inter_vlan_access1
DeviceD(config-ext-nacl)# deny udp any eq bootps any eq bootpc
DeviceD(config-ext-nacl)# deny udp any eq bootpc any eq bootps
DeviceD(config-ext-nacl)# remark Deny DHCP packets.
DeviceD(config-ext-nacl)# permit ip any any
DeviceD(config-ext-nacl)# remark Permit the communication using other packets.
DeviceD(config-ext-nacl)# exit
DeviceD(config)# ip access-list extended inter_vlan_access2
```

```
DeviceD(config-ext-nacl)# deny ip 192.168.2.0 0.0.0.255 192.168.3.0 0.0.0.255
DeviceD(config-ext-nacl)# remark Deny the mutual access between VLAN 2 and
VLAN 3.
DeviceD(config-ext-nacl)# deny udp any eq bootpc any eq bootps
DeviceD(config-ext-nacl)# deny udp any eq bootps any eq bootpc
DeviceD(config-ext-nacl)# remark Deny DHCP packets.
DeviceD(config-ext-nacl)# permit ip any any
DeviceD(config-ext-nacl)# remark Permit the communication using other packets.
DeviceD(config-ext-nacl)# exit
DeviceD(config)# ip access-list extended inter_vlan_access3
DeviceD(config-ext-nacl)# deny ip 192.168.3.0 0.0.0.255 192.168.2.0 0.0.0.255
DeviceD(config-ext-nacl)# remark Deny the mutual access between VLAN 2 and
VLAN 3.
DeviceD(config-ext-nacl)# permit ip any any
DeviceD(config-ext-nacl)# remark Permit the communication using other packets.
DeviceD(config-ext-nacl)# exit
```

On device C, configure an IP extended ACL and add access rules.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# ip access-list extended access_deny
DeviceC(config-ext-nacl)# deny tcp 192.168.1.0 0.0.0.255 eq telnet any eq
telnet
DeviceC(config-ext-nacl)# remark Deny VLAN 1 access to VLAN 3 through telnet.
DeviceC(config-ext-nacl)# deny tcp 192.168.1.0 0.0.0.255 eq 22 any eq 22
DeviceC(config-ext-nacl)# remark Deny VLAN 1 access to VLAN 3 through SSH.
DeviceC(config-ext-nacl)# permit any any
DeviceC(config-ext-nacl)# remark Permit communication of other packets
DeviceC(config-ext-nacl)# exit
```

(3) Apply the IP extended ACLs.

On device D, apply the IP extended ACL to the corresponding ports.

```
DeviceD(config)# interface vlan 1
DeviceD(config-if-VLAN 1)# ip access-group inter_vlan_access1 in
DeviceD(config-if-VLAN 1)# exit
DeviceD(config)# interface vlan 2
DeviceD(config-if-VLAN 2)# ip access-group inter_vlan_access2 in
DeviceD(config-if-VLAN 2)# exit
DeviceD(config)# interface vlan 3
DeviceD(config-if-VLAN 3)# ip access-group inter_vlan_access3 in
DeviceD(config-if-VLAN 3)# exit
```

On device C, apply the IP extended ACL to the interface GigabitEthernet 0/1 that is connected to Device D.

```
DeviceC(config)# interface gigabitethernet 0/1
DeviceC(config-if-GigabitEthernet 0/1)# ip access-group access_deny in
DeviceC(config-if-GigabitEthernet 0/1)# exit
```

5. Verification

(1) Verify the connectivity.

The ping operation succeeds between VLAN 1 and VLAN 2, and between VLAN 1 and VLAN 3.

```
DeviceA# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/8/10 ms
DeviceA#
DeviceA# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/8/10 ms
```

The ping operation fails between VLAN 2 and VLAN 3.

```
DeviceB# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5)
```

(2) The host in VLAN 1 cannot access VLAN 3 through telnet.

```
DeviceA# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/8/10 ms
DeviceA#
DeviceA# telnet 192.168.3.2
Trying 192.168.3.2, 23...
% Destination unreachable; gateway or host down
```

1.17.3 Configuring a MAC Extended ACL

1. Requirements

A MAC extended ACL needs to be configured to restrict the resources accessible to visitors.

2. Topology

Figure 1-5 Topology of Configuring MAC Extended ACL

3. Notes

- On device A, configure a MAC extended ACL and add access rules. The PCs in the visitor area are allowed to access the Internet and the company's internal public server, but are not allowed to access the company's financial data server, that is, the PCs are prohibited from accessing the server with MAC address 00e0.f800.000d.
- On device A, apply the MAC extended ACL to the inbound direction of a port connected to the visitor area.

4. Procedure

(1) Configure a MAC extended ACL and add access rules.

On device A, configure a MAC extended ACL and add access rules.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# mac access-list extended 700
DeviceA(config-mac-nacl)# deny any host 00e0.f800.000d
DeviceA(config-mac-nacl)# permit any any
DeviceA(config-mac-nacl)# exit
```

(2) Apply the MAC extended ACL to a port.

On device A, apply the ACL to the inbound direction of the port connected to the visitor area.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# mac access-group 700 in
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA# show access-lists
mac access-list extended 700
10 deny any host 00e0.f800.000d etype-any
20 permit any any etype-any
DeviceA# show access-group
mac access-group 700 in
Applied On interface GigabitEthernet 0/2
```

Ping the financial data server from a visitor PC and confirm that the ping operation fails.

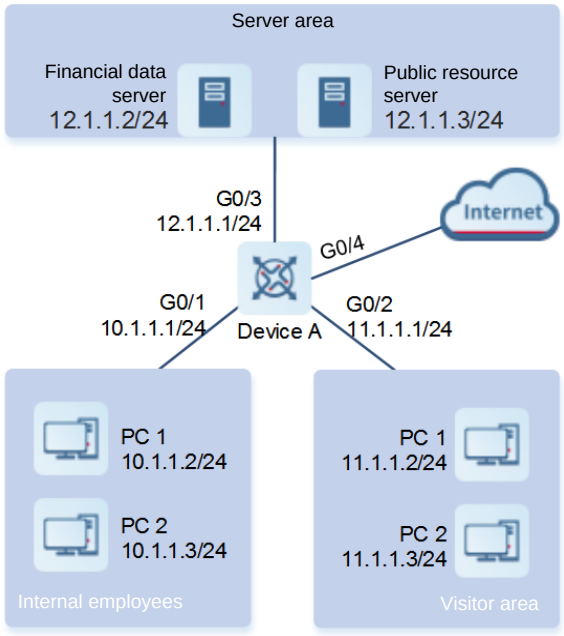
Ping the public resource server from a visitor PC and confirm that the ping operation succeeds.

Access the Internet through a visitor PC, for example, access www.baidu.com, and confirm that the home page can be opened.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
mac access-list extended 700
 10 deny any host 00e0.f800.000d
 20 permit any any
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
 no switchport
 mac access-group 700 in
 ip address 11.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/3
 no switchport
 ip address 12.1.1.1 255.255.255.0
!
```



1.17.4 Configuring an Expert Extended ACL

1. Requirements

An expert extended ACL needs to be configured to restrict the resources accessible to visitors. Visitors cannot access the PCs of internal employees or the financial data server of the company, but can access the public resource server and Internet.

2. Topology

Figure 1-6 Topology of Configuring Expert Extended ACL

3. Notes

- On device A, configure an expert extended ACL and add access rules, including:
  - Prohibiting the hosts in the visitor area from sending packets destined to the network segment of internal employees' PCs.
  - Prohibiting visitors from accessing the financial data server.
  - Permitting all the other packets to pass through.
- On device A, apply the ACL to the inbound direction of the port connected to the visitor area.

4. Procedure

(1) Configure an expert extended ACL and add access rules.

On device A, configure an expert extended ACL and add access rules.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# expert access-list extended 2700
DeviceA(config-exp-nacl)# deny ip any any 10.1.1.0 0.0.0.255 any
DeviceA(config-exp-nacl)# deny ip any any host 12.1.1.2 any
DeviceA(config-exp-nacl)# permit any any any any
DeviceA(config-exp-nacl)# exit
```

(2) Apply the expert extended ACL to a port.

On device A, apply the ACL to the inbound direction of the port connected to the visitor area.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# expert access-group 2700 in
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA# show access-lists
expert access-list extended 2700
 10 deny ip any any 192.168.1.0 0.0.0.255 any
20 deny ip any any host 10.1.1.1 any
30 permit ip any any any any

DeviceA# show access-group
expert access-group 2700in
Applied On interface GigabitEthernet 0/2
```

Ping the financial data server from a visitor PC and confirm that the ping operation fails.

Ping the public resource server from a visitor PC and confirm that the ping operation fails.

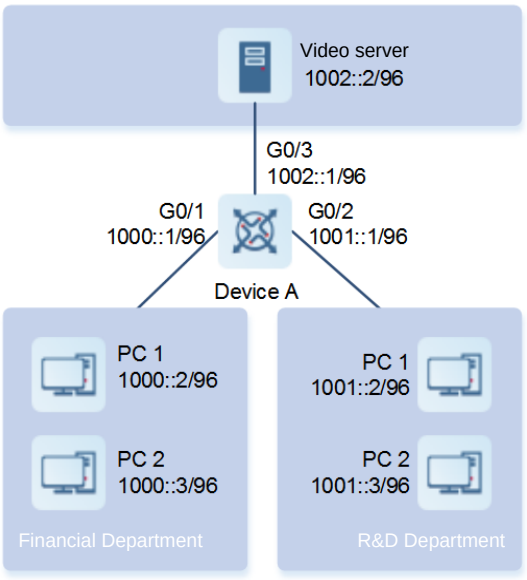
Ping the internal employee gateway 192.168.1.1 from a visitor PC and confirm that the ping operation fails.

Access the Internet through a visitor PC, for example, access www.baidu.com, and confirm that the home page can be opened.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
expert access-list extended 2700
 10 deny ip any any 10.1.1.0 0.0.0.255 any
 20 deny ip any any host 12.1.1.2 any
 30 permit ip any any any any
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
 no switchport
 expert access-group 2700 in
 ip address 11.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/3
 no switchport
 ip address 12.1.1.1 255.255.255.0
!
```



1.17.5 Configuring an IPv6 ACL

1. Requirements

An IPv6 ACL needs to be configured to prevent hosts in the R&D department from accessing the video server.

2. Topology

Figure 1-7 Topology of Configuring IPv6 ACL

3. Notes

- On device A, configure an IPv6 ACL and add access rules, including:
  - Prohibiting access to the IPv6 address of the video server.
  - Permitting all the IPv6 packets to pass through.
- On device A, apply the IPv6 ACL to the inbound direction of the port connected to the R&D department.

4. Procedure

(1) Configure an IPv6 ACL and add access rules.

On device A, configure an IPv6 ACL and add access rules.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# ipv6 access-list dev_deny_ipv6video
DeviceA(config-ipv6-nacl)# deny ipv6 any host 1002::2
DeviceA(config-ipv6-nacl)# permit ipv6 any any
DeviceA(config-ipv6-nacl)# exit
```

(2) Apply the IPv6 ACL to a port.

On device A, apply the ACL to the inbound direction of the port connected to the R&D department.

```
DeviceA(config)# interface gigabitethernet 0/2
```

```
DeviceA(config-if-GigabitEthernet 0/2)# ipv6 traffic-filter dev_deny_ipv6video
in
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA(config)# show access-lists

ipv6 access-list dev_deny_ipv6video
10 deny ipv6 any host 200::1
20 permit ipv6 any any

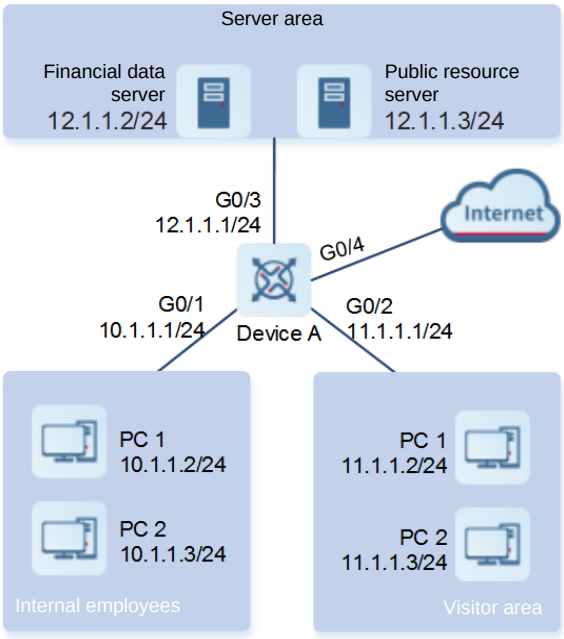
DeviceA(config)# show access-group
ipv6 traffic-filter dev_deny_ipv6video in
Applied On interface GigabitEthernet 0/2
```

Ping the video server from a PC in the R&D department and confirm that the ping operation fails.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
ipv6 access-list dev_deny_ipv6video
 10 deny ipv6 any host 1002::2
 20 permit ipv6 any any
!
interface GigabitEthernet 0/1
 no switchport
 ipv6 address 1000::1/96
!
interface GigabitEthernet 0/2
 no switchport
 ipv6 traffic-filter dev_deny_ipv6video in
 ipv6 address 1001::1/96
!
interface GigabitEthernet 0/3
 no switchport
 ipv6 address 1002::1/96
!
```



1.17.6 Configuring an ACL80

1. Requirements

An ACL80, namely, an expert advanced ACL needs to be configured to restrict the resources accessible by visitors. Visitors cannot access the PCs of internal employees or the financial data server of the company, but can access the public resource server and Internet.

2. Topology

Figure 1-8 Topology of Configuring ACL80

3. Notes

- On device A, configure an expert advanced ACL and add access rules, including:
  - Prohibiting the hosts in the visitor area from sending packets destined to the network segment of internal employees' PCs.
  - Prohibiting visitors from accessing the financial data server.
  - Permitting all the other packets to pass through.
- On device A, apply the ACL to the inbound direction of the port connected to the visitor area.

4. Procedure

(1) Configure an expert advanced ACL and add access rules.

On device A, configure an expert advanced ACL and add access rules.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# expert access-list advanced acl80-guest
DeviceA(config-exp-dacl)# deny 0800 FFFF 24 0A0101 FFFFFF 42
DeviceA(config-exp-dacl)# deny 0800 FFFF 24 0C010102 FFFFFFFF 42
DeviceA(config-exp-dacl)# permit 0806 FFFF 24
DeviceA(config-exp-dacl)# permit 0800 FFFF 24
DeviceA(config-exp-dacl)# exit
```

(2) Apply the expert advanced ACL to a port.

On device A, apply the ACL80 to the inbound direction of the port connected to the visitor area.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# expert access-group acl80-guest in
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA(config)# show access-lists
expert access-list advanced sss
 10 deny 0800 FFFF 24 0A0101 FFFFFF 42
 20 deny 0800 FFFF 24 0C010102 FFFFFFFF 42
 30 permit 0806 FFFF 24
 40 permit 0800 FFFF 24

expert access-group acl80-guest in
Applied On interface GigabitEthernet 0/2
```

Ping the financial data server from a visitor PC and confirm that the ping operation fails.

Ping the public resource server from a visitor PC and confirm that the ping operation succeeds.

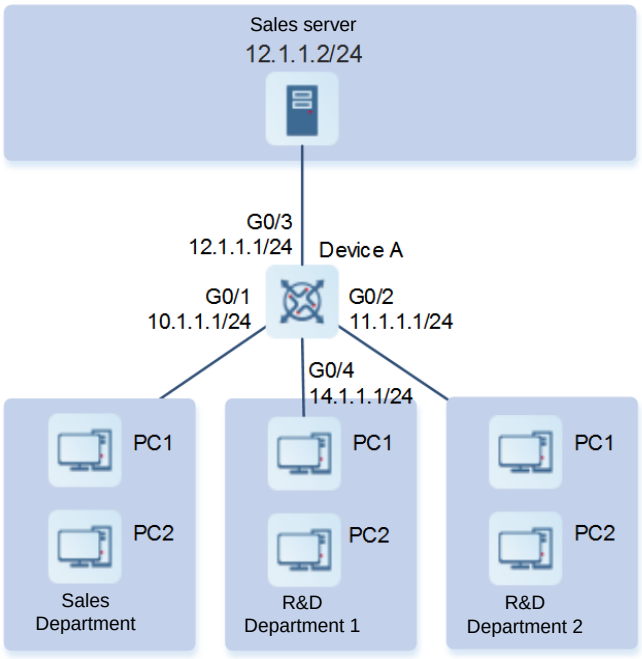
Ping the internal employee gateway 192.168.1.1 from a visitor PC and confirm that the ping operation fails.

Access the Internet through a visitor PC, for example, access www.baidu.com, and confirm that the home page can be opened.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
expert access-list advanced acl80-guest
 10 deny 0800 FFFF 24 0A0101 FFFFFF 42
 20 deny 0800 FFFF 24 0C010102 FFFFFFFF 42
 30 permit 0806 FFFF 24
 40 permit 0800 FFFF 24
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
 no switchport
 expert access-group 2700 in
 ip address 11.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/3
 no switchport
 ip address 12.1.1.1 255.255.255.0
!
```



1.17.7 Configuring a Global Security ACL

1. Requirements

The global security ACL function needs to be enabled to prohibit the R&D department from accessing the sales server, but permits the sales department to access it.

2. Topology

Figure 1-9 Topology of Configuring Global Security ACL

3. Notes

- On device A, configure an IP extended ACL and add the rule of denying packets with the destination address 12.1.1.2/24.
- Configure the ACL as a global security ACL on device A.
- Configure the port directly connected to the sales department as an excluded port of the global security ACL on device A.

4. Procedure

(1) Configure an IP extended ACL and add access rules.

On device A, configure an IP extended ACL and add access rules.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# ip access-list extended ip_ext_deny_dst_sale_server
DeviceA(config-ext-nacl)# deny ip any host 12.1.1.2
DeviceA(config-ext-nacl)# exit
```

(2) Configure a global security ACL.

Configure the ACL as a global security ACL on device A.

```
DeviceA(config)# ip access-group ip_ext_deny_dst_sale_server in
```

(3) Configure an excluded port of the global security ACL.

Configure the port directly connected to the sales department as an excluded port of the global security ACL on device A.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no global access-group
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA# show access-lists
ip access-list extended ip_ext_deny_dst_sale_server
 10 deny ip any host 10.1.1.3
DeviceA# show running
……
!
ip access-group ip_ext_deny_dst_sale_server in
!
……
!
interface GigabitEthernet 0/1
 no global access-group
!
```

Ping the sales server address from a PC in the sales department, and confirm that the ping operation succeeds.

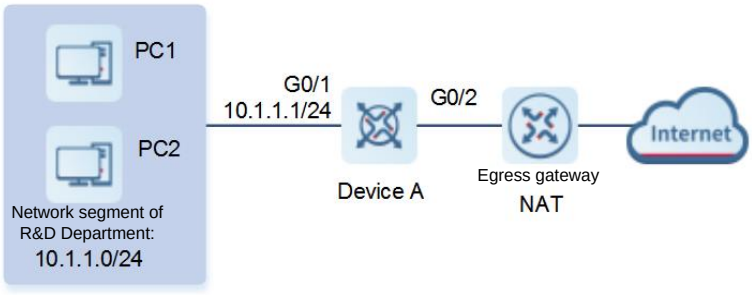
Ping the sales server address from PCs in R&D departments 1 and 2, and confirm that the ping operation fails.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
ip access-list extended ip_ext_deny_dst_sale_server
 10 deny ip any host 12.1.1.2
!
ip access-group ip_ext_deny_dst_sale_server in
!
interface GigabitEthernet 0/1
 no switchport
 no global access-group
 ip address 10.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
 no switchport
 ip address 11.1.1.1 255.255.255.0
!
```

```
interface GigabitEthernet 0/3
 no switchport
 ip address 12.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/4
 no switchport
 ip address 14.1.1.1 255.255.255.0
!
```



1.17.8 Configuring ACL Rules Based on Time Range

1. Requirements

- ACL rules based on time range need to be configured to permit the R&D department to access the Internet only from 12:00 to 13:30 every day.

2. Topology

Figure 1-10 Topology of Configuring Time Range-based ACL Rule

3. Notes

- Configure a time range on device A and add the time range entry from 12:00 to 13:30 every day.
- On device A, configure an IP standard ACL and add access rules, including:
  - Permitting packets from the source IP network segment 10.1.1.0/24 and associating the rule with the time range named access-internet.
  - Denying packets from the source IP network segment 10.1.1.0/24. This rule indicates that the Internet access is rejected beyond the time range.
  - Permitting packets from network segment addresses other than the R&D network segment addresses.
- On device A, apply the ACL to the inbound direction of the port connected to the R&D department.

4. Procedure

(1) Configure a time range.

Configure a time range on device A.

```
DeviceA> enable
DeviceA# configure terminal
```

```
DeviceA(config)# time-range access-internet
DeviceA(config-time-range)# periodic daily 12:00 to 13:30
DeviceA(config-time-range)# exit
```

(2) Configure an IP standard ACL and add access rules.

On device A, configure an IP standard ACL and add access rules.

```
DeviceA(config)# ip global access-list standard ip_std_internet_acl
DeviceA(config-std-nacl)# permit 10.1.1.0 0.0.0.255 time-range access-internet
DeviceA(config-std-nacl)# deny 10.1.1.0 0.0.0.255
DeviceA(config-std-nacl)# permit any
DeviceA(config-std-nacl)# exit
```

(3) Apply the IP standard ACL to a port.

On device A, apply the ACL to the inbound direction of the port connected the R&D department.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip access-group ip_std_internet_acl in
```

5. Verification

Check whether the ACL configuration commands are correct on device A.

```
DeviceA# show time-range

time-range entry: access-internet (inactive)
  periodic Daily 12:00 to 13:30

DeviceA# show access-lists

ip access-list standard ip_std_internet_acl
 10 permit 10.1.1.0 0.0.0.255 time-range access-internet (inactive)
 20 deny 10.1.1.0 0.0.0.255
 30 permit any

DeviceA# show access-group
ip access-group ip_std_internet_acl in
Applied On interface GigabitEthernet 0/1
```

During the effective period of the time range (12:00 to 13:30), visit the home page of www.baidu.com from a PC in the R&D department, and confirm that it can be accessed.

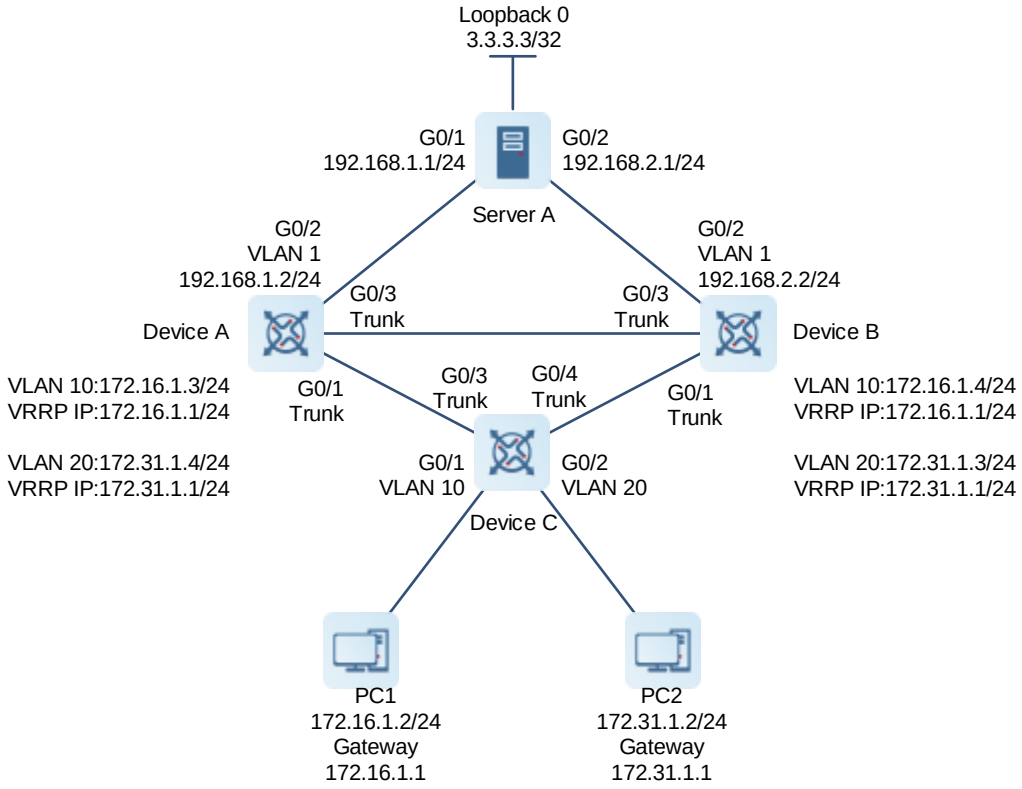
During the ineffective period (time beyond 12:00 to 13:30), visit the home page of www.baidu.com from a PC in the R&D department, and confirm that it cannot be accessed.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
ip access-list standard ip_std_internet_acl
 10 permit 10.1.1.0 0.0.0.255 time-range access-internet
 20 deny 10.1.1.0 0.0.0.255
```

```
 30 permit any
!
time-range access-internet
 periodic daily 12:00 to 13:30
!
interface GigabitEthernet 0/1
 no switchport
 ip access-group ip_std_internet_acl in
 ip address 10.1.1.1 255.255.255.0
!
```



1.17.9 Configuring an SVI Router ACL

1. Requirements

Only Layer 3 communication between hosts in the scenario of a VRRP with multiple VLANs. Configure an ACL that only permits the access between hosts any denies the access request from other network segments.

2. Topology

Figure 1-11 Topology of Configuring the VRRP with Multiple VLANs

3. Notes

- Device A and device B form a VRRP scenario. Both PC 1 and PC 2 are connected to device C.
- Configure STP to remove loops among device A, device B and device C.
- Use an SVI address as the gateway of PC 1 and PC 2.
- Configure an ACL that permits only the access between hosts and denies the access request from other

network segments. Apply the ACL to the SVI. In this case, device A and device B are both hosts in the VRRP group.

- After the **svi router-acls enable** command is configured. Device A and device B in the VRRP group serve as a host and a backup respectively. VRRP returns to normal.

4. Procedure

(1) Configure a VLAN.

The configurations on device A, device B, device C and device D are the same. The following example configures a VLAN on device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan 10
DeviceA(config-vlan)# exit
DeviceA(config)# vlan 20
DeviceA(config-vlan)# exit
```

(2) Configure a VRRP group.

Configure VRRP on device A.

```
DeviceA(config)# interface VLAN 10
DeviceA(config-if-VLAN 10)# ip address 172.16.1.3 255.255.255.0
DeviceA(config-if-VLAN 10)# vrrp 10 ip 172.16.1.1
DeviceA(config-if-VLAN 10)# vrrp 10 priority 120
DeviceA(config-if-VLAN 10)# exit
DeviceA(config)# interface VLAN 20
DeviceA(config-if-VLAN 20)# ip address 172.31.1.4 255.255.255.0
DeviceA(config-if-VLAN 20)# vrrp 20 ip 172.31.1.1
```

Configure VRRP on device B.

```
DeviceB(config)# interface VLAN 10
DeviceB(config-if-VLAN 10)# ip address 172.16.1.4 255.255.255.0
DeviceB(config-if-VLAN 10)# vrrp 10 ip 172.16.1.1
DeviceB(config-if-VLAN 10)# exit
DeviceB(config)# interface VLAN 20
DeviceB(config-if-VLAN 20)# ip address 172.31.1.3 255.255.255.0
DeviceB(config-if-VLAN 20)# vrrp 20 ip 172.31.1.1
DeviceB(config-if-VLAN 20)# vrrp 20 priority 120
DeviceB(config-if-VLAN 20)# exit
```

(3) Configure STP to remove loops.

The configurations on device A, device B, device C and device D are the same. The following example configures STP on device A.

```
DeviceA(config)# spanning-tree
```

(4) Configure an ACL.

The configurations on device A and device B are the same. The following example configures an ACL on device A.

```
DeviceA(config)# ip access-list standard 10
DeviceA(config-std-nacl)# permit host 3.3.3.3
DeviceA(config-std-nacl)# deny any
DeviceA(config-std-nacl)# exit
```

(5) Apply an ACL to an SVI.

The configurations on device A and device B are the same. The following example applies an ACL to an interface of device A.

```
DeviceA(config)# int vlan 20
DeviceA(config-if-VLAN 20)# ip access-group 10 in
```

- Configure the **svi router-acls enable** command on device A.
- The configurations on device A and device B are the same. The following example configures the **svi router-acls enable** command on device A.

```
DeviceA(config)# svi router-acls enable
```

5. Verification

Check the VRRP status on device A.

```
DeviceA# show vrrp
Interface    Grp  Pri   timer   Own  Pre   State   Master addr     Group addr
VLAN 10      10   120   3.53    -    P     Master  172.16.1.3     172.16.1.1
VLAN 20      20   100   3.60    -    P     Backup  172.31.1.3     172.31.1.1
```

6. Configuration Files

1.17.10 Configuring the ACL Packet Counting Function

1. Requirements

When you apply an ACL, you can configure the **counter-only** option to count the packets with some characteristics. The following example counts the ICMP packets discarded by the PC ping gateway and locate the discarded packets.

2. Topology

Figure 1-12 ACL Packet Statistics Topology

3. Notes

- Apply ACLs to both inbound and outbound directions of G0/1 and G0/2 on the device. You need to configure four ACLs on the device to match the ICMP packets from the PC to the gateway and from the gateway to the PC.
- Apply ACLs to both inbound and outbound directions of G0/1 on the gateway. You need to configure two ACLs on the gateway to match the ICMP packets from the PC to the gateway and from the gateway to the PC.
- Configure the **counter-only** option when you apply an ACL.
- The function only counts the packets matching the permit rule in the ACL and does not count those matching the deny rule.

4. Procedure

(1) Configure an ACL.

Configure four ACLs on the device to match the ICMP packets from the PC to the gateway and from the gateway to the PC.

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extend 100
Device(config-ext-nacl)# permit icmp host 10.10.10.2 host 10.10.10.254
Device(config-ext-nacl)# permit ip any any
Device(config-ext-nacl)# exit
Device(config)# ip access-list extend 101
Device(config-ext-nacl)# permit icmp host 10.10.10.254 host 10.10.10.2
Device(config-ext-nacl)# permit ip any any
Device(config-ext-nacl)# exit
Device(config)# ip access-list extend 102
```

```
Device(config-ext-nacl)# permit icmp host 10.10.10.2 host 10.10.10.254
Device(config-ext-nacl)# permit ip any any
Device(config-ext-nacl)# exit
Device(config)# ip access-list extend 103
Device(config-ext-nacl)# permit icmp host 10.10.10.254 host 10.10.10.2
Device(config-ext-nacl)# permit ip any any
Device(config-ext-nacl)# exit
```

Configure two ACLs on the gateway to match the ICMP packets from the PC to the gateway and from the gateway to the PC.

```
Gateway> enable
Gateway #configure terminal
Gateway(config)# ip access-list extend 100
Gateway(config-ext-nacl)# permit icmp host 10.10.10.2 host 10.10.10.254
Device(config-ext-nacl)# permit ip any any
Gateway(config-ext-nacl)# exit
Gateway(config)# ip access-list extend 101
Gateway(config-ext-nacl)# permit icmp host 10.10.10.254 host 10.10.10.2
Device(config-ext-nacl)# permit ip any any
Gateway(config-ext-nacl)# exit
```

(2) Apply ACLs.

Apply ACLs to both inbound and outbound directions of the interconnected interface, G0/1, on the gateway and the device.

```
Gateway(config)# interface gigabitEthernet 0/1
Gateway(config-if-GigabitEthernet 0/1)# ip access-group 100 in counter-only
Gateway(config-if-GigabitEthernet 0/1)# ip access-group 101 out counter-only
Gateway(config-if-GigabitEthernet 0/1)# exit
```

Apply ACLs to both inbound and outbound directions of the interconnected interface, G0/2, on the gateway and the device.

```
Device# configure terminal
Device(config)# interface gigabitEthernet 0/2
Device(config-if-GigabitEthernet 0/2)# ip access-group 103 in counter-only
Device(config-if-GigabitEthernet 0/2)# ip access-group 102 out counter-only
Device(config-if-GigabitEthernet 0/2)# exit
```

Apply ACLs to both inbound and outbound directions of the interconnected interface, G0/1, on the device and the PC.

```
Device# configure terminal
```

```
Device(config)# interface gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# ip access-group 100 in counter-only
Device(config-if-GigabitEthernet 0/1)# ip access-group 101 out counter-only
Device(config-if-GigabitEthernet 0/1)# exit
```

5. Verification

Send a total of 15 ICMP packets three times from the PC ping gateway address, 10.10.10.254. Display the count of ICMP packets on the device and the gateway respectively. Display the count of ICMP packets on the device.

```
Device# show access-lists
ip access-list extended 100
   10 permit ip host 10.10.10.2 host 10.10.10.254 (15 matches)
ip access-list extended 101
   10 permit ip host 10.10.10.254 host 10.10.10.2 (10 matches)
ip access-list extended 102
   10 permit ip host 10.10.10.2 host 10.10.10.254 (15 matches)
ip access-list extended 103
   10 permit ip host 10.10.10.254 host 10.10.10.2 (10 matches)
```

Display the count of ICMP packets on the gateway.

```
Gateway# show access-lists
ip access-list extended 100
   10 permit ip host 10.10.10.2 host 10.10.10.254 (15 matches)
ip access-list extended 101
   10 permit ip host 10.10.10.254 host 10.10.10.2 (15 matches)
```

Analyze the count of ICMP packets and locate the discarded packets

15 packets are received in the inbound direction of the interconnected interface, G0/1, of the device and the PC. (ACL 100 is applied to the device.)

15 packets are sent from the outbound direction of the interconnected interface, G0/2, of the device and the gateway. (ACL 102 is applied to the device.)

15 packets are received in the inbound direction of the interconnected interface, G0/1, of the gateway and the device. (ACL 100 is applied to the gateway.)

15 packets are sent from the outbound direction of the interconnected interface, G0/1, of the gateway and the device. (ACL 101 is applied to the gateway.)

10 packets are received in the inbound direction of the interconnected interface, G0/2, of the device and the gateway. (ACL 103 is applied to the device.)

The packets were discarded in the link between the device and the gateway.

6. Configuration Files

- Device configuration file

```
hostname Device
!
ip access-list extended 100
 10 permit icmp host 10.10.10.2 host 10.10.10.254
 20 permit ip any any
!
ip access-list extended 101
 10 permit icmp host 10.10.10.254 host 10.10.10.2
 20 permit ip any any
!
ip access-list extended 102
 10 permit icmp host 10.10.10.2 host 10.10.10.254
 20 permit ip any any
!
ip access-list extended 103
 10 permit icmp host 10.10.10.254 host 10.10.10.2
 20 permit ip any any
!
interface GigabitEthernet 0/1
 ip access-group 100 in counter-only
 ip access-group 101 out counter-only
!
interface GigabitEthernet 0/2
 ip access-group 103 in counter-only
 ip access-group 104 out counter-only
!
```

- Gateway configuration file

```
hostname Gateway
!
ip access-list extended 100
 10 permit icmp host 10.10.10.2 host 10.10.10.254
 20 permit ip any any
!
ip access-list extended 101
 10 permit icmp host 10.10.10.254 host 10.10.10.2
 20 permit ip any any
!
interface GigabitEthernet 0/1
 ip access-group 100 in counter-only
 ip access-group 101 out counter-only
 ip address 10.10.10.254 255.255.255.0
!
```

1 Configuring QoS

1.1 Introduction

1.1.1 Overview

Quality of service (QoS) can meet users' requirements for different applications and different levels of service quality. It allocates and schedules resources based on users' requirements and provides different levels of service quality for different packets.

On a traditional IP network, a device treats all the packets in the same way, in which the device processes packets based on their arrival time according to the queuing strategy of first in first out (FIFO), and transmits the packets to the destination on a best-effort basis. When the network bandwidth is abundant, all the packets are properly processed; when the network is congested, all the packets maybe discarded.

QoS assigns a transmission priority to the packets of a type to highlight the importance of the packets. Then, the devices provide special transmission services for these packets according to forwarding policies for different priorities, congestion avoidance, and other mechanisms. With QoS, a device processes real-time and important packets preferentially, processes non-real-time and common packets with lower priorities and even discards the packets upon network congestion.

QoS enhances the network performance predictability, effectively allocates network bandwidth, and reasonably utilizes network resources.

1.1.2 Principles

1. Basic Concepts

- DiffServ model

  The differentiated services (DiffServ) model classifies all packets transmitted on a network into different types. The classification information related to QoS priority marking is recorded in some fields of L2 or L3 packets, for example, the PRI field of IEEE 802.1Q frames, type of service (ToS) field of IPv4 packets, traffic class (TC) field of IPv6 packets.

  In the network of DiffServ model, the classification information of packets can be assigned by hosts or other network devices or based on different application policies or different packet contents. A device applies the same transmission service policy to packets containing the same classification information and applies different transmission service policies to packets containing different classification information. Based on the classification information carried by packets, a device may provide different transmission priorities for different packets, reserve bandwidth for a kind of packets, discard certain packets with lower priorities, or take some other actions.

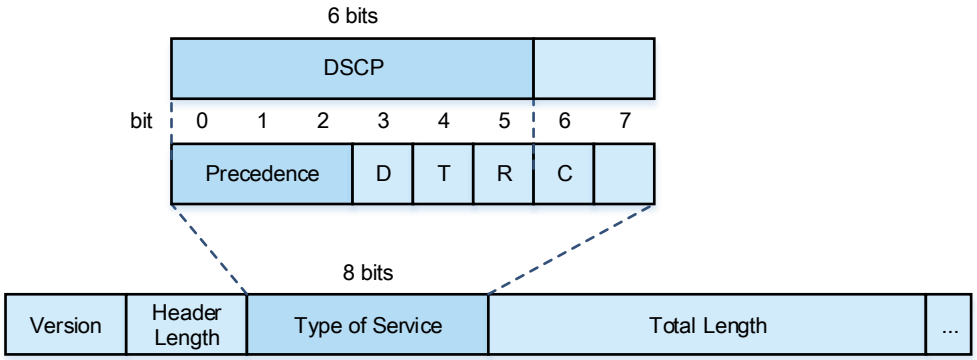
- PRI field of the IEEE 802.1q frames

  The PRI field of IEEE 802.1Q frames (namely, the IEEE 802.1p priority) is located in the header of an L2 packet containing an IEEE 802.1Q tag header, as shown in Figure 1-1.

Figure 1-1 Format of an L2 Frame with an IEEE 802.1Q Tag Header

The 4-byte IEEE 802.1Q tag header contains the 2-byte tag protocol identifier (TPID) and 2-byte tag control information (TCI). TCI contains the 3-bit PRI field, as shown in Figure 1-2.

Figure 1-2 PRI Field of the IEEE 802.1q Frames

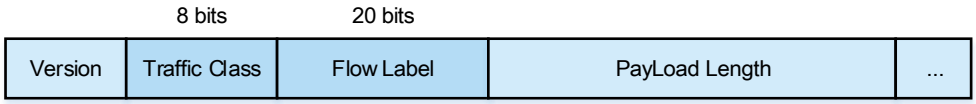


The PRI field represents eight priorities for packet transmission, and the priority values from high to low are 7, 6, ..., 1, and 0. The IEEE 802.1p priority is applicable to scenarios where L3 headers do not need to be analyzed and QoS needs to be implemented only at L2.

- ToS field of the IPv4 packets

  IPv4 packets use the ToS field in the IP header to indicate the priority of the packets, as shown in Figure 1-3.

Figure 1-3 ToS Field in the IP Header



The ToS field contains eight bits, of which the first three bits are the IP PRE (precedence) field and represent eight priorities for packet transmission, with the priority values from high to low being 7, 6, ..., 1, and 0.

RFC 2474 redefines the ToS field of the IP header, in which the first 6 bits (bits 0 to 5) represent the differentiated services code point (DSCP). DSCP is used to classify packets into a maximum of 64 different categories.

- ToS field of the IPv6 packets

  IPv6 packets use the TC field in the IPv6 header to indicate the packet priority, as shown in Figure 1-4Figure 1-4.

Figure 1-4 TC Field in the IPv6 Header

The TC field contains eight bits and provides the same function as the ToS field of IPv4 packets. The first six bits of the TC field indicate DSCP.

- CoS

  The class of service (CoS) is used to determine the packet queue number when an interface sends packets. The CoS values are 7, 6, ..., 1, and 0 from high to low.

2. Traffic Classification

Traffic classification identifies packets with certain characteristics according to rules. It is the prerequisite and basis for providing differentiated network services. Traffic classification is classified into simple traffic classification and complextraffic classification.

- Simple traffic classification

  Simple traffic classification classifies packets only based on the priorities carried in packets (for example, the PRI value of IEEE 802.1q frames, IP PRE or DSCP value of IP packets, TC value of IPv6 packets). Simple traffic classification implements the mapping from the priority to the CoS of the device based on whether an interface is configured to trust the priority tag carried in uplink packets.

- Complextraffic classification

  Complex traffic classification classifies packets based on the priorities carried in packets or by identifying packets meeting certain characteristics according to access control list (ACL) rules.

  A QoS policy based on complex traffic classification associates the complex traffic classification with relevant traffic behaviors to form a policy, which is then applied to an interface to take effect. A QoS policy comprises three elements: class, traffic behavior, and policy.

  - A class (Traffic Class) comprises the class name and class rule. A class defines the matching rules of traffic classification to classify packets.
  - A traffic (Traffic Behavior) behavior defines the action to be taken for the classified packets, including modifying the packet priority (also known as priority re-marking) and monitoring traffic.
  - A policy (Traffic Policy) comprises the policy name, and the binding relationship between a class and a traffic behavior. A policy binds a specified class and a traffic behavior and is applied to one or more interfaces to take effect.

The policy-based binding between multiple traffic classes and behaviors is as shown in Figure 1-6.

Figure 1-5 Policy-Based Binding Between Multiple Traffic Classes and Behaviors

- QoS logical interface group

  You can specify a series of interfaces (aggregation ports or Ethernet interfaces) as a QoS logical interface group, and associate a policy with the logical interface group for QoS processing. For example, the rate limiting function of a traffic behavior enables the packets complying with the rate limiting conditions to share the bandwidth limited by the policy on all the interfaces in the same logical interface group.

3. Priority Mapping

Priorities are used to identify the scheduling weights or forwarding priority of packets. Different priority types are defined for different packet types: IEEE 802.1q frames use the IEEE 802.1p priority, IP packets use the IP PRE or DSCP, and so on.

After a packet enters a device interface, the packet priority is mapped to the CoS according to the trust mode configured for the interface. Table 1-1 shows the mappings between trust mode configured for an interface and the priorities.

Table 1-1 Interface Trust Mode and Priority Mapping

Interface Trust Mode	Priority Mapping
Untrusted	● No priority carried in packets is trusted. ● All packets received from an interface use the IEEE 802.1p value configured for the interface. ● The CoS values are obtained from the 802.1p-to-DSCP mapping table and DSCP-to-CoS mapping table. Packets are sent to queues based on their CoS values. ● If an IEEE 802.1Q tagged packet is sent from an egress, the packet priority is changed to the corresponding CoS value.
Trusting 802.1p	● If a packet received by an interface is an IEEE 802.1Q tagged packet, the carried IEEE 802.1p value is directly used. If a packet does not carry any tag, the IEEE 802.1p value configured for the interface is used. ● The CoS values are obtained from the 802.1p-to-DSCP mapping table and DSCP-to-CoS mapping table. Packets are sent to queues based on their CoS values. ● If an IEEE 802.1Q tagged packet is sent from an egress, the packet priority is changed to the corresponding CoS value.

Interface Trust Mode	Priority Mapping
Trusting DSCP	If a packet received from an interface is a non-IP packet, it is processed in the same way of trusting 802.1p. If the received packet is an IP packet, the CoS value is obtained from the DSCP-to-CoS mapping table based on the DSCP value of the packet. Packets are sent to queues based on their CoS values.
Trusting IP PRE	● If a packet received from an interface is a non-IP packet, it is processed in the same way of trusting 802.1p. If the received packet is an IP packet, the CoS value is obtained from the IP PRE-to-DSCP mapping table and DSCP-to-CoS mapping table based on the IP PRE value of the packet. Packets are sent to queues based on their CoS values.

4. Traffic Policing

Traffic policing supervises the rate of the specific traffic, limits the rate within a reasonable range, and discards the traffic out of the limit or re-marks the priority. Traffic policing adopts the committed access rate (CAR) technology to control traffic. CAR uses the single-rate single-token bucket algorithm to judge whether the rate of each packet exceeds the specified traffic limit.

- Single-rate single token bucket

  The single-rate single token bucket contains two parameters: **CIR** and **CBS**.

  - Committed information rate (CIR): Indicates the rate at which a token is added to a token bucket.
  - Committed burst size (CBS): Indicates the capacity of a token bucket.

  The single-rate single token bucket adds tokens to a token bucket at a fixed rate (namely, CIR). When the number (that is, CBS) of tokens in a token bucket reaches the capacity of the token bucket, the excess tokens are discarded. When the device processes packets, it takes tokens out of the token bucket, with the number same as the size of packets (in bytes). When the number of tokens is sufficient, the packets can be forwarded. When the number of tokens is insufficient, the packets are discarded or the priorities of some packets are re-marked before forwarding.

- CAR processing

  CAR uses a token bucket to measure the packets passing through an interface, and implements the preset policing action based on the measurement results. These actions include:

  - Forwarding: Packets within the traffic limit are normally forwarded.
  - Discarding: Packets out of the traffic limit are discarded. The packets out of the total traffic limit of an interface are directly discarded.
  - Changing the priority and forwarding: The priorities of the packets out of the traffic limit are changed and then the packets are forwarded.

5. Congestion Management

When the receiving rate of packets exceeds the sending rate, congestion occurs on the sending interface. If no sufficient buffer is provided to store these packets, packet loss may occur. The congestion management mechanism determines the sending order of packets based on their local priorities. The congestion management function controls congestion and improves the local priorities of packets for some important data. When congestion occurs, the packets of higher priorities are sent first to ensure that key services are provided in time.

Congestion management adopts the queue scheduling mechanism. The processing is as follows:

(1) After each packet undergoes the QoS processing in a device, it obtains a CoS value finally.

(2) The device allocates the packets to the corresponding sending queues according to the CoS values.

(3) The outbound interface selects the packets in a queue for sending according to various queue scheduling policies (such as SP, RR, WRR, DRR, WFQ, SP+WRR, SP+DRR, and SP+WFQ).

- SP scheduling policy

  In strict-priority (SP) scheduling, packets are scheduled strictly based on their queue priorities from high to low. Before sending a packet, check whether there is a packet to be sent in a high-priority queue. If there is, send it. If not, check whether there is a packet to be sent in the next-level queue, and so on.

  The weakness of SP scheduling is that, when congestion occurs, if the packets in a higher priority queue exist for a long time, the packets in a lower priority queue have no opportunity of being scheduled.

- RR scheduling policy

  Round robin (RR) scheduling uses the round robin method to schedule multiple queues. Only one packet in a queue is processed each time.

- WRR scheduling policy

  The weighted round robin (WRR) scheduling solves the problem that weight cannot be set for RR scheduling. WRR scheduling also adopts the round robin method to schedule multiple queues. The number of packets in a queue processed each time is proportional to the weight of the queue. RR scheduling is equivalent to WRR scheduling with the weight 1.

  However, WRR scheduling fails to schedule the services with low delay requirements in time.

- DRR scheduling policy

  The deficit round robin (DRR) scheduling is similar to WRR scheduling, but the DRR scheduling is implemented based on the packet byte size instead of the number of packets.

  However, DRR scheduling fails to schedule the services with low delay requirements in time.

- WFQ scheduling policy

  Weighted fair queuing (WFQ) scheduling fixes the problem that the queues using WRR scheduling have no fixed egress bandwidth. WFQ scheduling allocates an egress bandwidth to queues based on the queue weight, and different queues can have the opportunity of fair scheduling.

- SP+WRR scheduling policy

  SP scheduling is configured for one or more sending queues, and the other queues are scheduled in the WRR mode. Among SP queues, only after all the packets in an SP queue with a higher priority are sent, can the packets in an SP queue with a next higher priority be sent. Among SP and WRR queues, only after the packets in all SP queues are sent, can the packets in WRR queues be sent.

- SP+DRR scheduling policy

  SP scheduling is configured for one or more sending queues, and the other queues are scheduled in the DRR mode. Among SP queues, only after all the packets in an SP queue with a higher priority are sent, can the packets in an SP queue with a next higher priority be sent. Among SP and DRR queues, only after the packets in all SP queues are sent, can the packets in DRR queues be sent.

- SP+WFQ scheduling policy

SP scheduling is configured for one or more sending queues, and the other queues are scheduled in the WFQ mode. Among SP queues, only after all packets in an SP queue with a higher priority are sent, can the packets in an SP queue with a next higher priority be sent. Among SP and WFQ queues, only after the packets in all SP queues are sent, can the packets in WFQ queues be sent.

Like unicast queues, multicast queues can also be configured with priority mapping and scheduling algorithms. Currently multicast queues support the following scheduling algorithms: SP, WRR, and SP+WRR.

6. Congestion Avoidance

Congestion avoidance monitors the usage of the outbound interface queues, and eliminates the network overload by actively discarding packets and adjusting the network traffic when network congestion occurs. Congestion avoidance avoids congestion by effectively monitoring the network traffic load, forecasting the occurrence of congestion, and discarding packets. Discarding policies include tail-drop, discarding based on random early detection (RED) results, and discarding based on weighted random early detection (WRED) results.

- Tail-drop

  Traditional packet loss policies use the tail-drop method. Tail-drop is effective for all traffic and cannot distinguish service levels. When congestion occurs, data packets at the tail of a queue are discarded until the congestion is removed.

- RED and WRED

  The hosts running Transmission Control Protocol (TCP) decreases the rate of sending packets to respond to massive packet loss. After congestion is removed, the hosts increase the rate of sending packets. Tail-drop may cause TCP global synchronization. Namely, when a queue discards multiple TCP packets simultaneously, multiple TCP connections enter the congestion avoidance and slow startup state simultaneously. In this case, the tail is dropped, and the traffic is reduced and adjusted. When congestion is removed, traffic peaks appear. The process repeats constantly, the network traffic goes up and down suddenly, and the line traffic always fluctuates between the lowest traffic and the full traffic. When TCP global synchronization occurs, the connection bandwidth cannot be fully used, which causes a bandwidth waste.

  To avoid this circumstance, you can use the RED or WRED packet discarding policy. The policy provides a mechanism for discarding packets at random and avoiding TCP global synchronization. When packets of a TCP connection are discarded and the remaining packets of the TCP connection are sent at a lower rate, packets of other TCP connections are still sent at higher rates. There are always some TCP connections whose packets are sent at higher rates, which increases the utilization of line bandwidth.

  When WRED is used, you can set the lower threshold and maximum discarding probability for a queue. When the length of a queue is smaller than the lower threshold, no packets are discarded. When the queue length is between the lower threshold and higher threshold, WRED starts to discard packets randomly and sets a maximum discarding probability. A longer queue leads to a higher discarding probability. When the length of a queue is greater the higher threshold, packets are discarded at the maximum discarding probability.

  Different from RED, WRED uses priorities to distinguish discarding policies. RED is a special case of WRED. When all the CoS values of an interface are mapped to the same lower and higher thresholds, WRED becomes RED.

1.2 Configuration Task Summary

QoS configuration includes the following tasks:

- Configuring Traffic Classification
  - Configuring a Class
  - Configuring a Policy
  - Applying a Policy
  - (Optical) Configuring a Logical Interface Group
- Configuring Priority Mapping
  - Configuring the Trust Mode
  - Configuring Mappings
- Configuring the Interface Rate Limit
- Configuring Congestion Management
  - Configuring the CoS-to-Queue Mappings
  - Configuring the Scheduling Policy and Round Robin Weights for Global Output Queues
  - Configuring the Scheduling Policy and Round Robin Weights for Output Queues on an Interface
  - Configuring Bandwidth for a Queue
- Configuring Congestion Avoidance
  - Enabling the WRED Function
  - Configuring Higher and Lower Threshold Values
  - Configuring the Maximum Discarding Probability
  - Configuring the CoS-to-Threshold Mappings
- Configuring the QoS Global Policy

1.3 Configuring Traffic Classification

1.3.1 Overview

Traffic classification uses certain rules to identify the packets with certain characteristics. You can define the binding between multiple traffic classes and traffic behaviors to form policies and apply the policies to interfaces to realize traffic classification and processing.

1.3.2 Configuration Tasks

Traffic classification configuration includes the following tasks:

(1) Configuring a Class

(2) Configuring a Policy

(3) Applying a Policy

(4) (Optional) Configuring a Logical Interface Group

1.3.3 Configuring a Class

1. Overview

This section describes how to create a class, and defines class matching rules in class configuration mode.

2. Restrictions and Guidelines

- A class name comprises a maximum of 31 characters.
- Run the **match** command to define a class matching rule.
- When setting the matching rule of a class to ACL matching, you need to create an ACL and ACL rules first.
- In AND mode, if the rules in a class conflict with each other, packets may fail to be matched by the class. Conflicting scenarios include the following:
  - A rule in an ACL duplicates with another rule. For example, if both **ip dscp** and **ipv4 acl** are configured and the IPv4 ACL contains a DSCP matching rule, the DSCP matching rule in the IPv4 ACL takes effect.
  - According to the protocol standard, **ip precedence** and **dscp** fields are mutually exclusive. When **match ip** and **match acl** rules contain the **ip precedence** and **dscp** fields simultaneously, the effective behavior is uncertain.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a class and enter the class configuration mode.

class-map *class-map-name* [**and** | **or**]

No class is configured by default. When the matching type of the traffic classification is not set, the OR mode is used by default.

(4) Define a matching rule for the class. Configure at least one of the tasks.

- Set the matching rule of the class to ACL matching.

  match access-group { *acl-name* | *acl-number* }

  Numerically indexed ACLs or named ACLs are supported.

- Set the matching rule of the class to matching the PRE priorities of IP packets.

  match ip precedence *precedence-value-list*

  Multiple IP PRE values can be matched at the same time. The value range of IP PRE is from 0 to 7.

- Set the matching rule of the class to matching the DSCP priorities of IP packets.

  match ip dscp *dscp-value-list*

  Multiple DSCP values can be matched at the same time. The value range of DSCP priority is from 0 to 63.

No class matching rules are defined by default.

1.3.4 Configuring a Policy

1. Overview

This section describes how to create a policy, and bind classes and traffic behaviors in the policy configuration mode.

2. Restrictions and Guidelines

- A policy name comprises a maximum of 31 characters.
- When multiple classes are associated with the same policy, you are not advised to match the same flow with multiple classes; otherwise the traffic behavior bound to a class is performed on the flow randomly, and, when the device restarts, the traffic behavior bound to a class is also performed on the flow randomly.
- The **set** command is used to modify the priority tag of a specified packet, such as IEEE 802.1p and DSCP.
- The **police** command is used to limit the bandwidth of the specified traffic and configure the processing action on traffic beyond the limit, for example, discarding the traffic out of the limit, or modifying the CoS or DSCP value.
- The **drop** command is used to drop all the identified streams. To configure other traffic behaviors, you must delete this traffic behavior.
- When you run the **policy-map** command and associate the policy with multiple classes, the priority configuration must be consistent among all classes. That is, if an associated class with a configured priority exist, you must configure the priority for a class to be associated with the policy. Otherwise, an error is displayed. If an associated class has no priority configuration, you cannot configure a priority for a class to be associated with the policy. Otherwise, an error is displayed.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a policy and enter the policy configuration mode.

policy-map *policy-map-name*

No policy is configured by default.

(4) Associate a class and enter the policy class configuration mode.

class *class-map-name* [**precedence** *precedence-value*]

No class is associated with a policy by default.

(5) Bind the class to a traffic behavior. Configure at least one of the tasks.

- Bind the class to the traffic behavior of modifying the IEEE 802.1p, DSCP.

  set { **cos** *cos-value* | **ip dscp** *dscp-value* }

- Bind the class to the traffic behavior of limiting the bandwidth and processing packets beyond the limit.

  police *rate-value burst-value* [**exceed-action** { **cos** *cos-value* [**none-tos**] | **drop** | **dscp** *dscp-value* }]

(6) Bind the class to the traffic behavior of discarding packets.

drop

A class is not bound to any traffic behavior by default.

This command can be configured only when a class associated with a policy is not bound to any traffic behavior. Namely, after a class associated with a policy is bound to the traffic behavior of discarding packets, you need to first delete the binding and then bind the class to other traffic behaviors.

1.3.5 Applying a Policy

1. Overview

This section describes how to apply a configured policy to a specified interface to make the policy take effect.

2. Restrictions and Guidelines

- A policy can be applied globally or to an interface.
- If a policy is applied globally, the policy is applied to all interfaces which can be configured with policies.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Apply a policy in global configuration mode.

service-policy { **input** | **output** } *policy-map-name*

No policy is applied globally by default.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the SVI configuration mode.
  interface vlan *vlan-id*

(5) Apply a policy in interface configuration mode.

service-policy { **input** | **output** } *policy-map-name*

No policy is applied to an interface by default.

1.3.6 Configuring a Logical Interface Group

1. Overview

This section describes how to associate a configured policywith a logical interface group.

2. Restrictions and Guidelines

- A maximum of 128 logical interface groups can be created.
- In global configuration mode, run the **virtual-group** command to create a logical interface group and enter the logical interface group configuration mode.
- In interface configuration mode, run the **virtual-group** command to add the interface to a specified logical interface group. If the logical interface group is not created, this command creates the logical interface group and adds the interface to the group.
- Physical interfaces or aggregation ports can be added to a logical interface group. The following types of interfaces cannot be added to a logical interface group:
  - Member interface of an aggregation port
  - VSL member interface

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a logical interface group

virtual-group *virtual-group-number*

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

(5) Add an interface to a logical interface group.

virtual-group *virtual-group-number*

An interface is not added to any logical interface group by default.

(6) Return to the global configuration mode.

exit

(7) Enter the logical interface group configuration mode.

virtual-group *virtual-group-number*

(8) Apply a policy to the logical interface group.

service-policy { **input** | **output** } *policy-map-name*

1.4 Configuring Priority Mapping

1.4.1 Overview

Priority mapping can be implemented based on the trust mode configured for an interface.

1.4.2 Configuration Tasks

Priority marking and mapping configuration includes the following tasks:

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Trust Mode
- Configuring Mappings

1.4.3 Configuring the Trust Mode

1. Overview

- You can set various priorities for packets according to the trust mode configured for an interface.
- Run the **mls qos trust** command to configure the trust mode for an interface.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

(4) Configure the trust mode for the interface. Please configure only one task.

- Configure trusting IEEE 802.1p.

  mls qos trust cos

- Configure trusting DSCP.

  mls qos trust dscp

- Configure trusting IP PRE.

  mls qos trust ip-precedence

An interface is in untrusted mode by default.

(5) (Optional) Configure the IEEE 802.1p value for the interface.

mls qos cos *cos-value*

The default IEEE 802.1p value of an interface is **0**.

1.4.4 Configuring Mappings

1. Overview

This section describes how to configure mappings, including:

- IEEE 802.1p-to-DSCP mappings.
- DSCP-to-CoS mappings.
- IP PRE-to-DSCP mappings.

2. Restrictions and Guidelines

- Run the **mls qos map cos-dscp** command to configure the mappings from IEEE 802.1p values to DSCP values.
- Run the **mls qos map dscp-cos** command to configure the mappings from DSCP values to CoS values.
- Run the **mls qos map ip-precedence-dscp** command to configure the mappings from IP PRE values to DSCP values.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure mappings. Configure at least one of the tasks.

- Configure the IEEE 802.1p-to-DSCP mappings.

  mls qos map cos-dscp *dscp-value-list*

  The IEEE 802.1p values 0 to 7 are mapped to the DSCP values 0, 8, 16, 24, 32, 40, 48, and 56 respectively by default.

- Configure the DSCP-to-CoS mappings.

  mls qos map dscp-cos *dscp-value*&<1-8> **to** *cos-value*

  DSCP values 0 to 7 are mapped to CoS 0, DSCP values 8 to 15 are mapped to CoS 1, DSCP values 16 to 23 are mapped to CoS 2, DSCP values 24 to 31 are mapped to CoS 3, DSCP values 32 to 39 are

mapped to CoS 4, DSCP values 40 to 47 are mapped to CoS 5, DSCP values 48 to 55 are mapped to CoS 6, and DSCP values 56 to 63 are mapped to CoS 7 by default.

- Configure the IP PRE-to-DSCP mappings.

  mls qos map ip-precedence-dscp *dscp-value-list*

  The IP PRE values 0 to 7 are mapped to the DSCP values 0, 8, 16, 24, 32, 40, 48, and 56 respectively by default.

1.5 Configuring the Interface Rate Limit

1.5.1 Overview

This section describes how to configure traffic limit for an interface.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

(4) Configure traffic limit for the interface. Configure at least one of the tasks.

- Configure the rate limit for the traffic in the input direction of an interface.

  rate-limit input *rate-value burst-value*

- Configure the rate limit for the traffic in the output direction of an interface.

  rate-limit output *rate-value burst-value*

No traffic limit is configured for an interface by default.

1.6 Configuring Congestion Management

1.6.1 Overview

This section describes how to control congestion. The priorities of important data packets can be raised so that they are sent first when congestion occurs, thereby ensuring that key services are provided in time.

1.6.2 Configuration Tasks

The congestion management configuration includes the following tasks:

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the CoS-to-Queue Mappings
- Configuring the Scheduling Policy and Round Robin Weights for Global Output Queues
- Configuring the Scheduling Policy and Round Robin Weights for Output Queues on an Interface
- Configuring Bandwidth for a Queue

1.6.3 Configuring the CoS-to-Queue Mappings

1. Overview

This section describes how to configure the CoS-to-queue mappings so that packets can enter various output queues based on their CoS values.

2. Restrictions and Guidelines

- Run the **priority-queue cos-map** command to configure the CoS-to-queue mappings.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the CoS-to-queue mappings.

priority-queue cos-map *queue-id cos-value* &<1-8>

The CoS values 0 to 7 are mapped to the queues 1 to 8 respectively by default.

1.6.4 Configuring the Scheduling Policy and Round Robin Weights for Global Output Queues

1. Overview

This section describes how to configure the scheduling policy and round robin weights for output queues.

2. Restrictions and Guidelines

- Run the **priority-queue** command to set the scheduling policy to SP scheduling.
- Run the **mls qos scheduler sp** command to set the scheduling policy to SP scheduling for output queues.
- Run the **mls qos scheduler rr** command to set the scheduling policy to RR scheduling for output queues.

- Run the **mls qos scheduler wrr** command to set the scheduling policy to WRR scheduling based on the packet quantity for output queues.
- Run the **mls qos scheduler drr** command to set the scheduling policy to WRR scheduling based on the packet size for output queues.
- Run the **mls qos scheduler wfq** command to set the scheduling policy to WFQ scheduling for output queues.
- Run the **drr-queue bandwidth** command to configure the round robin weight for the DRR scheduling policy of output queues. A higher weight means that more packet bytes can be sent.
- Run the **wrr-queue bandwidth** command to configure the round robin weight for the WRR scheduling policy of output queues. A higher weight means longer output time.
- Run the **wfq-queue bandwidth** command to configure the round robin weight for the WFQ scheduling policy of output queues. A higher weight means that more packet bytes can be sent.
- Run the **priority-queue out** command to set the scheduling policy of output queues to SP. The effect is the same as that of the **mls qos scheduler sp** command. Run the **show running-config** command. The command is displayed as **mls qos scheduler sp** instead of **priority-queue out**.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the scheduling policy for output queues. Please configure only one task.

- Configure the scheduling policy for global output queues.

  mls qos scheduler { **drr** | **rr** | **sp** | **wfq** | **wrr** }

  The default scheduling policy of global output queues is **WRR**.

- Set the scheduling policy to SP scheduling.

  priority-queue

  The default scheduling policy of output queues is **WRR**.

- Set the scheduling policy to SP scheduling.

  priority-queue out

  The default scheduling policy of output queues is **WRR.**

(4) Configure the round robin weight for the scheduling policy of global output queues.

{ **drr-queue** | **wfq-queue** | **wrr-queue** } **bandwidth** *weight-value-list*

The default round robin weight ratio of global queues is **1:1:1:1:1:1:1:1**.

1.6.5 Configuring the Scheduling Policy and Round Robin Weights for Output Queues on an Interface

1. Overview

This section describes how to configure the scheduling policy and round robin weights for output queues.

2. Restrictions and Guidelines

- Run the **priority-queue** command to set the scheduling policy to SP scheduling.
- Run the **mls qos scheduler sp** command to set the scheduling policy to SP scheduling for output queues.
- Run the **mls qos scheduler rr** command to set the scheduling policy to RR scheduling for output queues.
- Run the **mls qos scheduler wrr** command to set the scheduling policy to WRR scheduling based on the packet quantity for output queues.
- Run the **mls qos scheduler drr** command to set the scheduling policy to WRR scheduling based on the packet size for output queues.
- Run the **mls qos scheduler wfq** command to set the scheduling policy to WFQ scheduling for output queues.
- Run the **drr-queue bandwidth** command to configure the round robin weight for the DRR scheduling policy of output queues. A higher weight means that more packet bytes can be sent.
- Run the **wrr-queue bandwidth** command to configure the round robin weight for the WRR scheduling policy of output queues. A higher weight means longer output time.
- Run the **wfq-queue bandwidth** command to configure the round robin weight for the WFQ scheduling policy of output queues. A higher weight means that more packet bytes can be sent.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

(4) Configure the scheduling policy for interface output queues.

mls qos scheduler { **drr** | **rr** | **sp** | **wfq** | **wrr** }

No scheduling policy is configured on an interface by default.

(5) Configure the round robin weight for the scheduling policy of interface output queues.

{ **drr-queue** | **wfq-queue** | **wrr-queue** } **bandwidth** *weight-value-list*

The default round robin weight ratio of interface queues is **1:1:1:1:1:1:1:1**.

1.6.6 Configuring Bandwidth for a Queue

1. Overview

This section describes how to configure the minimum guaranteed bandwidth and maximum limited bandwidth for a queue.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregateport interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

(4) Configure the minimum guaranteed bandwidth and maximum limited bandwidth for a queue on an interface.

qos queue *queue-id* **bandwidth** { **maximum** *bandwidth* | **minimum** *bandwidth* }

No minimum guaranteed bandwidth or maximum limited bandwidth is configured for a queue by default.

1.7 Configuring Congestion Avoidance

1.7.1 Overview

Congestion avoidance monitors the usage of queues in an outbound interface and eliminates the network overload by actively discarding packets and adjusting the network traffic in the case of network congestion.

1.7.2 Configuration Tasks

Congestion avoidance configuration includes the following tasks:

(1) Enabling the WRED Function

(2) (Optional) Configuring Higher and Lower Threshold Values

(3) (Optional) Configuring the Maximum Discarding Probability

(4) (Optional) Configuring the CoS-to-Threshold Mappings

1.7.3 Enabling the WRED Function

1. Overview

This section describes how to configure WRED as the packet discarding policy.

2. Restrictions and Guidelines

The default packet discarding policy is tail-drop.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the WRED function.

queueing wred

The WRED function is disabled by default.

1.7.4 Configuring Higher and Lower Threshold Values

1. Overview

This section describes how to configure the higher and lower threshold values for WRED.

2. Restrictions and Guidelines

- When the packet length of a queue is smaller than the lower threshold, no packets are discarded. When the queue length is between the lower threshold and the higher threshold, WRED starts to discard packets randomly.
- Because the maximum value of the configuration range is equal to the current higher threshold, you need to pay attention to the configured higher threshold when configuring the lower threshold.
- The threshold for WRED to discard packets can be configured in the unit of percentage.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

(4) Configure a lower threshold value in percentage.

wrr-queue random-detect min-threshold *queue-id threshold*&<1-2>

The queue value range is from 1 to 8. The value range of the lower threshold value is from 1 to 100.

1.7.5 Configuring the Maximum Discarding Probability

1. Overview

When the packet length in a queue is between the lower threshold and the higher threshold, you can configure the maximum probability for discarding packets at random.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

(4) Configure the maximum discarding probability.

wrr-queue random-detect probability *queue-id probability*&<1-2>

The maximum discarding probability is not configured by default.

1.7.6 Configuring the CoS-to-Threshold Mappings

1. Overview

This section describes how to configure the CoS-to-threshold mappings.

2. Restrictions and Guidelines

- Multiple threshold groups can be configured for the lower threshold and maximum discarding probability.

- By configuring the mappings from CoS values and threshold groups, you can select the effective threshold group mapped to a CoS, for example, you can map CoS 0 to threshold group 1, and CoS 1 to threshold group 2.
- If the packets of CoS values 0 and 1 are all added to queue 1 for scheduling, the packets of CoS 0 are processed based on the lower threshold and maximum discarding probability in group 1, and the packets of CoS 1 are processed based on the lower threshold and maximum discarding probability in group 2.
- When all the CoS values are mapped to the same threshold group, the enabled WRED becomes RED.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate port interface configuration mode.

  interface aggregateport *interface-number*

(4) Configure the CoS-to-threshold mappings.

wrr-queue cos-map *threshold-id cos&*<1-8>

All the CoS values are mapped to the threshold in group 1 by default.

1.8 Configuring the QoS Global Policy

1.8.1 Overview

Enabling the QoS global policy enables some QoS policies by default, for example, changing the DSCP value of L2 flows.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the global QoS policy.

mls qos enable

1.9 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

Caution

Running the **clear** commands may interrupt services due to loss of important information.

Table 1-2 QoS Monitoring

Command	Purpose
show class-map [*class-map-name*]	Displays the traffic classification information.
show class-map nameid	Displays the mapping between class names and IDs.
show mls qos capacity	Displays QoS capabilities.
show mls qos features	Displays chip QoS capabilities.
show mls qos interface { *interface-type interface-number* | **policers** }	Displays the QoS information of an interface.
show mls qos intf_status	Displays the policy application status of all interfaces.
show mls qos istat [*interface-type interface-number*]	Displays the QoS capabilities and default information on an interface.
show mls qos maps { **cos-dscp** | **dscp-cos** | **ip-prec-dscp** }	Displays various mappings.
show mls qos mstat	Displays the memory usage statistics of QoS.
show mls qos queueing [**interface** *interface-type interface-number*]	Displays information about the QoS queues, scheduling policies, and round robin weights.
show mls qos rate-limit [**interface** *interface-type interface-number*]	Displays the rate limit information of an interface.
show mls qos scheduler [**interface** *interface-type interface-number*]	Displays the scheduling policy information of an output queue.
show mls qos status	Display the global QoS capabilities and default information.
show mls qos virtual-group { *virtual-group-number* | **policers** }	Displays information about a policy applied to a logical interface group.
show policy-map [*policy-map-name* [**class** *class-map-name*]]	Displays the QoS policy information.

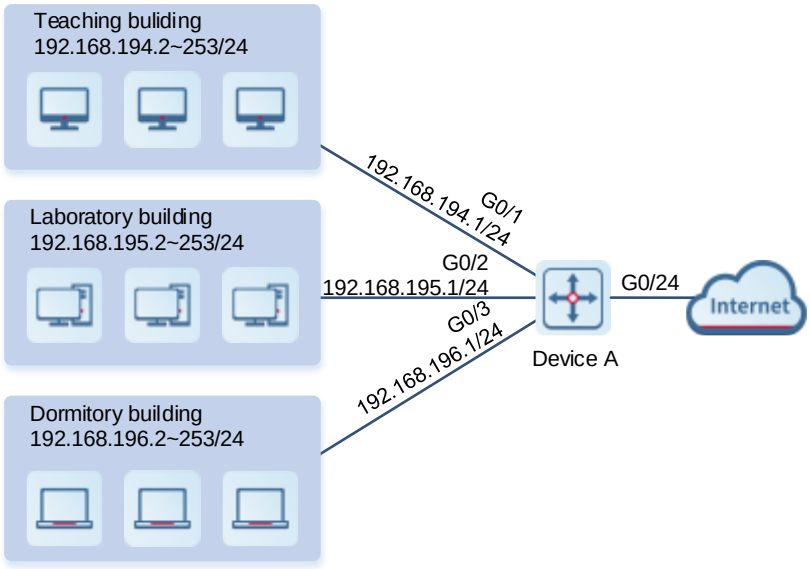
Command	Purpose
show policy-map interface *interface-type interface-number*	Displays information about a policy applied to an interface.
show policy-map nameid	Displays the mapping between policy names and IDs.
show qos bandwidth [**interface** *interface-type interface-number*]	Displays information about the queue bandwidth.
show qos res [**dev** *dev-number* [**slot** *slot-number*]]	Displays QoS resource usage of the current device.
show queueing wred interface *interface-type interface-number*	Displays the WRED configuration.
show virtual-group { *virtual-group-number* | **summary** }	Displays information about a logical interface group.
clear qos res	Clears historical peak values of QoS resource usage.
debug qos lib [**event** | **message**]	Debugs the QoS library.
debug qos server [**event** | **message**]	Debugs the QoS communication server.
debug qos mls	Debugs QoS user command processing.
debug qos vmsup	Debugs VMSUP configurations.

1.10 Configuration Examples

1.10.1 Configuring the Interface Rate Limit and Priority Re-marking

1. Requirements

To meet the service requirements of normal teaching, a school puts forwards the following requirements:



- Controlling the Internet access traffic of the school within 100 Mbps and discarding the packets out of the limit.
- Controlling the egress traffic of the dormitory building within 50 Mbps and discarding the packets out of limit.
- Controlling the rate of packets with DSCP priority 7 sent from laboratory building within 20 Mbps, and discarding the packets out of limit.
- Controlling the egress traffic of the teaching building within 30 Mbps and discarding the packets out of limit.

Note

The school connects to the Internet through G0/24 of device A, and G0/1, G0/2, and G0/3 of device A connect to the teaching building (192.168.194.2~253/24), laboratory building (192.168.195.2~253/24), and dormitory building (192.168.196.2~253/24) respectively.

2. Topology

Figure 1-6 Topology of Configuring Interface Rate Limit and Priority Re-marking

3. Notes

(1) For Internet access traffic on the outbound interface, configure the egress traffic limit on interface G0/24 of device A, and set the bandwidth limit to 102,400 kbps and burst traffic limit to 256 Kbytes per second.

(2) For the dormitory building, configure the ingress traffic limit on interface G0/3 of device A, and set the bandwidth limit to 51,200 kbps and burst traffic limit to 256 Kbytes per second.

(3) For the teaching building, configure the ingress traffic limit on interface G0/1 of device A, and set the bandwidth limit to 30,720 kbps and burst traffic limit to 256 Kbytes per second.

(4) For the laboratory building, create the class cmap_dscp7 to match DSCP priority 7, create the policy pmap_shiyan, associate cmap_dscp7 with the policy, bind the traffic behavior of changing the DSCP value of packets whose rates exceed 20 Mbps to 16, to the class, apply pmap_shiyan to interface G0/2, and configure the interface to trust DSCP.

4. Procedure

(1) Configure IP addresses for interfaces (omitted).

(2) Configure rate limits for the interfaces.

For Internet access traffic on the outbound interface, configure the egress traffic limit on interface G0/24.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/24
DeviceA(config-if-GigabitEthernet 0/24)# rate-limit output 102400 256
DeviceA(config-if-GigabitEthernet 0/24)# exit
```

For the dormitory building, configure the ingress traffic limit on interface G0/3.

```
DeviceA(config)# interface gigabitethernet 0/3
DeviceA(config-if-GigabitEthernet 0/3)# rate-limit input 51200 256
```

```
DeviceA(config-if-GigabitEthernet 0/3)# exit
```

For the teaching building, configure the ingress traffic limit on interface G0/1.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# rate-limit input 30720 256
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

(3) Configure traffic classification.

For the laboratory building, configure a class, traffic behavior, and policy.

```
DeviceA(config)# class-map cmap_dscp7
DeviceA(config-cmap)# match ip dscp 7
DeviceA(config-cmap)# exit
DeviceA(config)# policy-map pmap_shiyan
DeviceA(config-pmap)# class cmap_dscp7
DeviceA(config-pmap-c)# police 20480 128 exceed-action drop
DeviceA(config-pmap-c)# exit
DeviceA(config-pmap)# exit
```

Apply the policy to an interface and configure the interface to trust DSCP.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# service-policy input pmap_shiyan
DeviceA(config-if-GigabitEthernet 0/2)# mls qos trust dscp
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

5. Verification

Check whether the interface rate limits are successfully configured.

```
DeviceA# show mls qos rate-limit
Interface: GigabitEthernet 0/1
  rate limit input Kbps = 30720 burst = 256
Interface: GigabitEthernet 0/3
  rate limit input Kbps = 51200 burst = 256
Interface: GigabitEthernet 0/24
  rate limit output Kbps = 102400 burst = 256
```

Check whether the class is successfully created.

```
DeviceA# show class-map cmap_dscp7

 Class Map cmap_dscp7
   Match ip dscp 7
```

Check whether the policy is successfully created.

```
DeviceA# show policy-map pmap_shiyan

 Policy Map pmap_shiyan
    Class cmap_dscp7
      police 20480 128 exceed-action drop
```

Check whether the policy is applied to the interface successfully.

```
DeviceA# show mls qos interface gigabitethernet 0/2
```

```
Interface: GigabitEthernet 0/2
Ratelimit input:
Ratelimit output:
Attached input  policy-map: pmap_shiyan
Attached output policy-map:
Default trust: dscp
Default cos: 0
```

6. Configuration Files

Device A configuration file

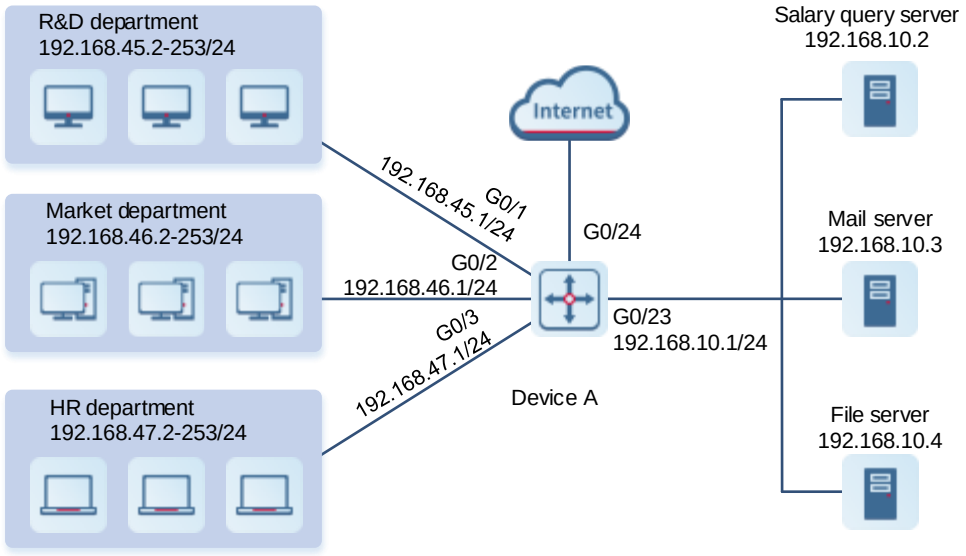
```
hostname DeviceA
!
class-map cmap_dscp7
 match ip dscp 7
!
policy-map pmap_shiyan
 class cmap_dscp7
  police 20480 128 exceed-action drop
!
interface GigabitEthernet 0/1
 ip address 192.168.194.1 255.255.255.0
 rate-limit input 30720 256
!
interface GigabitEthernet 0/2
 ip address 192.168.195.1 255.255.255.0
 service-policy input pmap_shiyan
 mls qos trust dscp
!
interface GigabitEthernet 0/3
 ip address 192.168.196.1 255.255.255.0
 rate-limit input 51200 256
!
interface GigabitEthernet 0/24
 rate-limit output 102400 256
!
end
```

1.10.2 Configuring Queue Scheduling and Congestion Avoidance

1. Requirements

Priority re-marking and queue scheduling need to be configured to meet the following requirements:

- When the R&D department and market department access the servers, the priorities of the server packets are as follows: packets destined for the mail server > packets destined for the file server > packets destined for the salary query server.
- No matter when the HR management department accesses the Internet or servers, device A processes the corresponding packets with the highest priority.



- Network congestion often occurs during operation of device A. WRR queue scheduling must be used to schedule IP packets from the R&D and market departments to access the mail database, file database, and salary query database based on the ratio of 6:2:1.

Note

The R&D department (192.168.45.2~253/24), market department (192.168.46.2~253/24), and HR department (192.168.47.2~253/24) are connected to interfaces G0/1, G0/2, and G0/3 of device A respectively; the salary query server (192.168.10.2/24), mail server (192.168.10.3/24), and file server (192.168.10.4/24) are connected to interface G0/23 of device A.

2. Topology

Figure 1-7 Topology of Configuring Queue Scheduling and Congestion Avoidance

3. Notes

(1) On device A, create ACLs to filter packets used for accessing servers, create classes, and associate the classes with these ACLs.

(2) Create policies to associate with the classes and specify the IEEE 802.1p values for the packets accessing various servers in the policies: Set the IEEE 802.1p value to 4 for the packets accessing the mail server, to 3 for the packets accessing the file server, and to 2 for the packets accessing the salary query server. Apply the policies to the inbound interfaces connected to the R&D and market departments and configure the interfaces to trust IEEE 802.1p.

(3) Assign the highest priority 7 to the IEEE 802.1p value of the interface connected to the HR department, to ensure that packets from the HR department are sent with the highest priority.

(4) Set the scheduling policy to WRR for output queues and set the round robin weight to 1:1:1:2:6:1:1:0 for the queues. This means that SP scheduling is used for packets of the HR department, and the packets for accessing the mail database, file database, and salary query database from the R&D and market departments are scheduled based on the ratio of 6:2:1.

(5) Enable the WRED function.

(6) Set the lower thresholds to 10 and 20 for queue 2 of interface G0/2.

(7) Set the maximum discarding probabilities to 60 and 80 for queue 2 of interface G0/2.

4. Procedure

(1) On device A, configure ACLs to filter packets used for accessing the servers and add ACL rules.

Configure the ACL for matching packets used for accessing the salary query server as well as ACL rules.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# ip access-list extended salary
DeviceA(config-ext-nacl)# permit ip any host 192.168.10.2
DeviceA(config-ext-nacl)# exit
```

Configure the ACL for matching packets used for accessing the mail server as well as ACL rules.

```
DeviceA(config)# ip access-list extended mail
DeviceA(config-ext-nacl)# permit ip any host 192.168.10.3
DeviceA(config-ext-nacl)# exit
```

Configure the ACL for matching packets used for accessing the file server as well as ACL rules.

```
DeviceA(config)# ip access-list extended file
DeviceA(config-ext-nacl)# permit ip any host 192.168.10.4
DeviceA(config-ext-nacl)# exit
```

(2) Configure classes on device A.

Associate a class named salary with the ACL rule for matching packets used for accessing the salary query server.

```
DeviceA(config)# class-map salary
DeviceA(config-cmap)# match access-group salary
DeviceA(config-cmap)# exit
```

Associate a class named mail with the ACL rule for matching packets used for accessing the mail server.

```
DeviceA(config)# class-map mail
DeviceA(config-cmap)# match access-group mail
DeviceA(config-cmap)# exit
```

Associate a class named file with the ACL rule for matching packets used for accessing the file server.

```
DeviceA(config)# class-map file
DeviceA(config-cmap)# match access-group file
DeviceA(config-cmap)# exit
```

(3) Configure policies on device A.

Configure the policy named toserver to access the server.

```
DeviceA(config)# policy-map toserver
DeviceA(config-pmap)#
```

Associate the class named salary with a traffic behavior.

```
DeviceA(config-pmap)# class salary
DeviceA(config-pmap-c)# set cos 2
```

```
DeviceA(config-pmap-c)# exit
```

Associate the class named mail with a traffic behavior.

```
DeviceA(config-pmap)# class mail
DeviceA(config-pmap-c)# set cos 4
DeviceA(config-pmap-c)# exit
```

Associate the class named file with a traffic behavior.

```
DeviceA(config-pmap)# class file
DeviceA(config-pmap-c)# set cos 3
DeviceA(config-pmap-c)# exit
DeviceA(config-cmap)# exit
```

(4) Apply policies on device A.

Apply a policy to the interface connected to the R&D department.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# service-policy input toserver
DeviceA(config-if-GigabitEthernet 0/1)# mls qos trust cos
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Apply a policy to the interface connected to the market department.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# service-policy input toserver
DeviceA(config-if-GigabitEthernet 0/2)# mls qos trust cos
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

(5) On device A, configure the 802.1p field for an interface.

Configure the highest priority for the 802.1p field for the interface connected to the HR department.

```
DeviceA(config)# interface gigabitethernet 0/3
DeviceA(config-if-GigabitEthernet 0/3)# mls qos cos 7
DeviceA(config-if-GigabitEthernet 0/3)# exit
```

(6) On device A, configure a scheduling policy for output queues.

Set the scheduling policy to WRR for output queues.

```
DeviceA(config)# wrr-queue bandwidth 1 1 1 2 6 1 1 0
DeviceA(config)# mls qos scheduler wrr
```

(7) Configure congestion avoidance on device A.

Enable the WRED function.

```
DeviceA(config)# queueing wred
```

Configure the higher and lower threshold values and maximum discarding probability.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# wrr-queue random-detect min-threshold 2
10 20
DeviceA(config-if-GigabitEthernet 0/2)# wrr-queue random-detect probability 2 60
80
```

Configure the CoS-to-threshold mappings.

```
DeviceA(config)# DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# wrr-queue cos-map 2 0 1 2 3
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

5. Verification

Check whether ACLs are successfully created.

```
DeviceA# show access-lists

ip access-list extended file
 10 permit ip any host 192.168.10.4

ip access-list extended mail
 10 permit ip any host 192.168.10.3

ip access-list extended salary
 10 permit ip any host 192.168.10.2
```

Check whether the classes are successfully associated with the ACLs.

```
DeviceA# show class-map

 Class Map salary
   Match access-group salary
 Class Map mail
   Match access-group mail
 Class Map file
   Match access-group file
```

Check whether policies are successfully created, and whether the classes and traffic behaviors are successfully bound.

```
DeviceA# show policy-map

 Policy Map toserver
    Class mail
      set cos 4
    Class file
      set cos 3
    Class salary
      set cos 2
```

Check whether a policy is successfully applied to interface GigabitEthernet 0/1.

```
DeviceA# show mls qos interface gigabitethernet 0/1
Interface: GigabitEthernet 0/1
Ratelimit input:
Ratelimit output:
Attached input  policy-map: toserver
Attached output policy-map:
Default trust: cos
```

```
Default cos: 0
```

Check whether a policy is successfully applied to interface GigabitEthernet 0/2.

```
DeviceA# show mls qos interface gigabitethernet 0/2
Interface: GigabitEthernet 0/2
Ratelimit input:
Ratelimit output:
Attached input  policy-map: toserver
Attached output policy-map:
Default trust: cos
Default cos: 0
```

Check whether a policy is successfully applied to interface GigabitEthernet 0/3.

```
DeviceA# show mls qos interface gigabitethernet 0/3
Interface: GigabitEthernet 0/3
Ratelimit input:
Ratelimit output:
Attached input  policy-map:
Attached output policy-map:
Default trust: none
Default cos: 7
```

Check whether the 802.1p value is successfully configured for the interface and whether the scheduling policy and the round robin weight are successfully configured.

```
DeviceA# show mls qos queueing
Cos-queue map:
cos qid

1 Configuring MMU

1.1 Introduction

1.1.1 Overview

The memory management unit (MMU) is a technology for allocating the chip buffers reasonably. This technology makes devices better deal with all kinds of burst flows.

Flows are not always steady and various burst flows exist in the network. When the network flow is steady and the bandwidth is sufficient, all the data flows are processed properly. When burst flows exist in the network, data flows may be discarded even if the average flow rate does not exceed the bandwidth. Data packets are stored in the buffers of a device before being forwarded. Normally, data packets in the buffers will be forwarded in microseconds. When a burst flow arises, if the instantaneous rate of the burst flow is out of the processing capacity of the device, the data packets that cannot be processed in time are piled up in the buffers and packet loss takes place once the buffers are insufficient. In this case, the MMU technology can used to reasonably configure buffers and allocate different buffer sizes to services, with a view to optimizing the network.

1.1.2 Principles

1. Basic Concepts

- Cell

  Cell is a buffer unit, namely, the minimum unit for the device to store packets. The size of each cell varies with the device. One packet can use multiple cells, while one cell can be used by only one packet.

- Port group

  All the ports that physically belong to the same switching chip and the same core (some chips are multi-core chips) are called a port group. All devices implement buffer management in port groups.

- Buffer slice

  The buffer of a port group may be divided into multiple buffer blocks, and each buffer block is called a buffer slice. Slice is the minimum unit for independent buffer management. Each buffer slice is managed independently, and a port queue may use one or more buffer slices.

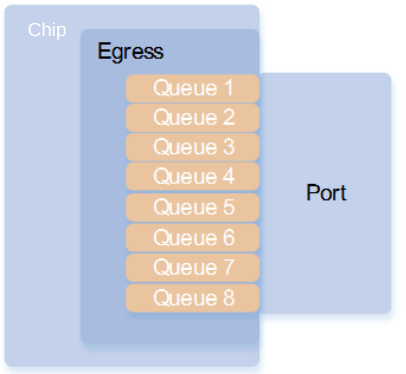
- Guaranteed buffer

  A guaranteed buffer is also called an exclusive buffer. This part of buffer is distributed based on each port queue. The guaranteed buffer of a queue can be used by this queue only. A fixed number of guaranteed buffers are allocated to each queue by default. This part of buffer enables a queue to normally forward packets at the line rate under the stable flow.

- Shared buffer

  In the total buffer of a port group, the remaining part obtained after the guaranteed buffer of each port queue is deducted is the total shared buffer. The shared buffer is available to all the queues. A shared buffer threshold can be set for each queue. This threshold restricts the maximum number of shared buffers that can be used by a queue. When the sum of shared buffers configured for queues in a port group

exceeds the total shared buffers of the port group, the "first-come first-served" buffer occupancy mechanism is adopted.



- Service pool

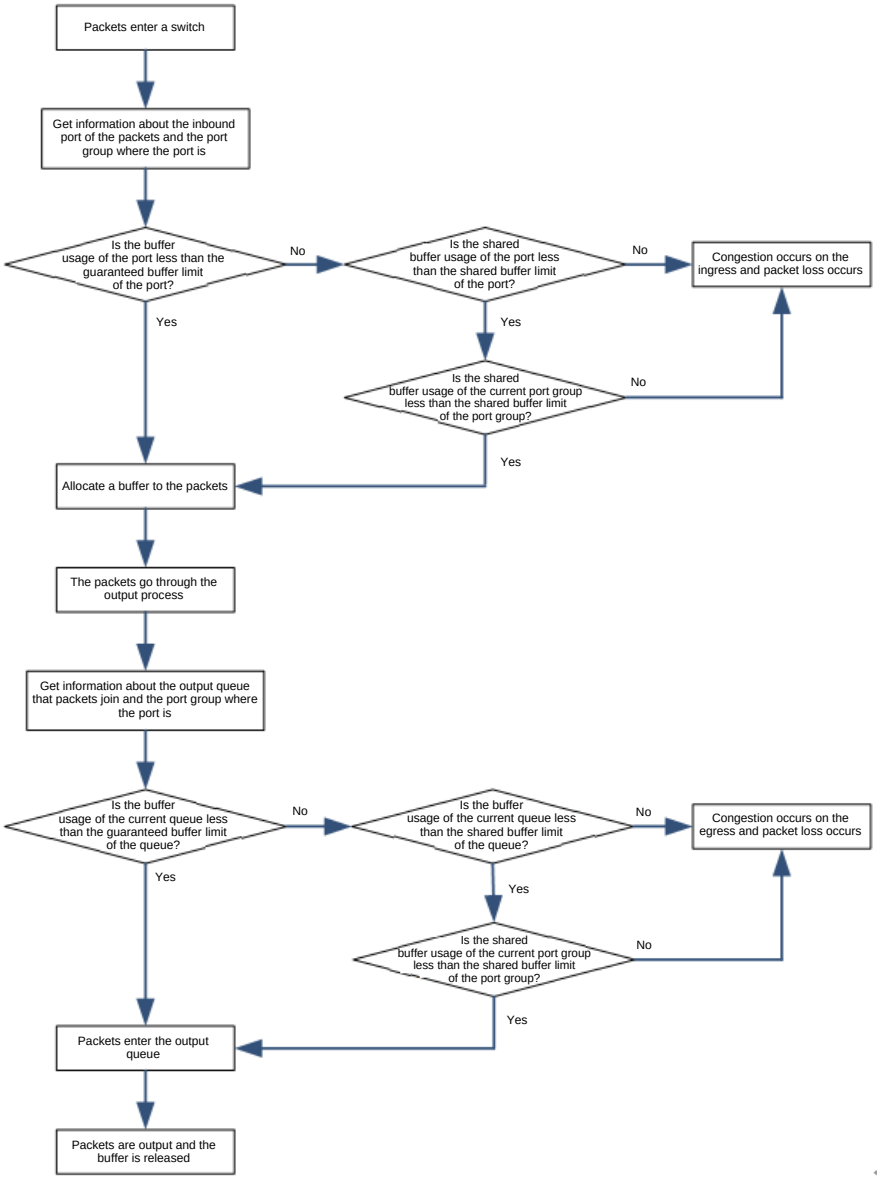
  In addition to the guaranteed buffer, each port queue can use shared buffers. The shared buffers are uniformly stored in the service pool for management. One buffer slice may have multiple service pools. After using its own guaranteed buffer, each queue can request a shared buffer from the service pool within the shared buffer threshold, and the mechanism of "first-request, first-served" is adopted for the service pool. One queue can use the shared buffer of only one service pool according to the mapping configuration.

- Egress queues

  Egress queues of a port are classified into unicast queues and multicast queues. Logically, a switching chip is divided into the ingress direction and egress direction. The egress queues are in the egress direction of a switching chip. Before packets are sent out of a device, they need to be queued at the egress queues, as shown in Figure 1-1.

Figure 1-1 Egress Queues Model

Currently, there are three types of egress queue models:



- There are eight unicast queues and eight multicast queues at the egress. The known unicast packets enter the unicast queues, and all the other packets enter the multicast queues.
- There are eight unicast queues and four multicast queues at the egress. The known unicast packets enter the unicast queues, and all the other packets enter the multicast queues.
- There are only eight queues at the egress, with unicast and multicast queues not differentiated. The queues are managed as unicast queues in the device.

2. Buffer Adjustment

Users can adjust the buffer allocation of a chip so that the queue of each service has a different buffer size available, services are treated differently, and services of different priorities are provided.

In terms of hardware, the buffer is managed in the input direction and output direction. Figure 1-2 shows the processing mechanism.

Figure 1-2 Buffer Processing Mechanism

During buffer management, the buffer size is adjusted to the maximum value in the input direction to prevent packet loss in the input direction, and packet loss takes place in the output direction. Therefore, buffer adjustment is not allowed in the input direction, and a CLI command is available for buffer adjustment in the output direction only, including the guaranteed buffer and shared buffer of queues. Buffer adjustment allocates different buffer sizes to queues based on the guaranteed buffer threshold and shared buffer threshold configured for the queues.

3. Status Monitoring

Status monitoring monitors the buffer usage and the queue packet forwarding and discarding by using statistical methods, with a view to providing data support for network optimization and reasonable buffer configuration.

Status monitoring adopts the polling mode to periodically read, from a chip, the buffer usage information and information about packets forwarded/discarded by queues, and analyzes the information so as to display the device operating status.

- Monitoring buffer occupancy in the egress direction

  The information about the guaranteed buffer, shared buffer, and service pool buffer occupancy of queues in the egress direction is regularly collected. The data can be displayed via a CLI command, in MIB mode, or other methods.

- Monitoring packet forwarding and discarding of the egress queues

  The information about the quantities and bytes of packets forwarded and discarded by queues in the egress direction is regularly collected, and the forwarding rate is also calculated. The data can be displayed via a CLI command, in MIB mode, or other methods.

- Sampling interval for status monitoring data

  Status monitoring data is sampled at a fixed interval, which can be configured based on user requirements.

4. Exception Detection

The exception detection function monitors the packet forwarding and discarding of each queue, and displays alarms when the buffer occupancy exceeds the threshold or queue packets are lost.

Exception detection adopts the polling mode to periodically read device buffer occupancy information and the number of packets forwarded by queues, and displays alarms through system logs based on the current configuration. When the buffer utilization of a queue exceeds the alarm threshold, a system log alarm is printed to alert users.

1.2 Configuration Task Summary

MMU configuration includes the following tasks:

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Buffer Adjustment
  - Configuring the Global Buffer Mode
  - Configuring a Guaranteed Buffer for a Queue
  - Configuring a Shared Buffer for a Queue
  - Configuring a Flow Control Threshold for a Port
- Configuring Status Monitoring
- Configuring Exception Detection
  - Configuring an Alarm Threshold for the Buffer Utilization of a Port Group or Slice
  - Configuring an Alarm Threshold for the Buffer Utilization of a Queue

1.3 Configuring Buffer Adjustment

1.3.1 Overview

The buffer adjustment function aims to adjust the objects (such as queues) managed based on chip buffers.

1.3.2 Restrictions and Guidelines

- Configuration on an interface can be made on a physical port only.
- You are advised to configure buffer adjustment when there is no traffic on the device; otherwise the

configuration may cause temporary interruption of service traffic.

1.3.3 Configuration Tasks

Buffer adjustment configuration includes the following tasks:

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Global Buffer Mode
- Configuring a Guaranteed Buffer for a Queue
- Configuring a Shared Buffer for a Queue
- Configuring a Flow Control Threshold for a Port

1.3.4 Configuring the Global Buffer Mode

1. Overview

This section describes how to configure the global buffer mode. After configuration, the device configures the default thresholds according to the mode.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the global buffer mode.

mmu buffer-mode { **burst-enhance** | **flowctrl-enhance** | **normal** | **qos-enhance** }

The default global buffer mode is **flowctrl-enhance**.

1.3.5 Configuring a Guaranteed Buffer for a Queue

1. Overview

This section describes how to configure a guaranteed buffer for a queue so that the queue uses this part of buffer exclusively.

2. Restrictions and Guidelines

- The *queue-id* &<1-8> parameter means that up to *n* queue numbers can be configured.
- The configuration is displayed when the **show running-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Configure a guaranteed buffer for queues.

mmu queue-guarantee output { **multicast** | **unicast** } [*queue-id*&<1-8>] **set** *value*

No guaranteed buffer is configured for a queue by default.

1.3.6 Configuring a Shared Buffer for a Queue

1. Overview

This section describes how to configure a shared buffer for a queue so as to control the size of the shared buffer that can be used by the queue.

2. Restrictions and Guidelines

- The *queue-id*&<1-8> parameter means that up to *n* queue numbers can be configured.
- The configuration is displayed when the **show running-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Configure a shared buffer for queues.

mmu queue-threshold output { **multicast** | **unicast** } [*queue-id*&<1-8>] **set** *threshold*

No shared buffer is configured for a queue by default.

1.3.7 Configuring a Flow Control Threshold for a Port

1. Overview

This section describes how to configure a flow control threshold for a port and adjust the flow control threshold of the ingress.

2. Restrictions and Guidelines

- The configuration takes effect only when flow control or priority-based flow control (PFC) is enabled on a port.

- The configuration is displayed when the **show running-config** command is executed even if the default value is used.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Configure a flow control threshold for the port.

mmu fc-threshold set *threshold*

No flow control threshold is configured for a port by default.

1.4 Configuring Status Monitoring

1.4.1 Overview

This section describes how to collect statistics on and monitor the buffer usage and queue packet forwarding and discarding so as to provide guidance for buffer adjustment configuration.

1.4.2 Restrictions and Guidelines

- The configuration is displayed when the **show running-config** command is executed even if the default value is used.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a sampling period.

mmu sample-period set *period*

No monitoring data sampling period is configured by default.

1.5 Configuring Exception Detection

1.5.1 Overview

The exception detection function is used to analyze the data about device buffer and forwarding status, and generate an alarm when an exception occurs.

1.5.2 Configuration Tasks

Exception detection configuration includes the following tasks:

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring an Alarm Threshold for the Buffer Utilization of a Port Group or Slice
- Configuring an Alarm Threshold for the Buffer Utilization of a Queue

1.5.3 Configuring an Alarm Threshold for the Buffer Utilization of a Port Group or Slice

1. Overview

When the buffer utilization of a port group or slice exceeds the configured value, a system log alarm is printed.

2. Restrictions and Guidelines

- To prevent frequent log refreshing, the alarm logs of the same port group or slice are printed once in 30s at most. The maximum printing interval depends on the configured sampling period.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a buffer utilization alarm threshold.

mmu usage-warn-limit set *threshold*

The default buffer utilization alarm threshold is **0**, indicating that no alarm is reported.

1.5.4 Configuring an Alarm Threshold for the Buffer Utilization of a Queue

1. Overview

When the buffer utilization of a queue exceeds the configured value, a system log alarm is printed.

2. Restrictions and Guidelines

- The *queue-id* &<1-8> parameter means that up to *n* queue numbers can be configured.
- To prevent frequent log refreshing, the alarm logs of the same queue are printed once in 30s at most. The maximum printing interval depends on the configured sampling period.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Configure a buffer utilization alarm threshold for a queue.

mmu usage-warn-limit { **multicast** | **unicast** } [*queue-id*&<1-8>] **set** *threshold*

The default buffer utilization alarm threshold is **0**, indicating that no alarm is reported.

1.6 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-1 MMU Monitoring

Command	Purpose
show [**mmu**] **queue-counter interface** [*interface-type interface-number*]	Displays the packet statistics of a queue.
show [**mmu**] **queue-buffer interface** [*interface-type interface-number*]	Displays the buffer utilization information of a queue.
show mmu buffer-mode	Displays the current buffer mode.
clear [**mmu**] **queue-counter interface** [*interface-type interface-number*]	Clears the packet statistics of a queue.
clear [**mmu**] **queue-buffer peaked** [**interface** *interface-type interface-number*]	Clears the historical buffer utilization peak values of a queue.

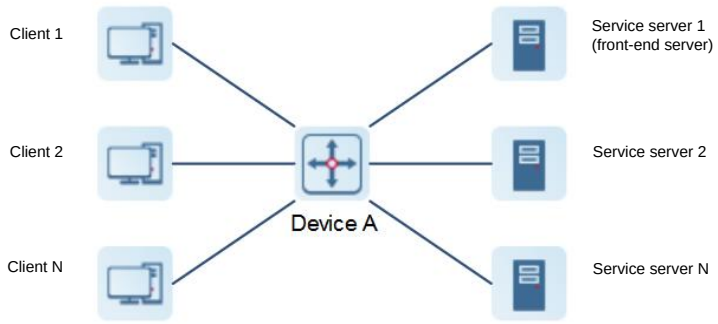
1.7 Configuration Examples

1.7.1 Configuring the Application of a Large Buffer Based on Egress Queues

1. Requirements

An enterprise needs a buffer large enough for the net disk service to avoid packet loss occurring in the service flow.

As shown in the following figure, device A is connected to 5 clients and 35 service servers, and 15 service servers are virtualized as 15 front-end servers.



The main service flow is as follows:

- A client sends a request packet to a front-end server.
- The front-end server sends the received request packet to a service server.
- After receiving the request packet, the service server sends a response packet to the front-end server.
- After receiving the response packet, the front-end server sends it to the client.
- The client receives the response packet, indicating that a session is created successfully.
- A many-to-one flow transmission mode exists in this service model:
- The request flows of multiple clients are sent to one front-end server.
- The request flows of multiple front-end servers are sent to one service server.
- The response flows of multiple service servers are sent to one front-end server.
- The response flows of multiple front-end servers are sent to one client.

These flows are basically transmitted through device A, which can easily lead to network congestion. Such a problem can be fixed by configuring a large buffer on the device.

2. Topology

Figure 1-3 Topology of Configuring a Large Buffer Based on Egress Queues

3. Notes

- On all the service ports (namely, the ports connecting to clients and servers), set the shared buffer to 100% for the queues where the service is.
- On all the service ports, set the guaranteed buffer to the minimum size for queues not in use.
- On all the ports not in use, set the guaranteed buffer to the minimum size for all the queues.

4. Procedure

(1) Configure a shared buffer.

On device A, set a shared buffer for queues on all the service ports.

```
DeviceA> enabel
DeviceA# configure terminal
DeviceA(config)# interface range gigabitethernet 0/1-40
```

```
DeviceA(config-if-range)# mmu queue-threshold output unicast 1 set 100
DeviceA(config-if-range)# mmu queue-threshold output multicast 1 set 100
DeviceA(config-if-range)# exit
```

(2) Configure a guaranteed buffer.

On device A, set a guaranteed buffer for queues on all the service ports.

```
DeviceA# configure terminal
DeviceA(config)# interface range gigabitethernet 0/1-40
DeviceA(config-if-range)# mmu queue-guarantee output unicast 2 3 4 5 6 7 8 set 1
DeviceA(config-if-range)# mmu queue-guarantee output multicast 2 3 4 5 6 7 8 set
1
DeviceA(config-if-range)# exit
```

On device A, set a guaranteed buffer for queues on all the ports not in use.

```
DeviceA(config)# interface range gigabitethernet 0/41-48
DeviceA(config-if-range)# mmu queue-guarantee output unicast set 1
DeviceA(config-if-range)# mmu queue-guarantee output multicast set 1
DeviceA(config-if-range)# exit
```

5. Verification

On device A, verify that the command configuration for interface GigabitEthernet 0/1 is correct.

```
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# show this

Building configuration...
!
 mmu queue-threshold output unicast 1 set 100
 mmu queue-threshold output multicast 1 set 100
 mmu queue-guarantee output unicast 2 set 1
 mmu queue-guarantee output unicast 3 set 1
 mmu queue-guarantee output unicast 4 set 1
 mmu queue-guarantee output unicast 5 set 1
 mmu queue-guarantee output unicast 6 set 1
 mmu queue-guarantee output unicast 7 set 1
 mmu queue-guarantee output unicast 8 set 1
 mmu queue-guarantee output multicast 2 set 1
 mmu queue-guarantee output multicast 3 set 1
 mmu queue-guarantee output multicast 4 set 1
 mmu queue-guarantee output multicast 5 set 1
 mmu queue-guarantee output multicast 6 set 1
 mmu queue-guarantee output multicast 7 set 1
 mmu queue-guarantee output multicast 8 set 1
```

6. Configuration Files

Device A configuration file

The configuration of interface GigabitEthernet 0/1 to interface GigabitEthernet 0/40 is exactly the same, and therefore only the configuration of GigabitEthernet 0/1 is provided below. The configuration of interface GigabitEthernet 0/41 to interface GigabitEthernet 0/48 is exactly the same, and therefore only the configuration of GigabitEthernet 0/41 is provided below.

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 mmu queue-threshold output unicast 1 set 100
mmu queue-guarantee output unicast 2 set 1
 mmu queue-guarantee output unicast 3 set 1
 mmu queue-guarantee output unicast 4 set 1
 mmu queue-guarantee output unicast 5 set 1
 mmu queue-guarantee output unicast 6 set 1
 mmu queue-guarantee output unicast 7 set 1
 mmu queue-guarantee output unicast 8 set 1
 mmu queue-threshold output multicast 1 set 100
 mmu queue-guarantee output multicast 2 set 1
 mmu queue-guarantee output multicast 3 set 1
 mmu queue-guarantee output multicast 4 set 1
 mmu queue-guarantee output multicast 5 set 1
 mmu queue-guarantee output multicast 6 set 1
 mmu queue-guarantee output multicast 7 set 1
 mmu queue-guarantee output multicast 8 set 1
!

1 Configuring AAA

1.1 Introduction

1.1.1 Overview

Authentication, authorization and accounting (AAA) is a network security management mechanism, which provides basic authentication, authorization, and accounting (billing) services for users who access networks. The content of AAA is described as follows:

- Authentication service: Identifies users before they access networks to check whether the users have access permissions.
- Authorization service: Classifies user permissions to grants different access permissions to users.
- Accounting service: Records users' usage of network resources. The statistical data can be used for analysis and billing.

AAA boasts strong flexibility and controllability, scalability, standardized authentication, and supports multiple backup systems. Compared with simple access control functions provided by devices such as local username authentication and line password-based authentication, AAA provides a higher level of security protection and therefore becomes the overriding access control method.

1.1.2 Principles

1. Basic Concepts

- Security method

  A security method refers to the method used to implement authentication, authorization, and accounting services. Security methods can be classified into AAA authentication methods, AAA authorization methods, and AAA accounting methods by service type.

  Based on the service provider, service methods can be further classified into service methods providing no security management, service methods providing security management through a local device, and service methods providing security management through a remote server. For details, see sections 1.1.2 3. AAA Authentication, 1.1.2 4. AAA Authorization, and 1.1.2 5. AAA Accounting.

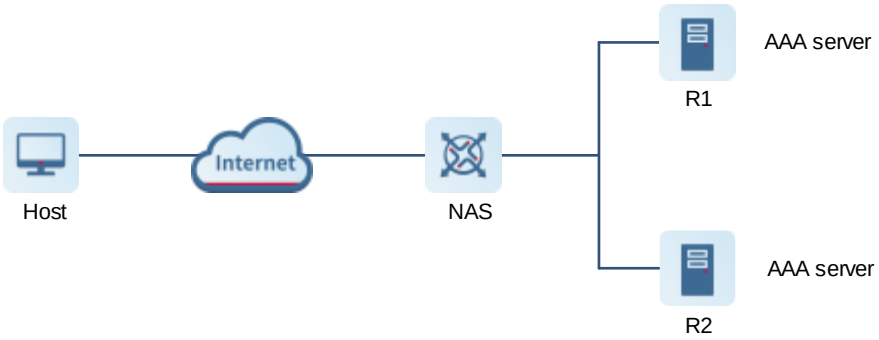
- Method list

  Method lists are classified into authentication method lists, authorization method lists, and accounting method lists based on the AAA service type. Each method list provides multiple security methods for this type of AAA service, to ensure that alternative methods are available if one method is unavailable.

  A method list contains one or more security methods. The sequence for the methods to take effect is subject to the sequence of security methods defined in the list, that is, a method defined earlier takes effect earlier. If a method fails to respond during AAA service provision, a device switches to the next method until all methods in the method list are tried. If a method returns a failure or all methods fail to respond, the process stops and the device cannot provide the security service for users.

Caution

A device tries the next method only when no response is received from the previous method. For example, if a method denies user access during identity authentication, the identity authentication process ends and the device does not switch to other identity authentication methods.



- AAA server group

  An AAA server is a device that provides remote AAA security services for users.

  An AAA server group is a collection of one or more AAA servers of the same type and provides security services for users as a security method.

2. AAA Basic Architecture

Figure 1-1 Topology of a Typical AAA Network

As shown in Figure 1-1, a typical AAA network consists of hosts (users), a network access server (NAS), and an AAA server (remote server). AAA uses the client/server (C/S) structure. A host sends an AAA request to the NAS as a client. After receiving the request, the NAS requests the AAA security services from the AAA server as a client and provides network access permissions for the host based on the returned result.

- Main roles

  Host: A host is a device that requests network access permissions and usually refers to a user.

  NAS: A NAS responds to hosts' network access requests and manages the hosts by using security methods provided by an AAA server.

  AAA server: An AAA server provides security methods for the NAS.

- Brief process of typical AAA services

  a Configure a method list and enable the AAA security services on the NAS. The method list provides three security methods: R1 server, R2 server, and local username database (with the effective sequence from left to right). Host-related identity information has been configured in the three methods.

  b After a host connects to the NAS through a network, the NAS provides the AAA security services for the host by using a method in the method list. According to the sequence that the methods take effect, the NAS requests the security services from R1 first.

  c If R1 responds to the NAS successfully, the NAS provides network access permissions for the host based on security information provided by R1. If R1 does not respond, the NAS switches the security

method and requests the security services from R2, and so on until all methods in the method list are used up.

Note

An AAA server can use a Remote Authentication Dial-In User Service (RADIUS) or Terminal Access Controller Access-Control System Plus (TACACS+) server. Unless otherwise specified in this document, the RADIUS server is used as the AAA server. For details about TACACS+, see *Configuring TACACS*.

3. AAA Authentication

AAA authentication checks information (username and password) about a user who requests the access service, to determine whether the user has the network access permission.

- AAA authentication methods

  AAA authentication methods are classified into authentication exemption, local authentication, and remote server group authentication based on the method provider.

  - Authentication exemption

    User legitimacy is not checked. This method is used only when users are very trustworthy. You are not advised to use this method.

  - Local authentication

    Local authentication uses the database on the NAS to manage user information (such as usernames, passwords, and attributes) and identify user identities.

  - Remote server group authentication

    This authentication method uses the user database on the remote server to manage user data and identify user identities. It can achieve multi-device centralized authentication with large capacity and high reliability. A remote server group supports RADIUS servers and TACACS+ servers.

- AAA authentication types

  AAA authentication is classified into login authentication, enable authentication, IEEE 802.1X authentication, 2nd-generation Web authentication, and File Transfer Protocol (FTP) authentication based on the user access mode.

  - Login authentication

    This authentication verifies user identities when the users log in to the command line interface (CLI) of the NAS through Secure Shell (SSH), telnet, or FTP.

  - Enable authentication

    After users log in to the NAS CLI, this authentication verifies the users' identity information before their CLI execution permissions are elevated, that is, users are authenticated before they enter the privileged EXEC mode.

  - IEEE 802.1X authentication

    This authentication is used to verify identities of IEEE 802.1X access users.

  - 2nd-generation Web authentication

    This authentication uses a 2nd-generation portal server to verify the identities of users who access networks.

- FTP authentication

  FTP authentication is especially used for FTP users. If no FTP authentication method is configured, login authentication is used to authenticate FTP users.

- General authentication method

  You can specify a general authentication method for IEEE 802.1X authentication and 2nd-generation Web authentication. If no authentication method is configured for 2nd-generation Web authentication and IEEE 802.1X authentication or the configured methods fail to respond, the configured general authentication method takes effect as an alternative method.

4. AAA Authorization

AAA authorization is used to manage services available to users and control network access permissions of access users. After the AAA authorization service is enabled, users can use only permitted services and are granted permissions in their permitted scopes.

- AAA authorization methods

  AAA authorization methods are classified into direct authorization, local authentication, and remote server group authentication based on the method provider.

  - Direct authorization

    Direct authorization provides default permissions that the access device allows users to use. It is used only when users are very trustworthy.

  - Local authorization

    Configure attribute authorization for local users on the NAS, which completes the authorization.

  - Remote server group authorization

    Configure user attribute authorization on the remote server. The NAS completes authorization by means of a remote server group. When all servers in a remote server group fail, you can configure local authorization or direct authorization as an alternative method.

- AAA authorization types

  AAA authorization is classified into EXEC authorization, command authorization, config-commands authorization, console authorization, and network authorization based on the permission type.

  - EXEC authorization

    EXEC authorization grants different privilege levels (0–15) to users when the users log in to the NAS CLI.

    EXEC authorization is usually used in conjunction with login authentication. After login authentication and EXEC authorization are configured on the same line, if a user passes login authentication but fails in EXEC authorization, the user cannot open the CLI.

  - Command authorization

    Command authorization grants authorization to commands after users log in to the NAS CLI.

    When a user enters a command and attempts to run it, AAA sends the command to the security server. If the security server allows this command, the command is executed. Otherwise, the command is not executed and a command execution denial message is displayed.

  - Config-commands authorization

This authorization grants authorization to commands in configuration modes (including the global configuration mode and sub-modes).

- Console authorization

  This authorization grants authorization to commands to be executed by users who log in through the console.

  The system can differentiate users who log in through the console from those who log in through other terminals. You can enable or disable command authorization for users who log in through the console. If command authorization is disabled for users who log in through the console, the command authorization method list that has been applied to the console line no longer takes effect.

- Network authorization

  Network authorization grants available network services to users, such as traffic, bandwidth, and timeout services.

  Network authorization is based on authentication. Network authorization is available only for authenticated users. The RADIUS or TACACS+ server grants permissions to authenticated users by returning a series of attributes.

5. AAA Accounting

AAA accounting is used to record users' usage of network resources to implement billing, auditing, and tracking functions.

The accounting service starts accounting after a user passes authentication and records the user's network access activities. It stops accounting when the user logs out, and generates a network resource access report for the user.

- AAA accounting methods

  AAA accounting methods are classified into no accounting, local accounting, and remote server group accounting based on the method provider.

  - No accounting

    Accounting is not performed on users.

  - Local accounting

    Local accounting is completed by the NAS, which collects statistics on and limits the number of local user connections. The fee calculation function is unavailable.

  - Remote server group accounting

    Accounting is performed by a remote server. You can configure local accounting as an alternative method to avoid an accounting failure occurring when all servers in a remote server group fail.

- AAA accounting types

  AAA accounting can be classified into EXEC accounting, command accounting, and network accounting based on the accounting content.

  - EXEC accounting

    Accounting is both performed when users log in to and log out of the NAS CLI.

  - Command accounting

Command accounting is used to record commands run by a user after the user logs in to the NAS CLI from a terminal.

- Network accounting

  Network accounting is used to record information about sessions of users who access the network (such as IEEE 802.1X users and 2nd-generation Web-authenticated users).

6. Multi-Domain AAA

In multi-domain AAA, users are assigned to different domains and independent security methods are defined for each domain so that users in different domains use different security methods.

In a multi-domain environment, you can configure a separate AAA method list for each domain on the NAS. Therefore, users with the same attribute can be assigned to the same domain for the ease of management.

- Basic principles of AAA service based on domain names
  a A user submits identity authentication information to the NAS.
  b The NAS resolves the domain name in the identity authentication information.
  c The NAS checks whether the domain name is defined. If no, the NAS refuses to provide security services. If yes, the NAS makes further judgment.
  d If no method list is defined for the domain name, the NAS refuses to provide security services. If a method list is defined, the NAS provides security services.
- Username forms

  A username can be expressed in four forms. In the usernames below, "domain-name" indicates a domain name.
  - userid@domain-name
  - domain-name\userid
  - userid.domain-name
  - userid

  In the preceding username forms, the username form (userid) with no domain name uses the default domain name (**default**).
- Domain name matching

  If the username of an authenticated user carries domain information but the domain is not configured on the NAS, the NAS cannot provide AAA services for the user.

  Exact match is adopted to match domain names carried in usernames with those configured on the NAS. For example, if domain.com and domain.com.cn are configured on the NAS and a username is expressed in the form of aaa@domain.com, the NAS determines that the user belongs to domain.com rather than domain.com.cn.

1.2 Restrictions and Guidelines

- Before configuring any AAA function, run the **aaa new-model** command to enable the AAA security services. Otherwise, no command can be configured.
- AAA authentication, authorization, and accounting are three independent processes. You can use only the authentication service without authorization or accounting.

- The basic methodology and process of configuring the AAA authentication, authorization, or accounting services are as follows:

  a Enable AAA security services.

  b Determine the required AAA security service type based on the scenario.

  c Configure an AAA method list for the security service type.

  d In a corresponding mode, apply an AAA method list to make it take effect (methods do not need to be applied for some security services. For details, see specific configuration tasks).

  If this step is not configured, methods configured in step C do not take effect but the default method is used.

- Configure user information before configuring security methods.
  - To use the remote server group method, configure user data on remote servers. For details about how to configure user data, see the operation instructions of the remote servers.
  - To use the local method, configure local user data on the local device. For details about local users, see *Configuring Basic Management*.
- Common errors:
  - When the AAA security service is provided using the local method, user information is not configured in the local database.
  - When the AAA security service is provided using the remote server group method, the RADIUS or TACACS+ server is not configured, or user information is not configured in the server.

1.3 Configuration Task Summary

AAA configuration includes the following tasks:

(1) (Optional) Configuring an AAA Server Group

(2) Configuring AAA Authentication
  - Configuring Basic Features of AAA Authentication
  - (Optional) Configuring a General Authentication Method
  - (Optional) Configuring AAA Authentication Logging

(3) (Optional) Configuring AAA Authorization
  - Configuring Basic Features of AAA Authorization
  - (Optional) Configuring the Function of Caching Command Authorization Results
  - (Optional) Configuring the Default Role for AAA Users

(4) (Optional) Configuring AAA Accounting
  - Configuring Basic Features of AAA Accounting
  - (Optional) Configuring a Policy for User Accounting Start Failures

(5) (Optional) Configuring Domain-Based AAA Services

1.4 Configuring an AAA Server Group

1.4.1 Overview

AAA usually uses the remote server group method to provide AAA services for users. This method provides more flexible and rich security services than the local method.

1.4.2 Restrictions and Guidelines

- One or more servers can be added to each server group.
- Both RADIUS and TACACS+ support server group configuration. The configuration procedure below uses RADIUS as an example. For details about a TACACS+ server group, see *Configuring TACACS*.
- When configuring the authentication, authorization, and accounting method lists, you can specify different server groups for them.
- In a custom server group, only servers in the default server group can be specified and applied.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an AAA custom server group and enter the server group configuration mode.

aaa group server radius *group-name*

No server group is configured by default.

The name of a server group cannot be set to a predefined keyword "radius" or "tacacs+".

(4) Add an AAA server group member.

server { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port* | **acct-port** *acct-port*] *

No AAA server group member is added to a server group by default.

(5) (Optional) Specify a VRF instance for the AAA server group.

ip vrf forwarding *vrf-name*

No VRF instance is specified for an AAA server group by default.

When a server group in a specified VRF instance is used, the source IP address used by the device to communicate with a remote server needs to be acquired from the VRF instance. If you run the **ip radius source-interface** command to specify the source interface of request packets, the IP address obtained from this source interface is prior to that acquired from the VRF instance.

(6) (Optional) Configure the MGMT interface for the AAA server group.

ip oob [**via mgmt** *mgmt-number*]

An AAA server group uses MGMT 0 by default.

1.5 Configuring Basic Features of AAA Authentication

1.5.1 Overview

AAA authentication is used to verify user identities. After AAA authentication is configured, users can access network resources only after passing the authentication specified in security methods in the method list.

1.5.2 Restrictions and Guidelines

- After AAA authentication is configured, if no authentication method is configured and the default authentication method does not exist, users can log in through the console without authentication but other types of access users need to pass local authentication.
- If multiple methods are defined in the method list, when a method fails to respond, the device switches to the next method. The execution sequence of methods is the sequence of methods configured in the method list. If a method responds and returns a failure, the device does not switch to the next method.
- If you have passed login authentication (except the authentication exemption method) when logging in to the CLI, the device records the username, and then uses the username for authentication when Enable authentication is performed. You do not need to enter the username again but the entered password must match the username. If login authentication fails or the authentication exemption method is used when you log in to the CLI, the username will not be recorded, and you need to enter the username for authentication in the further Enable authentication.
- The authentication exemption method allows any user to access network resources without authentication. You are not advised to use this method. Only in some special cases (all access users are trustworthy and no network failure caused by authentication system problems is allowed), this method can be used as an alternative method when the device receives no response in the remote server group authentication and local authentication.

1.5.3 Configuration Tasks

Configure basic features of AAA authentication. Select at least one of the following tasks to configure.

- Configuring Login Authentication
- Configuring Enable Authentication
- Configuring IEEE 802.1X Authentication
- Configuring 2nd-Generation Web Authentication

1.5.4 Configuring Login Authentication

1. Overview

After login authentication is configured, access users who log in through SSH, telnet, or FTP need to be authenticated before accessing network resources.

2. Restrictions and Guidelines

A configured login authentication method must be applied to a line that needs login authentication. Otherwise, the method does not take effect.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable AAA security services.

aaa new-model

The AAA security services are disabled by default.

(4) Configure a login authentication method list.

aaa authentication login { **default** | *list-name* } *method*&<1-4>

No login authentication method list is configured by default.

(5) (Optional) Configure the maximum number of consecutive failed login attempts.

aaa local authentication attempts *max-attempts*

The default maximum number of consecutive failed login attempts is **3**.

(6) (Optional) Configure the user lockout duration.

aaa local authentication lockout-time *lockout-time*

After the number of login attempts of a user exceeds the configured number of consecutive failed login attempts, the user is locked out for 15 minutes by default.

(7) Enter the configuration mode of a specified line.

line { **console** | **vty** } *first-line* [*last-line*]

(8) Apply the login authentication method list to the line.

login authentication { **default** | *list-name* }

The default login authentication method list applied to a line is the default method list.

1.5.5 Configuring Enable Authentication

1. Overview

After Enable authentication is configured and a user logs in to the NAS CLI through a terminal, the user must be authenticated before running the **enable** command to enter the privileged EXEC mode.

2. Restrictions and Guidelines

After an Enable authentication method list is configured, the Enable authentication function takes effect automatically.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable AAA security services.

aaa new-model

The AAA security services are disabled by default.

(4) Configure an Enable authentication method list.

aaa authentication enable default *method*&<1-4>

No Enable authentication method list is configured by default.

(5) (Optional) Configure **$enab[*level*]$** as the username when you configure Enable authentication through the RADIUS server. The value range of *level* is from 0 to 15.

aaa authentication enable private-user

After this command is executed, the device uses **$enab[*level*]$** to send an authentication request to the RADIUS server when you enter the privileged EXEC mode by using the **enable** *level* command. When the entered password matches the password of **$enab[*level*]$** on the RADIUS server, the authentication succeeds.

1.5.6 Configuring IEEE 802.1X Authentication

1. Overview

After IEEE 802.1X authentication is configured on an interface, users connected to the interface must be authenticated before accessing network resources.

2. Restrictions and Guidelines

For details about IEEE 802.1X configuration, see *Configuring IEEE 802.1X*.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable AAA security services.

aaa new-model

The AAA security services are disabled by default.

(4) Configure the address and key of a RADIUS server.

radius-server host { *ipv4-address* | *ipv6-address* } [**key** [**0** | **7**] *text-string*]

The address and key of a RADIUS server are not configured by default.

(5) Configure an IEEE 802.1X authentication method list.

aaa authentication dot1x { **default** | *list-name* } *method*&<1-4>

No IEEE 802.1X authentication method list is configured by default.

(6) Apply the IEEE 802.1X authentication method list.

dot1x authentication { **default** | *list-name* }

(7) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(8) Enable IEEE 802.1X authentication on the interface.

dot1x port-control auto

IEEE 802.1X authentication is disabled on a port by default.

1.5.7 Configuring 2nd-Generation Web Authentication

1. Overview

After 2nd-generation Web authentication is configured, identity authentication needs to be performed by a 2nd-generation portal server.

2. Restrictions and Guidelines

- For details about Web authentication configuration, see *Configuring Web Authentication*.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable AAA security services.

aaa new-model

The AAA security services are disabled by default.

(4) Configure the address and key of a RADIUS server.

radius-server host { *ipv4-address* | *ipv6-address* } [**key** [**0** | **7**] *text-string*]

The address and key of a RADIUS server are not configured by default.

(5) Configure the communication key between the NAS and the portal server.

web-auth portal key *key-string*

No key is configured for the communication between the device and the authentication server by default.

(6) Configure a 2nd-generation Web authentication method list.

aaa authentication web-auth { **default** | *list-name* } *method*&<1-4>

(7) Enter the 2nd-generation Web authentication template configuration mode.

web-auth template eportalv2

(8) Configure parameters for the 2nd-generation Web authentication template.

a Configure an authentication method list for the template.

authentication *method-list*

The default authentication method list is used by a template by default.

b Configure an IP address for the portal server used for Web authentication.

ip { *ip-address* | **oob** | **vrf** *name* }

No IP address and VRF instance are specified for the Web authentication server by default.

c Configure the authentication page of the portal server used for Web authentication.

url *url-string*

No page address of the authentication server is configured by default.

(9) Return to the global configuration mode.

exit

(10) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(11) Enable 2nd-generation Web authentication on the interface.

web-auth enable eportalv2

2nd-generation Web authentication is disabled on a port by default.

1.5.8 Configuring ClearPass Authentication

1. Overview

The ClearPass server can function as the Portal server to connect to the web authentication component, directing authenticated users to the authentication page for authentication.

2. Restrictions and Guidelines

- The device can only connect to the ClearPass server of Aruba that functions as the Portal server for ClearPass authentication.
- When you configure the ClearPass authentication service, you need to configure a ClearPass authentication template, enable the local HTTP server, and configure the IP addresses of the ClearPass server and the NAS device where the authentication service resides as authentication-free resources.
- The ClearPass web authentication server can exchange only HTTP packets with the ClearPass server.
- For details of the web configuration, see "Web Authentication" in *Security Configuration*.

3. Configuration Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the AAA security service.

aaa new-model

The AAA security services are disabled by default.

In ClearPass authentication, the device initiates authentication requests to the server, which is implemented by the AAA module.

(4) Configure the address, port number, and key of the RADIUS server.

radius-server host { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number*] [**acct-port** *acct-port-number*] [**key** [**0** | **7**] *text-string*]

No address, port number, or key is configured for a RADIUS server by default. The default authentication port number is 1812 and the default accounting port number is 1813.

User account information is stored on the RADIUS server. The device needs to connect to the RADIUS server to confirm user identity.

(5) Configure a method list for ClearPass authentication on the device.

aaa authentication cpweb { **default** | *list-name* } { [**group** *group-name*]&<1-4> | **group radius** | **local** | **none** }

No ClearPass authentication method list is configured by default.

The authentication method list associates the web authentication request with the RADIUS server. The device selects an authentication method and the corresponding server based on the authentication method list.

(6) Configure the network accounting method list.

aaa accounting network { **default** | *list-name* } **start-stop** { [**group** *group-name*]&<1-4> | **group radius** | **group tacacs+** | **none** }

The network accounting feature is disabled by default.

The accounting method is used to associate the accounting method with a server. Web authentication needs the accounting feature to record user information or fees.

(7) Create a ClearPass authentication template and enter the ClearPass authentication template configuration mode.

web-auth template cpweb

(8) Configure web authentication template parameters.

a Configure an IP address and VRF instance for the Portal server.

ip [*ipv4-address*]

No IP address is configured for the Portal server by default.

b Configure a page address for the Portal server.

url *url-string*

A page address is configured for the Portal server by default.

c Configure the URL format for redirection packets.

fmt { **custom** | **clearpass** }

The URL of the redirection packets use the ClearPass URL format by default.

d Configure a method used by the device to parse authentication requests.

http-method post [username-key *usrkey-string* **] [password-key** *pswkey-string* **] [init-url-key** *urlkey-string* **] [password-encrypt {none | uam }]**

The identified username is username and the password is password not encrypted, by default.

e Configure the redirection packet format.

redirect { **http** | **js** }

Redirection packets are in JS format by default.

f Configure a response method after successful authentication.

login-success response { **redirect-init-url** [**default-url** *def-string*] **| msg** *msg-string* **| redirect-url** *url-string* }

The device pops the default page after successful authentication by default.

g Configure a response method after authentication failure.

login-fail response { **redirect-login-url** | **redirect-url** *url-string* [**errmsg-key** *key-string*] | **msg** *msg-string* }

The device redirects to the authentication page after an authentication failure by default.

h Configure whether to pop the active logoff page after successful authentication. (This command takes effect only after a redirection URL for successful authentication is configured.)

logout-popup-window

This feature is disabled by default.

(9) Configure a communication IP address for the HTTP server.

web-auth auth-server ip { ***ipv4-address*** }

No communication IP address is configured for the HTTP server by default.

(10) Configure a communication port for the HTTP server.

web-auth auth-server http [***port***]

No communication port is configured for the HTTP server by default.

(11) Configure the URL used by the terminal to initiate authentication.

web-auth auth-server submit-url { ***url-string*** }

The URL used by the terminal to initiate authentication is not configured by default.

(12) Exit to the global configuration mode.

exit

(13) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(14) Enable ClearPass authentication on the interface.

web-auth enable cpweb

ClearPass authentication is disabled on the interface by default.

1.5.9 Configuring FTP Authentication

1. Overview

After FTP authentication is configured, FTP users need to pass FTP authentication upon login.

2. Restrictions and Guidelines

If the AAA FTP security service is enabled on a device, users must perform FTP authentication through AAA.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable AAA security services.

aaa new-model

The AAA security services are disabled by default.

(4) Enable the FTP server function.

ftp-server enable

The FTP server function is disabled by default.

(5) Configure an FTP authentication method list.

aaa authentication ftp { **default** | *list-name* } *method*&<1-4>

No FTP authentication method list is configured by default.

(6) Configure FTP to use AAA accounts for login authentication.

ftp-server authentication { **default** | *list-name* }

FTP does not support login authentication on AAA accounts by default.

1.6 Configuring a General Authentication Method

1.6.1 Overview

A general authentication method can be used as an alternative method of 2nd-generation Web authentication and IEEE 802.1X authentication. If no authentication method is configured for 2nd-generation Web authentication or IEEE 802.1X authentication or the configured method fails to respond, the general authentication method takes effect as an alternative method.

1.6.2 Restrictions and Guidelines

If both IEEE 802.1X authentication and 2nd-generation Web authentication are configured on the device, you can configure a general method for them together.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable AAA security services.

aaa new-model

The AAA security services are disabled by default.

(4) Configure a general authentication method list.

aaa authentication general { **default** | *list-name* } *method*&<1-4>

No general authentication method is configured by default.

1.7 Configuring AAA Authentication Logging

1.7.1 Overview

The device generates logs when an AAA user passes authentication. If a large number of users go online concurrently, the device generates considerable logs, which may degrade the device performance or cause frequent screen refreshing. In this case, you can disable the logging function or restrict the logging rate.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure AAA authentication logging. Please configure only one task.

- Disable AAA authentication logging.

  no aaa log enable

  AAA authentication logging is enabled by default.

- Configure the rate of AAA authentication logging.

  aaa log rate-limit *rate-limit*

  Five AAA authentication logs are printed per second by default.

1.8 Configuring Basic Features of AAA Authorization

1.8.1 Overview

AAA authorization is used to manage services available to users and control network use permissions of access users. After the basic features of AAA authorization are enabled, users can use only the permitted services and are granted permissions in their permitted scopes.

1.8.2 Restrictions and Guidelines

- EXEC authorization is usually used together with login authentication. Authentication and authorization can use different methods and different servers, and the authentication and authorization results of the same user may be different. If a user passes login authentication but fails in EXEC authorization, the user cannot

open the CLI.

- When configuring command authorization, specify the command level, which is used as the default level of commands. For example, if a command is visible to users above level 14, the default level of the command is 14.
- EXEC authorization and command authorization need to be applied to a line so that they take effect.
- Command authorization is unavailable when role-based access control (RBAC) is enabled. For details about RBAC, see *Configuring RBAC*.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an AAA authorization method. Configure at least one of the tasks.

- Configure an EXEC authorization method list to authorize permitted users to open the CLI.

  aaa authorization exec { **default** | *list-name* } *method*&<1-4>

  No EXEC authorization method list is configured by default.

- Configure a command authorization method list to authorize permitted users to run a command.

  aaa authorization commands *level* { **default** | *list-name* } *method*&<1-4>

  No command authorization method list is configured by default.

- Configure a network authorization method list to authorize permitted users to access network services.

  aaa authorization network { **default** | *list-name* } *method*&<1-4>

  No network authorization method list is configured by default.

- Grant authorization to all commands in configuration modes.

  aaa authorization config-commands

  The authorization for commands in configuration modes is disabled by default.

- Enable command authorization for users who log in through the console. You can enable command authorization for users who log in through the console and users who log in through other terminals separately.

  aaa authorization console

  Command authorization is disabled for users who log in through the console by default.

(4) (Optional) Enter the configuration mode of a specified line.

line { **console** | **vty** } *first-line* [*last-line*]

(5) (Optional) Apply the authorization method to the specific line. Please configure only one task.

- Apply the EXEC authorization method to the specific line.

  authorization exec { **default** | *list-name* }

  EXEC authorization is disabled by default.

- Apply the command authorization method to the specific line.

authorization commands *level* { **default** | *list-name* }

The command authorization function is disabled by default.

1.9 Configuring the Function of Caching Command Authorization Results

1.9.1 Overview

After this function is configured, the device locally caches command authorization results returned by the AAA server. For subsequent commands with the level same as the cached authorized commands, command authorization can be performed based on the locally cached results.

1.9.2 Restrictions and Guidelines

Authorization results in the local cache apply only to the current session and commands of the current level. The authorization of other sessions or commands of other levels are performed by the remote server and local authorization can be performed only after their results are cached locally.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the function of caching command authorization results.

aaa command-author cache

The function of caching command authorization results is disabled by default.

1.10 Configuring the Default Role for AAA Users

1.10.1 Overview

This function is used to configure the global user role. If no role is configured for an authorized user, the role is used by default. Different roles have different levels of command execution permissions on the device. The global user role **network-operator** is used by default. This role has the permission to run commands of the lowest level on the device.

1.10.2 Restrictions and Guidelines

- Run the **aaa new-model** and **role enable** commands before configuring this function.
- For details about user roles, see *Configuring RBAC*.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the default role for AAA authorized users.

aaa user-role default { *priv-level* | *role-name* | **network-admin** | **network-operator** }

The default role of AAA authorized users is **network-operator**.

1.11 Configuring Basic Features of AAA Accounting

1.11.1 Overview

AAA accounting is used to record users' usage of network resources, login and logout processes, and command execution information.

1.11.2 Restrictions and Guidelines

- EXEC accounting is performed only on users who pass login authentication and log in to the NAS. When login authentication is not configured or the authentication exemption method is adopted, EXEC accounting is not performed.
- If accounting start is not performed on a user upon login, accounting stop will not be performed when the user logs out.
- The remote server group method used in the command accounting function supports only the TACACS+ protocol.

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an AAA accounting method. Configure at least one of the tasks.

- Configure an EXEC accounting method list.

  aaa accounting exec { **default** | *list-name* } **start-stop** *method*&<1-4>

  NO EXEC accounting method list is configured by default.

  A configured EXEC accounting method list must be applied to a line so that it takes effect.

- Configure a command accounting method list.

  aaa accounting commands *level* { **default** | *list-name* } **start-stop** *method*&<1-4>

  No command accounting method list is configured by default.

  A configured command accounting method list must be applied to a line so that it takes effect.

- Configure a network accounting method list.

  aaa accounting network { **default** | *list-name* } **start-stop** *method*&<1-4>

  No network accounting method list is configured by default.

(4) (Optional) Enable the accounting update function.

aaa accounting update

Accounting update is disabled by default.

After this function is configured, the device updates accounting information periodically. This function helps improve the accounting accuracy. You are advised to configure it.

(5) (Optional) Configure the accounting update interval.

aaa accounting update periodic *interval*

The default accounting update interval is **5** minutes.

It is recommended that the accounting update interval not be configured unless otherwise specified.

(6) Apply the accounting method. Please configure only one task.

- Enter the line configuration mode and apply the EXEC accounting method. Run the following commands in sequence:

  line { **console** | **vty** } *first-line* [*last-line*]

  accounting exec { **default** | *list-name* }

  A line is associated with the default method list by default.

- Enter the line configuration mode and apply the command accounting method. Run the following commands in sequence:

  line { **console** | **vty** } *first-line* [*last-line*]

  accounting commands [*accounting-commands-level*] { **default** | *list-name* }

  A line is associated with the default method list by default.

- Apply the network accounting method to IEEE 802.1X accounting.

  dot1x accounting { **default** | *list-name* }

  IEEE 802.1X accounting is associated with the default method by default.

1.12 Configuring a Policy for User Accounting Start Failures

1.12.1 Overview

After this function is configured, the user status is online or offline if the accounting start fails.

1.12.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the user online/offline status after the accounting start fails.

aaa accounting start-fail { **offline** | **online** }

The user online/offline status after an accounting start failure is not configured by default.

1.13 Configuring Domain-Based AAA Services

1.13.1 Overview

The domain-based AAA services classify users into different domains and the domains use different security methods to provide AAA services.

1.13.2 Restrictions and Guidelines

- The device supports a maximum of 32 domains.
- After the domain-based AAA services are enabled, if information of a user does not carry domain information, the user is assigned to the default domain **default**. A method list for the **default** domain must be configured on the device. Otherwise, users without domain information cannot use AAA services.
- After domain name-based AAA service is enabled, you can run the **aaa domain disable** command to switch the domain name-based service to global service for 802.1x, Enable, Login, and Web authentication users separately.

1.13.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable domain-based AAA services.

aaa domain enable

The domain-based AAA services are disabled by default.

(4) Create a domain and enter the AAA domain configuration mode.

aaa domain { **default** | *domain-name* }

No domain is configured by default.

(5) Configure an authentication method list for the AAA domain.

authentication { { **dot1x** | **login** | **web-auth** } { *list-name* | **default** } | **enable default** }

The default authentication method list used in an AAA domain is the default method list.

(6) Configure an accounting method list for the AAA domain.

accounting { **commands** | **exec** | **network** } { *list-name* | **default** }

The default accounting method list used in an AAA domain is the default method list.

(7) Configure an authorization method list for the AAA domain.

authorization { **commands** | **exec** | **network** } { *list-name* | **default** }

The default authorization method list used in an AAA domain is the default method list.

(8) (Optional) Set the domain status.

state { **active** | **block** }

A configured domain is active by default.

(9) (Optional) Configure whether usernames carry domain name information.

username-format { **with-domain** | **without-domain** }

Usernames carry domain name information during interaction between the NAS and the server by default.

(10) (Optional) Configure a limit on the number of users supported in the domain.

access-limit *access-limit-number*

No limit on the number of users supported in a domain is configured by default.

(11) (Optional) Disable the domain name-based AAA service for the specified authentication user.

aaa domain disable [**dot1x** | **enable** | **login** | **web-auth**]

By default, the domain name-based AAA service is not disabled for Enable and Login authentication users.

1.14 Enabling the AAA Heartbeat Keepalive Function

1.14.1 Overview

The heartbeat keepalive function in the AAA module is used to solve the problem that the AAA function is unavailable due to abnormal internal disconnection under special circumstances.

1.14.2 Restrictions and Guidelines

The interval for sending heartbeat messages is 60s, which has little impact on performance; therefore, it is recommended to enable this function.

1.14.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the AAA heartbeat keepalive function.

aaa heartbeat enable

By default, the AAA heartbeat keepalive function is enabled.

1.15 Monitoring

Run the **show** command to check the configuration.

Run the **clear** command to clear information.

Caution

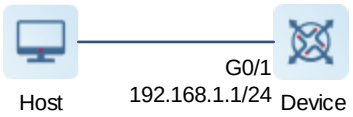
Running the **clear** command may lose vital information and thus interrupt services.

Table 1-1 AAA Monitoring

Command	Purpose
show aaa accounting update	Displays accounting update information.

Command	Purpose
show aaa capability	Displays AAA-related capabilities.
show aaa domain [**default** | *domain-name*]	Displays information about a configured domain.
show aaa lockout	Displays lockout parameter configuration in the current login authentication.
show aaa group	Displays all AAA server groups.
show aaa method-list	Displays all AAA method lists.
show aaa user { **all** | **by-id** *session-id* | **by-name** *user-name* | **lockout** }	Displays AAA user information.
clear aaa local user lockout { **all** | **user-name** *user-name-id* }	Clears the list of locked users.

1.16 Configuration Examples



1.16.1 Configuring Local Login Authentication and Local EXEC Authorization

1. Requirements

You can use local login authentication and local EXEC authorization together to control the permissions of users who log in to the device. In this method, you need to configure accounts and their permissions only in the local user database of the device, to control user permissions with no need to use an authentication server.

2. Topology

Figure 1-2 Topology of Local Login Authentication and Local EXEC Authorization

3. Notes

- Enable AAA security services on the device.
- Add accounts to the local user database of the device.
- Create an authentication method list and an authorization method list.
- Apply the authentication method and authorization method to a specific line.

4. Procedure

Enable AAA security services.

```
Device> enable
Device# configure terminal
```

```
Device(config)# aaa new-model
```

Add accounts **host1** and **host2** to the local user database of the device and configure account permissions.

```
Device(config)# username host1 privilege 15 password Abc123456
Device(config)# username host2 privilege 4 password Abc12345
```

Create a login authentication method list named **login-method**, in which the authentication method is local authentication, and create an EXEC authorization method list named **exec-method**, in which the authorization method is local authorization.

```
Device(config)# aaa authentication login login-method local
Device(config)# aaa authorization exec exec-method local
```

Apply the authentication method list and authorization method list to a line.

```
Device(config)# line vty 0 35
Device(config-line)# login authentication login-method
Device(config-line)# authorization exec exec-method
```

5. Verification

Run the **show aaa method-list** command on the device to display configured method lists.

```
Device# show aaa method-list

Authentication method-list:
aaa authentication login login-method local

Accounting method-list:

Authorization method-list:
aaa authorization exec exec-method local
```

Log in to the device through telnet by using client software (such as PuTTY or Xshell) and verify that different users have different account permissions.

- Log in to the device as user **host1** and check that the privilege level of the user is 15.

```
User Access Verification

Username:host1
Password: Abc123456

Device# show privilege
Current privilege level is 15
```

- Log in to the device as user **host2** and check that the privilege level of the user is 4.

```
User Access Verification

Username:host2
Password: Abc12345
```

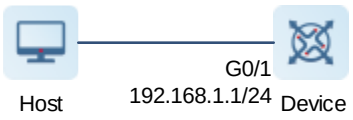
```
Device# show privilege
Current privilege level is 4
```

6. Configuration Files

```
!
username host1 privilege 15 password 7 $10$3b0$VyesigqNRs04$
username host2 privilege 4 password 7 $10$05f$wL8+5zw6/EY=$
!
aaa new-model
!
aaa authorization exec exec-method local
aaa authentication login login-method local
!
line vty 0 35
 authorization exec exec-method
 login authentication login-method
!
end
```

7. Common Errors

- No authentication method list and authorization method list are applied to a specific line.
- No account is configured in the local user database.



1.16.2 Configuring Enable Authentication

1. Requirements

Users can have execution permissions with a privilege level of 0 to 15. After Enable authentication is configured, users must be authenticated when running the **enable** command to switch the permission to a higher level. As shown in Figure 1-3, when both local authentication and Enable password authentication are configured on the device, local authentication is preferred. If local authentication is invalid, enable password authentication is used.

2. Topology

Figure 1-3 Topology of Enable Authentication

3. Notes

- Enable AAA security services on the device.
- Configure the local user database and Enable password.
- Configure an Enable authentication method list.

Note

Only one Enable authentication method list can be defined. Therefore, you do not need to define the name of the Enable authentication method list. After the default method list is configured, the Enable authentication function takes effect automatically.

4. Procedure

Enable AAA security services.

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
```

Add account **host1** to the local user database and set the privilege level of the account to **15**.

```
Device(config)# username host1 privilege 15 password Abc123456
```

Set the password to **Abc123456** for privilege level 15 in Enable authentication.

```
Device(config)# enable secret level 15 Abc123456
```

Configure an Enable authentication method list, in which local authentication is prior to Enable password authentication.

```
Device(config)# aaa authentication enable default local enable
```

5. Verification

Log in to the device as user **host1** and check that the privilege level of the user is 15.

```
User Access Verification

Username:host1
Password: Abc123456

Device# show privilege
Current privilege level is 15
```

Switch the privilege level to 4 and verify that no password is required for authentication.

```
Device# enable 4
Device# show privilege
Current privilege level is 4
```

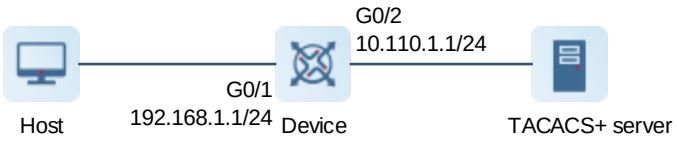
Switch the privilege level to 15 and verify that identity authentication is needed. Local authentication has a higher priority. Therefore, you can enter the password of **host1** (**Abc123456**) for authentication to successfully switch the privilege level to 15.

```
Device# enable 15
Password: Abc123456

Device# show privilege
Current privilege level is 15
```

6. Configuration Files

```
!
username host1 privilege 15 password 7 $10$3b0$VyesigqNRs04$
!
aaa new-model
!
aaa authentication enable default local enable
!
enable secret 8 $1c$js8h23u42A$:$6v$ln48$,|0.pl!:rtbr$:#h.j.462j$n,f.`($
!
end
```



1.16.3 Configuring Command Authorization

1. Requirements

Command authorization needs to be configured for login users so that users who log in to the device through terminals can only use commands in their authorized scopes.

2. Topology

Figure 1-4 Topology of Command Authorization

3. Notes

- Enable AAA security services on the device.
- Configure an IP address and a shared key for the TACACS+ server on the device.
- Configure the login authentication method list and command authorization method list on the device.
- Configure to-be-authenticated users and authorized command scopes on the TACACS+ server.
- Apply the authentication method and authorization method to a specific line.

4. Procedure

(1) On the TACACS+ server, add login users, configure authorized command scopes, and configure the server to provide AAA services for the device. (The configuration is omitted here. For the configuration of the TACACS+ server, use the operation manual of the server.)

(2) Enable AAA security services.

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
```

(3) Configure the IP address and shared key of the TACACS+ server (the IP address is set to **10.110.1.2** and shared key to **sharekey** in this example).

```
Device(config)# tacacs-server host 10.110.1.2 key sharekey
```

(4) Configure a login authentication method list named **login-method**, in which TACACS+ server authentication is prior to local authentication. Configure an EXEC authorization method list named **command-method**, in which TACACS+ server authentication is prior to local authentication

```
Device(config)# aaa authentication login login-method group tacacs+ local
Device(config)# aaa authorization exec command-method group tacacs+ local
```

(5) Add the account **host1** to the local user database and configure the account permissions.

```
Device(config)# username host1 privilege 15 password Abc123456
```

(6) Configure a command authorization method list named **command-method** for level-15 commands. In this list, TACACS+ server authorization is prior to local authorization.

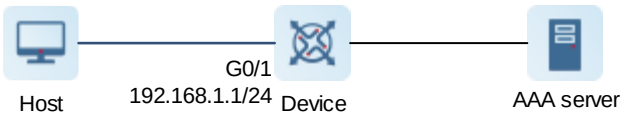
```
Device(config)# aaa authorization commands 15 command-method group tacacs+ local
```

(7) Apply the authentication method list and authorization method list to a line.

```
Device(config)# line vty 0 35
Device(config-line)# login authentication login-method
Device(config-line)# authorization exec command-method
```

5. Common Errors

- The shared key configured on the TACACS+ server is different from that configured on the device.
- A command authorization configuration error occurs on the TACACS+ server.



1.16.4 Configuring Network Authorization

1. Requirements

Network authorization needs to be configured to grant available network services to users, such as the traffic, bandwidth, and timeout services.

2. Topology

Figure 1-5 Topology of Network Authorization

3. Notes

- Enable AAA security services.
- Configure a network authorization method list.
- Apply the network authorization method list to a specific interface line (skip this step if you configure the default method).

4. Procedure

Enable AAA security services.

```
Device> enable
```

```
Device# configure terminal
Device(config)# aaa new-model
```

Configure the default network authorization method list.

```
Device(config)# aaa authorization network default group radius none
```

5. Verification

Run the **show aaa method-list** command on the device to displayconfiguration results.

```
Device# show aaa method-list

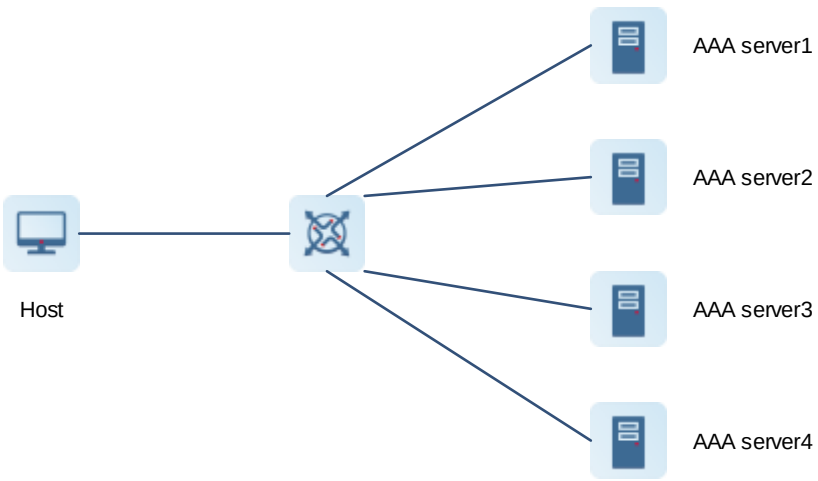
Authentication method-list:

Accounting method-list:

Authorization method-list:
aaa authorization network default group radius none
```

6. Configuration Files

```
!
aaa new-model
!
aaa authorization network default group radius none
!
```



1.16.5 Configuring an AAA Server Group

1. Requirements

A custom AAA server group needs to be created to provide AAA services.

2. Topology

Figure 1-6 Topology of an AAA Server Group

3. Notes

- Configure AAA servers.
- Create an AAA custom server group.
- Add server group members to the custom server group.

4. Procedure

(1) Add AAA servers (the following uses RADIUS servers as an example).

```
Device> enable
Device# configure terminal
Device(config)# radius-server host 10.1.1.1
Device(config)# radius-server host 10.1.1.2
Device(config)# radius-server host 10.1.1.3
Device(config)# radius-server host 10.1.1.4
```

(2) Configure a global RADIUS server communication key.

```
Device(config)# radius-server key radiuskey
```

(3) Create a server group named **group1** and add members to the group.

```
Device(config)# aaa group server radius group1
Device(config-gs-radius)# server 10.1.1.1
Device(config-gs-radius)# server 10.1.1.2
Device(config-gs-radius)#exit
```

(4) Create a server group named **group2** and add members to the group.

```
Device(config)#aaa group server radius group2
Device(config-gs-radius)# server 10.1.1.3
Device(config-gs-radius)# server 10.1.1.4
Device (config-gs-radius) #exit
```

5. Verification

Run the **show aaa group** command on the device to displaythe configuration results.

```
Device# show aaa group
Type      Reference  Name
---------- ---------- ----------
radius    1         radius
tacacs+    1         tacacs+
radius    1         group1
radius    1         group2
```

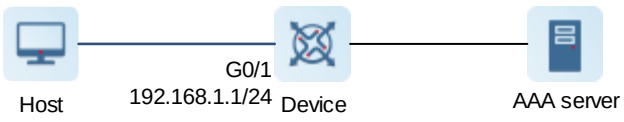
6. Configuration Files

```
!
radius-server host 10.1.1.1
radius-server host 10.1.1.2
radius-server host 10.1.1.3
radius-server host 10.1.1.4
radius-server key radiuskey
```

```
!
aaa group server radius group1
 server 10.1.1.1
 server 10.1.1.2
!
aaa group server radius group2
 server 10.1.1.3
 server 10.1.1.4
!
```

7. Common Errors

For RADIUS servers that use non-default authentication ports and non-default accounting ports, the authentication port or accounting port is not specified when the **server** command is run to add servers.



1.16.6 Configuring Domain-based AAA Services

1. Requirements

After a domain is created and a security method list is specified for the domain, users belonging to the domain use security methods of the domain for authentication, authorization, and accounting.

2. Topology

Figure 1-7 Topology of Domain-Based AAA Services

3. Notes

- Configure a RADIUS server in advance so that RADIUS server authentication and accounting can be performed.
- Enable AAA security services.
- Configure an AAA security method list.
- Enable domain-based AAA services.
- Create a domain.
- Associate the AAA security method list with the domain.
- Configure domain attributes.

4. Procedure

(1) Enable AAA security services.

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
```

(2) Configure an AAA server (the following uses the RADIUS server as an example).

```
Device(config)# radius-server host 192.168.1.2 key radiuskey
```

(3) Configure an AAA security method list.

```
Device(config)# aaa authentication dot1x default group radius
Device(config)# aaa accounting network list3 start-stop group radius
```

(4) Enable domain-based AAA services.

```
Hostname(config)# aaa domain enable
```

(5) Create a domain and configure domain attributes.

```
Device(config)# aaa domain domain.com
Device(config-aaa-domain)# authentication dot1x default
Device(config-aaa-domain)# accounting network list3
Device(config-aaa-domain)# username-format without-domain
```

5. Verification

Run the **show aaa domain** command on the device to display domain configuration.

```
Device# show aaa domain domain.com

=============Domain domain.com=============
State: Active
Username format: With-domain
Access limit: No limit
802.1X Access statistic: 0

Selected method list:
 authentication dot1x default
 accounting network list3
```

6. Configuration Files

```
!
aaa new-model
aaa domain enable
!
aaa domain domain.com
 authentication dot1x default
 accounting network list3
 username-format without-domain
!
aaa accounting network list3 start-stop group radius
aaa authentication dot1x default group radius
!
radius-server host 192.168.1.2 key radiuskey
!
```

1 Configuring RADIUS

1.1 Introduction

1.1.1 Overview

The Remote Authentication Dial-In User Service (RADIUS) is a distributed authentication, authorization and accounting (AAA) protocol based on the client/server architecture. It works with AAA to provide AAA security services for users.

When providing AAA security services, a network device serves as a RADIUS client to provide user information to the RADIUS server to initiate security service requests. The remote RADIUS server stores user information and network service information, and provides security services for users by responding to requests from the RADIUS client.

RADIUS is usually applied in networks that have high security requirements and allow remote user access. As a completely open protocol, many systems (such as UNIX, Windows 2000, and Windows 2008) support the installation of RADIUS as a system component. Therefore, the RADIUS server becomes the most widely used security server.

1.1.2 Principles

1. Basic Concepts

- Client/server mode

  RADIUS uses the client/server mode and consists of RADIUS clients and the RADIUS server.

  - As the initiator of RADIUS requests, a RADIUS client usually runs on a network access server (NAS). It provides user information for the RADIUS server, and receives and processes responses from the RADIUS server, for example, accepting or rejecting user access, and requesting user-specific information.
  - The RADIUS server maintains the IP addresses and shared key of RADIUS clients as well as configured user information, and provides authentication, authorization, and accounting services by responding to requests from RADIUS clients. One RADIUS server usually corresponds to multiple RADIUS clients.

- Shared key

  A shared key is a string shared between a RADIUS client and the server. It is used to encrypt and decrypt user passwords during RADIUS packet transmission and generate packet verification fields, in an effort to ensure RADIUS communication security.

- RADIUS server group

  Security methods used in AAA security services are based on server groups. Likewise, RADIUS provides AAA security services based on RADIUS server groups. One security method corresponds to one RADIUS server group and one or more RADIUS severs can be configured in each RADIUS server group.

  If multiple RADIUS servers are configured in a RADIUS server group, when a device fails to communicate with the first RADIUS server or the first RADIUS server is unreachable, the device automatically attempts

to communicate with the second RADIUS server, and so on. The attempt lasts till the communication succeeds or the communication with all RADIUS servers fails.

2. RADIUS Packet

- Packet structure

Figure 1-1 Structure of a RADIUS Packet

Fields contained in the packet structure shown in Figure 1-1 are described in Table 1-1.

Table 1-1 Description of Fields Contained in a RADIUS Packet

Field	Length	Description	Remarks
Code	1 byte	Identifies the packet type.	Values corresponding to common packet types and their meanings are as follows: **1**: Access-Request **2**: Access-Accept **3**: Access-Reject **4**: Accounting-Request **5**: Accounting-Response **11**: Access-Challenge
Identifier	1 byte	Matches a request with a response packet.	Request packets and response packets of the same type have the same identifier value.
Length	2 bytes	Indicates the length of a RADIUS packet.	The value is the sum of the lengths of the **Code**, **Identifier**, **Length**, **Authenticator**, and **Attributes** fields. If the length of a received packet is greater than the value of **Length**, the content beyond the value of **Length** is ignored as filling information. If the length of a received packet is smaller than the value of **Length**, the packet is discarded.

Field	Length	Description	Remarks
Authenticator	16 bytes	Verifies packets and encrypts and decrypts user passwords.	N/A
Attributes	Variable length	Carries authentication, authorization, and accounting information.	This field usually contains multiple attributes and each attribute is represented in the type, length, value (TLV) format.

- RADIUS attributes

  RADIUS attributes carry authentication, authorization, and accounting information, and each attribute is represented in the TLV format, as described in Table 1-2.

Table 1-2 Description of RADIUS Attribute Fields

Field	Length	Description
Type	1 byte	Attribute type
Length	1 byte	Total length of an attribute (TLV)
Value	Variable length	Attribute description

Table 1-3 RADIUS Attribute List

Attribute No.	Attribute Name	Attribute No.	Attribute Name
1	User-Name	43	Acct-Output-Octets
2	User-Password	44	Acct-Session-Id

38	Framed-AppleTalk-Network	83	Tunnel-Preference
39	Framed-AppleTalk-Zone	84	ARAP-Challenge-Response
40	Acct-Status-Type	85	Acct-Interim-Interval
41	Acct-Delay-Time	86	Acct-Tunnel-Packets-Lost
42	Acct-Input-Octets	87	NAS-Port-Id

- Introduction to RADIUS attributes

  This section describes some of the important attributes.

  - Attribute 31

    When a RADIUS client sends a request packet to the RADIUS server, information is filled in attribute 31 (**Calling-Station-ID**) to identify the user to be authenticated. The MAC address of a user is often used as the attribute content. For example, in IEEE 802.1X authentication, the device uses the MAC address of the device where the IEEE 802.1X client resides as the attribute content.

Different RADIUS servers have different requirements for the format of the MAC address in attribute 31. Therefore, ensure that the MAC address format used by RADIUS clients is the same as that used by the server. Currently, the following three MAC address formats are supported.

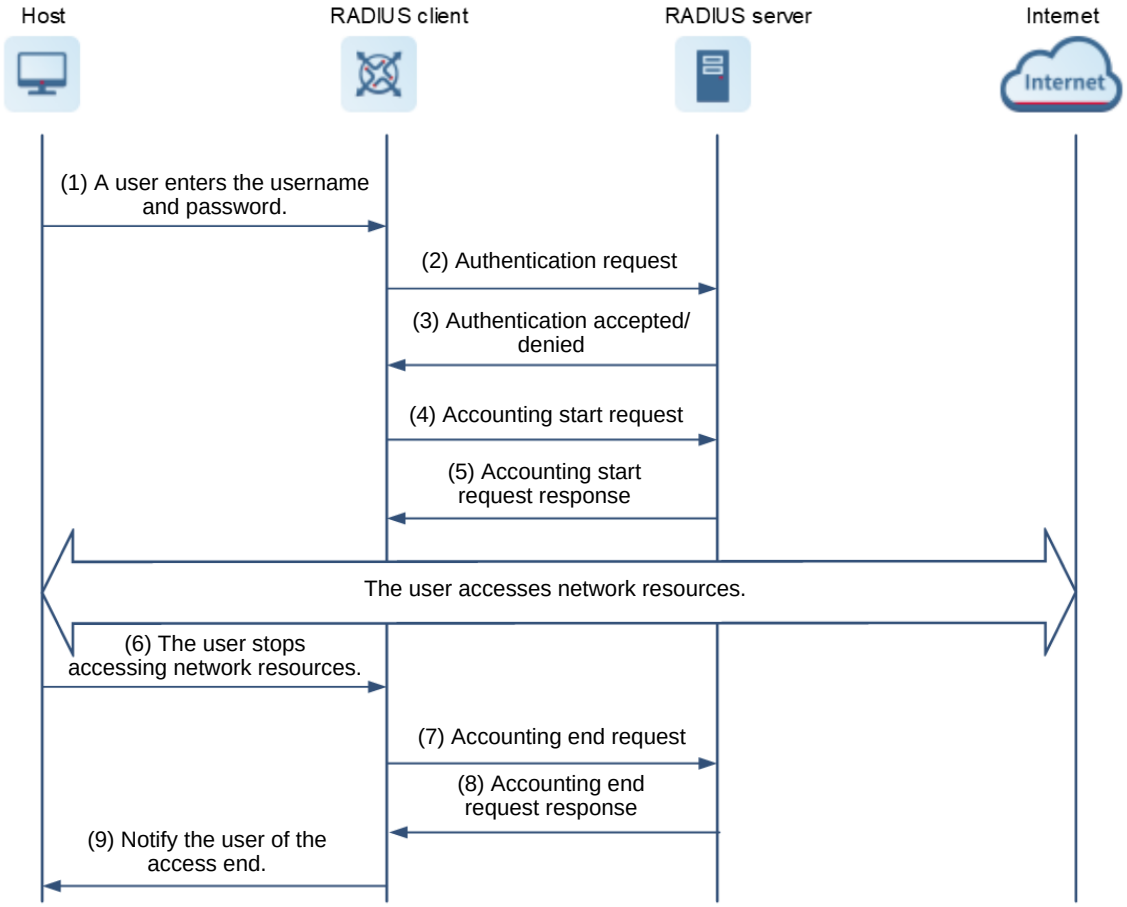
Table 1-4 Supported Formats of the MAC Address in Attribute 31

MAC Address Format	Description
ietf	Standard format specified in the Internet Engineering Task Force (IETF) standard (RFC3580). It uses hyphens (-) as the separator, for example, 00-D0-F8-33-22-AC.
normal	Dotted hexadecimal format using dots (.) as the separator, for example, 00d0.f833.22ac.
unformatted	Default format with no separator, for example, 00d0f83322ac.

- Attribute 26

Attribute 26 (**Vendor-Specific**) is also called a private attribute, which allows device vendors to define attributes. Device vendors can define multiple attributes in the TLV format in attribute 26. Table 1-5 lists private attributes supported by Ruijie products.

Table 1-5 List of Ruijie Private Attributes



ID	Function	Type	Extended Type
1	max-down-rate	1	76
2	port-priority	2	77
3	user-ip	3	3
4	VLAN-id	4	4
5	last-supplicant-version	5	5
6	net-ip	6	6
7	user-name	7	7
8	password	8	8
9	file-directory	9	9
10	file-count	10	10
11	file-name-0	11	11
12	file-name-1	12	12
13	file-name-2	13	13
14	file-name-3	14	14
15	file-name-4	15	15
16	max-up-rate	16	16
17	current-supplicant-version	17	17
18	flux-max-high32	18	18
19	flux-max-low32	19	19
20	proxy-avoid	20	20

ID	Function	Type	Extended Type
21	dailup-avoid	21	21
22	ip-privilege	22	22
23	login-privilege	42	42
26	IPv6-multicast-address	79	79
27	IPv4-multicast-address	87	87
62	sdg-type	62	62
85	sdg-zone-name	85	85
103	sdg-group-name	103	103

3. RADIUS Authentication, Authorization, and Accounting

RADIUS provides authentication, authorization, and accounting for users. The interaction process is shown in Figure 1-2.

Figure 1-2 RADIUS Authentication, Authorization, and Accounting Process

- RADIUS authentication and authorization process
  a A user enters the username and password and sends them to a RADIUS client.

b After receiving the username and password, the RADIUS client sends an authentication request packet to the RADIUS server. The password in the authentication request packet is encrypted.

c After receiving the authentication request, the RADIUS server checks whether the username and password are legitimate. If yes, the RADIUS server accepts the authentication request and delivers authorization information of the user. If no, the RADIUS server rejects the authentication request.

- RADIUS accounting process

a If the RADIUS server returns an authentication success message in the user authentication process, the RADIUS client sends an accounting start request packet to the RADIUS server.

b The RADIUS server returns an accounting start response packet and starts accounting.

c When stopping accessing network resources, the user sends a disconnection request to the RADIUS client.

d The RADIUS client sends an accounting end request packet to the RADIUS server.

e The RADIUS server returns an accounting end response packet and stops accounting.

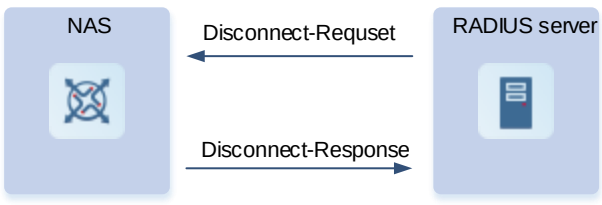
f The user is disconnected from the network and cannot access network resources.

4. RADIUS Packet Retransmission Upon Timeout

After sending a packet to the RADIUS server, a RADIUS client uses a timer to test whether the RADIUS server responds within the specified time. If the RADIUS server does not respond within the specified time, the RADIUS client retransmits the packet. The following timeout and retransmission parameters need to be configured:

- RADIUS server timeout duration

  The response time of a RADIUS server depends on its performance and the network environment. Configure a proper timeout duration based on the actual situation.



- Retransmission count
- Whether accounting update packets need to be retransmitted

5. RADIUS Forcible Logoff

Users can go offline actively. In addition, the RADIUS server can send messages to force authenticated users offline.

RADIUS forcible logoff is a user logoff management method defined in the protocol of Dynamic Authorization Extensions to RADIUS. The NAS and RADIUS server exchange Disconnect-Messages (DMs) to force authenticated users offline. The protocol of Dynamic Authorization Extensions to RADIUS enables NASs from different vendors to be compatible with RADIUS servers in user logoff processing.

Figure 1-3 DM Interaction of Dynamic Authorization Extensions to RADIUS

The DM interaction between a RADIUS server and the NAS is as follows:

(1) The RADIUS server actively sends a Disconnect-Request message to port UDP3799 of the NAS to initiate a user logoff request.

(2) The NAS searches for the user based on the user session information and username carried in the Disconnect-Request message and logs off the user.

(3) The NAS sends the logoff result to the RADIUS server through a Disconnect-Response message.

1.1.3 Protocols and Standards

- RFC 2865: Remote Authentication Dial In User Service (RADIUS)
- RFC 2866: RADIUS Accounting
- RFC 2867: RADIUS Accounting Modifications for Tunnel Protocol Support
- RFC 2868: RADIUS Attributes for Tunnel Protocol Support
- RFC 2869: RADIUS Extensions
- RFC 3576: Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)

1.2 Configuration Task Summary

RADIUS configuration includes the following tasks:

(1) Configuring RADIUS Basic Features

(2) Enabling Dynamic Extension Authorization on the RADIUS Server

(3) Configuring a RADIUS Server Group

(4) (Optional) Configuring RADIUS Attributes Select at least one of the following tasks to configure.

- Configure the Attribute Format
- Configuring Ruijie Private Attributes
- Configuring Compatibility with Devices of Other Vendors

(5) (Optional) Configuring RADIUS Reachability Detection

(6) (Optional) Configuring the DSCP Value for RADIUS Packets

(7) (Optional) Configuring the Units of Data Flows and Packets to Be Sent to a RADIUS Server

(8) (Optional) Configuring the Accounting-On Function

(9) (Optional) Configuring the Accounting Packet Copying Function

(10) Configuring the RadSec Server

1.3 Configuring RADIUS Basic Features

1.3.1 Overview

This section describes how to configure parameters for the communication between a network device and a RADIUS server to ensure normal communication between them. After the parameters are configured, the device can correctly send AAA authentication, authorization, and accounting requests to the RADIUS server and give responses.

1.3.2 Restrictions and Guidelines

- Before configuring RADIUS, ensure that the network communication between the device and the RADIUS server is in good condition.
- Before configuring RADIUS IPv6 authentication, ensure that the RADIUS server supports RADIUS IPv6 authentication.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a RADIUS remote server.

radius-server host [**oob** [**via mgmt** *interface-number*]] { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number* | **acct-port** *acct-port-number*] * [**test username** *username* [**ignore-acct-port**] [**ignore-auth-port**] [**idle-time** *idle-time*]] [**radsec-destination** *id-number*] [**key** [**0** | **7**] *text-string*]

no radius-server host [**oob** [**via mgmt** *interface-number*]] { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number* | **acct-port** *acct-port-number*] * [**test username** *username* [**ignore-acct-port**] [**ignore-auth-port**] [**idle-time** *idle-time*]] [**radsec-destination** *id-number*] [**key** [**0** | **7**] *text-string*]

default radius-server host [**oob** [**via mgmt** *interface-number*]] { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number* | **acct-port** *acct-port-number*] * [**test username** *username* [**ignore-acct-port**] [**ignore-auth-port**] [**idle-time** *idle-time*]] [**radsec-destination** *id-number*] [**key** [**0** | **7**] *text-string*]

radius-server host { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number* | **acct-port** *acct-port-number*] * [**test username** *username* [**ignore-acct-port**] [**ignore-auth-port**] [**idle-time** *idle-time*]] [**radsec-destination** *id-number*] [**key** [**0** | **7**] *text-string*]

no radius-server host { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number* | **acct-port** *acct-port-number*] * [**test username** *username* [**ignore-acct-port**] [**ignore-auth-port**] [**idle-time** *idle-time*]] [**radsec-destination** *id-number*] [**key** [**0** | **7**] *text-string*]

default radius-server host { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number* | **acct-port** *acct-port-number*] * [**test username** *username* [**ignore-acct-port**] [**ignore-auth-port**] [**idle-time** *idle-time*]] [**radsec-destination** *id-number*] [**key** [**0** | **7**] *text-string*]

No RADIUS remote server is configured by default.

If a RADIUS server is not added to a RADIUS server group, the device uses the global routing table when communicating with the RADIUS server. Otherwise, the device uses the virtual routing and forwarding (VRF) routing table of the RADIUS server group.

(4) Configure a shared key for the communication between the device and the RADIUS server.

radius-server key [**0** | **7**] *key*

No shared key for the communication between the device and the RADIUS server is configured by default.

A shared key is the basis for correct communication between the device and the RADIUS server. The same shared key must be configured on them both to ensure normal communication between them.

(5) (Optional) Configure the source address for RADIUS packets.

ip radius source-interface *interface-type interface-number*

The source IP address of RADIUS packets is set by the network layer by default.

After this command is configured, the device uses the first IP address of the interface specified in the command as the source address of RADIUS packets. Ensure that the communication between the configured address and the RADIUS server is normal. Specifying the source IP address for packets to be sent to the RADIUS server can reduce the NAS information maintenance workload on the RADIUS server.

(6) (Optional) Configure the source UDP port to be used by the device to send RADIUS packets.

radius-server source-port *source-port*

The source UDP port used by the device to send RADIUS packets is a random packet by default.

(7) (Optional) Configure the waiting time, after which the device retransmits a RADIUS request packet.

radius-server timeout *timeout*

The default waiting time before the retransmission of a RADIUS packet is **5** seconds.

(8) (Optional) Configure the accounting update packet retransmission function for Web-authenticated users.

radius-server account update retransmit

The accounting update packet retransmission function is enabled for Web-authenticated users by default.

The configuration does not affect users of other authentication types.

(9) (Optional) Enable the compatibility of encapsulated user name.

radius user-name compatible

By default, the compatibility of encapsulated user name is disabled.

After this function is enabled, the user names in RADIUS packets are encapsulated in the customer-specific format, rather than the UTF-8 format.

(10) (Optional) Configure the value of the NAS-IP-Address field in RADIUS packets.

radius-server nas-ip-address key { *ipv4-address* | *ipv6-address* }

By default, the value of the NAS-IP-Address field is not configured.

(11) (Optional) Configure the NAS-ID field in RADIUS packets.

radius-server nasid *nas-id*

The NAS-ID field in RADIUS packets is not configured by default.

1.4 Enabling Dynamic Extension Authorization on the RADIUS Server

1.4.1 Overview

After dynamic extension authorization of the RADIUS server is configured, the device can process dynamic extension authorization packets (such as DM or COA packets), allowing the server to perform dynamic authorization operations such as disconnecting online users and ACL authorization.

1.4.2 Restrictions and Guidelines

- The server can perform dynamic authorization for online users only when the server supports dynamic extension authorization and the device is enabled with dynamic extension authorization.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable dynamic extension authorization on the RADIUS server.

radius dynamic-authorization-extension enable

Dynamic extension authorization on the RADIUS server is enabled by default.

(4) Configure the communication port for dynamic extension authorization packets of the RADIUS server.

radius dynamic-authorization-extension port port-number

The default communication port for dynamic extension authorization packets of the RADIUS server is 3799.

(5) (Optional)Enable dynamic extension authorization of the RADIUS server to check the RADIUS timestamp.

radius dynamic-authorization-extension attribute check event-timestamp

The device is not enabled with dynamic extension authorization of the RADIUS server to check the RADIUS timestamp by default.

(6) (Optional) Enable dynamic extension authorization of the RADIUS server to check duplicate packets.

radius dynamic-authorization-extension duplicate-packet discard

The device is not enabled with dynamic extension authorization of the RADIUS server to check duplicate packets by default.

(7) (Optional) Enable the RADIUS server to check the timestamp in dynamic extension authorization packets.

radius dynamic-authorization-extension event-timestamp interval *interval-value*

The RADIUS server is not enabled to check the timestamp in dynamic extension authorization packets by default.

(8) (Optional) Configure the maximum number of dynamic extension authorization packets of the RADIUS server that the device can process concurrently.

radius dynamic-authorization-extension max-req *max-req-value*

The maximum number of dynamic extension authorization packets of the RADIUS server that the device can process concurrently is not configured by default.

(9) (Optional) Configure the timeout interval of dynamic extension authorization response packets of the RADIUS server.

radius dynamic-authorization-extension timeout *timeout-value*

The default timeout interval of dynamic extension authorization response packets of the RADIUS server is 30 seconds.

1.5 Configuring a RADIUS Server Group

1.5.1 Overview

One or more RADIUS servers can be added to each RADIUS server group, which provides AAA services for users as a whole.

1.5.2 Restrictions and Guidelines

- RADIUS security services are a type of AAA services and need to be used in combination with AAA features. RADIUS provides security services for users as one method in an AAA method list.
- When configuring the authentication and accounting method lists, you can specify server groups separately for them.
- In a user-defined server group, you can only specify and apply servers in the default server group.
- RADIUS server groups support VRF instances. When a server group in a specified VRF instance is used, the source address used by the device to communicate with a remote server must be obtained from the VRF instance. If you run the **ip radius source-interface** command to specify the source interface for request packets, the IP address obtained from this source interface takes priority over that found in the VRF instance.
- The name of a server group cannot be set to the predefined keyword **radius**.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a RADIUS server group.

aaa group server radius *group-name*

No RADIUS server group is configured by default.

You can group RADIUS servers so that authentication and accounting can be completed by different server groups.

(4) Add a server to the RADIUS server group.

server { *ipv4-address* | *ipv6-address* } [**acct-port** *acct-port* | **auth-port** *auth-port*] *

No server is added to a RADIUS server group by default.

(5) (Optional) Specify a VRF instance for the RADIUS server group.

ip vrf forwarding *vrf-name*

No VRF instance is specified for a RADIUS server group by default.

The VRF instance specified for a RADIUS server group must use a valid name configured using the **vrf definition** command in global configuration mode.

(6) (Optional) Configure an MGMT port to be used by the RADIUS server group.

ip oob [**via mgmt** *interface-number*]

No MGMT port to be used by a RADIUS server group is configured by default.

1.6 Configuring RADIUS Attributes

1.6.1 Overview

RADIUS attributes are used to carry authentication, authorization, and accounting information to be used in packet interaction. You can configure the attribute format, private attribute processing method, and vendor compatibility.

1.6.2 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configure the Attribute Format
- Configuring Ruijie Private Attributes
- Configuring Compatibility with Devices of Other Vendors

1.6.3 Configure the Attribute Format

1. Overview

This section describes how to configure the attribute format to be used in encapsulation and parsing.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure RADIUS attributes. Configure at least one of the tasks.

- Configure the format of the MAC address used in attribute 31 (**Calling-Station-ID**).

  radius-server attribute 31 mac format { **3hyphen** | **ietf** | **normal** | **unformatted** | { { **colon-split** | **dot-split** | **hyphen-split** } { **mode1** | **mode2** } [**lowercase** | **uppercase**] } }

  The MAC address used in attribute 31 uses the unformatted pattern.

  Some RADIUS servers (mainly used for IEEE 802.1X authentication) can identify only MAC addresses in the IETF format. In this case, set the format of MAC addresses used in attribute 31 to the IETF format.

- Configure the encapsulation format for the **NAS-Port-ID** attribute.

  radius-server attribute nas-port-id format { **mode**1 | **normal** | **port-vid** | **qinq** }

  The default encapsulation format of the **NAS-Port-ID** attribute is the normal format.

  Use this command to configure the encapsulation format for the **NAS-Port-ID** attribute applicable to 802.1Q in 802.1Q (QinQ) scenarios or non-QinQ scenarios.

- Configure the parsing mode for the **Class** attribute.

  radius-server attribute class user-flow-control { **format-16bytes** | **format-32bytes** | **unit bit/s** | **unit byte/s** }

The function of parsing the rate limit configuration from the **Class** attribute of RADIUS packets is disabled by default.

Configure this command if a server needs to deliver the rate limit value by using the **Class** attribute.

- Configure whether RADIUS authentication request packets carry a specified attribute.

  radius-server authentication attribute *type* { **package** | **unpackage** }

  According to the RFC standard, attributes that must be carried in authentication requests are carried by default, attributes that do not need to be carried are not carried by default, and other attributes are in the unset state by default.

- Configure whether RADIUS accounting request packets carry a specified attribute.

  radius-server account attribute *type* { **package | unpackage** }

  According to the RFC standard, attributes that must be carried in accounting requests are carried by default, attributes that do not need to be carried are not carried by default, and other attributes are in the unset state by default.

1.6.4 Configuring Ruijie Private Attributes

1. Overview

Vendors can define private attributes to implement multiple features that are not supported by the standard RADIUS protocol. You can configure the methods used by devices to process private attributes based on the actual environment. Private attributes configured in this section are all Ruijie private attributes.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure Ruijie private attributes. Configure at least one of the tasks.

- Configure the device to set the private attribute **port-priority** delivered by the server to the class of service (CoS) value of an interface.

  radius set qos cos

  The device sets the private attribute **port-priority** delivered by the server to the differentiated services code point (DSCP) value by default.

- Configure the device to support the **CUI** attribute.

  radius support cui

  The function of supporting the **CUI** attribute by RADIUS is disabled by default.

1.6.5 Configuring Compatibility with Devices of Other Vendors

1. Overview

In actual deployment environments, Ruijie devices may interconnect to RADIUS servers of other vendors. Private attributes defined by different vendors are different. It is necessary to enable compatibility with the configuration of devices of other vendors.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure compatibility with devices of other vendors. Configure at least one of the tasks.

- Configure whether RADIUS authentication request packets carry the private attributes of a specified vendor.

  radius-server authentication vendor { **cisco | cmcc** | **microsoft** } **package**

  Authentication request packets do not carry private attributes of other vendors by default.

- Configure whether RADIUS accounting request packets carry the private attributes of a specified vendor.

  radius-server account vendor { **cisco | cmcc** | **microsoft** } **package**

  Accounting request packets do not carry private attributes of other vendors by default.

- Configure RADIUS to parse private attributes of Cisco, Huawei, and Microsoft devices carried in packets.

  radius vendor-specific attribute support { **cisco** | **huawei** | **ms** }

  RADIUS parses private attributes of Cisco, Huawei, and Microsoft devices carried in packets by default.

- Enable the function of not differentiating private vendor IDs during RADIUS packet parsing.

  radius vendor-specific extend

  RADIUS identifies only Ruijie private vendor ID during packet parsing by default.

- Configure the mode of parsing private attributes.

  radius vendor-specific attribute support { **cisco** | **huawei** | **ms** }

  RADIUS parses private attributes of Cisco, Huawei, and Microsoft devices carried in packets by default.

  If the server is a Ruijie application server, the RADIUS private attribute type needs to be configured to achieve compatibility.

1.7 Configuring RADIUS Reachability Detection

1.7.1 Overview

A RADIUS server can be only in the reachable or unreachable state. The device will not send authentication, authorization, or accounting requests of access users to an unreachable RADIUS server unless all servers in the RADIUS server group are unreachable.

The device maintains the reachability status of each RADIUS server. The device selects a reachable RADIUS server preferentially to improve the handling performance of RADIUS services.

The device actively detects whether a specified RADIUS server is reachable. After the active detection function is configured, the device periodically sends detection requests (authentication requests or accounting requests) to the RADIUS server. The active detection interval is **60** minutes when the RADIUS server is reachable and **1** minute when the RADIUS server is unreachable.

1.7.2 Restrictions and Guidelines

- To enable active detection for a specified RADIUS server, perform the following configuration when configuring the RADIUS server:
  - Configure a test username for the RADIUS server.
  - Configure at least one tested port (authentication port or accounting port) for the RADIUS server.
- It is judged that a RADIUS server is unreachable only when both conditions below are met:
  - The device fails to receive a correct response packet from the RADIUS server within the specified timeout duration.
  - The number of times that the device sends request packets to the same RADIUS server consecutively reaches the specified timeout count.
- If any of the following conditions is met for an unreachable RADIUS server, the RADIUS server is considered reachable.
  - The device receives correct responses from the RADIUS server.
  - The duration in which the RADIUS server is unreachable exceeds the time configured using the **radius-server deadtime** command, and active detection is disabled for the RADIUS server.
  - The authentication port or accounting port of the RADIUS server is updated on the device.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the criteria for the device to judge that a RADIUS server is unreachable.

radius-server dead-criteria { **time** *timeout* | **tries** *tries-number* | **time** *timeout* **tries** *tries-number* }

The criteria for judging that a RADIUS server is unreachable are that the timeout duration is 60 seconds and the consecutive timeout count is 10 by default.

If a RADIUS server meets both the duration condition and the consecutive request timeout count condition, it is deemed that the RADIUS server is unreachable.

(4) Configure active detection and set the IP address, authentication port, or accounting port for the remote RADIUS server.

radius-server host { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number* | **acct-port** *acct-port-number*]*

No active detection is configured by default.

(5) (Optional) Configure the number of times that the device sends requests to a RADIUS server consecutively before confirming that the RADIUS server is unreachable.

radius-server retransmit *retransmit-times*

The device sends requests to a RADIUS server three times consecutively before confirming that the RADIUS server is unreachable by default.

(6) (Optional) Configure the duration for the device to stop sending request packets to an unreachable RADIUS server.

radius-server deadtime *deadtime*

Even if a RADIUS server is unreachable, the device still sends requests to the RADIUS server by default.

If active detection is enabled for a RADIUS server, the time parameter configured by the **radius-server deadtime** command does not take effect on the RADIUS server.

1.8 Configuring the DSCP Value for RADIUS Packets

1.8.1 Overview

DSCP is in the type of service (ToS) field of the IP header and is used to identify the packet transmission priority. A larger DSCP value indicates a higher packet priority. The default DSCP value of RADIUS packets is **0**. You can configure the DSCP value for RADIUS packets to change the transmission priority of RADIUS packets.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the DSCP value for RADIUS packets.

radius dscp *dscp-value*

The default DSCP value of RADIUS packets is **0**.

1.9 Configuring the Units of Data Flows and Packets to Be Sent to a RADIUS Server

1.9.1 Overview

The default units of data flows and data packets to be sent to a RADIUS server are bytes and packets respectively. You can configure the units of data flows and data packets to be sent to a RADIUS server based on the actual network situation.

1.9.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the units of data flows and data packets to be sent to a RADIUS server.

radius data-flow-format { { **data byte** | **data giga-byte** | **data kilo-byte** | **data mega-byte** } | { **packet giga-packet** | **packet kilo-packet** | **packet mega-packet** | **packet one-packet** } } *

The default units of data flows and data packets to be sent to a RADIUS server are bytes and packets respectively.

1.10 Configuring the Accounting-On Function

1.10.1 Overview

The accounting-on function is used to notify a RADIUS server of the device restart. After the device is restarted, online users are forced offline. However, the RADIUS server does not perceive the device restart and does not log off the users. As a result, the users encounter an exception when initiating re-authentication. Therefore, it is necessary to enable the accounting-on function.

1.10.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the function of sending accounting-on packets upon device restart.

radius-server accounting-on enable

The function of sending accounting-on packets upon device restart is enabled by default.

1.11 Configuring the Accounting Packet Copying Function

1.11.1 Overview

RADIUS accounting packets are sent to one server specified in the accounting method list by default. After this function is enabled, the device copies accounting packets and sends the packets to all servers in a server group.

1.11.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure the function of copying and sending accounting packets to servers in a specified group.

radius-sever accounting-copy *group*

The function of copying and sending RADIUS accounting packets is disabled by default.

1.12 Configuring the RadSec Server

1.12.1 Overview

You can configure a RADIUS over TLS (RadSec) server and change its destination service IP address and port number. RADIUS packets are exchanged through Transport LayerSecurity (TLS). You can configure TLS connection timeout duration and keepalive packet transmission interval to check the RadSec server status. You can also load a RadSec server certificate to better secure the RadSec server.

1.12.2 Restrictions and Guidelines

- A maximum of five RadSec servers can be configured.
- Use this command to configure a RadSec server. The RadSec and RADIUS servers can be the same or different.
- Empty RADIUS requests are sent as keepalive packets. The minimum interval for sending keepalive packets is 20s, and the maximum interval is 86,400s. The interval should be smaller than the server keepalive time.
- After downloading the RadSec server certificate to the **flash:** directory of the device, load the certificate and then manually delete the certificate file from the **flash:** directory.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a RadSec server.

radsec destination *id-number* **host** *ipv4-address* [**port** *port-number*] [**tls-timeout** *seconds*] [**keep-alive** *times*]

No RadSec server is configured by default.

(4) Load the certificate of the RadSec server.

radsec load-cert { **pem** { **cacert**s *path* [**cert** *path* **key** *path*] | **cert** *path* **key** *path* } | **pfx** } [**password** *passward*]

By default, no RadSec server certificate is loaded.

1.13 Monitoring

Run the **show** commands to check the configuration.

Run the **debug** commands to output debugging information.

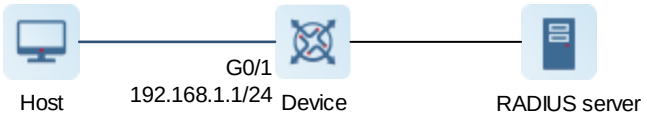
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-6 RADIUS Monitoring

Command	Purpose
show radius acct statistics	Displays RADIUS accounting statistics.
show radius attribute	Displays RADIUS standard attributes.
show radius auth statistics	Displays RADIUS authentication statistics.
show radius dynamic-authorization-extension statistics	Displays information about dynamic extension authorization packets.
show radius group	Displays the configuration of a RADIUS server group.
show radius parameter	Displays global parameters of a RADIUS server.
show radius server	Displays the configuration of a RADIUS server.
show radius timeout record	Displays timeout of outgoing RADIUS packets.
show radius vendor-specific	Displays the configuration of the RADIUS private attribute type.
show radius-server accounting-copy [**interface** *interface-type interface-number*]	Displays the configuration of copying RADIUS accounting packets and sending them to servers in a specified server group.
show radsec statistics	Displays statistics on the destination of the RadSec server.
show radsec state	Displays the RadSec server status.
show radsec pki	Displays information about the RadSec server certificate.
debug radius detail	Debugs RADIUS packets.
debug radius extend event	Debugs the function of Dynamic Authorization Extensions to RADIUS.
debug radius extend detail	Debugs packets of Dynamic Authorization Extensions to RADIUS.
debug radius extend error	Prints information related to packets of Dynamic Authorization Extensions to RADIUS for debugging.

1.14 Configuration Examples



1.14.1 Configuring RADIUS Authentication, Authorization, and Accounting

1. Requirements

A RADIUS server needs to be used for authentication, authorization, and accounting of login users.

2. Topology

Figure 1-4 Topology of RADIUS Authentication, Authorization, and Accounting

3. Notes

- Configure device information and add login users on the RADIUS server.
- Enable AAA securityservices on the device.
- Configure RADIUS server information on the device.
- Configure the RADIUS authentication method list, authorization method list, and accounting method list.
- Apply the RADIUS authentication, authorization, and accounting methods to a specific line.

4. Procedure

(1) Configure device information and add login users on the RADIUS server. The configuration is omitted here. For details, see the RADIUS server configuration.

(2) Enable AAA securityservices.

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
```

(3) Configure a RADIUS server (the IP address of the RADIUS server is set to 192.168.1.3 and the shared key is set to **sharekey** here).

```
Device(config)# radius-server host 192.168.1.3 key sharekey
```

(4) Configure the authentication, authorization, and accounting method lists.

```
Device(config)# aaa authentication login radius-method group radius
Device(config)# aaa authorization exec radius-method group radius
Device(config)# aaa accounting exec radius-method start-stop group radius
```

(5) Apply the authentication, authorization, and accounting methods to a line.

```
Device(config)# line vty 0 4
Device(config-line)# login authentication radius-method
Device(config-line)# authorization exec radius-method
Device(config-line)# accounting exec radius-method
```

5. Verification

After entering the correct username and password, a user can log in to the device successfully.

```
User Access Verification

Username:hostname1
Password: Abc123456

Device#
```

After login, the user has only the privilege level granted by the server and can run commands only under this privilege level.

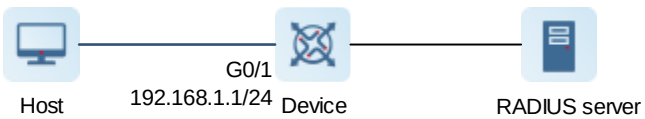
After the user logs out, accounting information of the user can be queried on the RADIUS server. For details about how to query accounting information, see the RADIUS server configuration.

6. Configuration Files

```
!
aaa new-model
!
aaa accounting exec radius-method start-stop group radius
aaa authorization exec radius-method group radius
aaa authentication login radius-method group radius
!
radius-server host 192.168.1.3 key 7 $10$275$g8oXDDIPVeA=$
!
line console 0
line vty 0 4
 accounting exec radius-method
 authorization exec radius-method
 login authentication radius-method
!
```

7. Common Errors

The shared key configured on the device is inconsistent with that used by the RADIUS server.



1.14.2 Configuring RADIUS Reachability Detection

1. Requirements

RADIUS reachability detection needs to be configured to identify unreachable RADIUS servers.

2. Topology

Figure 1-5 Topology of RADIUS Reachability Detection

3. Notes

- Configure the global criteria for judging that a RADIUS server is unreachable.

- Configure an IP address for the RADIUS server and configure active detection parameters.

4. Procedure

Configure the global criteria for judging that a RADIUS server is unreachable as follows: The consecutive timeout count is **5** and the timeout duration is **120** seconds.

```
Device> enable
Device# configure terminal
Device(config)# radius-server dead-criteria time 120 tries 5
```

Set the IP address of the RADIUS server to 192.168.1.3, detection username to **test**, and detection interval to **90** minutes, and disable the server authentication port detection.

```
Device(config)# radius-server host 192.168.1.3 test username test ignore-acct-port
idle-time 90
```

5. Verification

Disconnect the network communication between the device and the server with the IP address 192.168.1.3. Initiate RADIUS authentication through the device. After 120 seconds, run the **show radius server** command to check that the server status is "Dead".

```
Hostname# show radius server

Server IP:   192.168.1.3
Accounting Port:  1813
Authen  Port:    1812
mom    flag:    1
Test Username:    test
Test Idle Time:   1 Minutes
Test Ports:      Authen and Accounting
Server State:    Dead
   Current duration 1254s, previous duration 2918s
   Dead: total time 1257s, count 1
   Statistics:

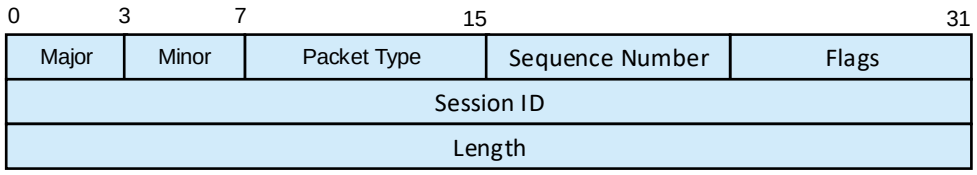
1 Configuring TACACS

1.1 Introduction

1.1.1 Overview

Terminal Access Controller Access Control System (TACACS) is a distributed authentication, authorization and accounting (AAA) protocol based on the client/server architecture. TACACS+ has enhanced functions on the basis of the TACACS protocol, to provide the authentication, authorization and accounting services for users. This following describes TACACS+.



Both TACACS+ and Remote Authentication Dial-In User Service (RADIUS) are capable of providing AAA security services. Compared with RADIUS, TACACS+ has the following advantages:

- It is implemented based on the Transmission Control Protocol (TCP) and provides more reliable network transmission.
- TACACS+ encrypts both packet bodies and passwords to boost security.
- Authentication is separated from authorization. The authentication server and authorization server can be deployed separately in remote deployment.
- TACACS+ supports authorization and accounting on configuration commands.

1.1.2 Principles

1. TACACS+ Packet

Figure 1-1 TACACS+ Packet Structure

Fields contained in the TACACS+ packet structure shown in Figure 1-1 are described in Table 1-1.

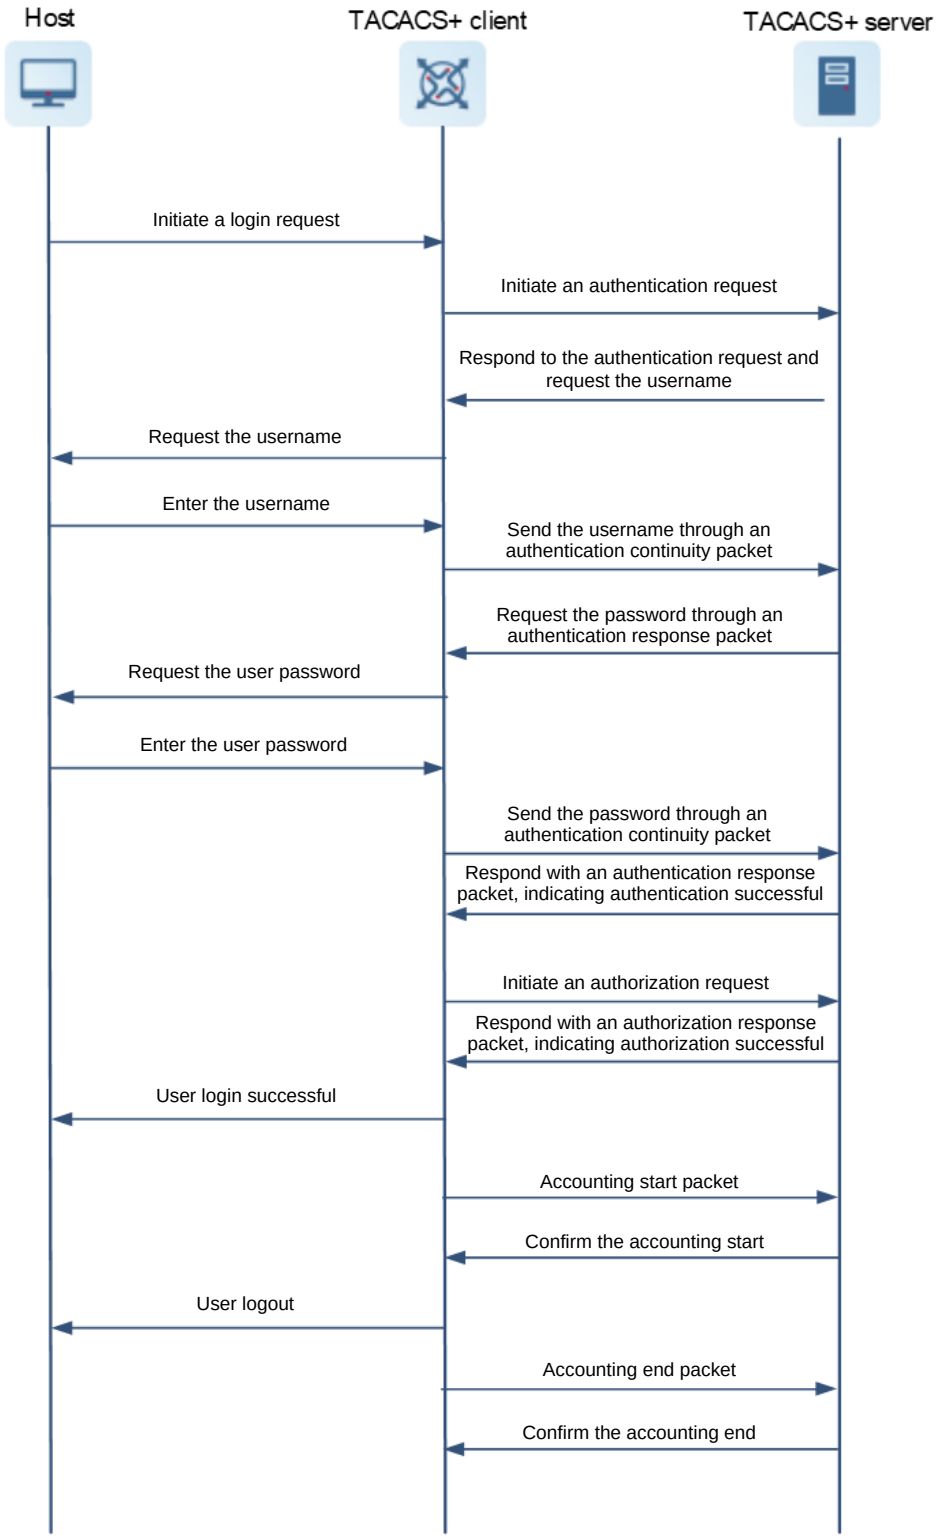


Table 1-1 Description of Fields Contained in a TACACS+ Packet

Field	Length	Description
Major Version	4 bits	Major TACACS+ version
Minor Version	4 bits	Minor TACACS+ version

Field	Length	Description
Packet Type	1 byte	Packet type. The options are as follows: **0x01**: Indicates an authentication packet. **0x02**: Indicates an authorization packet. **0x03**: Indicates an accounting packet.
Sequence Number	1 byte	Sequence number of a data packet in the current session (The sequence number of the first TACACS+ data packet in a session must be 1 and the sequence number of each subsequent data packet increases by one. The client sends data packets only with an odd sequence number and TACACS+ Daemon sends data packets only with an even sequence number.)
Flags	1 byte	Whether the data packet is encrypted
Session ID	4 bytes	TACACS+ session ID
Length	4 bytes	Body length of a TACACS+ data packet (excluding the header)

2. Packet Exchange Process

Figure 1-2 TACACS+ Packet Exchange Flowchart

As shown in Figure 1-2, the TACACS+ protocol basically involves the authentication, authorization, and accounting processes. The network access server (NAS) requests security services from the TACACS+ server as a TACACS+ client.

(1) Authentication process

a A user initiates a login request to the NAS.

b After receiving the user request, the NAS sends an authentication start packet to the TACACS+ server to initiate an authentication request.

c The TACACS+ server responds to the authentication request and asks the NAS to provide the username.

d The NAS asks the user terminal to provide the username.

e The user enters the username and sends it to the NAS.

f The NAS sends the username to the TACACS+ server through an authentication continuity packet.

g After receiving the username, the TACACS+ server continues to ask the NAS for the user password.

h The NAS requests the user terminal to provide the password.

i The user enters the password and sends it to the NAS.

j The NAS sends the password to the TACACS+ server through an authentication continuity packet.

k After receiving the password, the TACACS+ server verifies the password and then returns an authentication success message to the NAS.

(2) Authorization process

a The NAS initiates an authorization request to the TACACS+ server.

b The TACACS+ server responds to the authorization request by returning an authorization success message to the NAS.

c After receiving the authorization success message, the NAS allows the user to log in to the NAS and perform operations within the authorized scope.

(3) Accounting process

a The NAS sends an accounting start request to the TACACS+ server.

b After receiving the accounting start request, the TACACS+ server starts accounting and returns an accounting request acceptance message to the NAS.

c If the user logs out, the NAS sends an accounting end request to the TACACS+ server after receiving a user logout message.

d After receiving the accounting end request, the TACACS+ stops accounting and returns an accounting end message.

1.1.3 Protocols and Standards

- RFC 1492: Terminal Access Controller Access Control System

1.2 Configuration Task Summary

TACACS+ configuration includes the following tasks:

- Configuring TACACS+ Basic Features

- (Optional) Configuring TACACS+ Reachability Detection
- (Optional) Configuring a TACACS+ Server Group

1.3 Configuring TACACS+ Basic Features

1.3.1 Overview

This section describes how to configure parameters for the communication between the device and a TACACS+ server to ensure normal communication between them. After the parameters are configured, the device can correctly send AAA authentication, authorization, and accounting requests to the TACACS+ server and give responses.

1.3.2 Restrictions and Guidelines

Configuring TACACS+ basic features only ensures proper communication between the device and a TACACS+ server. To provide AAA security services for users, you still need to reference the TACACS+ server in an AAA method list.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable AAA.

aaa new-model

(4) Configure a TACACS+ server.

tacacs-server host [**oob** [**via mgmt** *interface-number*]] { *ipv4-address* | *ipv6-address* } [**port** *port-number* | **single-connection** | **test username** *username* [**idle-time** *idle-time*] | **timeout** *timeout*] * [**key** [**0** | **7**] *key*]

No TACACS+ server is configured by default.

You can specify a shared key for a TACACS+ server when configuring the server. If it is not specified, the global shared key will be used.

(5) (Optional) Configure the global shared key for the communication between the device and TACACS+ server.

tacacs-server key [**0** | **7**] *key*

No global shared key is configured for the device and TACACS+ server by default.

(6) (Optional) Configure the source address for TACACS+ packets.

ip tacacs source-interface *interface-type interface-number*

No source address is configured for TACACS+ packets and the address is set by the network layer by default.

You can run this command to specify an outbound interface for packets. After this command is configured, the first IP address of the interface is used as the source address of TACACS+ packets.

(7) (Optional) Configure the timeout duration for the TACACS+ server.

tacacs-server timeout *timeout*

The default timeout duration of a TACACS+ server is **5** seconds in the communication between the device and the TACACS+ server.

(8) (Optional) Configure the maximum keepalive time of TCP sessions in single-connection mode.

tacacs-server single-connect-timeout *single-connect-timeout*

By default, the maximum keepalive time of TCP sessions in single-connection mode is 30 minutes.

When the device communicates with a TACACS server in single-connection mode, the device actively tears down the connection if the TCP session exceeds the maximum keepalive time. If the device needs to communicate with the TACACS server again, it should set up the TCP session again.

1.4 Configuring TACACS+ Reachability Detection

1.4.1 Overview

A TACACS+ server can be only in the reachable or unreachable state. The device will not send authentication, authorization, or accounting requests of access users to an unreachable TACACS+ server unless all servers in the TACACS+ server group are unreachable.

The device maintains the reachability status of each TACACS+ server. The device selects a reachable TACACS+ server preferentially to improve the handling performance of TACACS+ services.

The device actively detects whether a specified TACACS+ server is reachable. After the active detection function is configured for a TACACS+ server, the device periodically sends detection requests (authentication requests or accounting requests) to the TACACS+ server. The active detection interval is **60** minutes when the TACACS+ server is reachable and **1** minute when the TACACS+ server is unreachable.

1.4.2 Restrictions and Guidelines

- To enable active detection for a specified TACACS+ server, perform the following configuration when configuring the TACACS+ server:
  - Configure a test username for the TACACS+ server.
  - Configure at least one tested port (authentication port or accounting port) for the TACACS+ server.
- It is judged that a TACACS+ server is unreachable only when both conditions below are met:
  - The device fails to receive a correct response packet from the TACACS+ server within the specified timeout period.
  - The consecutive transmission count of a request packet sent by the device to the same TACACS+ server reaches the specified timeout count.
- If any of the following conditions is met for an unreachable TACACS+ server, the TACACS+ server is considered reachable:
  - The device receives a correct response from the TACACS+ server.
  - The duration in which the TACACS+ server is unreachable exceeds the time configured using the **tacacs-server deadtime** command and active detection is disabled for the TACACS+ server.
  - The authentication port or accounting port of the TACACS+ server is updated on the device.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the criteria for the device to judge that a TACACS+ server is unreachable.

tacacs-server dead-criteria { **time** *timeout* **tries** *tries-number* | **time** *timeout* | **tries** *tries-number* }

The criteria for the device to judge that a TACACS+ server is unreachable are that the server timeout duration is **60** seconds and the consecutive timeout count is **10** by default.

(4) (Optional) Configure the duration for the device to stop sending request packets to an unreachable TACACS+ server.

tacacs-server deadtime *deadtime*

Even if a TACACS+ server is unreachable, the device still sends requests to the TACACS+ server by default.

If active detection is enabled for a TACACS+ server, the time parameter configured by the **tacacs-server deadtime** command does not take effect on the TACACS+ server.

1.5 Configuring a TACACS+ Server Group

1.5.1 Overview

One or more TACACS+ servers can be added to each TACACS+ server group, which provides AAA services for users as a whole.

1.5.2 Restrictions and Guidelines

- TACACS+ security services are a type of AAA services and need to be used in combination with the AAA features. TACACS+ provides security services for users as one method in an AAA method list.
- When configuring the authentication, authorization, and accounting method lists, you can specify server groups separately for them.
- In a user-defined server group, you can only specify and apply servers in the default server group.
- TACACS+ server groups support virtual routing and forwarding (VRF) instances. When a server group in a specified VRF instance is used, the source address used by the device to communicate with a remote server must be obtained from the VRF instance. If you run the **ip tacacs+ source-interface** command to specify the source interface for request packets, the IP address obtained from this source interface takes priority over that found in the VRF instance.
- The name of a server group cannot be set to the predefined keyword **tacacs+**.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a TACACS+ server group.

aaa group server tacacs+ *group-name*

No TACACS+ server group is configured by default.

You can group TACACS+ servers so that authentication, authorization, and accounting can be completed by different server groups.

(4) Add a server to the TACACS+ server group.

server { *ipv4-address* | *ipv6-address* } [**single-connection**]

No server is added to a TACACS+ server group by default.

(5) (Optional) Specify a VRF instance for the TACACS+ server group.

ip vrf forwarding *vrf-name*

No VRF instance is specified for a TACACS+ server group by default.

The VRF instance configured for a TACACS+ server group must use a valid name configured using the **vrf definition** command in global configuration mode.

(6) Configure an MGMT port to be used by the TACACS+ server group.

ip oob [**via mgmt** *interface-number*]

No MGMT port to be used by a TACACS+ server group is configured by default.

(7) (Optional) Configure the function of carrying the **nas-ip** attribute in packets.

nas-ip { *ipv4-address* | *ipv6-address* }

Packets do not carry the **nas-ip** attribute by default.

1.6 Monitoring

Run the **show** commands to check the configuration.

Run the **debug** commands to output debugging information.

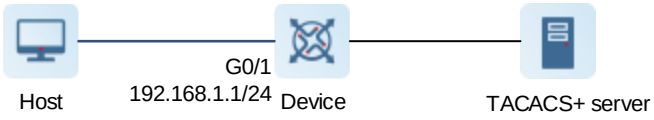
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-2 TACACS+ Monitoring

Command	Purpose
show tacacs	Displays the interaction between the device and each TACACS+ server.
show tacacs server	Displays statistics on a TACACS+ server group.
debug tacacs+	Debugs TACACS+.

1.7 Configuration Examples



1.7.1 Configuring TACACS+ for Login Authentication

1. Requirements

A TACACS+ server needs to be used for authentication of login users.

2. Topology

Figure 1-3 Topology of Login Authentication Using TACACS+

3. Notes

- Configure device information and add login users on the TACACS+ server.
- Enable AAA security services on the device.
- Configure TACACS+ server information on the device.
- Configure a TACACS+ authentication method list.
- Apply the TACACS+ authentication methods to a specific line.

4. Procedure

(1) Configure device information and add login users on the TACACS+ server. The configuration is omitted here. For details, see the TACACS+ server configuration.

(2) Enable AAA security services.

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
```

(3) Configure a TACACS+ server (the IP address of the TACACS+ server is set to 192.168.1.3 and the shared key is set to **sharekey** here).

```
Device(config)# tacacs-server host 192.168.1.3 key sharekey
```

(4) Configures an authentication method list.

```
Device(config)# aaa authentication login tacacs-method group tacacs+
```

(5) Apply the authentication methods to a line.

```
Device(config)# line vty 0 4
Device(config-line)# login authentication tacacs-method
```

5. Verification

After entering the correct username and password, a user can log in to the device successfully.

```
User Access Verification

Username:hostname1
```

```
Password: Abc123456

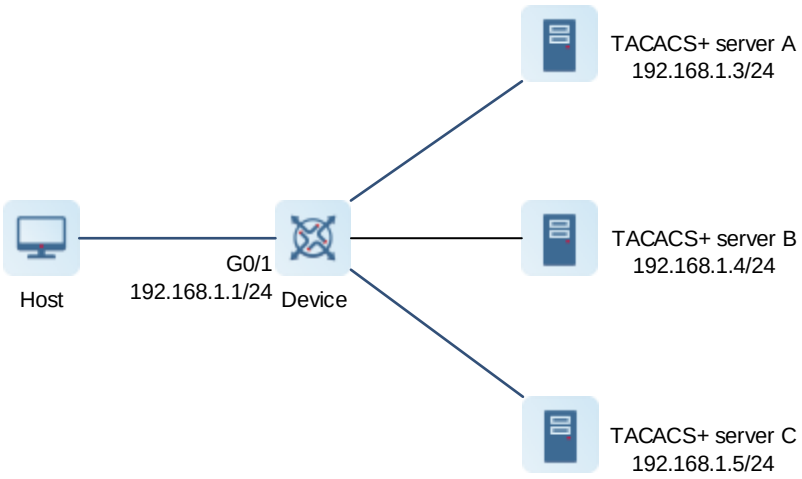
Device#
```

6. Configuration Files

```
!
aaa new-model
!
aaa authentication login tacacs-method group tacacs+
!
tacacs-server host 192.168.1.3 key 7 $10$275$g8oXDDIPVeA=$
!
line console 0
line vty 0 4
login authentication tacacs-method
!
```

7. Common Errors

The shared key configured on the device is inconsistent with that used by the TACACS+ server.



1.7.2 Configuring Separated Authentication, Authorization and Accounting by Using TACACS+

1. Requirements

The user authentication, authorization, and accounting services need to be separately completed by different TACACS+ server groups.

2. Topology

Figure 1-4 Topology of Separated Authentication, Authorization, and Accounting of TACACS+

3. Notes

- Configure device information and add login users on the TACACS+ server.

- Enable AAA securityservices on the device.
- Configure TACACS+ servers on the device and add them to different TACACS+ server groups.
- Configure TACACS+ authentication, authorization, and accounting method lists.
- Apply the TACACS+ authentication, authorization, and accounting methods to a specific line.

4. Procedure

(1) Configure device information and add login users on the TACACS+ server. The configuration is omitted here. For details, see the TACACS+ server configuration.

(2) Enable AAA securityservices.

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
```

(3) Configure TACACS+ server A and add it to TACACS+ server group **tacacs1**. (The IP address of TACACS+ server A is set to 192.168.1.3 and the shared key is set to **sharekey** here.)

```
Device(config)# tacacs-server host 192.168.1.3 key sharekey
Device(config)# aaa group server tacacs+ tacacs1
Device(config-gs-tacacs+)# server 192.168.1.3
Device(config-gs-tacacs+)# exit
```

(4) Configure server groups **tacacs2** and **tacacs3** by referring to the steps of configuring server group **tacacs1**.

```
Device(config)# tacacs-server host 192.168.1.4 key sharekey
Device(config)# aaa group server tacacs+ tacacs2
Device(config-gs-tacacs+)# server 192.168.1.4
Device(config-gs-tacacs+)# exit
Device(config)# tacacs-server host 192.168.1.5 key sharekey
Device(config)# aaa group server tacacs+ tacacs3
Device(config-gs-tacacs+)# server 192.168.1.5
Device(config-gs-tacacs+)# exit
```

(5) Configure an authentication method list to use server group **tacacs1**, an authorization method list to use server group **tacacs2**, and an accounting method list to use server group **tacacs3**.

```
Device(config)# aaa authentication login tacacs-method group tacacs1
Device(config)# aaa authorization exec radius-method group tacacs2
Device(config)# aaa accounting exec radius-method start-stop group tacacs3
```

(6) Apply the authentication methods, authorization methods, and accounting methods to a line.

```
Device(config)# line vty 0 4
Device(config-line)# login authentication tacacs-method
Device(config-line)# authorization exec radius-method
Device(config-line)# accounting exec radius-method
```

5. Verification

After entering the correct username and password configured on TACACS+ server A, a user can log in to the device successfully.

```
User Access Verification
```

```
Username:hostname1
Password: Abc123456

Device#
```

After login, the user has only the privilege level granted by TACACS+ server B and can only run commands under this privilege level.

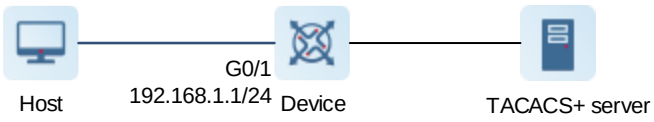
After the user logs out, accounting information of the user can be queried on TACACS+ server C. For details about how to query accounting information, see the TACACS+ server configuration.

6. Configuration Files

```
!
aaa new-model
!
aaa accounting exec radius-method start-stop group tacacs3
aaa authorization exec radius-method group tacacs2
aaa authentication login radius-method group tacacs1
!
tacacs-server host 192.168.1.3 key 7 $10$275$g8oXDDIPVeA=$
tacacs-server host 192.168.1.4 key 7 $10$275$g8oXDDIPVeA=$
tacacs-server host 192.168.1.5 key 7 $10$275$g8oXDDIPVeA=$
!
!
aaa group server tacacs+ tacacs1
 server 192.168.1.3
!
aaa group server tacacs+ tacacs2
 server 192.168.1.4
!
aaa group server tacacs+ tacacs3
 server 192.168.1.5
!
line console 0
line vty 0 4
 accounting exec radius-method
 authorization exec radius-method
 login authentication tacacs-method
!
```

7. Common Errors

- The shared key configured on the device is inconsistent with that used by the TACACS+ server.
- Undefined servers are added to a server group.



1.7.3 Configuring Reachability Detection

1. Requirements

TACACS+ reachability detection needs to be configured to identify unreachable TACACS+ servers.

1. Topology

Figure 1-5 Topology of TACACS+ Reachability Detection

2. Notes

- Configure the global criteria for judging that a TACACS+ server is unreachable.
- Configure an IP address for the TACACS+ server and configure active detection parameters.

3. Procedure

Configure the global criteria for judging that a TACACS+ server is unreachable as follows: The consecutive timeout count is **5** and the timeout duration is **120** seconds.

```
Device> enable
Device# configure terminal
Device(config)# radius-server dead-criteria time 120 tries 5
```

Set the IP address of the TACACS+ server to 192.168.1.3, detection username to **test**, detection interval to **90** minutes.

```
Device(config)# tacacs-server host 192.168.1.3 test username test idle-time 90
```

4. Verification

Disconnect the network communication between the device and the server with the IP address 192.168.1.3. Initiate TACACS+ authentication through the device. After 120 seconds, run the **show tacacs** command to check that the server status is "Dead".

```
Device# show tacacs
Tacacs+ Server : 192.168.1.3/49
state: dead
Socket Opens: 0
Socket Closes: 0
Total Packets Sent: 0
Total Packets Recv: 0
Reference Count: 1
Single-connection: no

Tacacs capability:
   mgmt enable: true
   vrf enable: true
```

5. Configuration Files

```
!
tacacs-server host 192.168.1.3 test username test idle-time 90
tacacs-server dead-criteria time 120 tries 5
!
```

1 Configuring IEEE 802.1X

1.1 Introduction

1.1.1 Overview

In a local area network (LAN) in compliance with the Institute of Electrical and Electronics Engineers (IEEE) 802 standards, users can connect to network devices to access network resources without authentication and authorization. This access mode does not pose obvious security problems in the early enterprise network application environment. However, with the large-scale development of applications such as mobile office and customer premises network (CPN) operation, this uncontrolled behavior brings great security risks. For this, IEEE develops the 802.1X protocol to solve LAN security problems.

IEEE 802.1X is a port-based network access control standard used to provide secure access services for LANs. This protocol complies with the authentication, authorization and accounting (AAA) security management mechanism. It is usually deployed on user access networks to provide port-based user AAA functions for network administrators.

1.1.2 Principles

1. Basic Concepts

- User

  Users usually refer to clients that need to access network resources. In an IEEE 802.1X wired environment, the MAC address and VLAN ID attributes of each user are unique for user differentiation. All other information (such as the account number and IP address) is changeable for users.

- RADIUS

  Remote Authentication Dial In User Service (RADIUS) is a remote authentication protocol applied widely to send authentication information between network devices and RADIUS servers. In actual IEEE 802.1X deployment, this protocol can be used to remotely deploy authentication servers.

- Timeout

  Timeout occurs when a device does not receive any response from a client or server within a specified period of time.

  The device needs to exchange packets with clients and servers during authentication. In response to unexpected factors such as network unavailability, a protocol sets the timeout duration for each exchange step. Each role needs to respond within the timeout duration during authentication. Otherwise, an authentication failure maybe caused.

- EAP

  Extensible Authentication Protocol (EAP) carries IEEE 802.1X authentication information.

  EAP provides a universal authentication framework, which supports multiple authentication methods, such as the message digest 5 (MD5) authentication, Challenge-Handshake Authentication Protocol (CHAP) authentication, Password Authentication Protocol (PAP) authentication, and Transport Layer Security (TLS) authentication. Ruijie IEEE 802.1X module supports the MD5, CHAP, PAP, Protected Extensible

Authentication Protocol with Microsoft Challenge Handshake Authentication Protocol (PEAP-MSCHAP), and TLS authentication methods.

- EAPOL

  EAP over LAN (EAPOL) is the encapsulation of EAP on a LAN.

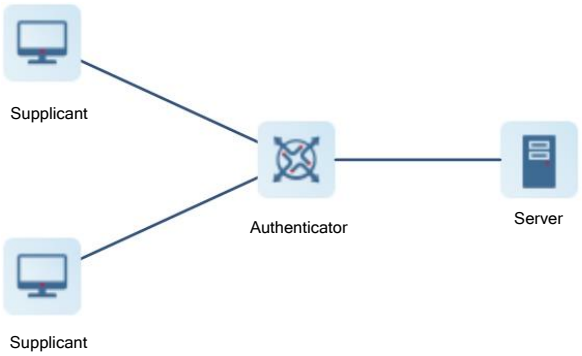
  EAPOL encapsulates packets based on the media access control (MAC) layer. The type number is 0x888E. The IEEE 802.1X standard assigns a multicast MAC address 01-80-C2-00-00-03 to the protocol to send packets in the initial authentication process. Ruijie authentication clients may use 01-D0-F8-00-00-03 as the multicast destination address at the beginning of authentication.

- EAPOR

  EAP over RADIUS (EAPOR) is the encapsulation of EAP over RADIUS.

  EAP packets are relayed by network devices. A network device encapsulates EAP packets into RADIUS packets over EAPOR and sends the packets to a RADIUS server for authentication.

2. Authentication



Authentication is a process of verifying user identities and determining whether a user has the legitimate permission to access network resources.

The basic principles of IEEE 802.1X authentication are as follows: A user submits the account and password to an authentication server through a network access server (NAS). The authentication server verifies the account and password. Only users who pass the authentication can obtain network access permissions.

- Authentication roles

  An IEEE 802.1X standard authentication system consists of three roles: supplicant, authenticator, and server, which correspond to the client, NAS, and authentication server (usually RADIUS server) in actual application.

Figure 1-1 Authentication Roles

- Supplicant

  A supplicant is an end user who requests to access network resources. A supplicant is usually a PC.

  A supplicant needs to submit information used for authentication to an authenticator and respond to requests from the authenticator. According to the IEEE 802.1X protocol, a supplicant must run software in compliance with the IEEE 802.1X client standard and the software is responsible for submitting the account and password during authentication. The most typical software is the IEEE 802.1X client embedded in the operating system (OS). You can also use client software developed by vendors such as Ruijie RG Supplicant.

- Authenticator

  An authenticator is a NAS that manages supplicants' authentication status and network connection status. An authenticator is usually a switch.

  An authenticator acts as an intermediary between a supplicant and an authentication server. It obtains the account and password used for authentication from a supplicant, and sends them to an authentication server. The authenticator also obtains authentication-related information from the authentication server and sends the information to the supplicant.

- Authentication server

  An authentication server provides the authentication service for users. An authentication server is usually a RADIUS server.

  An authentication server stores legitimate user information and users' authorization information. It checks whether a user is legitimate by verifying the account and password submitted by a supplicant, and manages accounting data submitted by an authenticator. One authentication server can provide the authentication service for multiple supplicants to implement centralized management of users.

- Port type

  There are two types of ports on the device that serves as an authenticator: controlled port and uncontrolled port.

  Users connected to a controlled port can access network resources only after passing authentication. Otherwise, the users can only transmit packets used for authentication. Users connected to an uncontrolled port can access network resources without authentication. The access to network resources needs to be controlled for supplicants and therefore, supplicants need to be connected to controlled ports. Network permission control is not required for authentication servers, and therefore, they need to be connected to uncontrolled ports.

- Authentication process

  A supplicant and an authenticator exchange information through the EAPOL protocol, and an authenticator and an authentication server exchange information through the EAPOR protocol.

  The figure below shows a typical IEEE 802.1X authentication process.

Figure 1-2 Authentication Packet Exchange

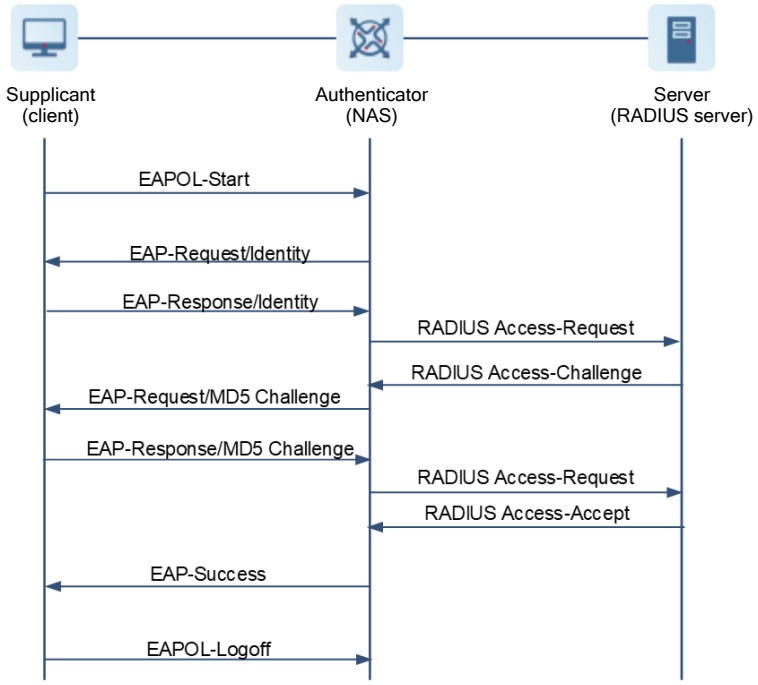


Figure 1-2 shows a typical user-initiated authentication process.

a A user starts the IEEE 802.1X client application on a client and enters the account and password. The client initiates an authentication request to a NAS. So the client sends an authentication request frame (EAPOL-Start) to the NAS.

b After receiving the frame, the NAS sends an EAP request frame of the identity type (EAP-Request/Identity) to the client, asking the client to provide the account for authentication.

c After receiving the request frame from the NAS, the client sends the account to the NAS through a response frame of the identity type (EAP-Response/Identity).

d After receiving the response frame from the client, the NAS retrieves the EAP packet from the frame, encapsulates the EAP packet into a RADIUS packet (RADIUS Access-Request), and sends the packet to an authentication server for processing.

e After receiving the Access-Request packet from the NAS, the authentication server parses the account and encrypts the password corresponding to the username by using a randomly generated MD5 Challenge to obtain the encrypted password. The authentication server sends the MD5 Challenge to the NAS through a RADIUS Access-Request packet.

f The NAS forwards the MD5 Challenge sent by the RADIUS server to the client.

g The client encrypts the local password by using the received MD5 Challenge and sends the encrypted password to the NAS through an EAP-Response/MD5 packet.

h The NAS encapsulates the received EAP-Response/MD5 packets into a RADIUS Access-Request packet and sends the packet to the authentication server.

i The authentication server retrieves the encrypted password from the RADIUS Access-Request packet and compares it with the encrypted password obtained in step e. If they are the same, the authentication

server considers the user legitimate and returns an authentication success packet (RADIUS access-Accept) to the NAS.

j After receiving the packet, the NAS sends an authentication success frame (EAP-Success) to the client, changes the port status to the authorized state, and allows the user to access the network through the port.

In special cases (for example, authentication is performed immediately when a user connects to a network), the NAS may actively initiate an authentication request and the step that a user actively initiates a request is skipped.

- User status during authentication

  All users connected to uncontrolled ports can use network resources. Whether users connected to controlled ports can access network resources depends on their authentication status. A user connected to a controlled port cannot access the network when just initiating authentication, and the user is in the unauthorized state. After passing authentication, the user can access the network normally and the status changes to authorized.

  On an IEEE 802.1X-supported network device, all ports are uncontrolled ports by default. You can configure a port as a controlled port to enable all users connected to the port to pass authentication before accessing the network.

  Common user authentication states and behaviors are described as follows:

  - If a user is still in the unauthorized state due to an authentication failure, the user can initiate authentication again.
  - If the network between the NAS and the authentication server is unreachable, a user connected to the NAS is in the unauthorized state.
  - After a user sends an EAPOL-LOGOFF packet, the user transitions from the authorized state to the unauthorized state.
  - When a port on an NAS changes to the LINK-DOWN state, all users connected to the port transition to the unauthorized state.
  - When the NAS is restarted, all users served by the NAS transitions to the unauthorized state.
  - If a client does not support IEEE 802.1X and is connected to a controlled port, the client cannot respond to requests from the NAS and cannot complete authentication. The client is always in the unauthorized state and cannot access network resources.
  - If a client supports IEEE 802.1X but the NAS does not, the NAS does not respond to the EAPOL-Start frame from the client. If the client still receives no response after sending a certain number of EAPOL-Start frames, the client considers the access port as an uncontrolled port and accesses network resources directly.

- Deploying an authentication server

  Ruijie IEEE 802.1X module is compatible with RADIUS servers. RADIUS servers can be used for environment deployment, such as Ruijie SAM/SMP, Microsoft IAS/NPS, and Cisco ACS and Free RADIUS Server.

- Configuring authentication parameters

  To make IEEE 802.1X on an NAS take effect, complete the following configuration:

a Configure RADIUS server parameters to ensure the network between the NAS and the RADIUS server is reachable.

b Ensure that the server timeout duration of IEEE 802.1X is greater than that of RADIUS.

c Configure and apply an AAA method list.

d Enable IEEE 802.1X authentication on the access port.

- Supplicant

  A supplicant refers to IEEE 802.1X-compliant client software installed on a terminal. A user can start the Supplicant software on a terminal and enter the account to initiate authentication.

  If a terminal uses the client embedded in the OS, when the network is available, the terminal automatically displays a dialog box, asking you to enter the account and password for authentication. The implementation and UI operation methods of different client software may be different. You are advised to use Ruijie Supplicant software as the authentication client. If you use other software, see relevant software instructions.

- Going offline

  When stopping accessing network resources, a user can go offline by shutting down the client, disconnecting the network, or logging out of Supplicant.

3. Authorization

Authorization refers to binding specified services to authenticated users, for example, binding an IP address, VLAN, access control list (ACL), quality of service (QoS), available Internet access time range, and available bandwidth. A user is identified by MAC address and VLAN ID (VID). Authorization is actually to add permission information on the basis of MAC address and VLAN ID, such as bound IP address and accessible VLANs.

- IP authorization

  The IEEE 802.1X authentication standard cannot identify IP information. Ruijie IEEE 802.1X module extends the application of IEEE 802.1X and supports MAC+IP binding, which is called IP authorization.

  IP authorization supports four modes:

  - Supplicant authorization: An IP address is provided by Supplicant and this authorization mode needs to be used in combination with Ruijie Supplicant.
  - RADIUS authorization: An IP address is delivered by a RADIUS server to the device after the authentication succeeds.
  - Dynamic Host Configuration Protocol (DHCP) authorization: An authenticated client initiates a DHCP request. After obtaining an IP address, the device binds the IP address with the client's MAC address. DHCP authorization applies to a dynamic IP address environment.
  - Mixed authorization: Authenticated clients select an IP authorization mode based on the sequence of Supplicant authorization, RADIUS authorization, and DHCP authorization, and then the device completes MAC+IP binding. That is, the IP address provided by Supplicant is preferentially used, followed by the IP address assigned by a RADIUS server. The IP address assigned by DHCP is used only when neither of the preceding two IP addresses exists.

- ACL authorization

  ACL authorization means that a server delivers specific ACL services to authenticated users.

ACL authorization is delivered based on RADIUS attributes and supports standard attributes, Ruijie private attributes, and Cisco private attributes. For details, see the RADIUS server configuration.

- Kicking users offline

  Kicking users offline is to force users to go offline. When Ruijie IEEE 802.1X module is used together with Ruijie SAM/SMP, servers can kick online users offline. Then, the users cannot access the network. This function applies to scenarios, in which the Internet access time range needs to be controlled and Internet access charges need to be checked in real time.

4. Accounting

The accounting function is used to audit Internet access behaviors and charges of access users (including auditing the online duration and traffic).

To make the accounting function take effect, configure the accounting function on the device and ensure that the RADIUS server supports the accounting audit function defined in RFC2869.

When a user goes online, the device sends an accounting start packet to the server and the server starts accounting. When the user goes offline, the device sends an accounting end packet to the server, and the server completes an audit and generates an Internet access fee audit list.

Caution

The implementation of the accounting function may vary with servers and not all servers support the accounting function. Therefore, refer to the server usage instructions during actual deployment.

- Accounting start

  After a user passes authentication, the device sends an accounting start packet to the server. After receiving the packet, the server starts the accounting for the user.

  The accounting start packet carries accounting attributes of the user, such as the username and accounting ID.

- Accounting update

  The device periodically sends accounting update packets to the server, making the accounting on the server more real-time.

  The interval for sending accounting update packets can be configured on the device or delivered by the server.

- Accounting end

  After a user logs out, the device sends an accounting end packet to the server. The accounting end packet carries the online duration and traffic of the user. The server generates Internet access records based on the information.

1.1.3 Protocols and Standards

- IEEE 802.1X: Port-Based Network Access Control
- RFC 2869: RADIUS Extensions

1.2 Configuration Task Summary

IEEE 802.1X configuration includes the following tasks:

(1) Configuring IEEE 802.1X Basic Features

(2) (Optional) Configuring IEEE 802.1X Parameters. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Re-authentication
- Configuring Packet Retransmission Parameters
- Configuring the Server Timeout Duration
- Configuring the Quiet Period After an Authentication Failure
- Configuring the Authentication Mode
- Configuring Ruijie Client Detection
- Configuring Automatic Domain Name Supplement for 802.1X Users

(3) (Optional) Configuring Authorization

(4) (Optional) Configuring MAB. Select any of the following configuration tasks to configure.

- Configuring Single-User MAB
- Configuring Multi-User MAB

(5) (Optional) Configuring MAB Parameters. All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Username Format for MAB
- Configuring the Username Uppercase/Lowercase for MAB
- Enabling Domain Name Completion for MAB Users
- Configuring MAB VLAN
- Configuring the MAB Timeout Duration
- Enabling Fast MAB
- Configuring a Permanent License
- Configuring MAB Users to Initiate Authentication After Obtaining an IP Address

(6) (Optional) Configuring IAB

(7) (Optional) Configuring the Port Control Mode

(8) (Optional) Configuring Automatic Dynamic VLAN Redirection on IEEE 802.1X Ports

(9) (Optional) Configuring the Guest VLAN Function

(10) (Optional) Configuring the Auth Fail VLAN Function

(11) (Optional) Configuring Extended Features. All the configuration tasks below are optional. Select the configuration tasks as required.

- Enabling Active Authentication
- Configuring a List of Hosts Allowed for Authentication
- Disabling the Virtual Source MAC Address Function

- Configuring Multi-Account Authentication with One MAC Address
- Configuring the Maximum Number of Users Who Can Be Authenticated on an Interface
- Configuring the Function of Initiating Accounting After an IP Address Is Obtained
- Configuring the Priority Order of IEEE 802.1X and MAB
- Configuring the Accounting Update Period
- Configuring Compatibility with H3C Clients and Servers
- Disabling the Global IEEE 802.1X Features
- Enabling Perception-free Migration Across VLANs for 802.1X Users
- Configuring the Function of Instantly Sending Accounting Update Packets Upon IP Address Changes of 802.1X Authenticated Users
- Converting User Names into TEXT Format
- Compatible with Third-Party Clients
- Recording Debugging Information to a File
- Configuring the Maximum Number of EAP-Success Packets Sent by a Device

1.3 Configuring IEEE 802.1X Basic Features

1.3.1 Overview

This section describes how to enable 802.1X features to provide basic authentication and accounting services.

1.3.2 Restrictions and Guidelines

- In interface configuration mode, you can enable/disable IEEE 802.1X authentication on the interface.
- Configure RADIUS parameters accurately to ensure that the basic RADIUS communication is proper. Configure an IP address and a protocol communication port for the authentication server as well as the encrypted key used for the communication between the NAS and the RADIUS server.
- The IEEE 802.1X authentication method list and accounting method list must be configured in AAA. Otherwise, an error may occur in authentication and accounting.
- IEEE 802.1X uses default method lists by default. To use other method lists, run the **dot1x authentication** and **dot1x accounting** commands to apply the method lists to be used by IEEE 802.1X.
- You can run the **aaa accounting update** command in global configuration mode to enable the accounting update function. The accounting update interval can be configured using the **aaa accounting update periodic** command or delivered by the server. If delivered by the server, the parameter configuration delivered by the server is used preferentially. If the server does not deliver the parameter configuration, the local configuration is used. For details about the accounting update function, see *Configuring AAA*.
- If IEEE 802.1X is enabled on a port and the number of authenticated users exceeds the maximum number of users supported by port security, port security cannot be enabled. For details about port security, see *Configuring Port Security*.
- When both port security and IEEE 802.1X are enabled, if the address of port security ages, IEEE 802.1X-authenticated users must be re-authenticated before making further communication.
- Users using static IP addresses or complying with IP+MAC binding can access the network without

authentication.

- When Ruijie SAM/SMP software is used together, the accounting function must be configured. Otherwise, the server cannot perceive users going offline.

1.3.3 Prerequisites

Complete required configuration (such as account configuration) on the authentication server to ensure smooth authentication. For details, see the authentication server configuration.

1.3.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable AAA security services.

aaa new-model

The AAA security services are disabled by default.

(4) Create an IEEE 802.1X authentication method list and an accounting method list.

a Create an IEEE 802.1X authentication method list.

aaa authentication dot1x { **default** | *list-name* } { *method* }&<1-4>

No IEEE 802.1X authentication method list is configured by default.

b Create an IEEE 802.1X accounting method list.

aaa accounting network { **default** | *list-name* } **start-stop** { *method* }&<1-4>

No IEEE 802.1X accounting method list is configured by default.

(5) (Optional) Configure RADIUS server parameters.

This step is mandatory if the authentication and accounting methods use a RADIUS server.

a Configure a RADIUS server.

radius-server host [**oob** [**via Mgmt** *Mgmt_number*]] { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number* | **acct-port** *acct-port-number*] * [**test username** *username* [**ignore-acct-port**] [**ignore-auth-port**] [**idle-time** *idle-time*]] [**key** [**0** | **7**] *text-string*]

No RADIUS server is configured by default.

b Configure a shared key for the communication between the device and the RADIUS server.

radius-server key [**0** | **7**] *text-string*

No shared key for the communication between the device and a RADIUS server is configured by default.

(6) Apply the IEEE 802.1X authentication method list and accounting method list.

a Apply the IEEE 802.1X authentication method list.

dot1x authentication { **default** | *list-name* }

b Apply the IEEE 802.1X accounting method list.

dot1x accounting { **default |** *list-name* }

(7) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the batch Layer 2 Ethernet interface configuration mode.

  interface range *ethernet-type interface-number*

- Enter the batch Layer 2 link aggregation configuration mode.

  interface range aggregateport *interface-number*

(8) (Optional) Apply 802.1x authentication method list and accounting method list on interface. If the commands are not run on interfaces, the global configuration takes effect.

- Apply 802.1x authentication method list on an interface.

  dot1x authentication { **default** | *list-name* }

- Apply 802.1x accounting method list on an interface.

  dot1x accounting { **default |** *list-name* }

(9) Enable IEEE 802.1X authentication.

dot1x port-control auto

1.4 Configuring IEEE 802.1X Parameters

1.4.1 Overview

After IEEE 802.1X basic features are configured, you may need to adjust protocol parameter configuration based on the actual deployment and network status.

1.4.2 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Re-authentication
- Configuring Packet Retransmission Parameters
- Configuring the Server Timeout Duration
- Configuring the Quiet Period After an Authentication Failure
- Configuring the Authentication Mode
- Configuring Ruijie Client Detection
- Configuring Automatic Domain Name Supplement for 802.1X Users

1.4.3 Configuring Re-authentication

1. Overview

Re-authentication refers that a device periodically requests users to perform re-authentication.

Re-authentication prevents authenticated users from being pretended by other users, and detects whether they are offline, making the accounting more accurate.

2. Restrictions and Guidelines

- After re-authentication is enabled, the device can periodically re-authenticate online users. Re-authentication brings great burden to the server. You are advised to disable this function in the existence of considerable users.
- The re-authentication function can be enabled/disabled, and the re-authentication interval can be configured. In duration-based accounting scenarios, determine the re-authentication interval based on the network scale to ensure reasonable interval and accurate accounting.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable re-authentication.

dot1x re-authentication

The re-authentication function is disabled by default.

(4) (Optional) Configure the re-authentication interval.

dot1x timeout re-authperiod *interval*

The default re-authentication interval is **3600** seconds.

1.4.4 Configuring Packet Retransmission Parameters

1. Overview

A supplicant and an authenticator exchange packets during authentication. Packets need to be retransmitted due to abnormal causes such as timeout. You can configure the retransmission count, retransmission interval, and other parameters based on the actual network conditions.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure packet retransmission parameters. Configure at least one of the tasks.

- Configure the retransmission interval of Request/Identity packets.

  dot1x timeout tx-period *interval*

  The default retransmission interval of Request/Identity packets is **3** seconds.

- Configure the maximum retransmission count of Request/Identity packets.

  dot1x reauth-max *reauth-max-number*

  The default maximum retransmission count of Request/Identity packets is **3**.

- Configure the retransmission interval of Request/Challenge packets.

  dot1x timeout supp-timeout *interval*

The default retransmission interval of Request/Challenge packets is **3** seconds.

- Configure the maximum retransmission count of Request/Challenge packets.

  dot1x max-req *max-req-number*

  The default maximum retransmission count of Request/Challenge packets is **3**.

1.4.5 Configuring the Server Timeout Duration

1. Overview

This section describes how to configure the server timeout duration of the IEEE 802.1X protocol.

2. Restrictions and Guidelines

- Both the IEEE 802.1X and RADIUS protocols have their own server timeout parameters. Ensure that the server timeout duration of IEEE 802.1X is greater than that of RADIUS. For details about the server timeout parameter of RADIUS, see *Configuring RADIUS*.
- In an environment with poor server performance, you are advised to set the server timeout duration to a larger value.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the server timeout duration.

dot1x timeout server-timeout *server-timeout*

The default server timeout duration is **5** seconds.

1.4.6 Configuring the Quiet Period After an Authentication Failure

1. Overview

After the quiet period after an authentication failure is configured, a user who fails the authentication needs to wait for a period of time before initiating another authentication. The purpose is to prevent malicious users from conducting frequent authentication to crack passwords in a brute force manner or launch denial of service (DoS) attacks.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the quiet period after an authentication failure.

dot1x timeout quiet-period *quiet-period*

The default quiet period after an authentication failure is **10** seconds.

1.4.7 Configuring the Authentication Mode

1. Overview

Authentication servers and authentication clients may support different authentication modes. You need to select an appropriate authentication mode based on the authentication modes supported by authentication servers and clients. Currently, CHAP, EAP, and PAP authentication modes are supported.

2. Restrictions and Guidelines

When local authentication is enabled for 802.1x users, only chap and pap modes are supported.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the authentication mode.

dot1x auth-mode { **chap** | **eap** | **pap** }

The default authentication mode is EAP.

1.4.8 Configuring Ruijie Client Detection

1. Overview

This section describes how to configure Ruijie client detection to detect whether clients are online.

2. Restrictions and Guidelines

Ruijie client detection applies only to Ruijie clients. You are advised to enable this function when Ruijie clients are used.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable online Ruijie client detection.

dot1x client-probe enable

Online Ruijie client detection is disabled by default.

(4) (Optional) Configure Ruijie client detection parameters. Configure at least one of the tasks.

- Configure the Ruijie client detection interval.

  dot1x probe-timer interval *interval*

  The default client detection interval is **20** seconds.

- Configure the Ruijie client detection duration.

  dot1x probe-timer alive *alive-time*

  The default Ruijie client detection duration is **250** seconds.

1.4.9 Configuring Automatic Domain Name Supplement for 802.1X Users

1. Overview

This function is used to automatically supplement the domain name for 802.1X users.

In some domain-based authentication scenarios (AD domain environment of Microsoft), usernames used for authentication must carry the corresponding domain name. The device supports configuration of a domain name for an 802.1X user. The username used by the device to initiate authentication to the authentication server carries the domain name automatically, to meet the environmental requirement of domain-based authentication.

2. Restrictions and Guidelines

- This function can take effect in interface and global configuration modes. The interface configuration prevails.
- This function can detect only string-type domain names suffixed with the at sign (@) and support only automatic domain name supplement using this sign. If the username of a user under authentication contains the at sign (@) and the specified domain name after the at sign (@), it is considered that the username carries a valid domain name and can be directly used for authentication. If the specified domain name is not contained in the username, it is considered that the username does not carry a valid domain name. In this case, the at sign (@) and specified domain name are forcibly added after the username for authentication.

3. Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable automatic domain name supplement for 802.1X users in global configuration mode, and specify the domain name that must be carried in the usernames.

dot1x domain-name *name*

Automatic domain name supplement for 802.1X users is globally disabled by default.

4. Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface ethernet-type interface-number

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Enable automatic domain name supplement for 802.1X users on an interface, and specify the domain name that must be carried in the usernames.

dot1x domain-name *name*

Automatic domain name supplement for 802.1X users is disabled on an interface by default.

1.5 Configuring Authorization

1.5.1 Overview

- IP authorization

  IP authorization aims to restrict authenticated users to using specified IP addresses to access the network, and prevent IP address embezzlement.

- Non-Ruijie client filtering

  This function aims to restrict clients to using Ruijie Supplicant for authentication, so as to obtain the anti-proxy, SMS, and other functions provided by Ruijie Supplicant.

- 2nd-generation Ruijie Supplicant deployment

  2nd-generation Ruijie Supplicant deployment means that a user downloads Ruijie Supplicant through the Web page and then initiates authentication by using Ruijie Supplicant. 2nd-generation Ruijie Supplicant deployment facilitates fast deployment of Ruijie Supplicant in an environment with massive users.

1.5.2 Restrictions and Guidelines

- If the function of kicking users offline in real time provided by Ruijie SAM/SMP software needs to be used, configure Simple Network Management Protocol (SNMP) parameters correctly. For the SNMP parameter configuration, see *Configuring SNMP*.
- When multiple types of authentication client software are used in the network, disable the non-Ruijie client filtering function.
- Changing the IP authorization mode will force authenticated users offline and they need to be re-authenticated before going online again.
- In mixed authorization mode, if an IP authorization mode with a higher priority takes effect during user authentication, the IP authorization mode with a higher priority is used. The priorities are in descending order: Supplicant authorization, RADIUS authorization, DHCP authorization, and static IP authorization. If RADIUS authorization is used originally but Supplicant provides an IP address during re-authentication, this address is used for authorization.
- 2nd-generation Ruijie Supplicant deployment and Web authentication are mutually exclusive.
- Redirection parameters need to be configured for 2nd-generation Ruijie Supplicant deployment. For details about redirection parameters, see *Configuring Web Authentication*.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the global IP authorization mode.

aaa authorization ip-auth-mode { **disable** | **supplicant** | **radius-server** | **dhcp-server** | **mixed** | **static-ip** }

Global IP authorization is disabled by default.

(4) (Optional) Enable 2nd-generation Ruijie Supplicant deployment function.

dot1x redirect

The 2nd-generation Ruijie Supplicant deployment function is disabled by default.

After 2nd-generation Ruijie Supplicant deployment is configured, users who are connected to controlled ports and have no IEEE 802.1X client installed can download the IEEE 802.1X client through the Web page.

(5) (Optional) Enable the non-Ruijie client filtering function.

dot1x private-supplicant-only

The non-Ruijie client filtering function is disabled by default.

1.6 Configuring MAB

1.6.1 Overview

In actual environments, the IEEE 802.1X client cannot be installed on some dumb terminals (such as network printers). They cannot complete IEEE 802.1X authentication but their security needs to be controlled. In this case, you can configure the MAC authentication bypass (MAB) to complete the authentication of these dumb terminals.

MAB is an authentication method that uses MAC addresses of terminals as the usernames and passwords for authentication without installing the client. MAB is mainly used to provide network access control for some dumb terminals.

1.6.2 Restrictions and Guidelines

- The IEEE 802.1X function must be enabled on a controlled port before MAB is configured.
- A MAB-enabled port sends an authentication request packet at an interval specified by **tx-period**. If the request packet is sent for a certain number of times specified by **reauth-max** but no response is received from the client, the port enters the MAB mode. Ports in MAB mode can learn MAC addresses and use them as accounts for authentication.
- When configuring MAC accounts that are used as usernames and passwords on the authentication server, be sure to use the format without separators. For example, assume that the MAC address of a terminal is 00-d0-f8-00-01-02. The account added on the authentication server should be 00d0f8000102.
- IEEE 802.1X has a higher priority than MAB. If a MAB-authenticated terminal needs to go through IEEE 802.1X authentication, the device will clear MAB authentication information of the terminal.
- MAB supports only the PAP authentication mode. Ensure that MAB parameter configurations on the device are consistent with those on the authentication server.
- MAB checks whether terminals can complete IEEE 802.1X authentication by using active authentication. Therefore, enable active authentication when deploying MAB.

1.6.3 Configuration Tasks

Configure MAB. Select any of the following configuration tasks to configure.

- Configuring Single-User MAB

- Configuring Multi-User MAB

1.6.4 Configuring Single-User MAB

1. Overview

Single-user MAB applies to the scenario, in which a port has only one dumb terminal attached to it or a port has only one dumb terminal to be authenticated. After successful authentication, other terminals connected to the port can access the network.

2. Restrictions and Guidelines

- As long as the MAC address of one terminal connected to a port passes MAB authentication, all terminals connected to the port are allowed to access the network. However, in some security applications, the administrator requires that only one MAC address exist under a single-user MAB port. In this case, you can configure MAB violation on this port. After MAB violation is configured on a port and the port enters the MAB mode, if more than one MAC address is found under the port, violation occurs on the port.
- When 802.1X users perform authentication for go-online or receive EAP packets on an interface, the interface automatically exits single-user MAB. After the interface changes from the Down state to the Up state or the IEEE802.1X function is enabled, single-user MAB is restored and takes effect again. The interface must meet the preceding conditions to enter the MAB mode. For more information, see Restrictions and Guidelines

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the batch Layer 2 Ethernet interface configuration mode.

(4) Enable single-user MAB.

dot1x mac-auth-bypass

Single-user MAB is disabled by default.

(5) (Optional) Enable MAB violation.

dot1x mac-auth-bypass violation

MAB violation is disabled by default.

1.6.5 Configuring Multi-User MAB

1. Overview

Multi-user MAB applies when multiple dumb terminals are connected to one port.

2. Restrictions and Guidelines

- Multi-user MAB can be used together with IEEE 802.1X authentication in mixed access scenarios such as the PC+VoIP daisy-chain topology.
- After multi-user MAB is enabled, illegitimate users connected to an interface may attack the device. Therefore, it is necessary to prevent illegitimate users from frequently initiating authentication, in an effort to reduce the server load. Configure the quiet period after a multi-user MAB failure in global configuration mode. After configuration, if a user fails the authentication, the user can re-initiate authentication only after the quiet period elapses. Configure this quiet period based on the network environment.
- With the LLDP function, the device can discover phones connected to its ports. If phone MAB is disabled, all devices on the ports access network resources over the Native VLAN after being authenticated. When phone MAB is enabled, the phones access network resources over the Voice VLAN after being authenticated, while non-phone devices still access network resources over the Native VLAN. This improves the call quality of the phones. Phone MAB can be used only when multi-user MAB is supported. If the Voice VLAN is different from the Native VLAN, the phones can access network resources by using the MAC VLAN and VLAN redirection method.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) **(Optional) Enable phone MAB.**

dot1x mult-mab voice-vlan-auth enable

Phone MAB is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the batch Layer 2 Ethernet interface configuration mode.

(5) Enable multi-user MAB.

dot1x mac-auth-bypass multi-user

Multi-user MAB is disabled by default.

(6) (Optional) Configure the quiet period after a multi-user MAB failure.

dot1x multi-mab quiet-period *quiet-period*

The default quiet period after a multi-user MAB failure is **30** seconds.

You can use this command to restrict the authentication frequency of dumb terminals connected to a port.

(7) (Optional) Configure the number of authentication failures required for user entry aging.

dot1x multi-mab quiet-user fail-times *fail-times*

The default number of authentication failures required for user entry aging is **60**.

(8) (Optional) Configure the rate of initiating authentication using the MAC address in a multi-user MAB quiet user entry.

dot1x multi-mab quiet-user authen-num [*authen-num*]

The default rate of initiating authentication using the MAC address in a multi-user MAB quiet user entry is **50** MAC addresses per second.

(9) (Optional) Configure the server rejection count for the device to delete a user entry.

dot1x multi-mab quiet-user reject-times *reject-times*

The default server rejection count for the device to delete a user entry is **1**.

1.7 Configuring MAB Parameters

1.7.1 Overview

This section describes how to configure MAB parameters to meet requirements of the authentication server for MAB.

1.7.2 Configuration Tasks

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Username Format for MAB
- Configuring the Username Uppercase/Lowercase for MAB
- Enabling Domain Name Completion for MAB Users
- Configuring MAB VLAN
- Configuring the MAB Timeout Duration
- Enabling Fast MAB
- Configuring a Permanent License
- Configuring MAB Users to Initiate Authentication After Obtaining an IP Address

1.7.3 Configuring the Username Format for MAB

1. Restrictions and Guidelines

The following four username formats are supported:

- **with-colon**: Indicates that the username format is xx:xx:xx:xx:xx:xx.
- **with-dot**: Indicates that the username format is xxxx.xxxx.xxxx.
- **with-hyphen**: Indicates that the username format is xx-xx-xx-xx-xx-xx.
- **with-3hyphen**: Indicates that the username format is xxxx-xxxx-xxxx.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the username format for MAB.

dot1x mab-username format [**with-colon** | **with-dot** | **with-hyphen** | **with-3hyphen**]

No username format for MAB is configured by default.

1.7.4 Configuring the Username Uppercase/Lowercase for MAB

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure usernames used for MAB to use uppercase letters.

dot1x mab-username upper

Usernames used for MAB use lowercase letters by default.

This command is used to meet requirements of different servers for username uppercase/lowercase in MAB.

1.7.5 Enabling Domain Name Completion for MAB Users

1. Overview

This function automatically completes domain names for MAB authentication users.

In some domain-based authentication scenarios (such as Microsoft AD scenario), the authentication user names must carry domain names. The device can configure domain names for MAB authentication users. When the device initiates an authentication request to the authentication server, the sent user name carries a domain name, which meets the domain authentication requirements.

2. Restrictions and Guidelines

This function can be enabled on interfaces or globally. The configuration on interface is prior to the global configuration.

3. Procedure (Global)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the global domain name completion function for MAB users and specify the domain name to be carried by MAB users.

dot1x mac-auth-bypass **domain-name** *name*

By default, the domain name completion function for MAB users is disabled globally.

4. Procedure (Interface)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Enable the domain name completion function for MAB users on the interface and specify the domain name to be carried by MAB users.

dot1x mac-auth-bypass domain-name *name*

By default, the domain name completion function for MAB users is disabled on interfaces.

1.7.6 Configuring MAB VLAN

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the batch Layer 2 Ethernet interface configuration mode.

(4) Configure MAB VLAN.

dot1x mac-auth-bypass vlan *vlan-id*

The MAB VLAN function is disabled by default.

If MAB is needed for users only in some VLANs of an interface, you can configure the VLANs as MAB VLANs. Users not in the MAB VLANs cannot perform MAB.

1.7.7 Configuring the MAB Timeout Duration

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the batch Layer 2 Ethernet interface configuration mode.

(4) Configure the MAB timeout duration.

dot1x mac-auth-bypass timeout-activity *timeout*

MAB does not time out by default.

You can configure this parameter to restrict the network access duration of dumb terminals.

1.7.8 Enabling Fast MAB

1. Overview

After the fast MAB function is enabled, the device can quickly receive MAC addresses and implement MAB in microseconds.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the fast MAB function.

dot1x mac-auth-bypass fast

The fast MAB function is disabled by default.

1.7.9 Configuring a Permanent License

1. Overview

You can configure a permanent license for MAB users.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a permanent license for MAB users.

dot1x mab session-timeout unlimited

The permanent license function is disabled for MAB users by default.

1.7.10 Configuring MAB Users to Initiate Authentication After Obtaining an IP Address

1. Overview

After this function is configured, MAB users can initiate authentication only after obtaining an IP address.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure MAB users to initiate authentication after obtaining an IP address.

dot1x mac-auth-bypass valid**-ip-auth**

MAB authentication can be initiated without obtaining an IP address by default.

1.7.11 Configuring MAB-based Logout Through ARP Prob

1. Overview

After this function is configured, the device can force an MAB user to log out if the user is detected as offline based on the ARP probe packet.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure MAB-based logout through ARP probe.

dot1x mac-auth-bypass probe-offline

This function is disabled by default.

1.8 Configuring IAB

1.8.1 Overview

Inaccessible authentication bypass (IAB) is a method provided for new to-be-authenticated users to access the network when all RADIUS servers configured on the device are all unreachable. After a RADIUS server becomes reachable, it verifies the identities of users authorized in the unavailability period of RADIUS servers.

When RADIUS servers connected to a port are inaccessible and cannot authenticate the identities of users for the time being, you can add the port to a specified VLAN so that users connected to the port can access network resources only in the specified VLAN. This VLAN is called an IAB VLAN.

1.8.2 Restrictions and Guidelines

- IAB takes effect only when the global IEEE 802.1X authentication method list contains only the RADIUS authentication method and all RADIUS servers in the method list fail. If the method list has other authentication methods (such as local and none), IAB does not take effect.
- Configure an account for testing whether a RADIUS server is reachable and the criteria for judging that a RADIUS server is unreachable. For details about the criteria for judging that a RADIUS server is unreachable, see *Configuring RADIUS*. After global multi-domain AAA is enabled, the global method list is not used during IEEE 802.1X authentication. When IAB configured on a port detects that all RADIUS servers configured in the global 802.1X authentication method list are inaccessible, it directly returns an authentication success message to users, who can access network resources with no need to enter usernames. In this case, multi-domain AAA does not take effect on this port.
- Users authenticated in IAB mode do not initiate accounting requests to the accounting server.
- Authenticated users can properly access the network and are not affected by server inaccessibility.

- In access authentication configuration mode, when 802.1X-based IP authentication is enabled globally, if a user connected to a port is authenticated, IAB cannot be performed on other users connected to the port. In gateway authentication mode, IP authorization can be performed only when IP addresses of authenticated users can be obtained.
- Complete IEEE 802.1X authentication is required on some IEEE 802.1X authentication clients (such as Windows IEEE 802.1X authentication clients) so that ports connected to the clients are considered authenticated. When IAB is performed on such clients, users actually have been authorized via IAB but an authentication failure maybe displayed on the clients.
- When the function of binding dynamic VLAN redirection to port control mode is disabled, if the configured IAB VLAN does not exist, it is dynamically created when a port is added to the IAB VLAN, and automatically deleted when the port is removed from the IAB VLAN.
- An IAB VLAN cannot be a private VLAN, remote VLAN, or super-VLAN (including sub-VLANs).
- When the function of binding dynamic VLAN redirection to port control mode is disabled, port and user redirection between auth fail VLAN, authorization VLAN, and guest VLAN is not supported.
- When the function of binding dynamic VLAN redirection to port control mode is enabled, the following actions occur:

  a If port-based control mode is used, after IAB is triggered, the port is added to the IAB VLAN so that users can access the network through the IAB VLAN. If authentication is triggered, the following actions occur:

  - If the authentication succeeds and the server delivers an authorization VLAN, the port is removed from the IAB VLAN and then added to the authorization VLAN. If the server does not deliver an authorization VLAN, the port is removed from the IAB VLAN and then added to the configured native VLAN.
  - If authentication fails and an auth fail VLAN is configured for the port, the port is removed from the IAB VLAN and then added to the auth fail VLAN. If no auth fail VLAN is configured but a guest VLAN is configured, the port is removed from the IAB VLAN and then added to the guest VLAN. Then, users can access resources in the guest VLAN. If no guest VLAN is configured, the port is added to the configured native VLAN and related users cannot access the network.
  - If authentication times out and the guest VLAN is configured, the port is removed from the IAB VLAN and then added to the guest VLAN. In this case, users can access resources in the guest VLAN. If the guest VLAN is not configured, the port is added to the configured native VLAN.
  - If IAB is continuously triggered, users still access the network through the IAB VLAN.

  b If MAC-based control mode and MAC-based VLAN are enabled, after IAB is triggered, a MAC-based VLAN entry with the VLAN ID set to the IAB VLAN ID and a user entry are dynamically created, so that the terminal can access resources in the IAB VLAN without affecting other users. If the terminal triggers authentication, the following actions occur:

  - If the authentication succeeds and the server delivers an authorization VLAN, the MAC-based VLAN entry with the VLAN ID set to the IAB VLAN ID is deleted, while the MAC-based VLAN entry with the VLAN ID set to the authorization VLAN ID is configured. If the server does not deliver an authorization VLAN, the MAC-based VLAN entry with the VLAN ID set to the IAB VLAN ID is deleted, and the terminal accesses the network through the configured native VLAN.
  - If authentication fails and an auth fail VLAN is configured for the port, the MAC-based VLAN entry with the VLAN ID set to the IAB VLAN ID is deleted, while the MAC-based VLAN entry with the VLAN ID set

to the auth fail VLAN ID is configured. If no auth fail VLAN is configured on the port but a guest VLAN is configured, a MAC-based VLAN entry with the VLAN ID set to the guest VLAN ID is configured on the port. In this case, users can access the network through the guest VLAN. If no guest VLAN is configured, the user goes offline and cannot access the network.

- If authentication times out and a guest VLAN is configured, the MAC-based VLAN with the VLAN ID set to the guest VLAN ID is used so that users access the network through the guest VLAN. If no guest VLAN is configured, the user goes offline and cannot access the network.
- If IAB is continuously triggered, users still access the network through the IAB VLAN.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Enable IAB.

dot1x critical

IAB is disabled by default.

(5) (Optional) Enable IAB recovery.

dot1x critical recovery action reinitialize

IAB recovery is disabled by default.

After this function is enabled on a port, when a server becomes reachable, users who are connected to the port and normally authenticated can access the network without re-authentication. For those who are IAB-authenticated during server unavailability, the device initiates active authentication.

(6) (Optional) Configure the IAB VLAN function.

dot1x critical vlan *vlan-id*

The IAB VLAN function is disabled by default.

1.9 Configuring the Port Control Mode

1.9.1 Overview

IEEE 802.1X control is classified into MAC-based control and port-based control. The control granularity of the two control modes is different. Configure the control mode as required.

In MAC-based control mode, each client connected to a port must pass authentication before accessing network resources. In port-based control mode, all clients connected to a port can access network resources as long as one of them is authenticated. The MAC-based control mode is used by default.

1.9.2 Configuration Tasks

Configure the port control mode. Select any of the following configuration tasks to configure.

- Configuring the MAC-based Control Mode
- Configuring the Port-based Control Mode

1.9.3 Configuring the MAC-based Control Mode

1. Overview

In MAC-based control mode, the MAC address of each client is used as an authentication unit. Clients with different MAC addresses can access network resources only after they pass authentication separately.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure the MAC-based control mode.

dot1x port-control-mode mac-based

A port is controlled based on MAC addresses by default.

1.9.4 Configuring the Port-based Control Mode

1. Overview

In port-based control mode, an entire port is used as an authentication unit. As long as one client connected to a port is authenticated, the port is an authenticated port and all clients connected to the port can access network resources.

To allow only one client connected to a port to pass the authentication, you can configure the port-based single-user mode on the basis of port-based control. In this mode, if other users exist on the port, the device deletes all users connected to the port and initiates re-authentication.

2. Restrictions and Guidelines

- In port-based control mode, inter-port migration can be allowed or prohibited for dynamic users. Dynamic users are allowed to migrate between different ports by default.
- In port-based authentication mode, a controlled port supports only one authenticated user while all the users are dynamic users.
- In port-based single-user control mode, only one user on the controlled port can pass authentication and make communication. The limit on the number of users on the port does not affect the limit on the number of users in this mode.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Disable migration of dynamic users.

dot1x stationarity enable

Migration is allowed for dynamic users by default.

Dynamic users on a controlled port cannot migrate to other ports before aging.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(5) Configure the port-based control mode.

dot1x port-control-mode port-based

A port is controlled based on MAC addresses by default.

(6) (Optional) Configure the port-based single-user control mode.

dot1x port-control-mode port-based single-host

The port-based single-user control mode is not configured by default.

After this command is configured, only one dynamic user can make communication.

1.10 Configuring Automatic Dynamic VLAN Redirection on IEEE 802.1X Ports

1.10.1 Overview

Automatic dynamic VLAN redirection on IEEE 802.1X ports is used to enable a server to deliver a redirected VLAN. After this function is enabled, when a server delivers a redirected VLAN, relevant users will be added to the redirected VLAN for communication.

The redirection mechanisms implemented by different types of controlled ports are different:

- If controlled ports to be redirected to a VLAN are access ports, trunk ports, or hybrid ports (with MAC VLAN disabled), you can change the native VLANs of these ports to implement dynamic VLAN redirection.
- If controlled ports to be redirected to a VLAN are hybrid ports (with MAC VLAN enabled), you can dynamically create MAC VLAN entries to add authenticated users to the delivered VLAN.

1.10.2 Restrictions and Guidelines

- The device can deliver a VLAN by extending RADIUS attributes. When a RADIUS server delivers a VLAN to an NAS by using an extended attribute, the server encapsulates the extended attribute into RADIUS standard attribute 26. The extended vendor ID is a hexadecimal number 0x00001311. The default type

number of the extended attribute is 4. You can run the **radius attribute 4 vendor-type type** command on the device to receive a delivered VLAN whose extended attribute type is **type**.

- The device allows a RADIUS server to deliver VLANs by using RADIUS standard attributes, including a combination of the following attributes:
  - Attribute 64 (**Tunnel-Type**): The value is VLAN (13).
  - Attribute 65 (**Tunnel-Medium-Type**): The value is 802 (6).
  - Attribute 81 (**Tunnel-Private-Group-ID**): The value is a VLAN ID or VLAN name.
- The device can perform IEEE 802.1X authentication on access, trunk, and hybrid ports. If automatic dynamic VLAN redirection is enabled on other ports, authentication will fail.
- The delivered VLAN attribute is used as a VLAN name. The NAS checks whether a VLAN with the same name is configured. If yes, the NAS automatically adds the user port, to which the VLAN attribute is delivered, to the VLAN. If no VLAN with the same name exists, the delivered VLAN attribute is used as a VLAN ID. If the VLAN ID is valid (within the VLAN ID range supported by the system), the device automatically adds the user port to the VLAN. If the VLAN ID is 0, the device considers no VLAN information delivered. The authentication will fail in other cases.
- Delivered redirected VLANs cannot be private VLANs, remote VLANs, or super VLANs (including sub VLANs).
- When VLAN redirection is configured on an access port and a delivered VLAN does not exist on the device, if the delivered VLAN is identified as a VLAN ID, the device creates the VLAN and adds the port, to which the VLAN attribute is delivered, to the new VLAN, and user authentication succeeds. If the delivered VLAN is identified as a VLAN name, no VLAN ID can be found and user authentication fails. If the delivered VLAN exists on the device and is configured as a redirected VLAN not supported by the access port on the device, users connected to the port will fail the authentication. If the delivered VLAN is configured as a redirected VLAN supported by the access port on the device, the port is removed from its VLAN and added to the delivered VLAN and user authentication succeeds.
- When VLAN redirection is configured on a trunk port and a delivered VLAN does not exist on the device, if the delivered VLAN is identified as a VLAN ID, the device creates the VLAN and changes the native VLAN of the port to the delivered VLAN, and user authentication succeeds. If the delivered VLAN is identified as a VLAN name, no VLAN ID can be found and user authentication fails. If the delivered VLAN exists on the device and is configured as a redirected VLAN not supported by the trunk port (see the description below), the authentication fails. If the delivered VLAN is configured as a redirected VLAN supported by the trunk port on the device, the device changes the native VLAN of the port to the delivered VLAN and user authentication succeeds.
- If the MAC VLAN function is disabled on a hybrid port, a delivered VLAN is processed as follows: If the delivered VLAN does not exist on the device and is identified as a VLAN ID, the device automatically creates the VLAN, allows the VLAN to pass through the current hybrid port in an untagged manner, and changes the native VLAN of the port to the delivered VLAN, and user authentication succeeds. If the delivered VLAN is identified as a VLAN name, no VLAN ID can be found and user authentication fails. If the delivered VLAN exists on the device and is configured as a redirected VLAN not supported by the hybrid port (or the VLAN is contained in the tagged VLAN list of the hybrid port), user authentication fails. Otherwise, the delivered VLAN is allowed to pass through the hybrid port in an untagged manner, the native VLAN of the port is changed to the delivered VLAN, user authentication succeeds.

- If the MAC VLAN function is enabled on a hybrid port, a delivered VLAN is processed as follows: User authentication fails if the VLAN delivered by the authentication server does not exist on the device (the VLAN must be statically configured according to requirements of the MAC VLAN function), the delivered VLAN has been added to the tagged VLAN list of the hybrid port, or the MAC VLAN function does not support the type of the VLAN (for details, see *Configuring MAC VLAN*). Otherwise, the device dynamically creates MAC VLAN entries based on the delivered VLAN and user MAC addresses, and user authentication succeeds. When a user goes offline, the MAC VLAN entry of the user will be dynamically deleted.
- If the MAC VLAN function is disabled on a port, after a VLAN is delivered, the device changes the native VLAN of the port but will not change the native VLAN command configuration of the port. The priority of a delivered VLAN is higher than that of a VLAN configured by a command. That is, after successful authentication, the delivered VLAN takes effect, and the native VLAN configured by a command functions after a user goes offline.
- If MAC VLAN is enabled on a port and user authentication is based on MAC addresses, VLANs are delivered through the dynamic creation of MAC VLAN entries, and the native VLAN of the port is not changed.
- No matter whether MAC VLAN is enabled on a hybrid port, if the VLAN delivered via authorization is added to the tagged VLAN list of the port, the VLAN delivery fails.
- The device trusts the VLAN delivered by the server completely. If the server delivers the VLAN reported by the device again, the device identifies the VLAN as an authorization VLAN for processing.
- After you enable binding between dynamic VLAN redirection and port control mode, VLAN redirection is bound to port control mode. If port-based control mode is used, dynamic VLAN redirection is implemented by changing the native VLAN of the port. If access control is based on MAC addresses, a MAC-based VLAN entry is created to add authenticated users to the delivered VLAN. The MAC-based VLAN function needs to be enabled. Otherwise, dynamic VLAN redirection is not performed.
- The **dot1x dynamic-vlan enable** (enabling automatic dynamic VLAN redirection), **dot1x vlan-bind-with control-mode (**binding automatic dynamic VLAN redirection to port control mode), **dot1x guest-vlan**, **dot1x auth-fail vlan**, **dot1x critical vlan** (VLAN configuration commands), and **dot1x port-control-mode** (port control mode) commands can be used together as needed. After these commands are configured, users on the port do not support VLAN migration.
- VLAN redirection applies only to scenarios where packets sent from terminals to devices are untagged packets. It is recommended that VLAN redirection be configured on access devices.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregation configuration mode.

interface aggregateport *interface-number*

(4) Enable automatic dynamic VLAN redirection on the interface.

dot1x dynamic-vlan enable

Dynamic VLAN redirection is disabled on a port by default.

(5) Enable the function of binding dynamic VLAN redirection to port control mode.

dot1x vlan-bind-with control-mode

This function is disabled by default.

1.11 Configuring the Guest VLAN Function

1.11.1 Overview

The guest VLAN function is used to provide network access permissions for terminals, on which the IEEE 802.1X client is not installed.

After the guest VLAN function is configured but dynamic VLAN redirection is not bound to the port control mode, if no IEEE 802.1X client is detected on a controlled port, the port is added to the guest VLAN to allow terminals connected to the port to access network resources in the guest VLAN.

1.11.2 Restrictions and Guidelines

When dynamic VLAN redirection is not bound to the port control mode, the guest VLAN function is as follows:

- If a port added to a guest VLAN receives an EAPOL packet, the port is considered to have an IEEE 802.1X-authenticated client attached to it. In this case, the port exits the guest VLAN and performs IEEE 802.1X authentication.
- If any of the following conditions is met, a controlled port is considered to have no IEEE 802.1X-authenticated client attached to it:
  - The port sends an active authentication packet three times consecutively, but receives no EAPOL response packet.
  - The port receives no EAPOL response packet within 90 seconds.
  - The MAC address authentication fails in MAB mode.
- Automatic dynamic VLAN redirection must be enabled on IEEE 802.1X ports.
- When a port switches from Linkup state to Linkdown state, it exits the guest VLAN. When it switches from Linkdown state to Linkup state, the device judges whether the port needs to be added to the guest VLAN.
- After a port fails to receive EAPOL packets within 90s and redirects to a guest VLAN, clients connected to the port need to wait for a long period of time before re-initiating DHCP requests because of the time increment mechanism in the transmission of DHCP discover packets. As a result, it takes a long time for clients to obtain IP addresses after the port redirects to the guest VLAN.
- To configure guest VLAN on a hybrid port, add the VLAN to the untagged VLAN list of the port and then configure the VLAN as a guest VLAN.
- After a port fails to receive EAPOL packets within 90s and redirects to a guest VLAN, clients connected to the port need to wait for a long period of time before re-initiating DHCP requests because of the time increment mechanism in the transmission of DHCP discover packets. As a result, it takes a long time for clients to obtain IP addresses after the port redirects to the guest VLAN.

- To configure guest VLAN on a hybrid port, add the VLAN to the untagged VLAN list of the port and then configure the VLAN as a guest VLAN.
- Port and user redirection between the guest VLAN of the server, the IAB VLAN, auth fail VLAN, and the authorization VLAN is not supported.
- When the function of binding dynamic VLAN redirection to port control mode is enabled, the following actions occur:

(1) If port-based control mode is configured, there is no need to check whether the port is associated with an IEEE 802.1X client, and the port is added to the guest VLAN. This way, terminals can access network resource in the guest VLAN. If a terminal triggers authentication, the following actions occur:

- If the authentication succeeds and the server delivers an authorization VLAN, the port is removed from the guest VLAN and then added to the authorization VLAN of the server. If the server does not deliver an authorization VLAN, the port is removed from the guest VLAN and added to the configured native VLAN.
- If authentication fails and an auth fail VLAN is configured for the port, the port is removed from the guest VLAN and added to the auth fail VLAN. If no auth fail VLAN is configured, the port remains in the guest VLAN.
- If IAB is triggered and the IAB VLAN is configured on a port, the port is removed from the guest VLAN and added to the IAB VLAN. If no IAB VLAN is configured, the port is removed from the guest VLAN and added to the configured native VLAN.
- If authentication times out, the port remains in the guest VLAN.

(2) If MAC-based control mode and MAC-based VLAN are enabled, a MAC-based VLAN entry with the VLAN ID set to the guest VLAN ID and a user entry are dynamically created for a terminal, so that the terminal can access resources in the guest VLAN without affecting other users. If the terminal triggers authentication again, the following actions occur:

- If the authentication succeeds and the server delivers an authorization VLAN, the MAC-based VLAN entry with the VLAN ID set to the guest VLAN ID is deleted, while the MAC-based VLAN entry with the VLAN ID set to the authorization VLAN ID is configured. If the server does not deliver an authorization VLAN, the MAC-based VLAN entry with the VLAN ID set to the guest VLAN ID is deleted, and the terminal accesses the network through the configured native VLAN.
- If authentication fails and an auth fail VLAN is configured for the port, the MAC-based VLAN entry with the VLAN ID set to the guest VLAN ID is deleted, while the MAC-based VLAN entry with the VLAN ID set to the auth fail VLAN ID is configured. If no auth fail VLAN is configured on the port, the terminal remains in the guest VLAN.
- If IAB is triggered and an IAB VLAN is configured on the port, the MAC-based VLAN entry with the VLAN ID set to the guest VLAN ID is deleted, and the terminal is added to the IAB VLAN based on the MAC-based VLAN entry with the VLAN ID set to the IAB VLAN ID. If no IAB VLAN is configured on the port, the MAC-based VLAN entry with the VLAN ID set to the guest VLAN ID is deleted and the terminal remains in the native VLAN.
- If authentication times out, the user can continue to access the network through the configured guest VLAN.

- After the device dynamically creates a MAC-based VLAN entry with VLAN ID set to the guest VLAN ID and a user entry for a terminal, the terminal can go offline only in idle timeout mode when the user entry needs to

be deleted. If MAB is configured on the port, after a user accesses the network, MAB is performed first. The MAC-based VLAN entry with VLAN ID set to the guest VLAN ID and the user entry are generated only after MAB fails. At this time, MAB can be triggered again only in specific scenarios, including user offline upon idle timeout, interface getting Down, and manual clearing of user entries.

VLAN redirection applies only to scenarios where packets sent from clients to devices are untagged packets. It is recommended that VLAN redirection be configured on access devices.

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure the guest VLAN function on the controlled port.

dot1x guest-vlan *vlan-id*

The guest VLAN function is disabled on a controlled port by default.

(Optional) After the guest VLAN function is enabled on a controlled port, the device judges whether the port has an IEEE 802.1X authentication client attached to it. If no, the device adds the port to the guest VLAN.

1.12 Configuring the Auth Fail VLAN Function

1.12.1 Overview

The auth fail VLAN function is used to provide network access permissions for clients that fail the authentication.

In the scenario where the function of binding dynamic VLAN redirection to port control mode is disabled, and the number of consecutive authentication failures reaches the configured threshold, the device dynamically creates a MAC-based VLAN entry with the VLAN ID set to the auth fail VLAN ID and a user entry if MAC-based authentication mode is used and MAC-based VLAN is enabled. If port-based authentication mode is configured or MAC-based VLAN is disabled, the port is added to the auth fail VLAN. In either case, users can access network resources in the auth fail VLAN after authentication failures.

1.12.2 Restrictions and Guidelines

- If the auth fail VLAN configured does not exist, an auth fail VLAN will be dynamically created when a port is added to the auth fail VLAN and automatically removed when the port exits the auth fail VLAN.
- Automatic dynamic VLAN redirection must be enabled on IEEE 802.1X ports.

- When a port switches to Linkdown state, the port automatically exits the auth fail VLAN.
- The auth fail VLAN and guest VLAN can be set to the same VLAN.
- In port-based control mode, after a controlled port is added to an auth fail VLAN, only the users who fail the authentication can re-initiate authentication and other users' authentication requests will be discarded. This restriction does not apply to the MAC-based control mode.
- Private VLANs cannot be configured as 802.1X auth fail VLANs.
- When the function of binding dynamic VLAN redirection to port control mode is disabled, port and user redirection between the guest VLAN of the server, the IAB VLAN, auth fail VLAN, and the authorization VLAN is not supported.
- When the function of binding dynamic VLAN redirection to port control mode is enabled, the following actions occur:

(1) The port redirects the user to the auth fail VLAN once the authentication fails.

(2) If the MAC-based control mode is configured but the MAC-based VLAN function is disabled, a user is not redirected after a failed authentication.

(3) If the port-based control mode is configured, after user authentication fails, the port will be added to the auth fail VLAN so that the user can access the network through the auth fail VLAN. Then, after authentication is triggered again, the following actions occur:

  - If the authentication succeeds and the server delivers an authorization VLAN, the port is removed from the auth fail VLAN and then added to the authorization VLAN of the server. If the server does not deliver an authorization VLAN, the port is removed from the auth fail VLAN and added to the configured native VLAN.
  - If the authentication fails again, the user remains in the auth fail VLAN.
  - If authentication times out, and the guest VLAN is configured, the port is removed from the auth fail VLAN and added to the guest VLAN, and the user can access resources in the guest VLAN. If the guest VLAN is not configured, the port is removed from the auth fail VLAN and added to the configured native VLAN, and related users cannot access the network.
  - If IAB is triggered and the IAB VLAN is configured, the port is removed from the auth fail VLAN and added to the IAB VLAN. In this case, related users can access the network. If the IAB VLAN is not configured, the port is removed from the auth fail VLAN, and added to the native VLAN. In this case, the user can access the network through the native VLAN.

(4) If MAC-based control mode and MAC-based VLAN are enabled, a MAC-based VLAN entry (with VLAN ID set to the auth fail VLAN ID) and user entry are dynamically created for a user that fails to be authenticated, so that the user can access resources in the auth fail VLAN without affecting other users. If the terminal triggers authentication again, the following actions occur:

  - If the authentication succeeds and the server delivers an authorization VLAN, the MAC-based VLAN entry with the VLAN ID set to the auth fail VLAN ID is deleted, while the MAC-based VLAN entry with the VLAN ID set to the authorization VLAN ID is configured. If the server does not deliver an authorization VLAN, the MAC-based VLAN entry with the VLAN ID set to the auth fail VLAN ID is deleted, and the terminal accesses the network through the configured native VLAN.
  - If the authentication fails again, the user still accesses the network in the auth fail VLAN.
  - If authentication times out and a guest VLAN is configured, the MAC-based VLAN entry with the VLAN ID set to the guest VLAN ID is used so that users access the network through the guest VLAN. If no

guest VLAN is configured, the user goes offline and cannot access the network.

- If IAB is triggered and an IAB VLAN is configured on the port, the MAC-based VLAN entry with the VLAN ID set to the auth fail VLAN ID is deleted, while the MAC-based VLAN entry with the VLAN ID set to the IAB VLAN ID is configured. If no IAB VLAN is configured on the port, the MAC-based VLAN entry with the VLAN ID set to the auth fail VLAN ID is deleted and the terminal remains in the native VLAN.

- VLAN redirection applies only to scenarios where packets sent from clients to devices are untagged packets. It is recommended that VLAN redirection be configured on access devices.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure auth fail VLAN.

dot1x auth-fail vlan *vlan-id*

The auth fail VLAN function is disabled by default.

(5) (Optional) Configure the maximum number of consecutive failed authentication attempts.

dot1x auth-fail max-attempt *max-attemp-number*

The default maximum number of consecutive failed authentication attempts is **3**.

This command is used to configure the maximum number of times that a user is consecutively rejected by the authentication server. If the rejection count reaches this number, the port, to which the user is connected, will be added to an auth fail VLAN.

1.13 Configuring Extended Features

1.13.1 Overview

This section describes how to configure extended features supported by Ruijie devices.

1.13.2 Configuration Tasks

Configure extended features. All the configuration tasks below are optional. Select the configuration tasks as required.

- Enabling Active Authentication
- Configuring a List of Hosts Allowed for Authentication
- Disabling the Virtual Source MAC Address Function
- Configuring Multi-Account Authentication with One MAC Address

- Configuring the Maximum Number of Users Who Can Be Authenticated on an Interface
- Configuring the Function of Initiating Accounting After an IP Address Is Obtained
- Configuring the Priority Order of IEEE 802.1X and MAB
- Configuring the Accounting Update Period
- Configuring Compatibility with H3C Clients and Servers
- Disabling the Global IEEE 802.1X Features
- Enabling Perception-free Migration Across VLANs for 802.1X Users
- Configuring the Function of Instantly Sending Accounting Update Packets Upon IP Address Changes of 802.1X Authenticated Users
- Converting User Names into TEXT Format
- Compatible with Third-Party Clients
- Configuring the Function of Carrying Static IP Addresses in Authentication and Accounting Packets of IEEE 802.1X and MAB
- Recording Debugging Information to a File

1.13.3 Enabling Active Authentication

1. Overview

Active authentication refers that the NAS actively sends a Request/Identity packet, which triggers IEEE 802.1X clients to initiate IEEE 802.1X authentication.

2. Restrictions and Guidelines

- Some clients use authentication clients embedded in the OS. They may not initiate authentication immediately after connecting to the network, and users cannot use the network promptly. The configured active authentication can urge such clients to initiate authentication in a timely manner after they connect to the network.
- You can use this function to detect whether a client is using Supplicant.
- This function must be configured for MAB deployment.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable active authentication.

dot1x auto-req

The default configuration of this command depends on the product version.

(4) (Optional) Configure the number of Request/Identity packets to be sent by a port added to an auth fail VLAN.

dot1x auto-req fail-vlan-pkt-num *packet-number*

The function of sending Request/Identity packets by a port added to an auth fail VLAN is disabled by default.

When both IEEE 802.1X authentication and MAB are enabled, a port may be added to an auth fail VLAN if MAB fails. Some clients cannot initiate IEEE 802.1X authentication actively. For this, you can configure this function to send Request/Identity packets to the clients to trigger authentication.

(5) (Optional) Configure the maximum number of active authentication request packets that can be sent.

dot1x auto-req packet-num *packet-number*

The device always sends authentication request packets actively by default.

(6) (Optional) Configure the interval for sending active authentication request packets.

dot1x auto-req req-interval *req-interval*

The default interval for the device to send active authentication request packets is **30** seconds.

(7) (Optional) Enable the function of detecting whether a user is being authenticated during active authentication.

dot1x auto-req user-detect

The function of detecting whether a user is being authenticated during active authentication is enabled by default.

1.13.4 Configuring a List of Hosts Allowed for Authentication

1. Overview

You can configure only clients with specific MAC addresses connected to specified ports to perform IEEE 802.1X authentication to improve network security.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a list of hosts allowed for authentication.

dot1x auth-address-table address *mac-address* **interface** *interface-type interface-number*

1.13.5 Disabling the Virtual Source MAC Address Function

1. Overview

The virtual source MAC address function enables the device to use a virtual MAC address as the source MAC address of EAP packets in IEEE 802.1X authentication.

This function is used together with Ruijie Supplicant to determine whether an NAS is a Ruijie device. Then, private features can be implemented on Supplicant if the NAS is a Ruijie device. The virtual source MAC address function is enabled by default. You can determine whether to disable the function as required.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable the virtual source MAC address function.

dot1x pseudo source-mac

The source MAC address of IEEE 802.1X packets sent by the device is a virtual MAC address by default.

1.13.6 Configuring Multi-Account Authentication with One MAC Address

1. Overview

The multi-account function allows a user to switch the account upon re-authentication. In special scenarios in which an account change is needed, such as Windows domain authentication, an access domain is used and an account may be changed for authentication. This function applies to such scenarios.

2. Restrictions and Guidelines

The multi-account authentication function must be disabled if accounting is enabled. Otherwise, accounting may be inaccurate.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable multi-account authentication with one MAC address.

dot1x multi-account enable

Multi-account authentication with one MAC address is disabled by default.

1.13.7 Configuring the Maximum Number of Users Who Can Be Authenticated on an Interface

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the maximum number of users who can be authenticated on an interface.

dot1x default-user-limit *limit-number*

The maximum number of users who can be authenticated on an interface is unlimited.

1.13.8 Configuring the Function of Initiating Accounting After an IP Address Is Obtained

1. Overview

Clients do not initiate accounting immediately after passing authentication, but wait until they obtain IP addresses.

Some servers request accounting request packets to carry IP addresses. This function can meet this requirement. Authenticated users go online and obtain IP addresses from Supplicant or DHCP snooping. IEEE 802.1X initiates accounting requests only after the users obtain IP addresses. The device may not initiate accounting within a long period of time due to a lack of IP addresses of authenticated clients. For this, the

function provides an IP address detection timeout duration. If the device does not obtain the IP address of a client within the timeout duration, the device brings the client offline.

2. Restrictions and Guidelines

- In an IPv4 environment where Ruijie Supplicant client is deployed, Supplicant is capable of uploading IPv4 addresses of clients and therefore, the function does not need to be enabled.
- This function is unavailable in static IP address environments.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of initiating accounting after a user's IP address is obtained.

dot1x valid-ip-acct enable

The function of initiating accounting after a user's IP address is obtained is disabled by default.

(4) Configure the timeout duration for an authenticated user to obtain an IP address.

dot1x valid-ip-acct timeout *timeout*

The default timeout duration for an authenticated user to obtain an IP address is **5** minutes.

1.13.9 Configuring the Priority Order of IEEE 802.1X and MAB

1. Overview

IEEE 802.1X authentication has a higher priority than MAB by default. This function allows you to configure the priority order of IEEE 802.1X authentication and MAB.

If both IEEE 802.1X authentication and MAB are enabled, IEEE 802.1X authentication or MAB is carried out, whichever is triggered first, and IEEE 802.1X authentication is prior to MAB. Therefore, if the device receives an EAPOL packet from a MAB-authenticated user, the device brings the user offline and performs IEEE 802.1X authentication on the user. Currently, the device performs IEEE 802.1X authentication on each user, and then performs MAB on users who fail the authentication. In addition, MAB takes priority over IEEE 802.1X authentication, and IEEE 802.1X authentication is ignored for MAB-authenticated users.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the priority of IEEE 802.1X authentication to be lower than that of MAB.

dot1x auth-with-order

IEEE 802.1X authentication has a higher priority than MAB by default.

1.13.10 Configuring the Accounting Update Period

1. Overview

Some servers do not deliver the accounting update period during user re-authentication, but require that accounting update packets be sent at the accounting update period delivered at the first authentication. In this case, you can use this function to configure the accounting update period delivered by the server at the first authentication as the accounting update period of re-authentication.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Set the accounting update period to that delivered by the server at the first authentication.

dot1x acct-update base-on first-time server

The accounting update period delivered by the server at the first authentication is not configured as the accounting update period for re-authentication by default.

1.13.11 Configuring Compatibility with H3C Clients and Servers

1. Overview

This function enables Ruijie devices to be compatible with H3C 802.1X clients and authentication servers.

When 802.1X authentication is performed by a Ruijie device on an H3C iNode, the username provided by the client for authentication uses a special format unrecognized by Ruijie device, resulting in an authentication failure. Usernames required by H3C authentication servers for MAB are in the format of xx-xx-xx-xx-xx-xx, which is different from the default MAB authentication username format of Ruijie devices. As a result, the authentication fails. You can configure this function to implement correct interworking with H3C devices.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the compatibility with H3C 802.1X authentication clients and authentication servers.

dot1x user-name compatible

The compatibility with H3C 802.1X authentication clients and authentication servers is disabled by default.

1.13.12 Disabling the Global IEEE 802.1X Features

1. Overview

You can disable IEEE 802.1X features on all ports at a time.

After global IEEE 802.1X features are disabled, users can access the network without authentication and online users will be brought offline. After global IEEE 802.1X features are enabled, if IEEE 802.1X authentication is configured on a port, users connected to the port need to be authenticated before accessing the network.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable global IEEE 802.1X features.

dot1x system disable

Global IEEE 802.1X features are enabled by default.

1.13.13 Enabling Perception-free Migration Across VLANs for 802.1X Users

1. Overview

This function enables and controls migration of 802.1X users across VLANs in perception-free mode.

When this function is disabled, user migration across VLANs is not allowed if only the VLAN ID of the users changes. If both the VLAN ID and interface change, migration across VLANs is allowed for users such as new users getting online, old users staying online, and users with two user entries on their devices.

After this function is enabled, migration across VLANs is allowed for users such as new users getting online, offline old users, and users with one user entry on their devices.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable perception-free migration across VLANs for 802.1X users.

dot1x vlan-move permit

Perception-free migration across VLANs is disabled for 802.1X users by default.

1.13.14 Configuring the Function of Instantly Sending Accounting Update Packets Upon IP Address Changes of 802.1X Authenticated Users

1. Overview

After this function is enabled, the device instantly sends accounting update packets when the IP address of an 802.1X authenticated user changes.

2. Restrictions and Guidelines

- This function can be enabled only after the IEEE802.1X authentication function is enabled.
- This function must be configured when the server requires instant accounting update upon IP address changes.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of instantly sending accounting update packets upon IP address changes of 802.1X authenticated users.

dot1x acct-update ip-addr-change instant

The function of instantly sending accounting update packets upon IP address changes of 802.1X authenticated users is disabled by default.

1.13.15 Converting User Names into TEXT Format

1. Overview

This function converts user names into TEXT format.

When the user names used by clients are of the string type, the user name length may contain the ending space. Running this command can recalculate the user name length.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of converting user names into TEXT format.

dot1x user-name format text

By default, user names are not converted into TEXT format.

1.13.16 Compatible with Third-Party Clients

1. Overview

The device is compatible with the third-party clients that encapsulate reply-msg messages in the format of type (1 byte, fixed as 09), length (1 byte, length of value), and value (character string in reply-msg).

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the device to be compatible with third-party clients.

dot1x not-private-supplicant compatible

By default, the device is not compatible with third-party clients.

1.13.17 Configuring the Function of Carrying Static IP Addresses in Authentication and Accounting Packets of IEEE 802.1X and MAB

1. Overview

After this function is configured, when the device receives an ARP packet sent by a terminal with a static IP address, the device reports the static IP address carried in the packet through IEEE 802.1X and MAB authentication packets and accounting packets.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the function of carrying static IP addresses in authentication and accounting packets of IEEE 802.1X and MAB.

dot1x get-static-ip enable

Authentication and accounting packets of IEEE 802.1X and MAB authentication do not carry static IP addresses by default.

1.13.18 Recording Debugging Information to a File

1. Overview

To locate faults on a network, you can enable the function of recording debugging information to a file to avoid login freeze or service impact caused by a large amount of debugging information.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of recording debugging information to a file.

dot1x dbg-to-file

The function of recording debugging information to a file is disabled by default.

1.13.19 Configuring the Maximum Number of EAP-Success Packets Sent by a Device

1. Overview

You can use this function to configure the maximum number of EAP-Success packets that can be sent by a device.

2. Restrictions and Guidelines

- If you configure the **dot1x eap-success supplicant-enhance disable** command on a device, the possibility that a client receives EAP-Success packets can be reduced.
- If the port dynamic VLAN redirection, guest VLAN, or auth fail VLAN function is enabled, the native VLAN

may be modified. You are advised not to configure the **dot1x eap-success supplicant-enhance disable** command.

- The device sends two EAP-Success packets at an interval of 1s by default, which may be regarded as exceptions by some third-party clients. You can configure the **dot1x eap-success supplicant-enhance disable** command to allow the device to send an EAP-Success packet only once for compatibility with third-party clients. In this case, when the native VLAN is changed, client authentication may time out in a short period of time, which can be restored after re-authentication. If the device receives an EAP packet from the client 1s later after sending the first EAP-Success packet, it does not send the second EAP-Success packet. If the client ignores the first EAP-Success packet, authentication failure may be displayed on the client while authentication success appears on the device. If the client continues to initiate authentication, the device starts the authentication process again.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the device to send one EAP-SUCCESS packet an interval of 1s.

dot1x eap-success supplicant-enhance disable

Two EAP-Success packets are sent an interval of 1s by default.

1.14 Monitoring

Run the **show** commands to check the configuration.

Run the **dot1x** commands to restore global configuration.

Run the **clear** commands to clear information.

Run the **debug** commands to output debugging information.

Caution

- Running the clear commands may lose vital information and thus interrupt services.
- Debugging occupies system resources, so disable it immediately if not required.

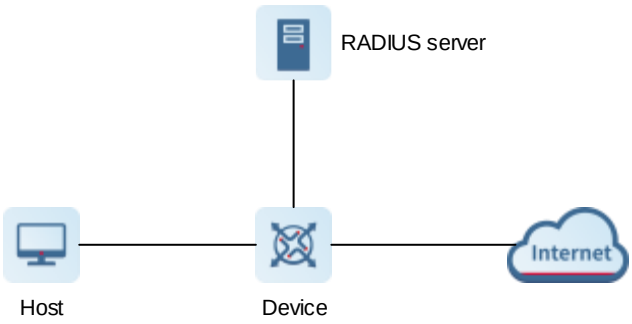
Table 1-1 IEEE 802.1X Monitoring

Command	Purpose
show radius server	Displays the configuration of a RADIUS server.
show dot1x	Displays IEEE 802.1X protocol parameters.
show dot1x authmng [**mab**] **abnormal** [**auth** | **offline** | **reauth**]	Displays all authentication records of 802.1X or MAB authentication in global configuration mode.

Command	Purpose
show dot1x authmng [**mab**] **statistic** [**auth-detail** | **fail** | **offline-detail** | **reauth-detail**]	Displays global static statistics of IEEE 802.1X or MAB authentication.
show dot1x auth-address-table [[**address** *mac-address*] **interface** *interface-type interface-number*]	Displays the list of hosts allowed for authentication.
show dot1x auto-req	Displays the active authentication status and parameters.
show dot1x max-req	Displays the maximum retransmission count of Request/Challenge packets.
show dot1x multi-mab quiet user	Displays the list of quiet users for multi-MAB authentication.
show dot1x port-control [**interface** *interface-type interface-number*]	Displays information about controlled ports.
show dot1x private-supplicant-only	Displays the status of the non-Ruijie client filtering function.
show dot1x probe-timer	Displays client detection parameters.
show dot1x re-authentication	Displays the status of the re-authentication function.
show dot1x reauth-max	Displays the maximum retransmission count of Request/Identity packets.
show dot1x summary	Displays entries of authenticated users.
show dot1x timeout quiet-period	Displays the quiet period after an authentication failure.
show dot1x timeout re-authperiod	Displays the re-authentication interval.
show dot1x timeout server-timeout	Displays the server timeout duration.
show dot1x timeout supp-timeout	Displays the retransmission interval of Request/Challenge packets.
show dot1x timeout tx-period	Displays the retransmission interval of Request/Identity packets.
show dot1x user id *user-id*	Displays details about a user with a specific user ID.
show dot1x user mac *mac-address*	Displays details about a user with a specific MAC address.
show dot1x user name *user-name*	Displays details about a user with a specific username.
show dot1x user diag *mac-address*	Displays the configuration of the user track recording function.
show dot1x user diag all	Display track records of all users.
show dot1x user diag mac	Displays track records of the specified user.

Command	Purpose
clear dot1x user { **all** | **ip** *ipv4-address* | **mac** *mac-address* | **name** *user-name* }	Deletes an IEEE 802.1X-authenticated user.
clear dot1x memory	Clears IEEE 802.1X memorystatistics.
dot1x default	Restores the default IEEE 802.1X configuration.
debug aaa	Debugs AAA (for details, see *Configuring AAA*).
debug radius	Debugs RADIUS (for details, see *Configuring RADIUS*).
debug dot1x event	Debugs IEEE 802.1X events.
debug dot1x packet	Debugs IEEE 802.1X packet processing.
debug dot1x stm	Debugs the IEEE 802.1X authentication state machine.
debug dot1x com	Debugs IEEE 802.1X internal communication.
debug dot1x error	Debugs IEEE 802.1X errors.

1.15 Configuration Examples



1.15.1 Configuring IEEE 802.1X Authentication

1. Requirements

IEEE 802.1X basic features need to be enabled on a device port so that clients connected to the port can access the network only after passing IEEE 802.1X authentication.

2. Topology

Figure 1-3 Topology of IEEE 802.1X Authentication

3. Notes

- Configure a RADIUS server and add IEEE 802.1X users on the RADIUS server.
- Enable AAA services.
- Configure the server address and key.
- Configure the authentication and accounting method lists.
- Apply the authentication and accounting method lists.

- Enable IEEE 802.1X basic features on an interface.

4. Procedure

(1) Configure a RADIUS server and add an IEEE 802.1X user with the username **hostname1** and password **Abc123456** on the RADIUS server. (The configuration is omitted here. For the configuration of the RADIUS server, see the RADIUS server configuration.)

(2) Enable AAA services.

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
```

(3) Configure the address and shared key of the AAA server (a RADIUS server is used as an example here, the IP address is set to 192.168.1.3, and the shared key is set to **radiuskey**).

```
Device(config)# radius-server host 192.168.1.3 key radiuskey
```

(4) Configure the authentication and accounting method lists.

```
Device(config)# aaa authentication dot1x auth-method group radius
Device(config)# aaa accounting network account-method start-stop group radius
```

(5) Apply the authentication and accounting method lists.

```
Device(config)# dot1x authentication auth-method
Device(config)# dot1x accounting account-method
```

(6) Enable IEEE 802.1X basic features on an interface.

```
Device(config)# int gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# dot1x port-control auto
```

5. Verification

The user cannot access network resources before authentication, but can access network resources after authentication.

Run the **show dot1x summary** command to display information about the authenticated user.

```
Device# show dot1x summary
ID       Username   MAC           Interface VLAN Auth-State     Backend-State
Port-Status User-Type Time
-------- ---------- --------------  --------- ---- --------------- -------------
----------- --------- ------------------
16778217  hostname1    0023.aeaa.4286  Gi0/1    1    Authenticated   Idle
Authed     static    0days 0h 0m 7s
```

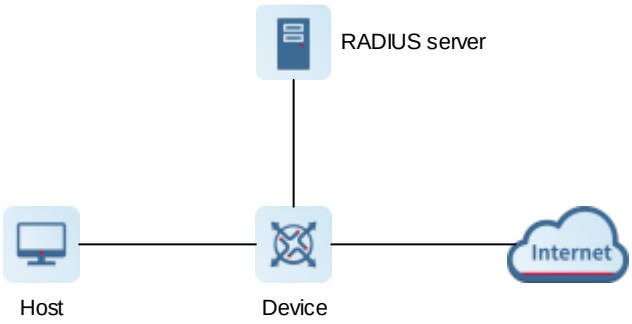
6. Configuration Files

```
!
dot1x authentication auth-method
dot1x accounting account-method
!
aaa new-model
!
radius-server host 192.168.1.3 key 7 $10$3b4$ln0s66i8XfEi$
```

```
!
aaa accounting network account-method start-stop group radius
aaa authentication dot1x auth-method group radius
!
interface GigabitEthernet 0/1
 dot1x port-control auto
!
```

7. Common Errors

- RADIUS parameters are incorrectly configured.
- A server uses a special access policy, for example, RADIUS packets must carry certain attributes.
- The AAA method list is different from the IEEE 802.1X method list, causing an authentication failure.



1.15.2 Configuring the IP Authorization Mode

1. Requirements

After IP authorization is configured, only clients with specified IP addresses can pass authentication.

2. Topology

Figure 1-4 Topology of IP Authorization Mode

3. Notes

- Enable IEEE 802.1X authentication on a port.
- Configure the IP authorization mode.

4. Procedure

(1) Enable IEEE 802.1X basic features on a port. For configuration steps, see Configuring IEEE 802.1X Authentication.

(2) Configure the Supplicant authorization mode.

```
Device> enable
Device# configure terminal
Device(config)# aaa authorization ip-auth-mode supplicant
```

5. Verification

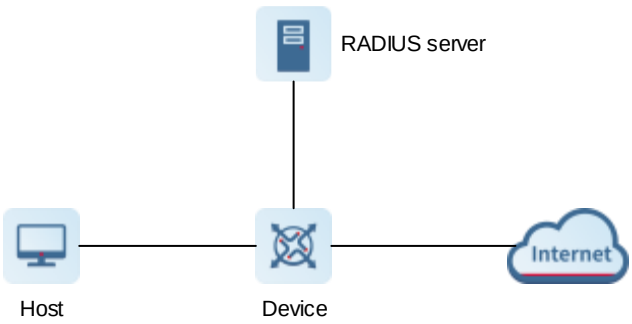
A client using a non-specified IP address fails the authentication.

6. Configuration Files

```
!
aaa authorization ip-auth-mode supplicant
dot1x authentication auth-method
dot1x accounting account-method
!
aaa new-model
!
radius-server host 192.168.1.3 key 7 $10$3b4$ln0s66i8XfEi$
!
aaa accounting network account-method start-stop group radius
aaa authentication dot1x auth-method group radius
!
interface GigabitEthernet 0/1
 dot1x port-control auto
!
```

7. Common Errors

- There are multiple authentication clients in the network. After non-Ruijie client filtering is enabled, some clients fail the authentication.
- Ruijie SAM/SMP is used but SNMP parameters are not configured on the device. As a result, the function of kicking users offline fails.



1.15.3 Configuring Multi-user MAB

1. Requirements

Multi-user MAB applies when multiple dumb terminals are connected to one port. After multi-user MAB is configured, each dumb terminal connected to a port needs to be authenticated so that they can access the network.

2. Topology

Figure 1-5 Topology of Multi-user MAB

3. Notes

- Enable IEEE 802.1X authentication on a port.

- Configure multi-user MAB.

4. Procedure

(1) Enable IEEE 802.1X basic features on a port. For configuration steps, see Configuring IEEE 802.1X Authentication.

(2) Configure multi-user MAB.

```
Device> enable
Device# configure terminal
Device(config)# int gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# dot1x mac-auth-bypass multi-user
```

5. Verification

Connect dumb terminals A and B to a port.

(1) If the MAC account of dumb terminal A is added on the RADIUS server, dumb terminal A can access the network properly but dumb terminal B cannot.

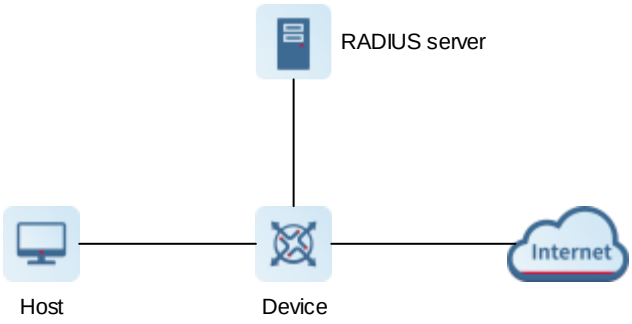
(2) Both dumb terminals A and B can access the network properly only after both their MAC accounts are added on the RADIUS server.

6. Configuration Files

```
!
dot1x authentication auth-method
dot1x accounting account-method
!
aaa new-model
!
radius-server host 192.168.1.3 key 7 $10$3b4$ln0s66i8XfEi$
!
aaa accounting network account-method start-stop group radius
aaa authentication dot1x auth-method group radius
!
interface GigabitEthernet 0/1
 dot1x port-control auto
dot1x mac-auth-bypass multi-user
!
```

7. Common Errors

The MAC account format is incorrect on the server.



1.15.4 Configuring IAB

1. Requirements

After IAB is configured, when all RADIUS servers configured on the device are unreachable, new access users are allowed to access the network directly.

2. Topology

Figure 1-6 Topology of IAB

3. Notes

- Enable IEEE 802.1X authentication on a port.
- Configure RADIUS server reachability detection.
- Configure IAB.

4. Procedure

(1) Enable IEEE 802.1X basic features on a port. For configuration steps, see Configuring IEEE 802.1X Authentication.

(2) Configure the criteria for judging that a RADIUS server is unreachable as follows: The consecutive timeout count is 5 and the timeout duration is 60 seconds.

```
Device> enable
Device# configure terminal
Device(config)# radius-server dead-criteria time 60 tries 5
```

(3) Configure IAB.

```
Device(config)# int gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# dot1x critical
```

5. Verification

When all RADIUS servers are unreachable, a client can directly access the network after initiating IEEE 802.1X authentication. Authentication will not fail due to the unavailability of RADIUS servers.

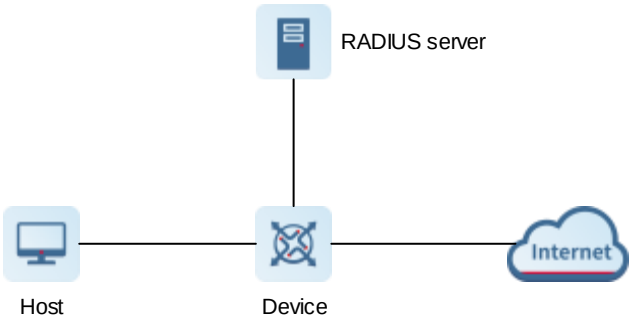
6. Configuration Files

```
!
dot1x authentication auth-method
dot1x accounting account-method
!
aaa new-model
!
radius-server host 192.168.1.3 test username testname key 7 $10$3b4$ln0s66i8XfEi$
radius-server dead-criteria time 60 tries 5
!
```

```
aaa accounting network account-method start-stop group radius
aaa authentication dot1x auth-method group radius
!
interface GigabitEthernet 0/1
 dot1x port-control auto
dot1x critical
!
```

7. Common Errors

- There is a RADIUS server reachable.
- The IEEE 802.1X authentication method list contains other methods besides the RADIUS method.



1.15.5 Configuring Automatic Dynamic VLAN Redirection

1. Requirements

After automatic dynamic VLAN redirection is enabled, when the server delivers a redirected VLAN to a port, users connected to the port will be added to the VLAN for communication.

2. Topology

Figure 1-7 Topology of Automatic Dynamic VLAN Redirection

3. Notes

- Enable IEEE 802.1X authentication on a port.
- Enable automatic dynamic VLAN redirection on a controlled port.

4. Procedure

(1) Enable IEEE 802.1X basic features on a port. For configuration steps, see Configuring IEEE 802.1X Authentication.

(2) Enable automatic dynamic VLAN redirection on an interface.

```
Device> enable
Device# configure terminal
Device(config)# int gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# dot1x dynamic-vlan enable
```

5. Verification

Configure the RADIUS server to deliver VLAN attributes. Run the **show dot1x summary** command to display information about the authenticated user. The port, to which the user is connected, redirects from VLAN 2 to VLAN 3.

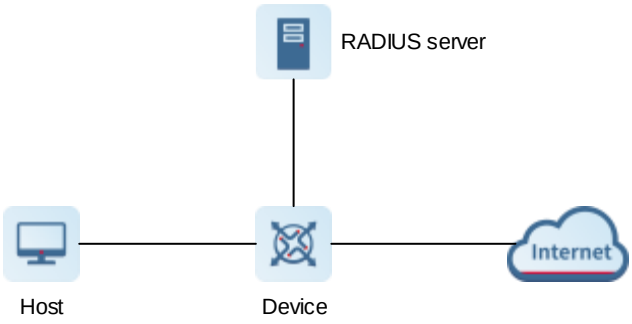
```
Device# show dot1x summary
ID       Username   MAC           Interface VLAN Auth-State     Backend-State
Port-Status User-Type Time
--------- ---------- --------------  --------- ---- --------------- -------------
----------- --------- ------------------
16778217  Hostname1    0023.aeaa.4286  Gi0/1     3    Authenticated   Idle
Authed     static    0days 2h17m29s
```

6. Configuration Files

```
!
dot1x authentication auth-method
dot1x accounting account-method
!
aaa new-model
!
radius-server host 192.168.1.3 key 7 $10$3b4$ln0s66i8XfEi$
!
aaa accounting network account-method start-stop group radius
aaa authentication dot1x auth-method group radius
!
interface GigabitEthernet 0/1
 dot1x port-control auto
dot1x dynamic-vlan enable
!
```

7. Common Errors

- RADIUS attributes of the VLAN to be delivered are not correctly configured on the authentication server.
- The RADIUS command for supporting delivered VLAN attributes is not configured on the device.
- When the MAC VLAN configured on a hybrid port is a redirected VLAN, the delivered VLAN is a tagged VLAN.



1.15.6 Configuring Guest VLAN

1. Requirements

IEEE 802.1X authentication needs to be enabled on a device port and guest VLAN needs to be configured on the port. If the IEEE 802.1X client is not installed on a terminal connected to the port, the terminal is allowed to access network resources in the guest VLAN.

2. Topology

Figure 1-8 Topology of Guest VLAN

3. Notes

- Enable IEEE 802.1X authentication on a port.
- Enable automatic dynamic VLAN redirection on a controlled port.
- Add the port to a guest VLAN.

4. Procedure

(1) Enable IEEE 802.1X basic features on a port. For configuration steps, see Configuring IEEE 802.1X Authentication.

(2) Enable automatic dynamic VLAN redirection on the port.

```
Device> enable
Device# configure terminal
Device(config)# int gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# dot1x dynamic-vlan enable
```

(3) Add the port to the guest VLAN with the VLAN ID 1.

```
Device(config-if-GigabitEthernet 0/1)# dot1x guest-vlan 1
```

5. Verification

After the port is added to the guest VLAN, the device generates the following log:

```
%DOT1X-5-TRANS_DEFAULT_TO_GUEST: Transformed interface GigabitEthernet 0/1 from
default-vlan 1 to guest-vlan 1 OK.
```

When the IEEE 802.1X client is not configured on a terminal, the terminal can and can only access network resources in VLAN 1 without authentication.

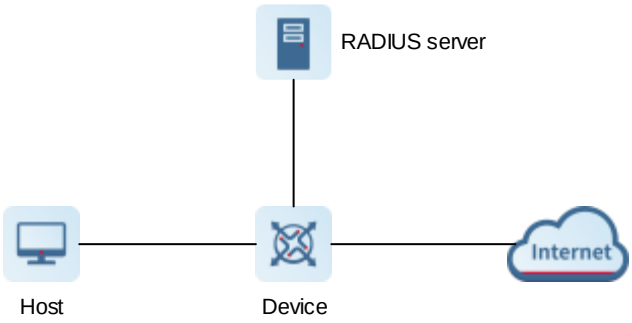
6. Configuration Files

```
!
dot1x authentication auth-method
dot1x accounting account-method
!
aaa new-model
!
radius-server host 192.168.1.3 key 7 $10$3b4$ln0s66i8XfEi$
```

```
!
aaa accounting network account-method start-stop group radius
aaa authentication dot1x auth-method group radius
!
interface GigabitEthernet 0/1
 dot1x port-control auto
dot1x dynamic-vlan enable
 dot1x guest-vlan 1
!
```

7. Common Errors

A port receives an EAPOL packet, and as a result, the port cannot be added to a guest VLAN.



1.15.7 Configuring Auth Fail VLAN

1. Requirements

IEEE 802.1X authentication needs to be enabled on a device port and auth fail VLAN needs to be configured on the port. If a terminal fails the IEEE 802.1X authentication, it is allowed to access network resources in the auth fail VLAN.

2. Topology

Figure 1-9 Topology of auth fail VLAN

3. Notes

- Enable IEEE 802.1X authentication on a port.
- Add the port to an auth fail VLAN.

4. Procedure

(1) Enable IEEE 802.1X basic features on a port. For configuration steps, see Configuring IEEE 802.1X Authentication.

(2) Add the port to an auth fail VLAN with the VLAN ID 1.

```
Device> enable
Device# configure terminal
Device(config)# int gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# dot1x auth-fail vlan 1
```

5. Verification

A terminal cannot access the network before authentication. The terminal uses an incorrect account for authentication. After the authentication fails, the terminal can access network resources in the auth fail VLAN.

6. Configuration Files

```
!
dot1x authentication auth-method
dot1x accounting account-method
!
aaa new-model
!
radius-server host 192.168.1.3 key 7 $10$3b4$ln0s66i8XfEi$
!
aaa accounting network account-method start-stop group radius
aaa authentication dot1x auth-method group radius
!
interface GigabitEthernet 0/1
 dot1x port-control auto
dot1x auth-fail vlan 1
!
```

7. Common Errors

If a user fails the authentication not due to the rejection from the authentication server, for example, the authentication client cannot be installed because of underlying resource insufficiency, the user will not be added to an auth fail VLAN.

1 Configuring Web Authentication

1.1 Introduction

1.1.1 Overview

Web authentication is an identity authentication method for controlling users' network access permissions. When an unauthenticated user attempts to access the Internet through a browser, the network access server (NAS) forcibly redirects the browser to a specified site (portal server). The user can access services of the portal server without authentication. If the user wants to access network resources beyond the portal server, the user must pass through authentication.

Web authentication has the following advantages:

- Convenient to use: Users do not need to install dedicated client software and can complete authentication through a browser.
- Personalized services and service extension: Through interaction between the browser and the portal server, users can customize services, such as advertisements, notifications, and business links on the portal server page.

1.1.2 Principles

1. Basic Concepts

- Authentication client

  Generally, an authentication client refers to a browser running Hypertext Transfer Protocol (HTTP). When a user accesses the Internet via a browser, the browser will send HTTP requests.

- NAS

  Generally, the NAS refers to an access-layer device in a network. It is directly connected to user hosts and needs to be enabled with web authentication.

- Portal server

  The portal server provides the web authentication page to interact with user hosts.

- RADIUS server

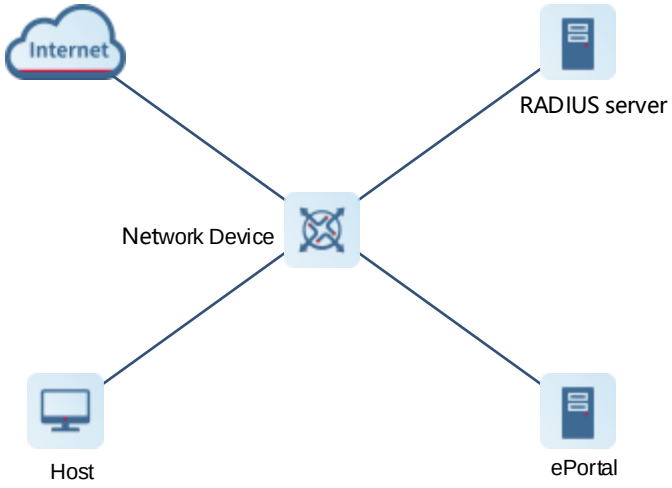
  The RADIUS server provides RADIUS-based remote user authentication.

- HTTP interception

  HTTP interception means that the NAS intercepts to-be-forwarded HTTP packets.

  These HTTP packets are sent by the browsers of the user hosts connected to the NAS but they are not destined for the NAS. For example, a user accesses www.google.com via the Internet Explorer (IE). The NAS is supposed to forward the HTTP request packets from the user to the gateway. If HTTP interception is enabled, these packets will not be forwarded.

  HTTP interception is the foundation of web authentication. Web authentication is triggered automatically once HTTP interception succeeds.



- HTTP redirection

In normal cases, after a user host sends an HTTP GET or HEAD request through a browser, the receiver responds with a 200 response if it can provide resources and a 302 response if it cannot provide resources. The 302 response provides a new site path. After receiving the response, the user host can send an HTTP GET or HEAD packet to the new site to request resources. This is called redirection.

2. Web Authentication Solutions

Ruijie web authentication has multiple versions that use different web authentication processes. Currently, Ruijie first-generation and second-generation web authentications are supported. You can select a version based on your actual requirements.

Figure 1-1 Typical Networking for Web Authentication

- Ruijie first-generation web authentication

  Ruijie first-generation web authentication requires cooperation of the Ruijie dedicated ePortal server. The ePortal server provides the authentication and accounting functions, which relieves the NAS from service burden.

  The authentication process is as follows:
  A user submits authentication information through the authentication page provided by the ePortal server.
  The ePortal server initiates an authentication request to the RADIUS server.
  After authentication succeeds, the ePortal server sends the user information to the NAS through Simple Network Management Protocol (SNMP).
  The NAS controls user access permissions.

- Ruijie second-generation web authentication

  Ruijie second-generation web authentication complies with the China Mobile Communications Corporation (CMCC) WLAN Service Portal Specification that is widely used in the industry. The portal server is responsible for interaction on the user page only and is easily compatible with products of different vendors. However, the main authentication process is performed on the NAS, and therefore higher requirements are raised for the NAS.

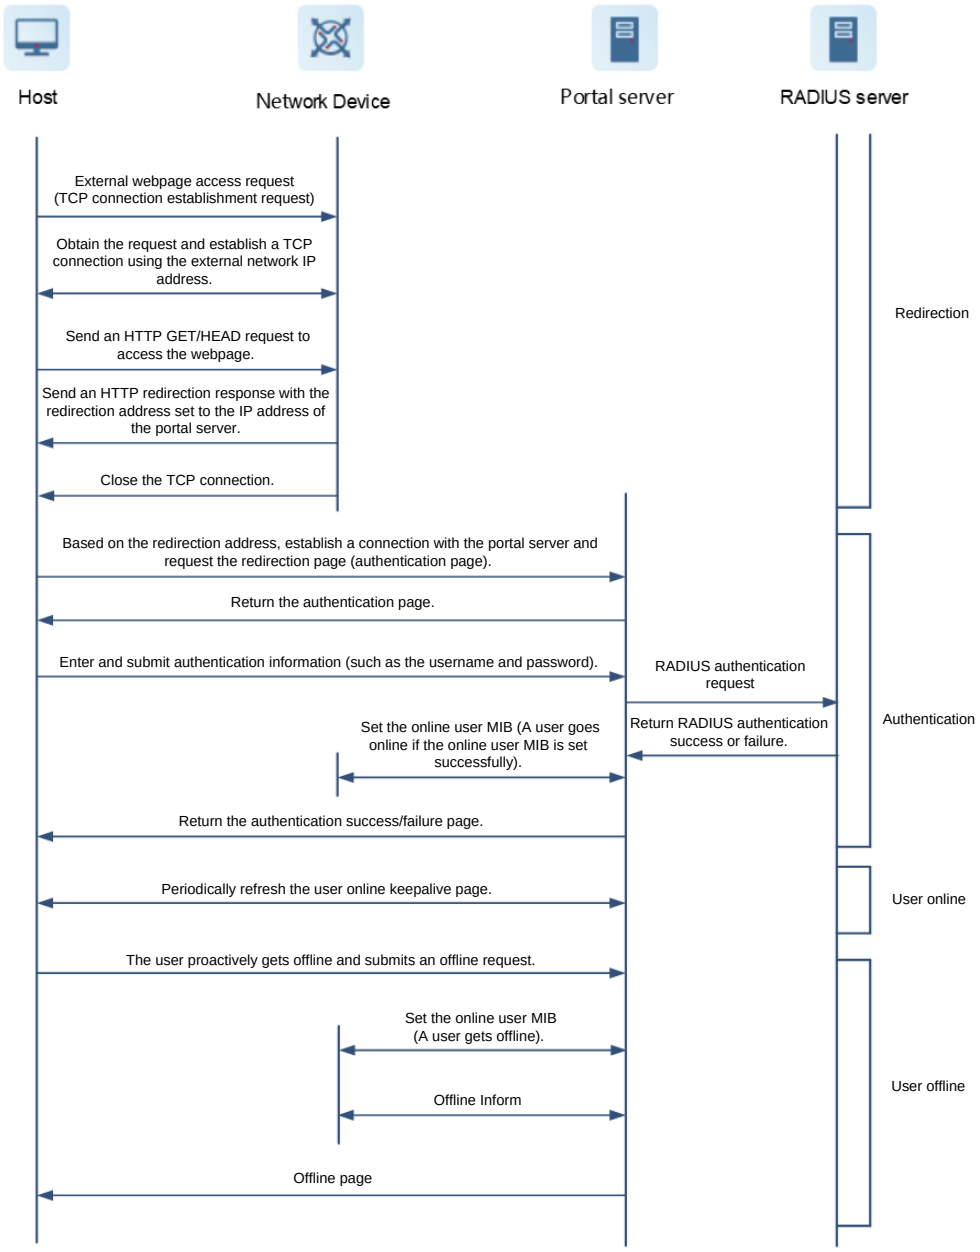
  The authentication process is as follows:
  A user submits authentication information through the authentication page provided by the portal server.
  The portal server informs user identity information to the NAS through the portal protocol. The NAS initiates

an authentication request to the RADIUS server using the identity information, assigns access permissions to authenticated users, and returns authentication results to the portal server.

- Web authentication solutions

Table 1-1 Web Authentication Solutions

Authentication Solution		Ruijie First-Generation Web Authentication	Ruijie Second-Generation Web Authentication
Authentication roles	Client	In these two authentication solutions, clients have the same functions.	
	NAS	The NAS redirects users and exchanges user online/offline notifications with the portal server.	The NAS redirects and authenticates users, and notifies the portal server of the authentication results.
	Portal server	The portal server interacts with clients through the authentication page, authenticates users, and notifies the NAS of the authentication results.	The portal server interacts with clients through the authentication page, notifies the NAS of users' authentication information, and receives the authentication results from the NAS.
	RADIUS server	In these two authentication solutions, the RADIUS servers have the same functions.	
Authentication process	Authentication and accounting	The portal server initiates authentication and accounting to the RADIUS server.	The NAS initiates authentication and accounting to the RADIUS server.
Offline process	Offline action	An offline action may be triggered by a notification from the portal server and traffic detection or port status detection performed by the NAS.	An offline action may be triggered by a notification from the portal server, a kickout notification from the RADIUS server, and traffic detection or port status detection performed by the NAS.
	Accounting completion packet	Accounting completion packets are initiated by the portal server.	Accounting completion packets are initiated by the NAS.



Note

The web authentication solution is selected based on the type of the portal server in use.

Some parameters can be shared by different web authentication solutions but some are not. Distinguish these parameters carefully to avoid abnormal web authentication due to parameter misconfiguration.

3. Ruijie First-Generation Web Authentication

Figure 1-2 Flowchart of Ruijie First-Generation Web Authentication

As shown in Figure 1-2, the Ruijie first-generation web authentication process includes four phases: redirection, authentication, user online, and user offline.

(1) Redirection

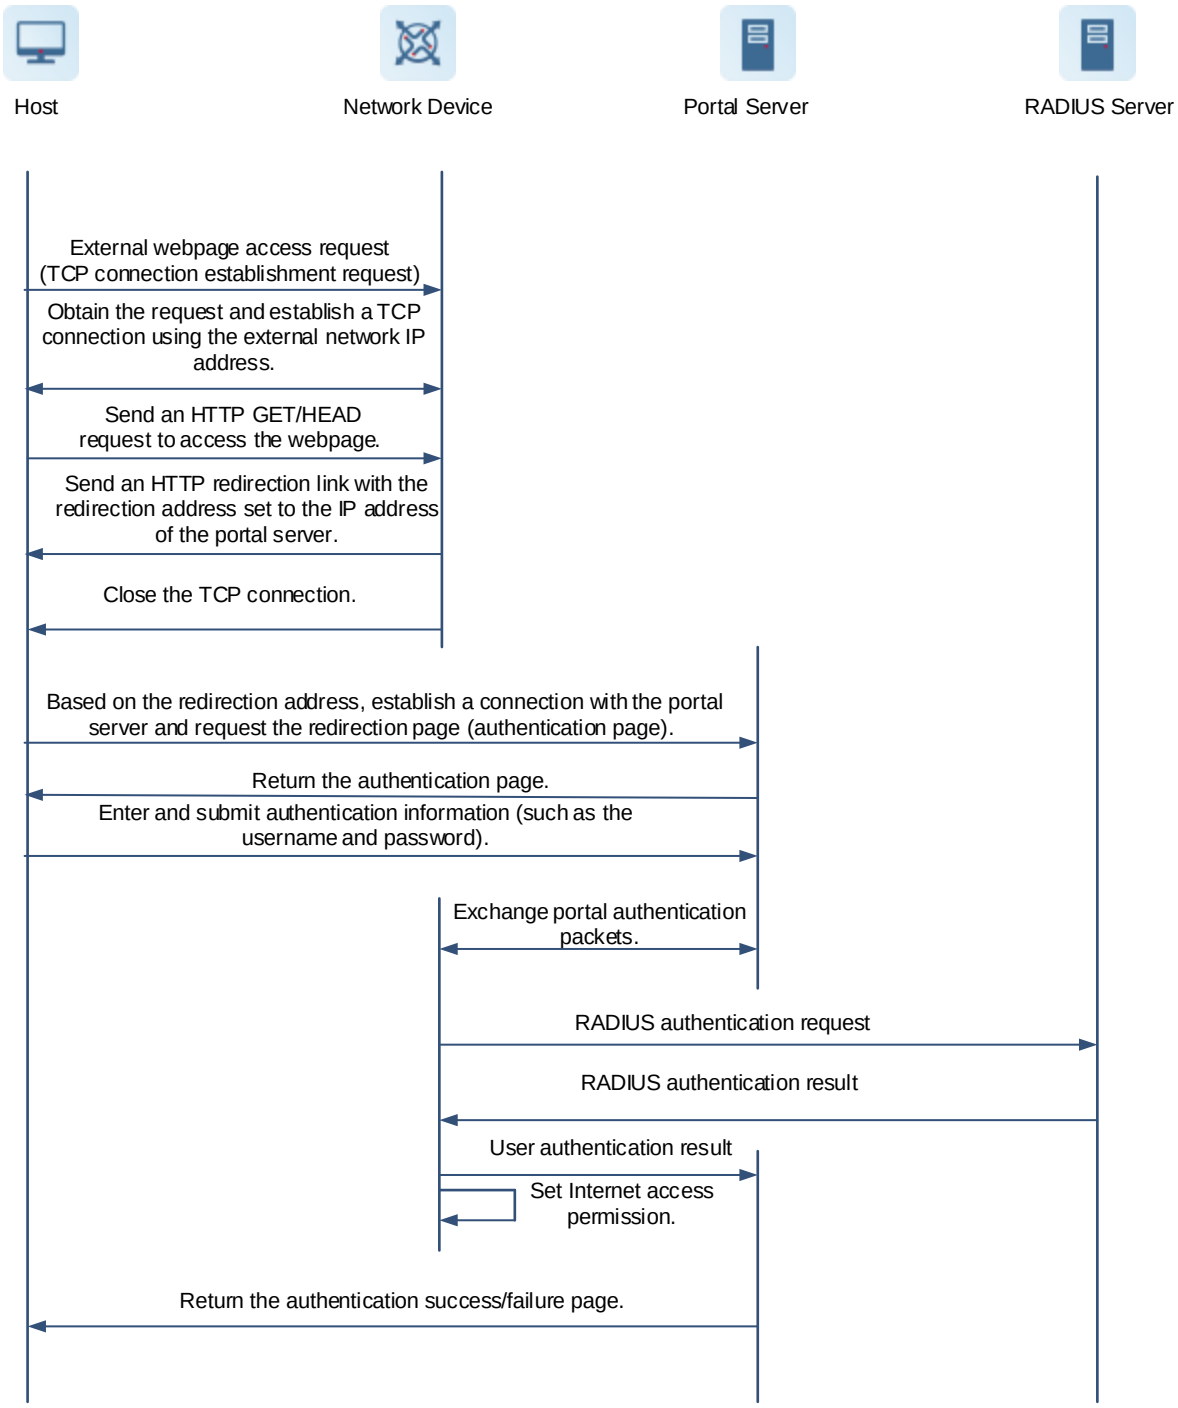
Before authentication, the NAS intercepts all HTTP requests from unauthenticated users and redirects these requests to the portal server. An authentication page is displayed on the browser of a user.

(2) Authentication

During authentication, the user enters information, for example, the username, password, and verification code on the web authentication page to interact with the portal server and complete authentication.

(3) User online

After the user succeeds in the authentication, the portal server notifies the NAS that the user has been authenticated. The NAS allows the user to access Internet resources.



(4) User offline

After the user gets offline, the portal server sends an accounting completion request to the RADIUS server and notifies the RADIUS server that the user has gotten offline. There are two user offline detection types:

- The NAS detects offline of a user when the user's time is due, the data quota is reached, or the link is disconnected. The NAS will notify the portal server of a user offline message. After receiving the message, the portal server requires the NAS to delete user information through SNMP and returns the offline page to the user host.
- The portal server detects getting offline of a user when the user triggers an offline request through the offline page or the keepalive page becomes invalid. The portal server notifies the NAS of a user offline message and returns the offline page to the user host.

4. Ruijie Second-Generation Web Authentication

Figure 1-3 Flowchart of Ruijie Second-Generation Web Authentication

- Authentication process

  a Before authentication, the NAS intercepts all HTTP requests from unauthenticated users and redirects these requests to the portal server. An authentication page is displayed on the browser of a user.

  b The user enters authentication information, such as the username, password, and verification code on the authentication page to interact with the portal server.

c The portal server sends the user authentication information to the NAS.

d The NAS initiates authentication to the RADIUS server and returns the authentication result to the portal server.

e The portal server displays the authentication result (success or failure) to the user on a page.

- User offline

  There are two user offline detection types: (1) The NAS detects offline of a user when the user's time is due, the data quota is reached, or the link is disconnected. (2) The portal server detects offline of a user when the user triggers an offline request through the offline page.

  Common offline scenarios are as follows:

  - When a user clicks the Logout button on the page, the portal server instructs the NAS to get the user offline.
  - The NAS forces a user offline when detecting that the traffic of the user is lower than the threshold, depending on the configured traffic threshold detection parameter.
  - When the RADIUS server plans to force a user offline based on a certain policy, the NAS instructs the portal server to push an offline page to the user host.

5. ClearPass Authentication

- Authentication roles
  - Authentication client

    In most cases, an authentication client is a browser running the HTTP protocol. When a user accesses the network from the browser, the browser initiates an HTTP request.
  - Network device

    In most cases, a network device in ClearPass authentication is an access layer device (such as the wireless AP on the wireless network) in the network topology, which is directly connected to user terminal. The web authentication function must be enabled on the network device. This device controls users' network access permissions, accepts the token verification requests from authentication clients or permits network access requests, and verifies the token information of the Portal server.
  - Portal server

    The Portal server is used to provide the authentication page and related operations of web authentication. The Portal server accepts an HTTP-based authentication request from an authentication client, extracts account information from the request, authenticates the information in the background, and forwards the authentication result to the network device through the authentication client. After the network device completes verification, the authentication client is redirected to the relevant page of the Portal server.
  - Authentication server

    The authentication server is used to provide the user authentication service through the specific protocol (such as the RADIUS protocol) negotiated by the Portal server and the authentication server.

- Authentication process

  a Before authentication, the device blocks all the HTTP requests from the user not authenticated, directs the user to the Portal server, and pops an authentication page on the user browser.

b During the authentication process, the user enters the authentication information (such as the username, password, and verification code) on the authentication page to exchange with the Portal server.

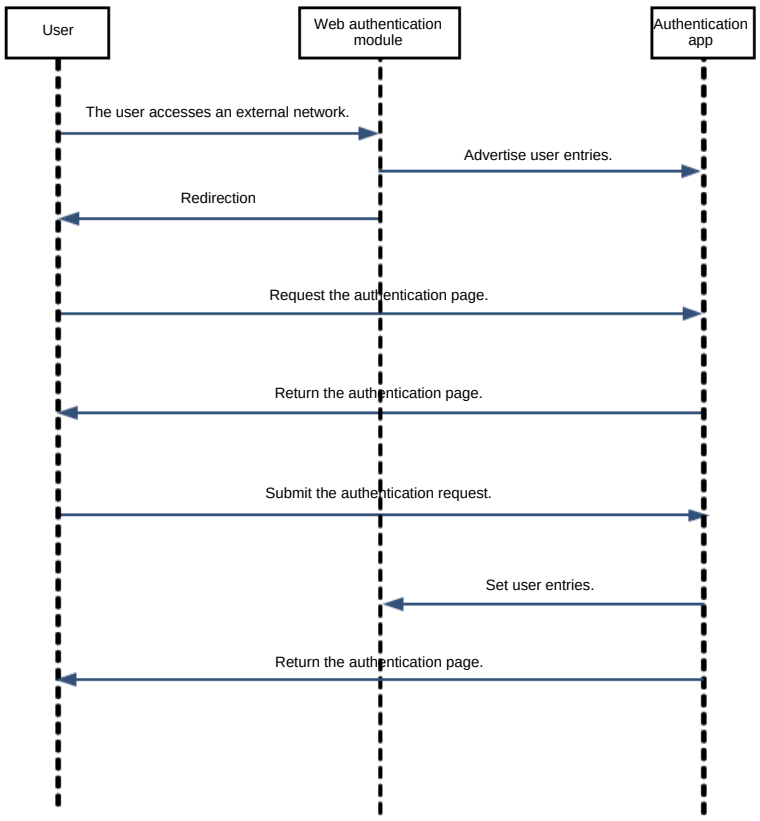
c The Portal server verifies the validity of user information in the background. If authentication fails, the server returns the authentication failure page to the client. If authentication succeeds, the server redirects the client to the network device.

d After the network device receives a request from the authentication client, it initiates verification to the Portal server and redirects the client to the relevant page of the Portal server based on the verification result.

Figure 1-4 Flowchart of ClearPass Authentication

- User logout process

  User logout occurs in either of the following cases: passive user logout by the device when the maximum user online duration is reached, the traffic is used up, or the link is disconnected and active user logout when the user clicks the Logout button.



- The user actively clicks the Logout button on the page and confirms to log out. A logout request is sent to both the Portal server and the network device. (The request may not be sent simultaneously, depending on the implementation of the Portal server.)
- The device logs the user out when it detects that the user has low traffic. This method depends on the configured low traffic detection parameters.

6. App-based Authentication

App-based authentication is actually performed by a third-party app. The web authentication module is not responsible for authentication. It serves as an agent to connect the user host and authentication app.

- Main roles
  - User host: user host to be authenticated when accessing network resources.
  - Webauth: web authentication component that is responsible only for redirection and user entry settings and not for interaction with the server.
  - Authentication app: performs authentication.
- Authentication process

Figure 1-5 Flowchart of App-based Web Authentication

As shown in Figure 1-5, the authentication app interacts with the server, and the web authentication component does not need to care about the internal authentication process of the authentication app. In the preceding figure, the portal server role is not provided. The app-based authentication process is as follows:

a A user host accesses an external network and triggers HTTP redirection. Webauth creates a user and advertises it to the authentication app.

b The user host accesses the redirection page.

c The user submits an authentication request on the login page.

d The authentication app authenticates the user. After authentication succeeds, the authentication app sends a message to Webauth to allow packets from the user to pass through.

e The authentication app returns the authentication result to the user host.

1.1.3 Protocols and Standards

- RFC 1945: Hypertext Transfer Protocol -- HTTP/1.0
- RFC 2068: Hypertext Transfer Protocol -- HTTP/1.1
- RFC 2818: HTTP Over TLS
- RFC 1157: Simple Network Management Protocol (SNMP)
- RFC 2865: Remote Authentication Dial In User Service (RADIUS)
- RFC 2866: RADIUS Accounting
- RFC 3576: Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)

1.2 Restrictions and Guidelines

- Different web authentication versions are highly divergent in the authentication processes and configurations. Read the relevant chapters carefully before configuring functions related to web authentication to prevent misconfiguration.
- Ruijie second-generation web authentication supports local account authentication on the NAS. Because RADIUS authentication is more commonly used in networks, it is generally used in application examples.
- Web authentication supports the authentication of domain names. That is, accounts can be authenticated in the format of user name@domain name. This requires enabling the domain-name-based authentication, authorization and accounting (AAA) service. For details, see *Configuring AAA*.

1.3 Configuration Task Summary

Web authentication configuration includes the following tasks:

(1) Configure basic web authentication functions. Select any of the following configuration tasks to configure.

- Configuring Ruijie First-Generation Web Authentication
- Configuring Ruijie Second-Generation Web Authentication
- Configuring ClearPass Authentication
- Configuring App-based Authentication

(2) (Optional) Configure web authentication template attributes. Perform the following optional configuration tasks as required.

- Configuring an Authentication Method List
- Configuring an Accounting Method List
- Configuring the Portal Communication Destination Port

- Configuring the Binding Mode

(3) (Optional) Configure parameters for communicating with the portal server. Perform the following optional configuration tasks as required.

- Configuring the Redirection HTTP Port
- Configuring the Redirection Connection Timeout Time
- Configuring Portal Detection
- Configuring Portal Escape
- Configuring the Portal Communication Source Port
- Disabling Portal Specification Extension
- Configuring Transparent Transmission of RADIUS Private Attributes

(4) (Optional) Configure authentication-free resources. Perform the following optional configuration tasks as required.

- Configuring the Authentication-Free Network Resource Range
- Configuring a Straight-through ARP Resource Range
- Configuring an Authentication-Exempted User Range

(5) (Optional) Configure user management functions. Perform the following optional configuration tasks as required.

- Configuring Logging of the Web Authentication Module
- Configuring the Maximum Number of HTTP Sessions for Unauthenticated Users
- Configuring the Interval for Updating Online User Information
- Enabling DHCP Address Check
- Configuring VLAN-based Authentication on a Port
- Configuring the Authenticated User Logout Delay on a Port
- Enabling RADIUS Server Escape
- Configuring DHCP Server Detection
- Configuring Uniqueness Check of Portal Authentication Accounts
- Enabling Automatic Adding of Domain Information After Usernames
- Configuring Seamless Migration of Web Authentication Users

(6) (Optional) Configure other functions. Perform the following optional configuration tasks as required.

- Configuring HTTPS Certificate Import
- Enabling Adding the Authentication Page to Favorite
- Configuring a Template Mapping Method
- Configuring the User State Timeout Duration

1.4 Configuring Ruijie First-Generation Web Authentication

1.4.1 Overview

After Ruijie first-generation web authentication is enabled, unauthenticated users will be redirected to the authentication page for authentication.

When an unauthenticated user attempts to access network resources, the NAS redirects the user to the authentication page, where the user can initiate authentication to the portal server.

1.4.2 Restrictions and Guidelines

- To apply web authentication successfully, you need to configure and apply a portal server.
- To apply web authentication successfully, you need to configure the key used for the communication between the access or convergence device and the portal server.
- To apply web authentication successfully, you need to configure the SNMP parameters used for the communication between the NAS and portal server. For more information about SNMP, see *Configuring SNMP*.
- When the access or convergence device finds an unauthenticated user attempting to access network resources through HTTP, it redirects the access request to the specified portal authentication page, where the user can initiate authentication to the portal server. Unauthenticated users can directly visit the IP address of the portal server only if the IP address is configured as an authentication-free network resource.
- When web authentication is enabled in interface configuration mode, it is disabled by default. Web authentication is not performed on user hosts connected to the port.

1.4.3 Prerequisites

Valid to-be-authenticated user information is configured on the RADIUS server. For details about configuration of to-be-authenticated user information, see the RADIUS server configuration.

1.4.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable AAA security services.

aaa new-model

The AAA security services are disabled by default.

(4) Create a first-generation web authentication template and enter the template configuration mode.

web-auth template eportalv1

(5) Configure parameters for interaction between the NAS and portal server.

a Configure the IP address and virtual routing and forwarding (VRF) instance of the portal server.

ip [*ipv4-address* | **oob** | **vrf** *vrf-name*]

No portal server IP address or VRF instance is configured by default.

After this command is configured, the NAS allows server access requests and can set a rate limit for requests sent to the server.

b Configure the authentication page address of the portal server.

url *url-string*

No authentication page address of the portal server is configured by default.

The URL to which a user is redirected is usually the authentication page address of the portal server.

c (Optional) Configure the URL format of redirection packets.

fmt { **ace** | **default** }

The Ruijie URL format is used for redirection packets by default.

Access control entry (ACE) association is supported when **fmt** is set to **ace**.

d (Optional) Configure the custom URL format of redirection packets.

fmt custom encry { **des | des_ecb | des_ecb3 | md5 | none** } { **ac-serialno** *ac-serialno-string* | **additional** *additional-string* | **ap-group** *ap-group-string* | **ap-mac** *ap-mac-string* **mac-format** { **5colon | dot | line | none** } | **ap-name** *ap-name-string* | **ap-serialno** *ap-serinalno-string* | **nas-id** *nas-id-string* | **nas-id2** *nas-id2-string* | **nas-ip** *nas-ip-string* | **nas-nam**e *nas-name-string* | **port** *port-string* | **ssid** *ssid-string* | **url** *url-string* | **user-id** *user-id-string* | **user-ip** *user-ip-string* | **user-mac** *user-mac-string* **mac-format** { **5colon | dot | line | none** } | **user-vid** *user-vid-string* }*

The Ruijie URL format is used for redirection packets by default.

e Configure the binding mode used by a template.

bindmode { **ip-mac-mode** | **ip-only-mode** }

The default binding mode used by a template is IP address+MAC address.

f Configure the encapsulation format of redirection packets.

redirect { **http** | **js** }

Redirection packets of the Ruijie URL format use the JavaScript (JS) encapsulation format, and redirection packets of CMCC-related URL formats use the HTTP encapsulation format by default.

Some apps cannot execute JS actions, and packets need to be encapsulated in HTTP format to trigger redirection.

(6) Return to the global configuration mode.

exit

(7) Configure the communication key between the NAS and the portal server.

web-auth portal key *key*

No communication key between the NAS and the portal server is configured by default.

During authentication, the communication key is used to encrypt some data exchanged between the NAS and portal server to improve security.

(8) Configure SNMP parameters.

The NAS and portal server use SNMP to manage users to be authenticated. SNMPv2 and SNMPv3 are available.

SNMPv2 is used as an example here. If high security requirements are raised, you are advised to use SNMPv3.

a Configure the SNMP community string on the NAS for the portal server to manage online users on the NAS.

snmp-server community { *community-string* } **rw**

The portal server uses the SNMP community string to read/write user information from/to the NAS.

b Configure the SNMP server.

snmp-server host { *ipv4-address* } **inform version 2c** { *community-string* } **web-auth**

The NAS sends Inform/Trap packets to notify the portal server of user offline.

c Enable the Webauth Trap/Inform function.

snmp-server enable traps web-auth

The Webauth Trap/Inform function is configured to enable the NAS to inform the portal server of user offline.

(9) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(10) Enable first-generation web authentication on a port.

web-auth enable

The web authentication function is disabled on a port by default.

1.5 Configuring Ruijie Second-Generation Web Authentication

1.5.1 Overview

After Ruijie second-generation web authentication is enabled, unauthenticated users will be redirected to the authentication page for authentication.

When an unauthenticated user attempts to access network resources, the NAS redirects the user to the authentication page, where the user can initiate authentication to the portal server.

1.5.2 Restrictions and Guidelines

Ruijie second-generation web authentication complies with the *CMCC WLAN Service Portal Specification*. Furthermore, it is extended to support the Ruijie ePortal server. In actual deployment, compatible configuration is required based on the server performance.

1.5.3 Prerequisites

Authenticated user information is configured on the RADIUS server. For details about user information configuration on the RADIUS server, see the RADIUS server configuration.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable AAA security services.

aaa new-model

The AAA security services are disabled by default.

In Ruijie second-generation web authentication, the NAS initiates authentication to the portal server through the AAA module.

(4) Configure the address, port number, and key of the RADIUS server.

radius-server host { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number*] [**acct-port** *acct-port-number*] [**key** [**0** | **7**] *text-string*]

No RADIUS server IP address, port number, or key is configured by default. The default authentication port is **1812** and the default accounting port is **1813**.

Users' account information is stored on the RADIUS server. The NAS needs to connect to the RADIUS server to validate a user.

(5) Configure a second-generation web authentication method list.

aaa authentication web-auth { **default** | *list-name* } { [**group** *group-name*]&<1-4> | **group radius** | **local** | **none** } *

No second-generation web authentication method list is configured by default.

A web authentication method list associates web authentication requests with the RADIUS server. The NAS selects an authentication method and a server based on the web authentication method list.

(6) Configure a network accounting method list.

aaa accounting network { **default** | *list-name* } **start-stop** { [**group** *group-name*]&<1-4> | **group radius** | **group tacacs+** | **none** } *

The web accounting function is disabled by default.

An accounting method list associates an accounting method and server. In web authentication, accounting is implemented to record user information or fees.

(7) Create a second-generation web authentication template and enter the template configuration mode.

web-auth template eportalv2

(8) Configure web authentication template parameters.

a Configure an authentication method list for the template.

authentication *method-list*

The default authentication method list is used by a template by default.

b Configure the accounting method list used by a template.

accounting *method-list*

The default accounting method list is used by a template by default.

c Configure the IP address and VRF instance of the portal server.

ip [*ipv4-address* | **oob** | **vrf** *vrf-name*]

No portal server IP address or VRF instance is configured by default.

d Configure the authentication page address of the portal server.

url *url-string*

The authentication page address of the portal server is configured by default.

When you configure the URL of the second-generation portal server, if the URL contains an IPv6 address, enclose it with a pair of square brackets. For example, when the IPv6 address is 2001::1, the actual configured URL is http://[2001::1]/index.jsp. The IPv6 template does not support **fmt** configuration.

e (Optional) Configure the URL format of redirection packets.

fmt { **cmcc-ext1** | **cmcc-ext2** | **cmcc-ext3** | **cmcc-mtx** | **cmcc-normal** | **ct-jc** | **cucc** | **default** }

The Ruijie URL format is used for redirection packets by default.

When **fmt** is set to **cmcc-normal** or **cmcc-ext1**, only the IPv4 format is supported.

f (Optional) Configure the cutom URL format of redirection packets.

fmt custom encry { **des | des_ecb | des_ecb3 | md5 | none** } { **ac-serialno** *ac-serialno-string* | **additional** *additional-string* | **ap-group** *ap-group-string* | **ap-mac** *ap-mac-string* **mac-format** { **5colon | dot | line | none** } | **ap-name** *ap-name-string* | **ap-serialno** *ap-serinalno-string* | **nas-id** *nas-id-string* | **nas-id2** *nas-id2-string* | **nas-ip** *nas-ip-string* | **nas-nam**e *nas-name-string* | **port** *port-string* | **ssid** *ssid-string* | **url** *url-string* | **user-id** *user-id-string* | **user-ip** *user-ip-string* | **user-mac** *user-mac-string* **mac-format** { **5colon | dot | line | none** } | **user-vid** *user-vid-string* }*

The Ruijie URL format is used for redirection packets by default.

g Configure the binding mode used by a template.

bindmode { **ip-mac-mode** | **ip-only-mode** }

The default binding mode used by a template is IP address+MAC address.

h Configure the encapsulation format of redirection packets.

redirect { **http** | **js** }

Redirection packets of the Ruijie URL format use the JS encapsulation format, and redirection packets of the CMCC-related URL formats use the HTTP encapsulation format by default.

(9) Return to the global configuration mode.

exit

(10) Configure the communication key between the NAS and the portal server.

web-auth portal key *key*

No communication key between the NAS and the portal server is configured by default.

(11) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(12) Enable second-generation web authentication on a port.

web-auth enable eportalv2

1.6 Configuring ClearPass Authentication

1.6.1 Overview

The ClearPass server can function as a portal server to interconnect with the web authentication component, redirect authenticated users to the authentication page, and complete authentication.

1.6.2 Restrictions and Guidelines

- The device can only connect to the ClearPass server of Aruba that functions as the Portal server for ClearPass authentication.
- When you configure the ClearPass authentication service, you need to configure a ClearPass authentication template, enable the local HTTP server, and configure the IP addresses of the ClearPass server and the NAS device where the authentication service resides as authentication-free resources.
- The ClearPass authentication server can exchange only HTTP packets with the ClearPass server.

1.6.3 Prerequisites

- Valid user information is configured on the RADIUS server. For details about user information configuration on the RADIUS server, see the RADIUS server configuration.
- Portal authentication services are configured on the ClearPass server. For detailed configuration, see the ClearPass server configuration.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the AAA security services.

aaa new-model

The AAA security services are disabled by default.

When ClearPass authentication is used, the device is responsible for initiating authentication to the server. The detailed functions are implemented by the AAA module.

(4) Configure the address, port number, and key for a RADIUS server.

radius-server host { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number*] [**acct-port** *acct-port-number*] [**key** [**0** | **7**] *text-string*]

No address, port number, or key is configured for a RADIUS server by default. The default authentication port number is 1812 and the default accounting port number is 1813.

User account information is stored on the RADIUS server. The device needs to connect to the RADIUS server to confirm user identity.

(5) Configure a ClearPass authentication method list.

aaa authentication cpweb { **default** | *list-name* } { [**group** *group-name*]&<1-4> | **group radius** | **local** | **none** } *

No ClearPass authentication method list is configured by default.

The authentication method list associates the web authentication request with the RADIUS server. The device selects an authentication method and the corresponding server based on the authentication method list.

(6) Configure a network accounting method list.

aaa accounting network { **default** | *list-name* } **start-stop** { [**group** *group-name*]&<1-4> | **group radius** | **group tacacs+** | **none** } *

The network accounting function is disabled by default.

The accounting method is used to associate the accounting method with a server. Web authentication needs the accounting feature to record user information or fees.

(7) Create a ClearPass authentication profile and enter the ClearPass authentication template configuration mode.

web-auth template cpweb

(8) Configure web authentication template parameters.

a Configure an IP address and a VRF instance for the Portal server.

ip [*ipv4-address*]

No IP address is configured for the Portal server by default.

b Configure a page address for the Portal server.

url *url-string*

No page address is configured for the Portal server by default.

c (Optional) Configure the URL format of redirection packets.

fmt clearpass

The URL format of redirection packets is ClearPass URL format by default.

d (Optional) Configure the custom URL format of redirection packets.

fmt custom encry { **des | des_ecb | des_ecb3 | md5 | none** } { **ac-serialno** *ac-serialno-string* | **additional** *additional-string* | **ap-group** *ap-group-string* | **ap-mac** *ap-mac-string* **mac-format** { **5colon | dot | line | none** } | **ap-name** *ap-name-string* | **ap-serialno** *ap-serinalno-string* | **nas-id** *nas-id-string* | **nas-id2** *nas-id2-string* | **nas-ip** *nas-ip-string* | **nas-nam**e *nas-name-string* | **port** *port-string* | **ssid** *ssid-string* | **url** *url-string* | **user-id** *user-id-string* | **user-ip** *user-ip-string* | **user-mac** *user-mac-string* **mac-format** { **5colon | dot | line | none** } | **user-vid** *user-vid-string* }*

The Ruijie URL format is used for redirection packets by default.

e Configure a method used by the device to parse authentication requests.

http-method post [init-url-key *urlkey-string* | **password-encrypt** { **none** | **uam** } | password-key *pswkey-string* | **username-key** *usrkey-string*] *

By default, the authentication packet is parsed based on the username, password, and URL parameter name. The password is not encrypted.

f Configure the encapsulation format of redirection packets.

redirect { **http** | **js** }

The JS format is used for redirection packets by default.

g Configure the response mode after successful authentication.

login-success response { redirect-init-url [reset-url *def-string*] | **msg** *msg-string* | **redirect-url** *url-string* }

The authentication success page is displayed after successful user authentication by default.

h Configure the response mode after failed authentication.

login-fail response { **redirect-login-url** | **redirect-url** *url-string* [**errmsg-key** *key-string*] | **msg** *msg-string* }

The user is redirected to the authentication page after failed authentication by default.

i Pop up the active logout page after successful authentication. (This command takes effect only when a redirection URL for successful authentication is configured.)

logout-popup-window

This function is disabled by default.

(9) Configure a communication IP address for the HTTP/HTTPS server.

web-auth auth-server ip ipv4-address

No communication IP address is configured for the HTTP/HTTPS server by default.

(10) Configure a communication port for the HTTP/HTTPS server.

web-auth auth-server { http | https } [port *port* **]**

No communication port is configured for the HTTP/HTTPS server by default.

(11) Exit to the global configuration mode.

exit

(12) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(13) Enable ClearPass authentication on the interface.

web-auth enable cpweb

ClearPass authentication is disabled on the interface by default.

1.7 Configuring App-based Authentication

1.7.1 Overview

The authentication app can interwork with the web authentication component to redirect unauthenticated users to the authentication page for authentication.

1.7.2 Restrictions and Guidelines

In template configuration mode, the authentication app name must be correctly configured.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an app-based authentication template and enter the template configuration mode.

web-auth template appauth

(4) Configure the authentication app name in the template.

app-name { **APP_AUTH** | *app-name* }

(5) Configure attribute parameters of the app-based authentication template.

a Configure the communication port of the portal server.

port *port-number*

The default communication port of the portal server is **80**.

b Configure the authentication page address of the portal server.

url *url-string*

The authentication page address of the portal server is configured by default, and must be started with http:// or https://.

c (Optional) Configure the custom URL format of redirection packets.

fmt { **default** | **custom encry** { **des | des_ecb | des_ecb3 | md5 | none** } { **ac-serialno** *ac-serialno-string* | **additional** *additional-string* | **ap-group** *ap-group-string* | **ap-mac** *ap-mac-string* **mac-format** { **5colon | dot | line | none** } | **ap-name** *ap-name-string* | **ap-serialno** *ap-serinalno-string* | **nas-id** *nas-id-string* | **nas-id2** *nas-id2-string* | **nas-ip** *nas-ip-string* | **nas-nam**e *nas-name-string* | **port** *port-string* | **ssid** *ssid-string* | **url** *url-string* | **user-id** *user-id-string* | **user-ip** *user-ip-string* | **user-mac** *user-mac-string* **mac-format** { **5colon | dot | line | none** } | **user-vid** *user-vid-string* }*}

The Ruijie URL format is used for redirection packets by default.

d Configure the binding mode used by a template.

bindmode { **ip-mac-mode** | **ip-only-mode** }

The default binding mode used by a template is IP address+MAC address.

e Configure the encapsulation format of redirection packets.

redirect { **http** | **js** }

Redirection packets of the Ruijie URL format use the JS encapsulation format, and redirection packets of the CMCC-related URL formats use the HTTP encapsulation format by default.

When some apps cannot execute JS actions, packets need to be encapsulated in HTTP format to trigger redirection.

f Configure the IP address of the NAS.

nas-ip { *ipv4-address* }

No NAS IP address is configured by default.

During app-based authentication, **nas-ip** is used only to specify the redirection URL transmitted to the portal server. If **nas-ip** is not configured, the local device address is automatically obtained based on the server IP address as **nas-ip**.

(6) Return to the global configuration mode.

exit

(7) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(8) Enable app-based authentication on a port.

web-auth enable appauth

1.8 Configuring an Authentication Method List

1.8.1 Overview

After an authentication method list is configured, the NAS selects a server for authentication based on the specified authentication method list.

When a user submits authentication information, the portal server sends an authentication request to the NAS. The NAS resolves the authentication server and other information based on the configured authentication method list name before initiating authentication.

1.8.2 Restrictions and Guidelines

- Before you configure an authentication method list, ensure that the authentication methods in the list have been configured on the AAA module.
- The same authentication method needs to be used for IPv4 and IPv6 packets.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the second-generation web authentication template configuration mode.

web-auth template { **eportalv2** | *template-name* **v2** }

(4) Configure an authentication method list for the template.

authentication *method-list*

The default authentication method list is used by a template by default.

1.9 Configuring an Accounting Method List

1.9.1 Overview

After an accounting method list is configured, the NAS selects a server for accounting based on the specified accounting method list.

After a user passes authentication, the NAS sends an accounting request. The recipient of the request depends on the configuration of the accounting method list and is usually the portal server.

1.9.2 Restrictions and Guidelines

- Before you configure an accounting method list, ensure that the accounting methods in the list have been configured on the AAA module.
- The same accounting method needs to be used for IPv4 and IPv6 packets.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the second-generation web authentication template configuration mode.

web-auth template { **eportalv2** | *template-name* **v2** }

(4) Configure the accounting method used by a template.

accounting *method-list*

The default accounting method list is used by a template by default.

1.10 Configuring the Portal Communication Destination Port

1.10.1 Overview

After the portal communication destination port is configured, the NAS regards the port as the communication port of the portal server, monitors packets from the portal server over this port, and specifies this port in packets sent to the portal server.

The NAS interacts with the portal server through the portal protocol, which specifies the port number used to listen to and send/receive packets. When the NAS detects that a user gets offline, it notifies the portal server. When the portal server listening port is changed, the NAS needs to re-configure the portal server communication port.

1.10.2 Restrictions and Guidelines

- Only second-generation web authentication and app-based authentication are supported.
- The configured port number must be consistent with the port actually used by the portal server.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the second-generation web authentication template configuration mode or app-based authentication template configuration mode.

web-auth template { **eportalv2** | *template-name* **v2** | **appauth** }

(4) Configure the communication port of the portal server.

port *port-number*

The default portal server communication port is **50100** for second-generation web authentication and **80** for app-based authentication.

1.11 Configuring the Binding Mode

1.11.1 Overview

The binding mode defines the binding relationship between users and packets and is classified into the IP address binding mode and IP address+MAC address binding mode.

- In IP address binding mode, it is regarded that a packet belongs to a user if the IP address in the packet is the same as that of the user.
- In IP address+MAC address binding mode, it is regarded that a packet belongs to a user only if the IP address and MAC address in the packet are the same as those of the user.

1.11.2 Restrictions and Guidelines

The binding mode is selected based on the user information that the NAS can obtain. If the NAS can obtain a user's IP address and MAC address, the IP address+MAC address binding mode is preferred (such as L2 network deployment). Otherwise, the IP address binding mode is preferred (such as L3 network deployment, in which the NAS cannot obtain users' MAC addresses and can obtain only the gateway's MAC address).

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the authentication template configuration mode.

web-auth template { **appauth** | **eportalv1** | **eportalv2** | *template-name* { **app** | **v1** | **v2** } }

(4) Configure the binding mode used by a template.

bindmode { **ip-mac-mode** | **ip-only-mode** }

The default binding mode used by a template is IP address+MAC address.

1.12 Configuring the Redirection HTTP Port

1.12.1 Overview

The NAS needs to intercept HTTP packets with specified ports from users and redirect these HTTP packets to the authentication page to complete authentication. The NAS intercepts HTTP packets with destination ports 80 and 443 by default. By configuring the redirection HTTP port, the NAS can intercept HTTP packets with custom ports.

1.12.2 Restrictions and Guidelines

- The commonly used management ports on the access or convergence device, such as ports 22, 23, and 53, and ports reserved by the system are not allowed to be configured as the redirection port.
- HTTP seldom uses ports with numbers smaller than 1000 except port 80. To avoid a conflict with well-known Transmission Control Protocol (TCP) ports, do not configure a port with a small number as the redirection port.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the redirection HTTP port.

http redirect port *port-num*

The NAS intercepts HTTP packets with port numbers 80 and 443 from users and redirects them to the authentication page by default.

A maximum of 10 different destination port numbers can be configured, excluding the default ports 80 and 443.

1.13 Configuring the Redirection Connection Timeout Time

1.13.1 Overview

HTTP redirection is implemented by establishing a TCP connection between the NAS and a user host and adding the redirection page URL to the 302 packet replied by the NAS. After a TCP connection is established between the NAS and a user host, the TCP connection is closed after the NAS receives an HTTP GET/HEAD packet from the user host and responds with an HTTP redirection packet.

The redirection connection timeout time prevents a TCP connection being occupied for a long time because the user host does not send a GET/HEAD packet. After the timeout time expires, the NAS will forcibly disconnect the TCP connection.

1.13.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the redirection connection timeout time.

http redirect timeout *timeout*

The default redirection connection timeout time is **3** seconds.

1.14 Configuring Portal Detection

1.14.1 Overview

The portal detection function periodically detects whether the active portal server is available. When the active portal server is unavailable, the standby server automatically takes over the services.

The portal detection methods vary depending on the web authentication solution. The simple principles are as follows:

- First-generation web authentication: The NAS attempts to establish a connection with the portal server. If the connection can be established, the NAS determines that the portal server is available.
- Second-generation web authentication: The NAS constructs and sends portal packets to the portal server. If the portal server returns response packets, the NAS determines that the portal server is available.

1.14.2 Restrictions and Guidelines

- This function is used when multiple portal servers are deployed. In this case, when the active portal server is unavailable, services are automatically switched to a standby portal server.
- This function can be configured in first-generation and second-generation web authentication. However, the detection method varies depending on the web authentication solution.

1.14.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure portal detection.

web-auth portal-check [**interval** *interval*] [**timeout** *timeout*] [**retransmit** *retransmit-times*]

Portal detection is disabled by default.

1.15 Configuring Portal Escape

1.15.1 Overview

After portal escape is configured, new users are allowed to access network resources without authentication when no portal server is available.

Configure this function if some key services in the network need to be maintained when the portal server is faulty.

1.15.2 Restrictions and Guidelines

- To use this function, you must configure portal detection.
- If multiple portal servers are configured, the escape function takes effect only when all the portal servers are unavailable.
- This function is intended only for the portal server and does not take effect to the RADIUS server.

1.15.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure portal escape.

web-auth portal-escape [**nokick**]

Portal escape is disabled by default.

If the nokick attribute is configured, the system does not force users offline when the escape function takes effect. If the nokick attribute is not configured, the system forces users offline when the escape function takes effect.

1.16 Configuring the Portal Communication Source Port

1.16.1 Overview

After the portal communication source port is configured, the NAS uses the source port to communicate with the portal server, and the used source IP address is the IP address configured on the source port.

1.16.2 Restrictions and Guidelines

Only one portal communication source port can be configured.

1.16.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the portal communication source port.

ip portal source-interface *interface-type interface-number*

No portal communication source port is configured by default.

1.17 Disabling Portal Specification Extension

1.17.1 Overview

Disabling portal specification extension is configured to support different portal servers.

Ruijie second-generation web authentication extends the CMCC WLAN Service Portal Specification. You need to determine whether to use the extension mode based on the server performance. If the portal server is a Ruijie product, enable portal specification extension. If the portal server complies with the CMCC WLAN Service Portal Specification, disable portal specification extension.

1.17.2 Restrictions and Guidelines

- Only second-generation web authentication is supported. When the NAS interworks with a portal server that complies with the CMCC WLAN Service Portal Specification, you can select multiple redirection URL formats to achieve compatibility with different servers.

1.17.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable portal specification extension.

no web-auth portal extension

Portal specification extension is enabled by default.

1.18 Configuring Transparent Transmission of RADIUS Private Attributes

1.18.1 Overview

After transparent transmission of RADIUS private attributes is enabled, the web authentication module uploads the private attributes delivered by the portal server to the RADIUS server and transparently transmits Ruijie private attributes in RADIUS authentication results to the portal server.

1.18.2 Restrictions and Guidelines

This function is used only on Ruijie Serverless Application Model (SAM) servers and portal servers. If the NAS interworks with a portal server provided by other vendors, you are not advised to enable this function. If this function is enabled, the portal server may not respond to packets.

1.18.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure transparent transmission of RADIUS private attributes.

web-auth portal-import attr-26

Transparent transmission of RADIUS private attributes is disabled by default.

1.19 Configuring the Authentication-Free Network Resource Range

Caution

Before configuring the range of authentication-free network resources, check whether there is an ACL that conflicts with the authentication-free network resources. Otherwise, packet forwarding fails. Perform this operation after evaluating the affected service range.

1.19.1 Overview

Authentication-free network resources allow user access without authentication.

After web authentication or 802.1X authentication is enabled on a port, the user hosts connecting to the port need to pass authentication before accessing network resources. After the authentication-free network resource range is configured, unauthenticated users can access resources within the range without authentication.

1.19.2 Restrictions and Guidelines

The number of authentication-free network resources and the number of authentication-exempted users cannot exceed 1000. The actual number of available resources may be reduced because of other security modules. Therefore, it is recommended that network segments be configured if many addresses need to be configured.

1.19.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the authentication-free network resource range.

http redirect direct-site *ipv4-address* [*mask*] [**arp** | *port-number*&<1-8>]

No authentication-free network resource range is configured by default.

1.20 Configuring a Straight-through ARP Resource Range

1.20.1 Overview

You can configure a straight-through Address Resolution Protocol (ARP) resource range to permit the ARP packets from the specified address to pass.

When ARP check or a similar function is enabled, users cannot learn the ARP entries of the gateway or other devices, which affects user experience. You can configure this function to ensure normal ARP learning.

1.20.2 Restrictions and Guidelines

- When ARP check is enabled, you need to configure the gateway of the PCs connecting to the L2 access device as a straight-through ARP resource. If both straight-through websites and ARP resources are configured for the same address/network segment, the commands will be combined automatically. If no ARP option is specified in the straight-through website configuration, the option will be added automatically after combination.

- When ARP check is enabled, if the outbound interface address of the PC connecting to the L2 access device is not the gateway address, you need to configure the outbound interface address as a straight-through ARP resource. If multiple outbound addresses exist, configure these addresses as straight-through ARP resources.
- If ARP check is enabled, you must configure the authentication-free network resources and gateway address as straight-through ARP resources.

1.20.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a straight-through ARP resource range.

http redirect direct-arp { *ipv4-address* [*mask*] }

No straight-through ARP resource range is configured by default.

1.21 Configuring an Authentication-Exempted User Range

1.21.1 Overview

After an authentication-exempted user range is configured, users within the range can access all reachable network resources without authentication. The authentication-exempted user range can be defined by IP address and MAC address.

The authentication-exempted user range can be used to allow special user groups that do not need permission control to access network resources.

1.21.2 Restrictions and Guidelines

The number of authentication-exempted users and the number of authentication-free network resources cannot exceed 1000. The actual number of available resources may be reduced because of other security modules. Therefore, it is recommended that network segments be configured if many addresses need to be configured.

1.21.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an authentication-exempted user range. Configure at least one of the tasks.

- Configure the IP address range of users who do not require authentication.

  web-auth direct-host { *ipv4-address* [*ipv4-mask* | **arp**] }

- Configure the MAC address range of users who do not require authentication.

  web-auth direct-host *mac-address*

No IP/MAC address range of authentication-exempted users is configured by default. All users can access restricted network resources only after they pass web authentication.

1.22 Configuring Logging of the Web Authentication Module

1.22.1 Overview

The logging function of the web authentication module can send log messages to the administrator to display the information and relevant events of users who get online/offline and allow users to configure a log printing rate limit.

1.22.2 Restrictions and Guidelines

When the online/offline rate is high, you can configure a rate limit for log printing. This prevents frequent log output from affecting the device performance and resulting in spamming.

1.22.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure web authentication logging.

web-auth logging enable *log-rate*

The web authentication logging function is disabled by default.

1.23 Configuring the Maximum Number of HTTP Sessions for Unauthenticated Users

1.23.1 Overview

When an unauthenticated user accesses network resources, the user's PC sends requests for HTTP session connection. The access or convergence device intercepts the HTTP packets and redirects the user to a web authentication page. To prevent an unauthenticated user from initiating too many HTTP connection requests and save resources on the NAS, you need to limit the maximum number of HTTP sessions that the unauthenticated users can initiate on the NAS.

1.23.2 Restrictions and Guidelines

- User authentication occupies one HTTP session, and other applications of a user may also need HTTP sessions. Therefore, you are not advised to set the maximum number of HTTP sessions to 1 for unauthenticated users.
- If the authentication page fails to be displayed during web authentication, the maximum number of HTTP sessions may be reached. When this happens, the user can close the application programs that occupy HTTP sessions and perform web authentication again.

1.23.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the maximum number of HTTP sessions allowed for an unauthenticated user.

http redirect session-limit *session-number*

The maximum number of HTTP sessions allowed for an unauthenticated user is **255** by default.

1.24 Configuring the Interval for Updating Online User Information

1.24.1 Overview

The NAS needs to periodically update maintained online user information, for example, the online time. The interval for updating online user information can be manually configured based on different monitoring requirements for online user information in different scenarios.

1.24.2 Restrictions and Guidelines

The interval for updating online user information must be a multiple of 60. If the configured value is not a multiple of 60, the actual effective value is rounded up to the multiple of 60.

1.24.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the interval for updating online user information.

web-auth update-interval *update-interval*

The default interval for updating online user information is **180** seconds.

1.25 Enabling DHCP Address Check

1.25.1 Overview

After Dynamic Host Configuration Protocol (DHCP) address check is configured, authentication is performed only for addresses assigned through DHCP. This function can be configured in global and interface configuration modes based on actual requirements.

1.25.2 Restrictions and Guidelines

- To use this function, you must configure DHCP Snooping.
- Only second-generation web authentication is supported for users with IPv4 addresses.
- This function applies only to network environments with IP addresses assigned through DHCP. If users with

statically configured IP addresses exist, network access of these users will be limited.

- If only a few users need to use static IP addresses, configure these IP addresses as straight-through addresses. In this case, these users are exempted from authentication.
- To apply this function to an interface, disable global DHCP address check first.

1.25.3 Configuration Tasks

The following DHCP address check configuration tasks are optional. Perform the configuration tasks as required.

- Configuring Global DHCP Address Check
- Configuring DHCP Address Check on an Interface

1.25.4 Configuring Global DHCP Address Check

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable DHCP address check globally.

web-auth dhcp-check

DHCP address check is disabled globally by default.

1.25.5 Configuring DHCP Address Check on an Interface

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(4) Enable DHCP address check on an interface. The following configuration tasks are mutually exclusive. Perform one of the tasks as required.

- Enable DHCP address check for all VLANs on an interface.

  web-auth dhcp-check

- Enable DHCP address check for a specified VLAN on an interface.

  web-auth dhcp-check vlan *vlan-list*

- Enable DHCP address check for VLANs except the specified VLAN on an interface by running the following commands in sequence.

  web-auth dhcp-check

  no web-auth dhcp-check vlan *vlan-list*

  DHCP address check is disabled for all VLANs on an interface by default.

If both the **web-auth dhcp-check** and **web-auth dhcp-check vlan** commands are configured, DHCP address check is enabled for all VLANs on the interface.

(5) (Optional) Disable DHCP address check on a VLAN.

web-auth dhcp-check disable

DHCP address check is disabled on an interface by default.

The **web-auth dhcp-check disable** command and the **no web-auth dhcp-check** command on an interface have the same configuration effect. The later configuration on the interface takes effect.

1.26 Configuring an Address Whitelist

1.26.1 Overview

After an address whitelist is configured, users can access some network resources before authentication.

1.26.2 Restrictions and Guidelines

- A whitelist can contain a maximum of 1000 addresses.
- When whitelisted addresses are configured in domain name format, you need to configure the domain name server (DNS) function for the NAS to enable the NAS to correctly parse domain names.
- Some domain names correspond to multiple IP addresses. A domain name can map to eight IP addresses at most.

1.26.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an address whitelist.

web-auth acl [**oob** | **vrf** *vrf-name*] **white-url** *white-url-name*

No whitelist is configured by default.

1.27 Configuring VLAN-based Authentication on a Port

1.27.1 Overview

After VLAN-based authentication is configured on a port, only the user hosts in the configured VLAN can initiate web authentication.

1.27.2 Restrictions and Guidelines

When this function is configured, multiple VLANs can be specified.

1.27.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure VLAN-based authentication on a port.

web-auth vlan-control *vlan-list*

VLAN-based authentication is not configured on a port by default. Port-based authentication is used by default.

1.28 Configuring the Authenticated User Logout Delay on a Port

1.28.1 Overview

After the authenticated user logout delay is configured on a port, the user hosts connected to the port go offline after the delay when the port is down.

1.28.2 Restrictions and Guidelines

You are advised to configure this function to prevent repeated user authentication in scenarios when a port goes down and then up quickly.

1.28.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the authenticated user logout delay after a port is down.

web-auth linkdown-timeout *linkdown-timeout*

The default authenticated user logout delay after a port is down is **60** seconds.

1.29 Enabling RADIUS Server Escape

1.29.1 Overview

After the RADIUS server escape function is configured, users can still perform authentication to access the Internet when the RADIUS server fails.

1.29.2 Restrictions and Guidelines

This function must be used together with RADIUS server detection function. For details about the RADIUS server detection command, see *Configuring RADIUS*.

1.29.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable RADIUS server escape.

web-auth radius-escape

The RADIUS server escape function is disabled by default.

1.30 Configuring DHCP Server Detection

1.30.1 Overview

DHCP server detection can find offline web authentication users in a DHCP environment in time, ensuring accurate accounting.

In a network environment where IP addresses are dynamically assigned through DHCP, a DHCP client can send a DHCP RELEASE packet to proactively release the IP address assigned by the DHCP server. The DHCP client without an IP address cannot access the network. If the DHCP server detection function is enabled, the NAS with DHCP Server and web authentication enabled will force the corresponding authenticated user offline when receiving a DHCP RELEASE packet from the DHCP client. If the DHCP server detection function is disabled, the NAS will not force the corresponding authenticated user offline in the preceding scenario.

1.30.2 Restrictions and Guidelines

- The DHCP server detection function is enabled by default.
- This function applies only to network environments with DHCP deployed and takes effect only when both DHCP server and web authentication are enabled on the device.

1.30.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable DHCP server detection.

no web-auth dhcp-server check

The DHCP server detection function is enabled by default.

1.31 Configuring Uniqueness Check of Portal Authentication Accounts

1.31.1 Overview

After uniqueness check of portal authentication accounts is enabled, the NAS returns an ACK_AUTH message carrying Errcode 2 to the portal server if account information of a new authenticated user is being used by an

online user. Upon receiving such a reply message, some portal servers will send the "Terminal Preemption" prompt to users.

1.31.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable uniqueness check of portal authentication accounts.

web-auth portal-valid unique-name

Uniqueness check of portal authentication accounts is disabled by default.

1.32 Enabling Automatic Adding of Domain Information After Usernames

1.32.1 Overview

After automatic adding of domain information after usernames is enabled, the web authentication module will automatically add configured domain information after the original usernames and use the new usernames for authentication.

1.32.2 Restrictions and Guidelines

- The domain information can be 63 bytes at most.
- The new username is obtained by adding configured domain information after the username sent by the portal server. If the new username exceeds 253 bytes, the excess of domain information will be intercepted.

1.32.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the authentication template configuration mode.

web-auth template { **appauth** | **eportalv1** | **eportalv2** | *template-name* **app** | *template-name* **v1** | *template-name* **v2** }

(4) Enable automatic adding of domain information after usernames.

domain *domain-info*

No domain information is added after usernames by default.

1.33 Configuring Seamless Migration of Web Authentication Users

1.33.1 Overview

A migration policy is used by the authentication component when a web authentication user performs migration on an interface or VLAN. After the seamless migration function is enabled, users who pass web authentication can be migrated without being logged out.

1.33.2 Restrictions and Guidelines

- Seamless user migration takes effect only after migration of authentication users is enabled through the **station-move permit** command. For details, see *Configuring SCC*.

1.33.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the seamless migration function for web-authenticated users.

web-auth station-move auto

The MAB migration function is disabled by default.

(4) (Optional) Configure the function of immediately updating accounting information after a user is migrated.

web-auth station-move info-update

The function of immediately updating accounting information after seamless migration is disabled by default, that is, accounting information is not updated immediately after seamless migration, but is updated by accounting packets sent based on the accounting interval.

1.34 Configuring HTTPS Certificate Import

1.34.1 Overview

HTTPS is an encrypted data transmission protocol and relies on a certificate to ensure transmission security. Before enabling the HTTPS server function, you need to import an available certificate.

To configure HTTPS certificate import, first upload available HTTPS certificate and key files to the NAS and then apply the HTTPS certificate and key files.

Two types of HTTPS certificates can be imported: HTTPS redirection certificate and HTTPS certificate of ClearPass authentication.

1.34.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Upload the HTTPS certificate and key files.

web-auth import-ssl [**auth-server**] { **cert ftp:***path* | **cert tftp:***path* | **cert oob_ftp:***path* | **cert oob_tftp:***path* } { **key ftp:***path* | **key tftp:***path* | **key oob_ftp:***path* | **key oob_tftp:***path* } [**vrf** *vrf-name*]

(3) Enter the global configuration mode.

configure terminal

(4) Apply the HTTPS certificate and key files.

web-auth ssl-policy { **https-redirect** | **auth-server** }

No HTTPS certificate or key file is applied by default.

1.35 Enabling Adding the Authentication Page to Favorite

1.35.1 Overview

After the function of adding the authentication page to Favorite is enabled, a user can add the authentication page to Favorite and open the Favorite page for web authentication without needing redirection.

1.35.2 Restrictions and Guidelines

- This function must be used together with DHCP Snooping.
- This function cannot be configured with 802.1x authentication simultaneously. Otherwise, a user may be online for web authentication and 802.1x authentication at the same time.

1.35.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of adding the authentication page to Favorite.

web-auth portal direct-auth

The function of adding the authentication page to Favorite is disabled by default.

1.36 Configuring a Template Mapping Method

1.36.1 Overview

The template mapping method is configured when multiple authentication scenarios exist on one port.

When web authentication is enabled on a port, and the method of template A is used, but some users do not apply to template A and want to use template B for authentication, you can configure a template mapping method for these users to enable these users to use the authentication method of template B.

1.36.2 Restrictions and Guidelines

By setting the VLAN or IP address range, you can select users for whom a template mapping method needs to be configured.

1.36.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a template mapping method, and determine the user range and the corresponding authentication template method.

web-auth mapping *mapping-method* { **vlan** *vlan-list* | **ip-mapping** *ipv4-address ipv4-mask* } **template** *tmpltate-name*

No template mapping method is configured bydefault.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(5) Apply the template mapping method.

web-auth apply-mapping *mapping-method*

No template mapping method is applied on an interface by default.

No template mapping method is applied on an interface by default.

1.37 Configuring the User State Timeout Duration

1.37.1 Overview

This function is used to control the internal state refresh time of users. For example, in a DHCP short lease scenario, after user A obtains an IP address for authentication, the user information is still stored in the component even if the IP address is released. In this case, another user that obtains this IP address cannot be authenticated because the previous user information is not cleared. To address this issue, you can shorten the user state timeout period to increase the information update frequency so that outdated information can be removed from the component and new users can be authenticated smoothly.

1.37.2 Restrictions and Guidelines

- This command is used to configure the base value, and the actual value is a multiple of the base value. The actual update time varies with users in different scenarios and states, but shortening the timeout period will accelerate the information update speed.

1.37.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a base value for the user state timeout period.

web-auth state timeout *timeout*

By default, the base user state timeout duration is 120 seconds.

1.38 Monitoring

Run the **show** command to check the configuration.

Run the **clear** command to clear information.

Caution

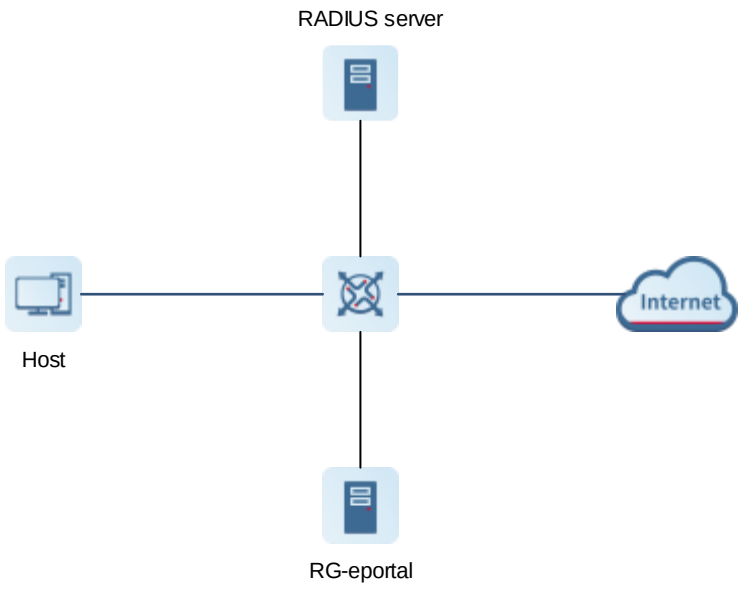
Running the **clear** command may lose vital information and thus interrupt services.

Table 1-2 Monitoring

Command	Purpose
show web-auth acl white-url	Displays whitelist configurations.
show web-auth authmng [**statistic** | **abnormal**]	Displays the web authentication data.
show web-auth auth-server	Displays parameters of the local HTTP server.
show web-auth parameter	Displays basic parameter configurations for web authentication.
show web-auth control	Displays authentication control configuration.
show web-auth dhcp-bind-info	Displays the DHCP information of users in the web authentication buffer. The information source is DHCP snooping.
show web-auth direct-arp	Displays the straight-through ARP resource range.
show web-auth direct-host	Displays the authentication-exempted user range.
show web-auth direct-site	Displays the straight-through website range.
show web-auth ip-mapping	Displays the configured mapping between servers and users.
show web-auth portal-check	Displays portal-check parameters.
show web-auth rdport	Displays the TCP interception port.
show web-auth syslog [**ip** *ipv4-address* | ***name*** *name* | ***mac*** *mac-address*]	Displays user online and offline records.
show web-auth template	Displays portal server configurations.
show web-auth capability	Displays Web authentication capability.

Command	Purpose
show web-auth ssl-policy info	Displays SSL certificate information.
show web-auth user { **all** | **ip** *ipv4-address* | **mac** *mac-address* | **name** *name* }	Displays user online information.
clear web-auth ac white-url	Clears web authentication blacklist and whitelist configurations.
clear web-auth direct-arp	Clears all ARP resources.
clear web-auth direct-host	Clears all authentication-exempted users.
clear web-auth direct-site	Clears all authentication-free network resources.
clear web-auth user { **all** | **id** *num* | **ip** *ipv4-address* | **mac** *mac-address* | **name** *name* }	Forces users offline.
debug web-auth all	Debugs web authentication.

1.39 Configuration Examples



1.39.1 Configuring First-Generation Web Authentication

1. Requirements

The NAS serves as the network access server (NAS) and enables first-generation web authentication for user hosts connecting to a specified port. These user hosts can access the network only after authentication by using valid accounts and passwords.

2. Topology

Figure 1-6 Configuring First-Generation Web Authentication

3. Notes

- Configure the portal server to support first-generation web authentication.
- Configure the RADIUS server to support first-generation web authentication.
- Configure the first-generation web authentication template and specify the portal server IP address, redirection page, and other parameters.
- Configure the communication key between the NAS and the portal server.
- Configure SNMP parameters between the NAS and the portal server.
- Enable first-generation web authentication on a port of the NAS.

4. Procedure

(1) Configure the portal server and RADIUS server to support first-generation web authentication. For details about the configuration procedure, see the corresponding configuration guide.

(2) Configure the first-generation web authentication template and set the portal server IP address to 192.168.1.3 and redirection page URL to http://192.168.1.3/eportal/index.jsp.

```
Device> enable
Device# configure terminal
Device(config)# web-auth template eportalv1
Device(config.tmplt.eportalv1)# ip 192.168.1.3
Device(config.tmplt.eportalv1)# url http://192.168.1.3/eportal/index.jsp
Device(config.tmplt.eportalv1)# exit
```

(3) Set the communication key between the NAS and the portal server to key_1 (which must be the same as that configured on the portal server).

```
Device(config)# web-auth portal key key_1
```

(4) Enable the SNMPv2 function.

```
Device(config)# enable service snmp-agent
Device(config)# snmp-server enable version v2c
```

(5) Configure SNMP community string community_1 and enable the SNMP trap/inform function. The SNMP server address is the portal server address.

```
Device(config)# snmp-server community community_1 rw
Device(config)# snmp-server host 192.168.1.3 inform version 2c community_1 web-auth
Device(config)# snmp-server enable traps web-auth
```

(6) Enable first-generation web authentication on GigabitEthernet 0/2 and GigabitEthernet 0/3.

```
Device(config)# interface range gigabitEthernet 0/2-3
Device(config-if-range)#web-auth enable eportalv1
```

5. Verification

Check that first-generation web authentication takes effect on GigabitEthernet 0/2 and GigabitEthernet 0/3.

```
Device# show web-auth control
 Port                  Control  Server Name    Online User Count Arp-detect Vlan
Control List
```

```
------------------------ -------- ------------------------------
---------------- ----------
GigabitEthernet 0/2      On      eportalv1      0              Off
GigabitEthernet 0/3      On      eportalv1      0              Off
```

Check that parameters of the web authentication template are correctly configured.

```
Device# show web-auth template
Webauth Template Settings:
-------------------------------------------------------------
  Name:             eportalv1
  BindMode:          ip-only-mode
  Type:             v1
  Ip:               192.168.1.3
  Url:              http://192.168.1.3/eportal/index.jsp
```

When user hosts connecting to GigabitEthernet 0/2 and GigabitEthernet 0/3 on the NAS access a webpage, the hosts will be redirected to http://192.168.1.3/eportal/index.jsp for authentication. The hosts can access the network after they pass authentication.

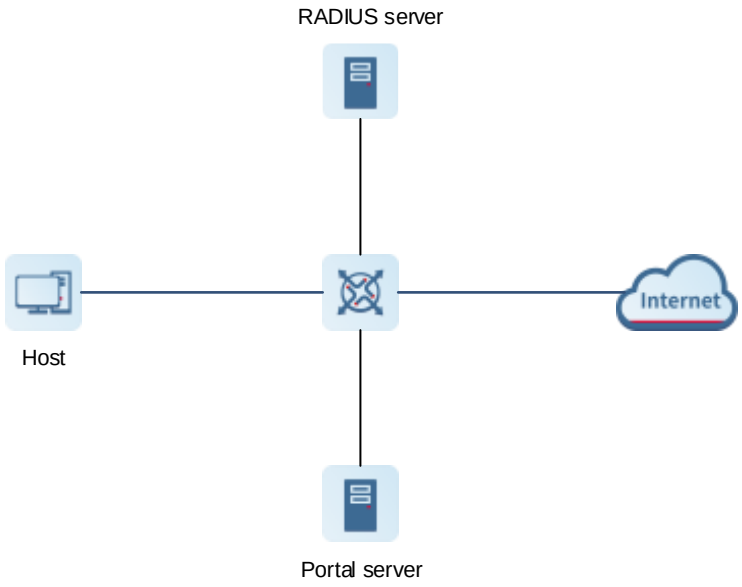
6. Configuration Files

```
!
web-auth template eportalv1
 ip 192.168.1.3
 url 192.168.1.3/eportal/index.jsp
!
web-auth portal key key_1
!
enable service snmp-agent
!
snmp-server host 192.168.1.3 informs version 2c 7 $10$255$lxTDxZBSy7ToI2s=$ web-auth
snmp-server enable traps web-auth
snmp-server enable version v2c
snmp-server community 7 $10$255$lxTDxZBSy7ToI2s=$ rw
!
interface GigabitEthernet 0/2
 web-auth enable eportalv1
!
interface GigabitEthernet 0/3
 web-auth enable eportalv1
!
```

7. Common Errors

- The SNMP parameters used for the communication between the portal server and the NAS are configured incorrectly, causing authentication failures.
- When web authentication is deployed on L3 networks, **ip-only-mode** is not selected as the binding mode in the template.
- When web authentication is used together with Virtual Router Redundancy Protocol (VRRP), the

snmp-server trap-source ip command is not configured to specify the VRRP address. As a result, the portal server cannot process Trap packets correctly.



1.39.2 Configuring Second-Generation Web Authentication

1. Requirements

The NAS serves as the NAS and enables second-generation web authentication for user hosts connecting to a specified port. These user hosts can access the network only after authentication by using valid accounts and passwords.

2. Topology

Figure 1-7 Configuring Second-Generation Web Authentication

3. Notes

- Configure the portal server to support second-generation web authentication.
- Configure the RADIUS server to support second-generation web authentication.
- Enable AAA security services on the device.
- Configure the IP address and communication key of the RADIUS server.
- Configure the default web authentication and accounting method lists for the AAA module.
- Configure the key used to communicate with the portal server.
- Configure the second-generation web authentication template.
- Enable second-generation web authentication on a port of the NAS.

4. Procedure

(1) Configure the portal server and RADIUS server to support second-generation web authentication. For details about the configuration procedure, see the corresponding configuration guide.

(2) Configure the second-generation web authentication template and set the portal server IP address to 192.168.1.3 and redirection page URL to http://192.168.1.3/eportal/index.jsp.

```
Device> enable
Device# configure terminal
Device(config)# web-auth template eportalv2
Device(config.tmplt.eportalv2)# ip 192.168.1.3
Device(config.tmplt.eportalv2)# url http://192.168.1.3/eportal/index.jsp
Device(config.tmplt.eportalv2)# exit
```

(3) Set the communication key between the NAS and the portal server to key_1 (which must be the same as that configured on the portal server).

```
Device(config)# web-auth portal key key_1
```

(4) Configure the IP address and communication key of the RADIUS server.

```
Device(config)# radius-server host 192.168.1.4 key radiuskey
```

(5) Enable AAA security services.

```
Device(config)# aaa new-model
```

(6) Configure the default web authentication and accounting method lists for the AAA module.

```
Device(config)# aaa authentication web-auth default group radius
Device(config)# aaa accounting network default start-stop group radius
```

(7) Enable second-generation web authentication on GigabitEthernet 0/2 and GigabitEthernet 0/3.

```
Device(config)# interface range gigabitEthernet 0/2-3
Device(config-if-range)#web-auth enable eportalv2
```

5. Verification

Check that second-generation web authentication takes effect on GigabitEthernet 0/2 and GigabitEthernet 0/3.

```
Device# show web-auth control
 Port                   Control  Server Name    Online User Count Arp-detect Vlan
Control List
 ------------------------ -------- --------------------------------
----------------- ----------
 GigabitEthernet 0/2      On      eportalv2      0              Off
 GigabitEthernet 0/3      On      eportalv2      0              Off
```

Check that parameters of the second-generation authentication template are correctly configured.

```
Device#show web-auth template
Webauth Template Settings:
-------------------------------------------------------------
  Name:             eportalv2
  BindMode:          ip-mac-mode
  Type:             v2
  Port:             50100
  vrf:
  Ip:               192.168.1.3
  Url:              http://192.168.1.3/eportal/index.jsp
  Authentication:
  Accounting:
  Portal-State:      Enable
```

```
  Radius-State:      Enable
```

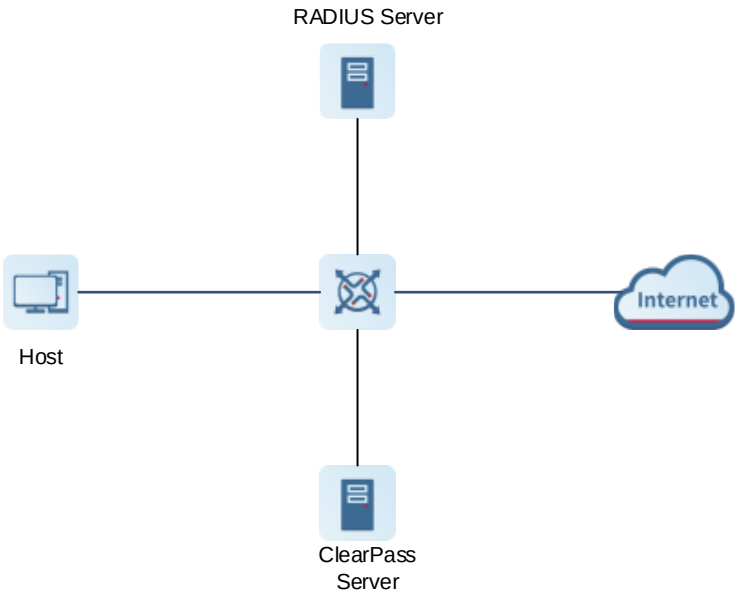
When user hosts connecting to GigabitEthernet 0/2 and GigabitEthernet 0/3 on the NAS access a webpage, the hosts will be redirected to http://192.168.1.3/eportal/index.jsp for authentication. The hosts can access the network after they pass authentication.

6. Configuration Files

```
!
web-auth template eportalv2
 ip 192.168.1.3
 url 192.168.1.3/eportal/index.jsp
!
web-auth portal key key_1
!
aaa new-model
!
aaa accounting network default start-stop group radius
aaa authentication web-auth default group radius
!
radius-server host 172.26.147.194 key 7 $10$3ed$f/3upXnVEhd9$
!
interface GigabitEthernet 0/2
 web-auth enable eportalv2
!
interface GigabitEthernet 0/3
 web-auth enable eportalv2
!
```

7. Common Errors

- The communication key between the portal server and NAS is configured incorrectly, or is configured only on the portal server or NAS, causing authentication errors.
- The communication parameters between the RADIUS server and the NAS are set incorrectly, causing authentication errors.
- The portal server does not support the CMCC WLAN Service Portal Specification, causing a compatibility failure.



1.39.3 Configuring ClearPass Authentication

1. Requirements

The device functions as the network access server to provide ClearPass authentication to access users on a specific port. Users need to pass authentication using valid account and password before they can access the network.

2. Topology

Figure 1-8 Topology of ClearPass Authentication

3. Notes

- Configure the ClearPass server as the Portal server to support ClearPass authentication.
- Configure the RADIUS server to support ClearPass Web authentication.
- Configure a ClearPass web authentication template and specify parameters such as the Portal server IP address and redirection page.
- Enable the ClearPass authentication service on the port of the device.

4. Procedure

(1) Configure the ClearPass server and the RADIUS server to support ClearPass authentication. For details, see the corresponding configuration guide.

(2) Configure a ClearPass web authentication template and set the Portal server IP address to 172.29.121.53 and the redirection URL to http://172.29.121.53/ruijie.php. In the URL, ruijie is the web template name configured on the ClearPass server.

```
Device> enable
Device# configure terminal
Device(config)# web-auth template cpweb
Device(config.tmplt.cpweb)# ip 172.29.121.53
Device(config.tmplt.cpweb)# url http://172.29.121.53/ruijie.php
Device(config.tmplt.cpweb)# exit
```

(3) Configure the communication IP address and port number of the HTTP server and the URL used to initiate authentication.

```
Device(config)# web-auth auth-server http port 8082
Device(config)# web-auth auth-server ip 172.20.74.159
```

(4) Configure to permit the addresses of the Portal server and the local HTTP server.

```
Device(config)# http redirect direct-site 192.168.197.79
Device(config)# http redirect direct-site 172.20.74.159
```

(5) Enable ClearPass authentication on GigabitEthernetwork 0/2 and GigabitEthernetwork 0/3.

```
Device(config)# interface range gigabitEthernetwork 0/2-3
Device(config-if-range)# web-auth enable cpweb
```

(6) Configure AAA authentication and accounting services.

```
Device(config)# aaa new-model
Device(config)# aaa authentication cpweb default group radius
Device(config)# aaa accounting network default start-stop group radius
```

(7) Configure the RADIUS service.

```
Device(config)# radius-server host 172.26.147.194 key test
```

5. Verification

Check whether ClearPass authentication takes effect on GigabitEthernetwork 0/2 and GigabitEthernetwork 0/3.

```
Device# display web-auth control
 Port                   Control  Server Name    Online User Count Arp-detect Vlan
Control Range
 ------------------------ -------- -------------------------------
----------------- ----------
 GigabitEthernetwork 0/2      On      cpweb          0               Off
 GigabitEthernetwork 0/3      On      cpweb          0               Off
```

Check whether the parameters in the ClearPass web authentication template are correct.

```
Device# display web-auth template
Webauth Template Settings:
-------------------------------------------------------------
  Name:          cpweb
  Type:          cpweb
  Ip:            172.29.121.53
  Url:           http://172.29.121.53/ruijie.php
  Logout-popup:   off
  Login-success:  redirect-init-url
  Login-fail:     show-msg
```

Check whether terminals connecting to GigabitEthernetwork 0/2 and GigabitEthernetwork 0/3 of the device are redirected to http://172.29.121.53/ruijie.php for identity authentication when they access any web page. The terminals can access the network only after they pass identity authentication.

6. Configuration Files

```
!
web-auth template cpweb
 ip 172.29.121.53
 url http://172.29.121.53/ruijie.php
!
```

```
aaa new-model
!
aaa authentication cpweb default group radius
aaa accounting network default start-stop group radius
!
radius-server host 172.26.147.194 key 7 $10$3ed$f/3upXnVEhd9$
!
web-auth auth-server http port 8082
web-auth auth-server ip 172.20.74.159
http redirect direct-site 192.168.197.79
http redirect direct-site 172.20.74.159
!
interface GigabitEthernetwork 0/2
 web-auth enable cpweb
!
interface GigabitEthernetwork 0/3
 web-auth enable cpweb
!
```

7. Common Errors

- The NAS device is not registered on the ClearPass server, causing authentication and login errors.
- The IP address of the Portal server and the IP address of the NAS device are not permitted, causing login errors.

1 Configuring SCC

1.1 Overview

The Security Control Center (SCC) provides common configuration methods and policy integration for various access control and network security services, so that these services can coexist on one device to meet diversified access and security control requirements in various scenarios.

Typical access control services include 802.1x, web authentication, Address Resolution Protocol (ARP) check, and IP source guard, and typical network security services include access control list (ACL), NFPP, and gateway-targeted ARP spoofing prevention. When two or more access control or network security services are enabled on the same device, the SCC coordinates coexistence based on related policies.

1.2 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring Authentication-Exempted VLANs
- Configuring the IPv4 User Capacity
- Configuring Authenticated User Migration
- Configuring User Online Status Detection

1.3 Configuring Authentication-Exempted VLANs

1.3.1 Overview

After an authentication-exempted virtual local area network (VLAN) is configured, users in this VLAN can access the Internet without 802.1x or web authentication. When the device detects that a received packet is destined for an authentication-exempted VLAN, the device skips authentication.

The authentication-exempted VLAN function aims to provide easy and convenient network access experience for special groups in networks that require authentication. For example, the headmaster's office in a campus network is configured to be within an authentication-exempted VLAN to ensure network access without authentication.

1.3.2 Restrictions and Guidelines

- When an authentication-exempted VLAN is configured, ensure that the ACL also permits the VLAN. The authentication-exempted VLAN function exempts user packets only from authentication detection. User packets still need to undergo ACL detection. If a specified user or VLAN is denied in the ACL, the specified user or users in the specified VLAN cannot access the Internet.
- A maximum of 100 authentication-exempted VLANs can be configured.
- Configuring authentication-exempted VLANs occupies system resources. If access authentication is disabled on a device, the authentication-exempted VLAN function is meaningless and needs to be disabled.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure authentication-exempted VLANs.

direct-vlan *vlan-list*

No authentication-exempted VLAN is configured by default.

1.4 Configuring the IPv4 User Capacity

1.4.1 Overview

The IPv4 user capacity is used to limit the maximum number of IPv4 access users on a port of the device. When the total number of IPv4 access users on a port reaches the limit, new users cannot access the network over this port. You need to select a proper user capacity based on the actual environment to guard against brutal force impacts from unauthorized users and improve the operational stability of the device.

1.4.2 Restrictions and Guidelines

IPv4 users include those generated through 802.1x authentication, web authentication, and other binding functions. IPv4 users on a port may be generated over the port or globally. For example, when a global IPv4 user is bound to a port by running the corresponding command, the user is also calculated as a user on the port.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure the IPv4 user capacity on a port.

nac-author-user maximum *max-user-number*

The IPv4 user capacity on a port is not limited by default.

1.5 Configuring Authenticated User Migration

1.5.1 Overview

In actual scenarios, access users usually pass authentication and get online through one physical location, and then switch to another physical location for office or entertainment. For example, an enterprise employee takes a tablet from one office to another office to access the Internet by directly removing the network cable instead of getting offline proactively. If the authenticated user migration function is not configured, the employee cannot pass authentication to access the Internet in the other office because the original account does not get offline.

By default, 802.1x and web authentication users cannot switch from one physical location (access port+VLAN) to another to perform authentication and access the Internet again if they do not get offline. The authenticated user migration function allows users to realize this.

When authenticated user migration is enabled, the 802.1x or web authentication module of the device detects that the port or VLAN corresponding to a user's media access control (MAC) address has changed. Then, the user is forced offline and needs to be authenticated again before getting online. This prevents malicious users from forging online users' MAC addresses to access the Internet and causing authenticated users being forced offline. The authenticated user migration function determines the MAC address authenticity. For a user who gets online through web authentication or 802.1x authentication with IP authorization, the 802.1x or web authentication module sends an ARP request to the original physical location of the user if detecting that the same MAC address is online in another VLAN or on another port. If no response is received within the specified time, the module determines that the user's location has changed and the migration is allowed.

1.5.2 Restrictions and Guidelines

- The authenticated user migration function requires a check of users' MAC addresses, and is invalid for users who have IP addresses only.
- When both 802.1x authentication and port security are enabled on a port, and port security and 802.1x authentication users get online simultaneously, 802.1x authenticated users will fail to be migrated to another port to get online because the same MAC address cannot go online through different ports.
- The user online detection function can kick users offline. When the authentication user migration function is not configured and a user does not proactively get offline, the user may be kicked offline by the online detection function and can implement authentication and get online in another physical location.
- When an online authenticated user moves to a new physical location, the user needs to perform 802.1x or web authentication again.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable authenticated user migration.

station-move permit

Authenticated user migration is disabled by default.

1.6 Configuring User Online Status Detection

1.6.1 Overview

After user online status detection is configured, if a user's traffic falls below a certain threshold within a specified period, the device automatically disconnects the user to avoid continuous accounting and consequent economic loss.

1.6.2 Restrictions and Guidelines

- If the go-offline function is configured but a terminal continuously sends packets, the device disconnects the terminal only when the terminal is powered off.
- This function can be configured on an access, aggregation, or core device based on the distribution of users. This function takes effect only on the configured device and does not affect other devices on the network.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) After the online status detection function for authenticated users is enabled, users with low traffic or no traffic within the specified period are forced to log out.

offline-detect interval *interval* **threshold** *threshold*

A user is disconnected when the user does not generate traffic for 8 hours by default.

1.7 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** commands to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging switch immediately after use.

Table 1-1 Monitoring

Command	Purpose
show direct-vlan	Displays authentication-exempted VLAN configurations.
show nac-author-user [**interface** *interface-type interface-number*]	Displays IPv4 user entries on a port.

Command	Purpose
show access-control packet statistics [**interface** *interface-type interface-number* | **vlan** *vlan-id*]	Displays statistics about packets filtered due to access control.
debug scc event	Debugs the SCC running process.
debug scc user	Debugs SCC user entries.
debug scc acl-show summary	Debugs ACL summary stored in the SCC delivered by various services.
debug scc acl-show all	Debugs all ACLs stored in the SCC.

1 Configuring Password Policies

1.1 Introduction

1.1.1 Overview

A password policy provides the password detection function for applications that need to configure accounts and passwords (for example, creating local users) on a device to ensure that users use passwords that meet security specifications and prevent password crackdown due to low password complexity.

1.2 Restrictions and Guidelines

The password lifecycle, repeated password use prevention, and forcible weak password change functions take effect only to global passwords (**enable password** and **enable secret**) and local user passwords (**username** *username* **password** *password*) and are invalid to passwords in line configuration mode.

1.3 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

(1) Configuring the Minimum Password Length

(2) Enabling Strong Password Detection

(3) Enabling Forcible Weak Password Change

(4) Configuring a Password Lifecycle

(5) Configuring Repeated Password Use Prevention

(6) Configuring Encrypted Password Storage

(7) Enabling Special Character Detection

1.4 Configuring the Minimum Password Length

1.4.1 Overview

The minimum password length is used to limit the length of user passwords.

If the password entered by a user is shorter than the minimum password length, the system displays an error prompt, asking the user to specify another password of an appropriate length.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the minimum password length.

password policy min-size *min-size*

No minimum length is configured for passwords by default.

1.5 Enabling Strong Password Detection

1.5.1 Overview

Strong password detection is used to detect the complexity of a password and prevent password crackdown due to low complexity.

After the strong password detection function is enabled, the password must meet the following conditions:

- The password cannot contain the account string. The case of the password is ignored during detection.
- If the special character detection function is disabled, the password must contain digits, lowercase letters, and uppercase letters.
- If special character detection is enabled, the password must contain at least three of the following types: digits, lowercase letters, uppercase letters, and special characters.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the strong password detection function.

password policy strong

The strong password detection function is enabled by default.

1.6 Enabling Forcible Weak Password Change

1.6.1 Overview

The forcible weak password change function is used together with another password policy (such as the minimum password length or strong password detection).

After the forcible weak password change function is enabled, a warning prompt will be displayed if a user uses a weak password (containing less than 8 bytes or only digits, uppercase letters, or lowercase letters) during login or configuration.

If both the forcible weak password change function and another password policy are enabled, the password will continue to be checked according to the other password policy during user login. If the password does not meet requirements of the other password policy, a prompt for changing the password will be displayed. The user is allowed to log in only after the new password meets requirements of the password policy.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable forcible weak password change.

password policy forced-password-modify

Forcible weak password change is disabled by default.

1.7 Configuring a Password Lifecycle

1.7.1 Overview

The password lifecycle defines the validity time of a password.

If a user enters a password that has already expired during login, the system gives a prompt, indicating that the password has expired, and asks the user to reset the password.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the password lifecycle.

password policy life-cycle *life-cycle*

password policy life-cycle { **7** | **15** | **30** }

No password lifecycle is configured by default.

1.8 Configuring Repeated Password Use Prevention

1.8.1 Overview

The repeated password use prevention function prevents users from using historically configured passwords as new passwords.

The system records passwords used by a user to a historical password list. If a newly configured password is within the list, the system gives a prompt and asks the user to specify another password. The maximum number of records in the password list can be manually configured. When the number of records in the password list reaches the limit, a new password record will overwrite the earliest password record.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Prevent repeated use of passwords configured in the latest specified number of times.

password policy no-repeat-times *no-repeat-times*

Repeated password use is allowed by default.

1.9 Configuring Encrypted Password Storage

1.9.1 Overview

Encrypted password storage is used to store passwords after encryption.

When administrators run the **show running-config** command to display configurations or run the **write** command to save configuration files, passwords configured by users are displayed in ciphertext format if encrypted password storage is enabled and displayed in plaintext format if encrypted password storage is disabled.

1.9.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable encrypted password storage.

service password-encryption

Encrypted password storage is disabled by default.

1.10 Enabling Special Character Detection

1.10.1 Overview

After strong password detection and special character detection are configured, passwords that contain only special characters are invalid and cannot be configured successfully. Special characters include space, tilde (~), backtick (`), exclamation mark (!), at sign (@), number sign (#), dollar sign ($), percent sign (%), caret (^), ampersand (&), asterisk (*), brackets (()), underscore (_), plus sign (+), minus sign (–), equal sign (=), braces ({}), vertical bar (|), square brackets ([]), backslash (\), colon (:), quotation mark ("), semicolon (;), apostrophe ('), angle brackets (<>), comma (,), period (.), and slash (/).

1.10.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable special character detection.

password policy printable-character-check

Special character detection is enabled by default.

1.11 Monitoring

Run the **show** command to check the configuration.

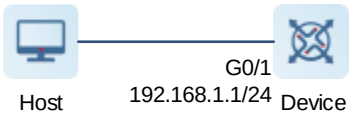
Table 1-1 Monitoring

Command	Purpose
show password policy	Displays configured password security policies.

1.12 Configuration Examples

1.12.1 Configuring Password Policy

1. Requirements



To ensure password complexity, you can configure password policies on a device to limit users' passwords.

Password security requirements are as follows:

- A password must be a string of at least eight characters.
- A password cannot contain the account string.
- A password must contain at least three types of the following: digits, uppercase letters, lowercase letters, and special characters.
- A password is valid for 90 days.
- Passwords must be stored in encrypted mode.
- A password cannot be the same as historical passwords configured in the latest three times.

2. Topology

Figure 1-1 Configuring Password Policies

3. Notes

- Set the minimum password length to 8.
- Enable strong password detection.
- Set the password lifecycle to 90 days.
- Enable encrypted password storage.
- Configure repeated password use prevention to disable the use of historical passwords configured in the latest three times.

4. Procedure

Enter the global configuration mode.

```
Device> enable
Device# configure terminal
```

Set the minimum password length to 8.

```
Device(config)# password policy min-size 8
```

Enable strong password detection.

```
Device(config)# password policy strong
```

Set the password lifecycle to 90 days.

```
Device(config)# password policy life-cycle 90
```

Enable encrypted password storage.

```
Device(config)# service password-encryption
```

Configure repeated password use prevention to disable the use of historical passwords configured in the latest three times.

```
Device(config)# password policy no-repeat-times 3
```

5. Verification

Run the **show password policy** command to display configured password policies.

```
Device# show password policy
Global password policy configurations:
 Password encryption:              Enabled
 Password strong-check:            Enabled
 Password forced-password-modify:    Disabled
 Password min-size:                Enabled (8 characters)
 Password life-cycle:              Enabled (90 days)
 Password no-repeat-times:          Enabled (max history record: 3)
 Password printable-character-check:  Enabled
```

6. Configuration Files

```
!
password policy life-cycle 90
password policy no-repeat-times 3
password policy printable-character-check
password policy min-size 8
password policy strong
service password-encryption
```

1 Configuring SSH

1.1 Introduction

1.1.1 Overview

Secure Shell (SSH) is a network security protocol that requires encryption and authentication and is used for remote access and file transfer.

SSH is based on the server/client structure. The device supports both the SSH server and client functions. As an SSH server, the device can connect to multiple SSH clients. As an SSH client, the device allows users to establish SSH connections with devices that support the SSH server function.

The SSH function is similar to the Telnet service. However, the encryption and authentication features of SSH can ensure stronger security guarantee for users. When users log in to the device through an insecure network environment, SSH can effectively protect the device against attacks, such as IP address spoofing and plaintext password interception.

1.1.2 Principles

1. SSH Version

SSHv1 and SSHv2 are available, and the two are mutually exclusive. Compared with SSHv1, SSHv2 provides higher performance and security.

The device supports both versions and supports SSH interaction using the IPv4 and IPv6 addresses. Unless otherwise specified, SSH in this document refers to SSHv2.

2. SSH Exchange Process

Interaction between an SSH client and an SSH server is classified into seven phases: connection establishment, version negotiation, key exchange and algorithm negotiation, user authentication, session request, session interaction, and session closure.

- Connection establishment
  a The server listens on Transmission Control Protocol (TCP) port 22 and waits for a connection request from the client.
  b The client initiates a TCP connection request to port 22 of the server to establish a TCP connection with the server.
- Version negotiation
  a The server sends a version negotiation packet to the client.
  b The client receives and processes the packet and replies the version to be used to the server.
  c The server processes the reply from the client and determines whether version negotiation is successful.
- Key exchange and algorithm negotiation

  If the version negotiation succeeds, key exchange and algorithm negotiation are performed.

a The server and the client exchange the algorithm negotiation packet with each other and determine the final algorithm based on their capacity.

b The server and the client work together to generate a session key and session ID according to the key exchange algorithm and host key, which will be applied to subsequent user authentication, data encryption, and data decryption.

- User authentication

  After the encrypted channel is set up, user authentication is performed.

  a The client sends an authentication request to the server.

  b The server repeatedly conducts authentication for the client until the authentication succeeds or the server shuts down the connection because the maximum number of authentication attempts is reached.

- Session request

  a After the authentication is successful, the client sends a session request to the server.

  b The server waits and processes the client's session request. After the session request is successfully processed, the SSH client and server enter the session interaction phase.

- Session interaction

  In this phase, bidirectional transmission and processing of encrypted data are allowed.

  a The client sends commands that need to be executed to the server.

  b The server decrypts, parses, and processes these commands.

  c The server encrypts and sends the processing result to the client.

  d The client decrypts and processes the message from the server.

- Session closure

  The server and client disconnect the connection, and close the session.

3. User Authentication Mechanism

SSH supports password authentication, public key authentication, and other client authentication mechanisms.

- Password authentication

  Password authentication authenticates a client by verifying the username and password.

  a The client sends encrypted username and password to the server to request password authentication.

  b After receiving the request, the server decrypts the information, authenticates the client's identity through the Authentication, Authorization and Accounting (AAA) service (including local authentication and remote authentication), and sends an authentication success or failure message to the client.

- Public key authentication

  Public key authentication uses digital signature algorithms, such as Rivest-Shamir-Adleman (RSA) and Digital Signature Algorithm (DSA) to authenticate a client.

  a The client sends a public key authentication request to the server. This request contains information, including the username, public key, and public key algorithm.

  b After receiving the request, the server checks whether the public key is valid.

c If not, the server directly returns an authentication failure message. If yes, the server performs digital signature authentication on the client and returns a message indicating successful or failed authentication.

Note

Public key authentication applies only to SSHv2 clients.

4. Public Key Algorithm

A public key algorithm is an asymmetric encryption algorithm used to encrypt communication data between an SSH client and server to ensure data transfer security.

The device supports four public key algorithms: RSA, DSA, Elliptic Curves Cryptography (ECC), and SM2 (Elliptic Curves Public Key Cryptography).

- RSA

  RSA is based on most factorization algorithms and can be used for key and signature exchange. Due to low encryption and decryption efficiency, it does not apply to encryption and decryption of a large number of data.

- DSA

  Compared with RSA, DSA can be used only for signature and cannot be used for data encryption and decryption or key exchange. However, its efficiency is much higher than that of RSA.

- ECC

  ECC is based on the discrete logarithm algorithm and is difficult to be cracked down. In same security conditions, ECC has higher processing efficiency and lower storage and bandwidth requirements than RSA and DSA.

- SM2

  Elliptic Curve Pubic Key Cryptography is a public key cryptography algorithm independently designed by China, which is a national secret algorithm based on ECC, and is used to replace the RSA algorithm in the commercial cryptography of China. The password is complex, processing speed is fast, and machine performance consumption is small.

1.1.3 Protocols and Standards

- RFC 4251: The Secure Shell (SSH) Protocol Architecture
- RFC 4252: The Secure Shell (SSH) Authentication Protocol
- RFC 4253: The Secure Shell (SSH) Transport Layer Protocol
- RFC 4254: The Secure Shell (SSH) Connection Protocol
- RFC 4419: Diffie-Hellman Group Exchange for the Secure Shell (SSH) Transport Layer Protocol
- RFC 4716: The Secure Shell (SSH) Public Key File Format
- RFC 4819: Secure Shell Public Key Subsystem
- RFC 3526: More Modular Exponential (MODP) Diffie-Hellman groups for Internet Key Exchange (IKE)
- RFC 2409: The Internet Key Exchange (IKE)
- RFC 1950: ZLIB Compressed Data Format Specification version 3.3

1.2 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

(1) Configuring SSH Server

- Enabling SSH Server
- (Optional) Configuring the SSH Server Version
- (Optional) Configuring the Listening Port
- (Optional) Configuring the Key and Key Exchange Algorithm of the SSH Server
- (Optional) Configuring the Encryption Algorithm
- (Optional) Configuring Authentication Parameters
- (Optional) Configuring an ACL
- (Optional) Configuring IP Address Blocking
- (Optional) Disconnecting an SSH Client Connection

(2) Configuring SCP Server

(3) Configuring SFTP Server

- Establishing a Connection with the SSH Server
- (Optional) Restoring an Established SSH Client Session
- (Optional) Disconnecting a Suspended SSH Client Session

(4) Configuring SCP Client

1.3 Configuring SSH Server

1.3.1 Overview

After the SSH server function is configured on a device, SSH clients can remotely log in to the device.

1.3.2 Configuration Tasks

SSH server configuration includes the following tasks:

- Enabling SSH Server
- (Optional) Configuring the SSH Server Version
- (Optional) Configuring the Listening Port
- (Optional) Configuring the Key and Key Exchange Algorithm of the SSH Server
- (Optional) Configuring the Encryption Algorithm
- (Optional) Configuring Authentication Parameters
- (Optional) Configuring an ACL
- (Optional) Configuring IP Address Blocking
- (Optional) Disconnecting an SSH Client Connection

1.3.3 Enabling SSH Server

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the SSH server function.

enable service ssh-server

The SSH server function is disabled by default.

(4) (Optional) Enable the SSHv1 function.

ip ssh compatible-ssh1x enable

The SSHv1 function is disabled by default.

To use the SSHv1 version, enable the SSHv1 function first.

1.3.4 Configuring the SSH Server Version

1. Overview

The SSH server supports the SSHv1 and SSHv2 versions. Compared with SSHv1, SSHv2 has higher performance and security. During actual configuration, select a proper SSH server version based on the client version and security requirements.

2. Restrictions and Guidelines

The SSH server is compatible with SSHv1 and SSHv2 clients by default, that is, clients of both versions can connect to the SSH server. After an SSH server version is configured, only clients of the corresponding version can connect to the server.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the SSH server version.

ip ssh version *version-type*

The SSH server is compatible with the SSHv1 and SSHv2 clients by default.

1.3.5 Configuring the Listening Port

1. Overview

An SSH server uses port 22 to listen to client connections by default. The listening port can be changed through configuration.

Port 22 is a protocol-defined standard port and vulnerable to attacks from malicious users. If an attacker accesses this port frequently in a short time, problems such as bandwidth waste and performance deterioration may occur. As a result, other users cannot access the server (that is, the DoS attack). Changing the listening port can effectively prevent the problems.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the listening port of the SSH server.

ip ssh port *ssh-monitor-port*

The default listening port of the SSH server is port **22**.

1.3.6 Configuring the Key and Key Exchange Algorithm of the SSH Server

1. Overview

The key and key exchange algorithm of the SSH server are configured to establish a communication connection between the client and server.

2. Restrictions and Guidelines

- SSHv1 supports RSA and SM2 keys. SSHv2 supports DSA, RSA, and SM2 keys. If the RSA or SM2 key has been generated, both SSH1 and SSH2 are available. If only the DSA key is generated, only SSH2 is available.
- A longer public key provides higher security but slower calculation speed and higher CPU usage.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Generate the public key of the SSH server.

crypto key generate { **dsa** | **ecc** | **rsa** | **sm2** }

No public key is generated on the SSH server by default.

If no key is generated on the SSH server, this parameter must be configured. To delete the public key of the SSH server, run the **crypto key zeroize** { **dsa** | **ecc** | **rsa** } command instead of the **no** form of this command.

(4) Configure the DH key exchange algorithms supported by the SSH server.

ip ssh key-exchange { **dh_group_exchange_sha1** | **dh_group14_sha1** | **dh_group1_sha1** | **ecdh_sha2_nistp256** | **ecdh_sha2_nistp384** | **ecdh_sha2_nistp521** | **sm2dh_sm3** } *

Ruijie SSHv2 servers support diffie-hellman-group14-sha1, ecdh_sha2_nistp256, ecdh_sha2_nistp384, ecdh_sha2_nistp521 and sm2dh_sm3 for key exchange, and SSHv1 servers support none by default.

(5) (Optional) Configure the minimum length of the key generated by the key exchange algorithm of the SSH server.

ip ssh dh-exchange min-len { **1024** | **2048** }

The default minimum length is **2048** bytes.

1.3.7 Configuring the Encryption Algorithm

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the encryption modes supported by the SSH server.

ip ssh cipher-mode { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-cbc** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **blowfish-cbc** | **cbc** | **ctr** | **des-cbc** | **gcm** | **others** } *

The encryption modes supported by the SSH server are **ctr** and **gcm** by default.

It is approved that **cbc** and **others** encryption algorithms can be decrypted in a limited period of time. Therefore, organizations or companies that have high security requirements can set the encryption modes supported by the SSH server to **ctr** and **gcm** to enhance the security level of the SSH server.

(4) Configure the message authentication algorithms supported by the SSH server.

ip ssh hmac-algorithm { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }

SSHv1 servers do not support any message authentication algorithms, and SSHv2 servers support the SHA2-256, SHA2-512, and SM3 message authentication algorithms by default.

1.3.8 Configuring Authentication Parameters

1. Overview

Parameters related to user authentication include the authentication timeout time, number of authentication attempts, and public key authentication.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the user authentication timeout time on the SSH server.

ip ssh time-out *timeout-time*

The default user authentication timeout time on the SSH server is **120** seconds.

If authentication still does not succeed when the user authentication timeout time expires, user authentication fails.

(4) Configure the number of authentication attempts allowed on the SSH server.

ip ssh authentication-retries *retry-times*

The default maximum number of authentication attempts allowed on the SSH server is **3**.

If the number of authentication attempts of a user by using the account and password exceeds the configured number of authentication attempts, user authentication fails.

(5) Associate with the public key file and username of a client.

ip ssh peer *username* **public-key** { **dsa** | **ecc** | **rsa** | **sm2** } *filename-path*

If a client needs to use public key authentication, the client's public key and username need to be associated with the device. Only SSHv2 supports public key authentication.

1.3.9 Configuring an ACL

1. Overview

An ACL can filter out users who meet specific rules. This prevents unauthorized users from accessing the device through SSH and causing security risks.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an ACL on the SSH server.

(IPv4 address)

ip ssh access-class {*acl-name* | *acl-number*}

No IPv4 ACL is configured on the SSH server by default.

(IPv6 address)

ipv6 ssh access-class *acl-name*

No IPv6 ACL is configured on the SSH server by default.

1.3.10 Configuring IP Address Blocking

1. Overview

When the number of authentication failures for login through SSH reaches the configured limit in an authentication failure count period, the source IP address is blocked. That is, the SSH client that uses this source IP address is not allowed to log in to the device to prevent the device being attacked. The SSH client can log in to the device only after the IP address is awakened. This function is enabled by default and can be manually disabled.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable IP address blocking on the SSH server.

ip ssh ip-block disable

The IP address blocking function of the SSH server is enabled by default.

Run the **no** form of this command to disable this feature.

(4) (Optional) Configure the number of authentication failures for blocking an IP address and the time period for counting authentication failures on the SSH server.

ip ssh ip-block failed-times *failed-times* **period** *period-time*

The allowed maximum number of authentication failures is **6**, and the time period for counting authentication failures is **5** minutes by default.

(5) (Optional) Configure the time period for awakening blocked IP addresses on the SSH server.

ip ssh ip-block reactive *reactive-interval*

Blocked IP addresses are awakened every **5** minutes by default.

After the time period for awakening blocked IP addresses is reached, SSH clients using these IP addresses can log in to the SSH server again.

(6) (Optional) Clear user information with blocked IP addresses and authentication failures.

clear ssh ip-block { **all** | *ipv4-address* | *ipv6-address* }

After the user information is cleared, corresponding clients can log in to the SSH server again.

1.3.11 Disconnecting an SSH Client Connection

(1) Enter the privileged EXEC mode.

enable

(2) Disconnect an established SSH client connection.

disconnect ssh { **vty** *session-id* | *session-id* }

Serving as an SSH server, the device may connect to multiple SSH clients. You can run this command to forcibly disconnect a client from the device. The client disconnection methods are as follows:

- Specify an SSH session ID. To display the SSH session ID of a client, run the **show ssh** command.
- Specify a Virtual Teletype (VTY) session ID. To display the VTY session ID of a client, run the **show users** command. This command can be used to disconnect SSH connections only.

1.4 Configuring SCP Server

1.4.1 Overview

Secure copy protocol (SCP) is a protocol that supports network file transfer. SCP is implemented based on Remote Copy Protocol (RCP). RCP is responsible for file transfer, and SSH provides the authentication and encryption functions for RCP.

After the SCP server function is configured on the device, users can run the **scp** command to upload files to or download files from the device. Data exchanged during the process is encrypted for security.

1.4.2 Restrictions and Guidelines

The SSH server function must be enabled before the SCP server function is configured.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the SCP server function.

ip scp server enable

The SCP server function is disabled by default.

(4) (Optional) Configure the transmission path for uploading files to or downloading files from the SCP server.

ip scp server topdir { **flash:/***path* | **flash2:/***path* | **sd0:/***path* | **sata0:/***path* | **tmp:/***path* | **usb0:/***path* | **usb1:/***path* }

The default transmission path for file upload and download is **flash:/**.

1.5 Configuring SFTP Server

1.5.1 Overview

After the SSH File Transfer Protocol (SFTP) server function is configured on the device, users can use commands of the SFTP client console to upload files to and download files from the device. All the data exchanged in this process is transmitted in encrypted mode to provide high security.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the SFTP server function.

ip sftp server enable

The SFTP server function is disabled by default.

(4) (Optional) Configure the root path for uploading files to or downloading files from the SFTP server.

ip sftp server topdir { **flash:/***path* | **flash2:/***path* | **sd0:/***path* | **sata0:/***path* | **tmp:/***path* | **usb0:/***path* | **usb1:/***path* }

The default root path on the SFTP server is **flash:/**.

(5) (Optional) Configure the maximum number of SFTP session connections.

ip sftp server max-sessions *session-numbers*

The maximum number of SFTP session connections is 36 by default.

1.6 Configuring SSH Client

1.6.1 Overview

When the local device is configured as an SSH client, the device can establish an SSH connection to another device that provides the SSH server service to remotely log in to the device for management operations.

1.6.2 Configuration Tasks

SSH client configuration includes the following tasks:

(1) Establishing a Connection with the SSH Server

(2) (Optional) Restoring an Established SSH Client Session

(3) (Optional) Disconnecting a Suspended SSH Client Session

1.6.3 Establishing a Connection with the SSH Server

(1) Enter the privileged EXEC mode.

enable

(2) Establish a remote encrypted session with the SSH server as an SSH client.

ssh [**oob**] [-**c** { **3des** | **aes128-cbc** | **aes192-cbc** | **aes256-cbc** | **aes128-ctr** | **aes192-ctr** | **aes256-ctr** | **aes128-gcm** | **aes256-gcm** | **sm4-cbc** | **sm4-ctr** } | -**l** *username* | -**m** { **hmac-md5-96** | **hmac-md5-128** | **hmac-sha1-96** | **hmac-sha1-160** | **hmac-sha2-256** | **hmac-sha2-512** | **hmac-sm3** } | -**p** *port-number* | **-v** { **1** | **2** }] * { *ipv4-address* | *ipv6-address* | *hostname* } [**/source** { **ip** ipv4-address | **ipv**6 ipv6-address | interface interface-type interface-number }] [**/**vrf vrf-name | **via mgmt** *mgmt-number*]

SSHv1 supports only the DES (56-bit key) and 3DES (168-bit key) encryption algorithms. SSHv2 supports the following Advanced Encryption Standards (AES): ASE128-CBC, AES192-CBC, AES256-CBC, AES128-CTR, AES192-CTR, AES256-CTR, AES128-GCM, and AES256-GCM. In addition, SM4 (128-bit key) is supported: SM4-CBC and SM4. If you specify an unmatched encryption or authentication algorithm when selecting an SSH version, the unmatched algorithm will be ignored when a connection is established.

(3) Enter the global configuration mode.

configure terminal

(4) (Optional) Configure the source interface of the SSH client.

ip ssh source-interface *interface-type interface-number*

No SSH client source interface is configured by default.

After the source interface is configured, the SSH client uses the IP address on this interface as the global source address during communication. If no source interface is configured, the source address of SSH packets will be obtained by querying the corresponding route based on the destination address. If no source interface or source IP address is independently specified for an SSH connection, the global configuration is used.

1.6.4 Restoring an Established SSH Client Session

1. Overview

After the device establishes an SSH session with the SSH server as a client, you can press Ctrl+Shift+6+X to exit the session temporarily. After exiting the session, you can run the corresponding command to restore the session.

2. Restrictions and Guidelines

To display information about the SSH connections established by the device as an SSH client, run the **show ssh-session** command.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Restore an established SSH client session.

ssh-session *session-id*

1.6.5 Disconnecting a Suspended SSH Client Session

1. Overview

After the device connects to the SSH server as an SSH client, you can run the corresponding command to disconnect an SSH session with the specified session ID.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Disconnect a suspended SSH client session.

disconnect ssh-session *session-id*

You can run the **show ssh-session** command to display *session-id* of the device.

1.7 Configuring SCP Client

1.7.1 Overview

When the local device is configured as an SCP client, the device can run the **scp** command to upload files to or download files from a device that provides the SCP server service. Data exchanged during the process is encrypted for security.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the source interface of the SCP client.

ip scp client source-interface *interface-type interface-number*

No SCP client source interface is configured by default.

After the source interface is configured, the SCP client uses the IP address on the interface as the global source address during communication. If no source interface is configured, the source address of SCP packets will be obtained by querying the corresponding route based on the destination address. If no source interface or source IP address is independently specified for an SCP connection, the global configuration is used.

(4) Upload files to or download files from the remote SCP server as an SCP client.

scp [**oob**] [**-c** { 3**des** | **aes128-cbc** | **aes192-cbc** | **aes256-cbc** | **aes128-ctr** | **aes192-ctr** | **aes256-ctr** | **aes128-gcm** | **aes256-gcm** | **sm4-cbc** | **sm4-ctr** } | **-m** { **hmac-md5-96** | **hmac-md5-128** | **hmac-sha**1-96 | **hmac-sha1-160** | **hmac-sha2-256** | **hmac-sha2-512** | **hmac-sm3** } | **-p** *port-number* | **-v** { **1** | **2** }] * *source-file destination-file* [**/source** { **ip** *ipv4-address* | **ipv6** *ipv6-address* | **interface** *interface-type interface-number* }] [**/vrf** *vrf-name* | **via mgmt** *mgmt-number*]

1.8 Configuring SFTP Client

1.8.1 Overview

After the local device is configured as the SFTP client, you can connect to the SFTP server by using an SFTP command to upload and download files locally or remotely in the client console. All the data exchanged in this process is transmitted in encrypted mode to provide high security.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the source interface used by the SFTP client.

ip sftp client source-interface interface-type interface-number

No source interface is configured for the SFTP client by default.

After the source interface is configured, the SFTP client uses the IP address of this interface as the global source address. If no source interface is configured, the device obtains the source address of the SFTP packets by querying the destination address in the corresponding route. If no source interface or address is specified separately for an SFTP connection, the global configuration applies.

(4) (Optional) Configure an SSH version for global SFTP connections.

ip sftp client version { **1** | **2** }

SSHv2 is used for global SFTP connections by default.

(5) (Optional) Configure the global SSH encryption algorithms supported by the SFTP client.

ip sftp client cipher-mode { **3des | aes128-cbc | aes128-ctr | aes128-gcm | aes192-cbc | aes192-ctr | aes256-cbc | aes256-ctr | aes256-gcm** | **sm4-cbc** | **sm4-ctr** }

The SFTP client supports the following encryption algorithms by default: 3DES-CBC, AES-128-CBC, AES128-CTR, AES128-GCM, AES-192-CBC, AES192-CTR, AES-256-CBC, AES256-CTR, AES256-GCM, SM4-CBC, and SM4-CTR.

(6) (Optional) Configure the global SSH message authentication algorithms supported by the SFTP client.

ip sftp client hmac-algorithm { hmac-md5-96 | hmac-md5-128 | hmac-sha1-96 | hmac-sha1-160 | hmac-sha2-256 | hmac-sha2-512 | hmac-sm3 }

SSHv1 does not support any message authentication algorithms, and SSHv2 supports the following message authentication algorithms by default: HMAC-MD5-96, HMAC-MD5-128, HMAC-SHA1-96, HMAC-SHA1-160, HMAC-SHA2-256, HMAC-SHA2-512, and HMAC-SM3.

(7) (Optional) configure the global Diffie–Hellman (DH) key exchange algorithms used by the SFTP client.

ip sftp client key-exchange { **dh_group_exchange_sha1** | **dh_group14_sha1** | **dh_group1_sha1** | **ecdh_sha2_nistp256** | **ecdh_sha2_nistp384** | **ecdh_sha2_nistp521** | **sm2dh_sm3** }

SSHv1 does not support any key exchange algorithms, and SSHv2 supports the following key exchange algorithms by default: diffie-hellman-group-exchange-sha1, diffie-hellman-group14-sha1,

diffie-hellman-group1-sha1, ecdh_sha2_nistp256, ecdh_sha2_nistp384, ecdh_sha2_nistp521, and sm2dh_sm3.

(8) (Optional) Configure the top directory on the SFTP client.

ip sftp client topdir { *WORD* | **flash:**/*path* | **flash2:**/*path* | **sd0:**/*path* | **sata0:**/*path* | **tmp:**/*path* | **usb0:**/*path* | **usb1:**/*path* }

The default top directory on the SFTP client is **flash:/**.

(9) (Optional) Configure a rate limit for file transfer using SFTP.

ip sftp client speed-limit *speed-limit-rate*

The default rate limit for file transfer using SFTP is 8192 kbit/s.

(10) Configure the device as the SFTP client, connect it to the SFTP server, and enter the SFTP client console to manage files.

sftp [oob] [-c { 3des | aes128-cbc | aes128-ctr | aes128-gcm | aes192-cbc | aes192-ctr | aes256-cbc | aes256-ctr | aes256-gcm | sm4-cbc | sm4-ctr } | -k { dh_group14_sha1 | dh_group1_sha1 | dh_group_exchange_sha1 | ecdh_sha2_nistp256 | ecdh_sha2_nistp384 | ecdh_sha2_nistp521 | sm2dh_sm3 } | -m { hmac-md5-96 | hmac-md5-128 | hmac-sha1-96 | hmac-sha1-160 | hmac-sha2-256 | hmac-sha2-512 | hmac-sm3 } | -p *port-number* | **-v** { **1** | **2** }] * { *user@hostname* | *user@ip-address* } [**/source** { **ip** *ipv4-address* | **ipv6** *ipv6-address* | **interface** *interface-type interface-number* }] [**/vrf** *vrf-name* | **via mgmt** *mgmt-number*]

1.9 Monitoring

Run the **show** command to check the configuration.

Run the **debug** command to output debugging information.

Caution

Debugging occupies system resources, so disable it immediately if not required.

Table 1-1 Monitoring

Command	Purpose
show ip ssh	Displays effective configurations of the SSH server.
show ssh	Displays information about established SSH connections.
show ssh ip-block { **all** | **list** }	Displays information about blocked IP addresses and authentication failures.
show crypto key mypubkey { **dsa** | **ecc** | **rsa** | **sm2** }	Displays partial public key information of the SSH server.
show ssh-sessions	Displays information about established SSH client sessions.

Command	Purpose
debug ssh	Debugs sessions of the SSH server.
debug ssh client	Debugs sessions of the SSH client.

1.10 Configuration Examples

1.10.1 Configuring Line Password Authentication for SSH Users

1. Requirements

After the SSH server function is enabled on a device, users can use the password configured in line configuration mode to log in to the device.

2. Topology

Figure 1-1 Configuring Line Password Authentication for SSH Clients

3. Notes

- Enable the SSH server function.
- Configure the line password.
- Enable password authentication in the line.

4. Procedure

(1) Enable the SSH server function.

```
Device> enable
Device# configure terminal
Device(config)# enable service ssh-server
```

(2) Set the line password to **Abc123456**.

```
Device(config)# line vty 0 4
Device(config-line)# password Abc123456
```

(3) Enable password authentication in the line.

```
Device(config-line)# login
```

5. Verification

- Use the client software to log in to the device through SSH. The password is **Abc123456**, and the username can be any value. Verify that the login is successful. Use the PuTTY software as an example. The login page is as follows:

```
login as: anyname
anyname@192.168.1.1's password:
```

```
Last login: Apr  2 2021 10:00:00 from 192.168.1.2 through ssh.
Device#
```

- Run the **show ip ssh** command to verify that the SSH server takes effect.

```
Device# show ip ssh
SSH Enable - version 2.0
SSH Port:             22
SSH Cipher Mode:       cbc,ctr,gcm
SSH HMAC Algorithm:    md5-96,md5,sha1-96,sha1,sha2-256,sha2-512,sm3
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server:        disabled
SSH dh-exchange min-len: 2048
SSH SFTP Server:       disabled
SSH ip-block:          enabled
```

- Run the **show ssh** command to display the SSH connection information. Verify that a connection with username **anyname** (used during login) exists.

```
Device# show ssh
Connection Version Encryption      Hmac        Compress   State          Username
       1    2.0 aes256-ctr      hmac-sha2-256 none       Session started anyname
```

- Run the **show users** command to display information about connected clients.

```
Device#show users
Line           User        Host(s)             Idle      Location
---------------- ------------ -------------------- ---------- ------------------
   0 con 0      ---         idle               00:00:16   ---
*  1 vty 0      ---         idle               00:00:00   192.168.1.2
```

6. Configuration Files

```
!
enable service ssh-server
!
line console 0
line vty 0 4
 login
password 7 $10$ 36e$17V7Zlip85+o$
!
```

1.10.2 Configuring Local User Authentication for SSH Clients

1. Requirements

After the SSH server function is enabled on a device, users can use the local account created on the device to log in to the device through SSH.

2. Topology

Figure 1-2 Configuring Local User Authentication for SSH Clients

3. Notes

- Enable the SSH server function.
- Add a local user account.
- Enable local user authentication in the line.

4. Procedure

(1) Enable the SSH server function.

```
Device> enable
Device# configure terminal
Device(config)# enable service ssh-server
```

(2) Add a local user whose username is **hostname1** and password is **Abc123456**.

```
Device(config)# username hostname1 password Abc123456
```

(3) Enable local user authentication in the line.

```
Device(config)# line vty 0 4
Device(config-line)# login local
```

5. Verification

- Use the client software to log in to the device through SSH. The username is **hostname1**, and the password is **Abc123456**. Verify that the login is successful. Use the PuTTY software as an example. The login page is as follows:

```
login as: hostname1
hostname1@192.168.1.1's password:

Last login: Apr  2 2021 10:00:00 from 192.168.1.2 through ssh.
Device>
```

- Run the **show ip ssh** command to verify that the SSH server takes effect.

```
Device# show ip ssh
SSH Enable - version 2.0
SSH Port:             22
SSH Cipher Mode:       ctr,gcm
SSH HMAC Algorithm:    sha2-256,sha2-512
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server:        disabled
```

```
SSH dh-exchange min-len: 2048
SSH SFTP Server:       disabled
SSH ip-block:          enabled
```

- Run the **show ssh** command to display the SSH connection information. Verify that a connection with username **hostname1** exists.

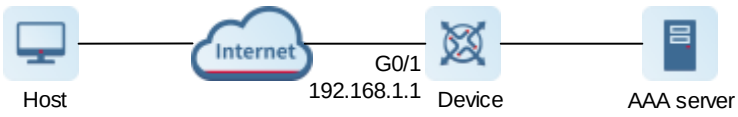
```
Device# show ssh
Connection Version Encryption      Hmac        Compress   State          Username
       1    2.0 aes256-ctr      hmac-sha2-256 none      Session started
hostname1
```

- Run the **show users** command to display information about connected clients. Verify that a client whose username is **hostname1** exists.

```
Device#show users
Line           User        Host(s)             Idle      Location
---------------- ------------ -------------------- ---------- ------------------
   0 con 0      ---         idle               00:00:16   ---
*  1 vty 0      hostname1    idle                00:00:00   192.168.1.2
```

6. Configuration Files

```
!
username hostname1 password 7 $10$204$ItROApnKrcmH$
!
enable service ssh-server
!
line console 0
line vty 0 4
 login local
!
```



1.10.3 Configuring AAA Authentication for SSH Clients

1. Requirements

SSH clients can be authenticated using the AAA mode.

2. Topology

Figure 1-3 Configuring AAA Authentication for SSH Clients

3. Notes

- Configure the AAA server and add an AAA user on the AAA server.
- Enable the SSH server function.
- Enable the AAA service on the device and set the SSH authentication method to AAA server.
- Enable AAA authentication in the line.

4. Procedure

(1) Configure the AAA server and add an AAA user whose username is **hostname1** and password is **Abc123456** on the AAA server. (For details about AAA server configuration, see *Configuring AAA*.)

(2) Enable the SSH server function.

```
Device> enable
Device# configure terminal
Device(config)# enable service ssh-server
```

(3) Enable AAA services.

```
Device(config)# aaa new-model
```

(4) Configure the address and shared key of the AAA server (a RADIUS server is used as an example here, the IP address is set to **192.168.1.3**, and the shared key is set to **radiuskey**).

```
Device(config)# radius-server host 192.168.1.3 key radiuskey
```

(5) Configure the login authentication method list **login-method** and select **radius** as the authentication method. The backup method **local** is configured. This ensures that a backup solution is available when the AAA server is faulty.

```
Device(config)# aaa authentication login login-method group radius local
```

(6) Enable AAA authentication in the line.

```
Device(config)# line vty 0 4
Device(config-line)# login authentication login-method
```

5. Verification

- Use the client software to log in to the device through SSH. The username is **hostname1**, and the password is **Abc123456**. Verify that the login is successful. Use the PuTTY software as an example. The login page is as follows:

```
login as: hostname1
hostname1@192.168.1.1's password:

Last login: Apr  2 2021 10:00:00 from 192.168.1.2 through ssh.
Device>
```

- Run the **show ip ssh** command to verify that the SSH server takes effect.

```
Device# show ip ssh
SSH Enable - version 2.0
SSH Port:             22
SSH Cipher Mode:       cbc,ctr,gcm
SSH HMAC Algorithm:    md5-96,md5,sha1-96,sha1,sha2-256,sha2-512,sm3
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server:        disabled
SSH dh-exchange min-len: 2048
SSH SFTP Server:       disabled
SSH ip-block:          enabled
```

- Run the **show ssh** command to display the SSH connection information. Verify that a connection with username **hostname1** exists.

```
Device# show ssh
Connection Version Encryption      Hmac        Compress   State          Username
       1    2.0 aes256-ctr      hmac-sha2-256 none      Session started
hostname1
```

- Run the **show users** command to display information about connected clients. Verify that a client whose username is **hostname1** exists.

```
Device#show users
Line           User        Host(s)             Idle      Location
---------------- ------------ -------------------- ---------- ------------------
   0 con 0      ---         idle                00:00:16   ---
*  1 vty 0      hostname1    idle                 00:00:00   192.168.1.2
```

6. Configuration Files

```
!
aaa new-model
aaa authentication login login-method group radius local
!
radius-server host 192.168.1.3 key 7 $10$3b4$ln0s66i8XfEi$
!
line vty 0 4
 login authentication login-method
!
```

1.10.4 Configuring Public Key Authentication for SSH Clients

1. Requirements

When the device serves as the SSH server, users can use public key authentication to log in to the device without needing a password.

2. Topology

Figure 1-4 Configuring Public Key Authentication for SSH Clients

3. Notes

- Use the client software to generate a pair of keys (public key and private key).
- Copy the public key file to the flash memory of the device and associate the key with the user.

4. Procedure

(1) Configure a local user and enable local user authentication in a line. For details, see 1.10.2 Configuring Local User Authentication for SSH Clients.

(2) Use the client software to generate a pair of keys. The Ubuntu environment is used as an example. The generated private key is **id_rsa** and public key is **id_rsa.pub**.

```
root@ubuntu:~# ssh-keygen
Generating public/private rsa key pair.
Enter file in which to save the key (/root/.ssh/id_rsa):
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /root/.ssh/id_rsa.
Your public key has been saved in /root/.ssh/id_rsa.pub.
The key fingerprint is:
SHA256:6a/sWJjpx97QQEs9Aoiph5Ry452ybIyNyZUsT48Irrw root@ubuntu
The key's randomart image is:
+---[RSA 2048]----+
|  .o ..          |
|.o= .  . .       |
|o=.o..  + o      |
|+.+=o  o + .     |
|+O*oo   S        |
|++*o . = o       |
|o.    +.+ .      |
|..   . +o+       |
| E.   o+=.o      |
+----[SHA256]-----+
```

(3) Copy the public key file to the flash memory of the device (omitted).

(4) Associate the public key with **hostname1**.

```
Device> enable
Device# configure terminal
Device(config)# ip ssh peer hostname1 public-key rsa flash:test_key.pub
```

5. Verification

Verify that users can log in to the device through public key authentication. (The Ubuntu environment is used as an example.)

```
root@ubuntu:~/.ssh# ls
id_rsa  id_rsa.pub
root@ubuntu:~/.ssh# ssh -i id_rsa hostname1@192.168.1.1

Last login: Apr 2 2021 10:00:00 through console.
Device>
```

6. Configuration Files

```
!
username hostname1 password 7 $10$204$ItROApnKrcmH$
!
ip ssh peer hostname1 public-key rsa flash:id_rsa.pub
```

```
!
enable service ssh-server
!
line console 0
line vty 0 4
 login local
!
```

1.10.5 Configuring SCP Server

1. Requirements

When the device serves as the SCP server, users can run the **scp** command to upload files to and download files from the device.

2. Topology

Figure 1-5 Configuring SCP Server

3. Notes

- Enable the SSH server function.
- Enable the SCP server function.

4. Procedure

(1) Configure a local user and enable local user authentication in a line. For details, see 1.10.2 Configuring Local User Authentication for SSH Clients.

(2) Enable the SSH server function.

```
Device> enable
Device# configure terminal
Device(config)# enable service ssh-server
```

(3) Enable the SCP server function.

```
Device(config)# ip scp server enable
```

5. Verification

Verify that the client can run the **scp** command to upload files to the device. The Ubuntu environment is used as an example here.

(1) In the Ubuntu shell environment, run the **scp** command to upload **file.txt** to the device.

```
root@ubuntu:~# scp file.txt hostname1@192.168.1.1:/
hostname1@192.168.1.1's password:
file.txt                                    100%   14     0.0KB/s   00:00
```

(2) Check whether **file.txt** exists in the flash directory of the device.

```
Device> enable
```

```
Device# dir flash:file.txt
Number  Properties     Size            Time                   Name
------  ----------  ----------  ------------------------  --------------------
  1       -rwx      14B       Fri Apr 2 10:00:00 2021  file.txt
```

Verify that the client can run the **scp** command to download files from the device. The Ubuntu environment is used as an example here.

(1) The **file.txt** file exists in the flash directory of the device.

```
Device> enable
Device# dir flash:file.txt
Number  Properties     Size            Time                   Name
------  ----------  ----------  ------------------------  --------------------
  1       -rwx      14B       Fri Apr 2 10:00:00 2021  file.txt
```

(3) In the Ubuntu shell environment, run the **scp** command to download **file.txt** from the device and rename it as **file1.txt**.

```
root@ubuntu:~# scp hostname1@192.168.1.1:/file.txt file1.txt
hostname1@192.168.1.1's password:
file.txt                                    100%   14     0.0KB/s   00:00
```

(4) In the Ubuntu shell environment, verify that the **file1.txt** file has been downloaded.

```
root@ubuntu:~# ls -l file1.txt
-rwxr--r-- 1 root root 14 Apr 2 10:00 file1.txt
```

6. Configuration Files

```
!
username hostname1 password 7 $10$204$ItROApnKrcmH$
!
enable service ssh-server
!
ip scp server enable
!
line console 0
line vty 0 4
 login local
!
```

1.10.6 Configuring SFTP Server

1. Requirements

The device functions as the SFTP server to receive file upload and download commands from the SFTP client.

2. Topology

Figure 1-6 Topology for Configuring the SFTP Server

3. Notes

- Enable the SSH service and configure the username and password.
- Enable the SFTP server function.

4. Procedure

(1) Enable the SSH service.

```
Device> enable
Device# configure terminal
Device(config)# enable service ssh-server
Device(config)# username hostname1 password Abc123456
```

(2) Enable the SFTP server function.

```
Device(config)# ip sftp server enable
```

(3) Connect the PC to the SFTP server using the SFTP client or the **sftp** command.

```
PC> sftp ruijie@192.168.1.1
Connected to 192.168.1.1.
sftp>
```

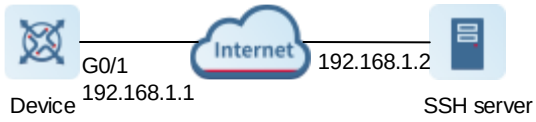
5. Verification

Run the **ls** command to check the files in the device directory.

```
sftp> ls -l
drwxrwxrwx    2 root     root          160 Dec 17  2020 addr
drwxr-xr-x    3 root     root          224 Dec 17  2020 cmpnt
-rw-rw-rw-    1 root     root        10162 Aug  8 15:30 config.text
-rw-r--r--    1 root     root         9002 Oct 22  2021 config.text.bak
-rwxrwxrwx    1 root     root          171 Aug  8 15:30 config_vsu.dat
......
sftp>
```

Check that files are downloaded to the device directory.

```
sftp> get config.text
Fetching /data/config.text to config.text
/data/config.text                                100% 2295KB   6.4MB/s   00:00
sftp>
```



1.10.7 Configuring SSH Client

1. Requirements

When the device serves as an SSH client, the device can log in to the SSH server through SSH.

2. Topology

Figure 1-7 Configuring SSH Client

3. Notes

- Configure a valid user on the SSH server.
- Run the **ssh** command to log in to the SSH server.

4. Procedure

(1) Configure a valid user on the SSH server. (For details, see the SSH server configuration.)

(2) Run the **ssh** command to log in to the SSH server.

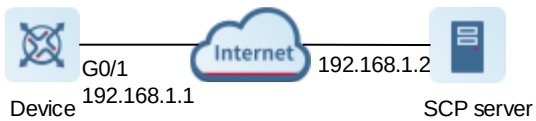
```
Device> enable
Device# ssh -l admin 192.168.1.2
```

5. Verification

Verify that the device logs in to the SSH server successfully.

```
Device# ssh -l hostname1 192.168.1.2
%Trying 192.168.1.2, 22,...open
hostname1@192.168.1.2's password:

Last login: Apr 2 2021 10:00:00 from 192.168.1.1 through ssh.
```



1.10.8 Configuring SCP Client

1. Requirements

When the device serves as an SCP client, the device can run the **scp** command to upload files to and download files from the SCP server.

2. Topology

Figure 1-8 Configuring SCP Client

3. Notes

- Configure a valid user on the SCP server.
- Run the **scp** command to upload files to or download files from the SCP server.

4. Procedure

(1) Configure a valid user on the SCP server. For details, see the SCP server configuration.

(2) Run the **scp** command to copy **file.txt** from the SCP server to the flash memory of the device and name it as **s2c-file.txt**.

```
Device> enable
Device# scp oob hostname1@192.168.1.2:/file.txt flash:/s2c-file.txt
%Trying 192.168.1.2, 22,...open
hostname1@192.168.1.2's password:
Press Ctrl+C to quit
!
Transmission success.
```

(3) Run the **scp** command to copy local file **file.txt** from the device to the SCP server and name it as **c2s-file.txt**.

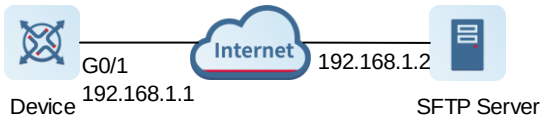
```
Device> enable
Device# scp flash:/file.txt hostname1@192.168.1.2:/c2s-file.txt
%Trying 192.168.1.2, 22,...open
hostname1@192.168.1.2's password:
Press Ctrl+C to quit
!
Transmission success.
```

5. Verification

Check whether the **s2c-file.txt** file exists in the flash directory. If so, the file is successfully copied from the SCP server to the local.

```
Device# dir flash:s2c-file.txt
Number  Properties    Size           Time                  Name
------  ----------  ----------  ------------------------  --------------------
  1       -rwx      5.9k      Fri Feb 23 10:14:21 2024  s2c-file.txt
```

Check whether the **s2c-file.txt** file exists in the file directory of the SCP server. If so, the file is successfully copied from the local to the SCP server.



1.10.9 Configuring SFTP Client

1. Requirements

The device functions as the SFTP client. The **sftp** command can be used to establish a connection for accessing the console to upload files to and download files from the SFTP server.

2. Topology

Figure 1-9 Topology for Configuring the SFTP Client

3. Notes

- Configure users on the SFTP server.
- Run the **sftp** command to connect the device to the SFTP server and access the console.
- Run the **put** and **get** commands to upload and download files.

4. Procedure

(1) Configure available users on the SFTP server. (The configuration is omitted. For details, see the *SFTP Server User Manual*.)

(2) Run the **sftp** command on the device to access the client console.

```
Device> enable
Device# sftp admin@192.168.1.2
%Trying 192.168.1.2, 22,...open
admin@192.168.1.2's password:
Connected to 192.168.1.2:22.
sftp>
```

(3) Run the **get** command to copy the **file.txt** file from the SFTP server to the flash drive of the device.

```
sftp> get file.txt
```

(4) Run the **put** command to copy the local file **file.txt** to the SFTP server.

```
sftp> put file.txt
```

5. Verification

- Check that the file on the SFTP server is copied to the local device.

```
sftp> get file.txt
Fetching /home/admin/file.txt to file.txt
/home/admin/file.txt                                  100% 2295KB   1.7MB/s
00:00
sftp>
```

- Check that the local file is copied to the SFTP server.

```
sftp> put file.txt
Uploading file.txt to /home/admin/file.txt
file.txt                                          100% 2295KB  1.5MB/s   00:00
sftp>
```

1.1.2 Principles 1

1.2 Restrictions and Guidelines 2

1.3 Configuring Global IP-MAC Address Binding 2

1.4 Monitoring 3

1 Configuring Global IP-MAC Address Binding

1.1 Introduction

1.1.1 Overview

The global IP-Media Access Control (MAC) address binding function is used to verify the IP address and MAC address binding relationship of input packets. If a specified IP address is bound with a MAC address, the device receives only the IP packets containing matched IP address and MAC address. The other packets are discarded.

The address binding function strictly controls the validity of input packets to improve network security.

The address binding function has higher priority than 802.1x authentication and port security in controlling the validity of input packets.

1.1.2 Principles

1. IPv6 Address Binding Mode

IPv6 address binding modes include the compatible, loose, and strict modes. The default mode is the strict mode. If the IPv4-MAC address binding policy is not configured, the IPv6 packet forwarding control rules based on the IPv4-MAC address binding policy do not take effect and all IPv4 and IPv6 packets are allowed to pass through. If the IPv4-MAC address binding policy is configured, the IPv6 packet forwarding control rules take effect, and the device forwards IPv4 and IPv6 packets based on the forwarding rules. The following table describes the forwarding rules.

Table 1-1 Forwarding Rules

Binding Mode	IPv4 Packet Forwarding Rule	IPv6 Packet Forwarding Rule
Strict	Packets matching the IPv4-MAC address binding conditions are forwarded.	Packets matching the IPv6-MAC address binding conditions are forwarded.
Loose	Packets matching the IPv4-MAC address binding conditions are forwarded.	● If IPv6-MAC address binding is configured, packets matching the IPv6-MAC address binding conditions are forwarded. ● If IPv6-MAC address binding is not configured, all IPv6 packets are forwarded.
Compatible	Packets matching the IPv4-MAC address binding conditions are forwarded.	● IPv6 packets are forwarded if they contain MAC addresses matching the MAC address in the IPv4-MAC address binding policy. ● Packets matching the IPv6-MAC address binding conditions are forwarded.

The IPv4-MAC address binding policy can be generated by global IP-MAC address binding or other access security functions, such as port security and IP source guard.

The IPv6-MAC address binding policy can be generated by global IPv6-MAC address binding or other access security functions, such as port security and IPv6 source guard.

2. Excluded Ports

The IP-MAC address binding function takes effect on all ports of the device by default. You can configure excluded ports on which this function does not take effect. In practice, the IP-MAC address bindings of the IP packets on the uplink port are not fixed. Generally, the uplink port of the device is configured as an excluded port so that the packets on the uplink port are not checked for IP-MAC address binding.

1.2 Restrictions and Guidelines

Caution

- Before you enable IP-MAC address binding, complete the configuration of binding policies or excluded ports. Otherwise, the user connection may be interrupted. Evaluate the service scope that may be affected and perform operations according to the guidelines.
- If you configure the IPv6 address binding mode to the strict mode, IPv6 services may be interrupted. Perform this operation after evaluating the service scope affected.

- When no IP-MAC address binding policy is configured, the IP-MAC address binding function does not take effect after the **address-bind install** command is run and all packets are allowed to pass through.
- The **address-bind uplink** *interface-type interface-number* command can configure Layer 2 Ethernet interface, Layer 2 aggregate interface, Layer 3 Ethernet interface, and Layer 3 aggregate interface as excluded ports for address binding.
- After the global IP-MAC address binding function is configured, Telnet to the non-MGMT port of the local device fails because packets not matching the binding rules are discarded. To prevent Telnet disconnection, you need to set the Telnet interface as an excluded port or configure a security channel rule to skip search on global IP addresses and MAC addresses and permit Telnet packets.

1.3 Configuring Global IP-MAC Address Binding

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a global IP-MAC address binding policy.

address-bind { *ipv4-address mac-address* | *ipv6-address mac-address* }

No IP-MAC address binding policy is configured by default.

(4) (Optional) Configure a port as an excluded port for address binding.

address-bind uplink *interface-type interface-number*

No port is configured as an excluded port for address binding by default.

(5) Enable the IP-MAC address binding function.

address-bind install

The IP-MAC address binding function is disabled by default.

(6) (Optional) Configure the IPv6 address binding mode.

address-bind ipv6-mode { **compatible** | **loose** | **strict** }

The default IPv6 address binding mode is the strict mode.

(7) (Optional) Enable address binding log filtering.

address-bind binding-filter logging [**rate-limit** *rate*]

Address binding log filtering is disabled by default.

1.4 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-2 Monitoring

Command	Purpose
show address-bind	Displays the global IP-MAC address binding policy.
show address-bind uplink	Displays excluded ports for address binding.

1 Configuring Port Security

1.1 Introduction

1.1.1 Overview

Port security is used to control packets entering a device port based on the source Media Access Control (MAC) address in the packets.

You can configure static MAC addresses or the maximum number of dynamically learned MAC addresses on a port to control packets entering the port.

1.1.2 Principles

1. Basic Concepts

- Secure port

  Ports configured with port security are called secure ports.

- Secure address and maximum number of secure addresses

  Addresses bound to secure ports are called secure addresses. Secure addresses can be Layer 2 addresses, namely, source MAC addresses, or Layer 3 addresses, namely, IP addresses or IP-MAC address bindings. The maximum number of secure addresses is the sum of statically configured secure addresses and dynamically learned secure addresses. When the number of secure addresses for a secure port does not reach the maximum number, the secure port can dynamically learn new secure addresses. When the number of secure addresses for the secure port reaches the maximum number, the secure port will not learn dynamic secure addresses any longer. If a new user host accesses the secure port after the number of secure addresses reaches the maximum number, a security violation event occurs.

- Dynamic binding

  The device automatically learns addresses and converts learned addresses into secure addresses.

- Static binding

  You can manually configure secure addresses.

- Terminal migration violation

  In a scenario where you bind a static MAC address to port A and enable port B as a secure port. After this function is enabled, if the terminal bound to port A send packets to port B, terminal migration violation is identified.

2. Port Security and Security Violation

After port security is enabled on a port, user packets that access the network through the port will be controlled.

The security module of the device will check the source MAC addresses of received packets. Only packets from addresses in the secure address list will be forwarded, and other packets will be discarded.

When the number of MAC addresses learned by a port exceeds the secure address limit or a terminal with a static MAC address bound to a port is migrated (with terminal migration violation enabled), a security violation event is triggered. You can configure the following modes for handling security violation events:

- **protect**: When security violation occurs, the corresponding secure port stops learning MAC addresses and discards all packets of newly accessed users. This is the default violation handling mode.
- **restrict**: When security violation occurs, a port violation trap notification will be sent in addition to the behavior in **protect** mode.
- **shutdown**: When security violation occurs, the port will be disabled in addition to the behavior in **protect** mode.

After a security violation event is generated, a violation log will be output if the number of secure addresses exceeds the maximum limit. In addition, the port is in violation status. If the number of users is less than the maximum limit, the port recovers to the non-violation status. For a terminal migration violation event, a terminal-specific violation log will also be output. If the terminal continues to trigger migration violations, the violation log will be continuously generated. You can run the **switchport port-security station-move violation logging interval** *interval* command to configure an interval for generating violation logs for the same terminal. Note that when the violation event processing mode is set to **shutdown**, you must run the **errdisable recovery** command on the port to restore the port to Up state automatically.

1.2 Restrictions and Guidelines

- When the port security function and other access control functions, such as IEEE 802.1X or IP Source Guard, are configured, a packet needs to meet only one security check rule to enter the port. For example, when the port security function and IEEE 802.1X are configured, and the MAC field of the packet meets the requirements of the static MAC address configured for IEEE 802.1X or the port security function, the packet can be forwarded to the port.
- If a security channel or the global IP address and MAC address binding is configured for the port, packets that meet the requirements of the security channel or global IP address and MAC address binding will bypass the security check of port and enter the port.

1.3 Configuration Task Summary

Port security configuration includes the following tasks:

(1) Configuring Secure Ports

(2) (Optional) Configuring Secure Address Management

(3) (Optional) Configuring Static Secure Addresses

(4) (Optional) Configuring Secure Address Binding

(5) (Optional) Enabling Binding Log Filtering

(6) (Optional) Configuring the Terminal Migration

1.4 Configuring Secure Ports

1.4.1 Overview

After port security is enabled on a port, you can configure the method for handling packets that violate port security requirements.

1.4.2 Restrictions and Guidelines

- The port security function can be configured only on Layer 2 Ethernet interfaces and link aggregations .
- Switch Port Analyzer (SPAN) destination ports cannot be configured as secure ports.
- The port security function cannot be configured for Dynamic Host Configuration Protocol (DHCP) Snooping trusted ports.
- The port security function cannot be configured for excluded ports of global IP-MAC address binding.
- **protect** indicates that the device discards packets that do not match the secure address. **restrict** indicates that the device discards packets that do not match the secure address and sends a trap notification. **shutdown** indicates that the device discards packets that do not match the secure address and disables the port.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Enable port security.

switchport port-security

The port security function is disabled by default.

(5) (Optional) Configure the method for handling packets that violate port security requirements.

switchport port-security violation { **protect** | **restrict** | **shutdown** }

Packets that do not match the secure address are discarded by default.

1.5 Configuring Secure Address Management

1.5.1 Overview

1. Maximum Number of Secure Addresses

The number of secure addresses is the sum of statically configured secure addresses and dynamically learned secure addresses. When the number of MAC addresses learned by a port exceeds the maximum number of secure addresses, a security violation event is triggered.

If you set the maximum number of secure addresses for a port to **1** and configure a secure address for this port, the workstation (whose address is the configured secure address) connected to this port will exclusively use all bandwidth of the port.

The maximum number of secure addresses takes effect only to secure addresses and is invalid to security bindings.

By configuring the maximum number of secure addresses and secure address aging time, the device can automatically add and delete secure addresses on a port.

2. Secure Address Aging

After the secure address aging time is configured, an aging timer is triggered to regularly query and delete secure addresses whose aging time expires. By configuring the maximum number of secure addresses and secure address aging time, the device can automatically add and delete secure addresses on a port.

The **switchport port-security aging time** *aging-time* command is used to configure the secure address aging time, in minutes. The value range is from 0 to 1440. The default secure address aging time is **0**, which indicates that secure addresses never age. If a non-zero value is configured, the device regularly queries and deletes secure addresses based on the configured time. When a non-zero aging time is configured, only dynamically learned addresses are aged by default. If the **switchport port-security aging static** command is configured, statically configured and dynamically learned secure addresses are aged.

3. Secure Address Preemption

After this function is enabled, a static secure address can be successfully configured by forcing a dynamic secure address (not fixed) to get offline after the number of secure addresses reaches the maximum value.

4. Sticky MAC Address

Sticky MAC addresses are special MAC addresses not affected by the aging mechanism. No matter whether dynamic or static aging is configured, sticky MAC addresses will not be aged.

If dynamically learned secure addresses are saved as static sticky MAC addresses, these addresses will not age. After the configurations are saved, these addresses do not need to be learned again upon a restart. If this function is not enabled, these addresses must be learned again after a device restart.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure the maximum number of secure addresses for a port.

switchport port-security maximum *number*

The default maximum number of secure addresses for a port is **128**.

(5) Configure the secure address aging time and its application scope on a port.

switchport port-security aging { **static** | **time** *aging-time* }

The secure address aging time is **0** (that is, not aged), and the aging time applies only to dynamically learned addresses by default.

(6) Enable secure address preemption.

switchport port-security preempt

Secure address preemption is disabled by default.

(7) Enable sticky MAC address learning and configure sticky MAC addresses.

switchport port-security mac-address sticky [*mac-address* [**vlan** *vlan-id*]]

Sticky MAC address learning is disabled by default.

1.6 Configuring Static Secure Addresses

1.6.1 Overview

After static secure addresses are configured on a secure port, only specified users can use this port. The secure addresses are periodically updated to ensure network security.

1.6.2 Restrictions and Guidelines

- The maximum number of secure addresses configured by running the **switchport port-security maximum** *number* command takes effect only to secure addresses, and the number of security bindings is not limited.
- If security binding and a static secure MAC address are configured, the static secure MAC address must be the same as the MAC address in the IP-MAC address binding. Otherwise, communication may fail due to inconsistency with the binding. Similarly, if only IP address binding is configured, only packets whose secure MAC addresses are statically configured or dynamically learned and whose source IP address is the bound IP address can enter the device.

1.6.3 Procedure (Global Configuration Mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

- Configure static secure addresses for a port in global configuration mode.

  switchport port-security interface *interface-type interface-number* **mac-address** *mac-address* [**vlan** *vlan-id*]

  No static secure address is configured for a port by default.

1.6.4 Procedure (Interface Configuration Mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure static secure addresses for ports.

switchport port-security mac-address *mac-address* [**vlan** *vlan-id*]

No static secure address is configured for a port by default.

1.7 Configuring Secure Address Binding

1.7.1 Overview

When security binding (IP address binding or IP-MAC address binding) is configured, IP packets are first checked for secure addresses (including statically configured and dynamically learned secure addresses). If secure address check fails, the IP packets are discarded. If secure address check is successful, the bound IP address is checked. If IP address check is successful, the data packets are forwarded. Otherwise, the packets are discarded.

1.7.2 Restrictions and Guidelines

- The maximum number of secure addresses configured by running the **switchport port-security maximum** *number* command takes effect only to secure addresses, and the number of security bindings is not limited.
- If security binding and a static secure MAC address are configured, the static secure MAC address must be the same as the MAC address in IP-MAC address binding. Otherwise, communication may fail due to inconsistency with the binding. Similarly, if only IP address binding is configured, only packets whose secure MAC addresses are statically configured or dynamically learned and whose source IP address is the bound IP address can enter the device.

1.7.3 Procedure (Global Configuration Mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

- Configure security bindings for a port in global configuration mode.

  switchport port-security interface *interface-type interface-number* **binding** [*mac-address* **vlan** *vlan-id*] { *ipv4-address* | *ipv6-address* }

  No security binding is configured by default.

1.7.4 Procedure (Interface Configuration Mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure security bindings for a port.

switchport port-security binding [*mac-address* **vlan** *vlan-id*] { *ipv4-address* | *ipv6-address* }

No secure address is bound to a port by default.

1.8 Enabling Binding Log Filtering

1.8.1 Overview

After the binding log filtering function is enabled, the device prints alert logs if received IP packets do not match the bound IP and MAC addresses or the bound IP address for port security.

When the binding log printing rate exceeds the configured rate, the number of suppressed logs will be displayed.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Enable binding log filtering.

switchport port-security binding-filter logging [**rate-limit** *rate*]

Address binding log filtering is disabled by default.

1.9 Configuring the Terminal Migration Violation Function

1.9.1 Overview

In a scenario where you bind a static MAC address to port A and set port B as a secure port, after the terminal migration violation function is enabled, if packets of the terminal bound to port A are sent to port B, a terminal migration violation event is identified. Port B processes the packets based on the configuration of the **switchport port-security violation** command.

1.9.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Enable the terminal migration violation function.

switchport port-security station-move violation enable

By default, the terminal migration violation function is disabled.

(4) (Optional) Configure an interval for outputting terminal migration violation logs.

switchport port-security station-move violation logging *interval*

1.10 Monitoring

Run the **show** command to check the configuration.

Table 1-1 Monitoring

Command	Purpose
show port-security	Displays all port security configurations.
show port-security all	Displays all effective secure addresses and secure address bindings on a port.
show port-security address [**interface** *interface-type interface-number*]	Displays secure addresses of all ports or a specified port.
show port-security binding [**interface** *interface-type interface-number*]	Displays secure address bindings of all ports or a specified port.
show port-security interface *interface-type interface-number*	Displays port security configurations of a specified port.

1.11 Common Errors

- Port security is enabled on a SPAN port.
- Port security is enabled on a DHCP trusted port.
- The configured maximum number of secure addresses is smaller than the current number of secure addresses.

1 Configuring IP Source Guard

1.1 Introduction

1.1.1 Overview

The IP Source Guard function enables the hardware to filter IP packets to ensure that only users whose IP packets match information in the database of the hardware can access the network normally, preventing users from privately setting IP addresses or forging IP packets.

1.1.2 Principles

1. Basic Concepts

- Source IP address

  Indicate the source IP address field in IP packets.

- Source MAC address

  Indicate the source media access control (MAC) address field in L2 packets.

- User record binding database

  The user record binding database is the basis for IP Source Guard. Data in the user record binding database comes from the following two sources:

  Dynamic Host Configuration Protocol (DHCP) Snooping binding database: When IP Source Guard is enabled, data of the DHCP Snooping binding database is synchronized to the user record binding database of IP Source Guard. In this case, IP packets are filtered strictly through IP Source Guard on devices with DHCP Snooping enabled.

  Static user configuration: static user information configured by running the **ip source binding** command.

- Excluded VLAN

  When IP Source Guard is enabled on an interface, it is effective to all the virtual local area networks (VLANs) under the interface by default. Users can specify excluded VLANs, within which IP packets are not checked or filtered, that is, such IP packets are not controlled by IP Source Guard. A maximum of 32 excluded VLANs can be specified for one interface.

2. Checking the Source Address Fields of Packets

IP packets passing through an interface are checked based on the source IP address or source IP address and MAC address to prevent malicious users from forging packets to launch attacks. When there is no need to check or filter IP packets within a VLAN, users can specify this VLAN as an excluded VLAN to release such packets.

When IP Source Guard is enabled on an interface, the device checks the source addresses of packets passing through the interface, which can be a Layer 2 Ethernet interface, Layer 2 link aggregation or member port of a Layer 2 link aggregation. Only the packets whose source addresses match entries in the user record binding database can pass through the interface. There are two matching methods:

- Filtering based on the source IP address

The source IP addresses of all IP packets passing through an interface are checked. Packets are allowed to pass through the interface only when the source IP addresses of these packets belong to the IP address set of the user record binding database. It is the default filtering policy of IP Source Guard.

- Filtering based on the source IP address and MAC address

  The source IP addresses and MAC addresses of IP packets passing through an interface are checked. Packets are allowed to pass through the interface only when both the L2 source MAC addresses and L3 source IP addresses of these packets match an entry in the user record binding database.

1.2 Restrictions and Guidelines

- Typically, IP Source Guard needs to work with DHCP Snooping. Therefore, DHCP Snooping should also be enabled. DHCP Snooping can be enabled either before or after IP Source Guard is enabled.
- IP Source Guard cannot be configured on the trusted interfaces of DHCP Snooping or IP Source Guard.
- IP Source Guard cannot be configured on the ports that do not verify the global IP address and MAC address binding.
- IP Source Guard can be configured based on interfaces or VLANs.

1.3 Configuration Task Summary

Select any of the following configuration tasks to configure.

- Enabling IP Source Guard on an Interface
- Enabling IP Source Guard on a VLAN
- Enabling the Sole Role of the IP Source Address Binding Database as the Source of DAI Binding Entries

1.4 Enabling IP Source Guard on an Interface

1.4.1 Restrictions and Guidelines

IP Source Guard can be enabled only on a Layer 2 Ethernet interface, Layer 2 link aggregation or member port of a Layer 2 link aggregation.

1.4.2 Prerequisites

DHCP Snooping is enabled by running the **ip dhcp snooping** command.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Add static user information to the source IP address binding database.

ip source binding *mac-address* **vlan** *vlan-id ipv4-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

No static user information is added by default.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(5) (Optional) Configure the function of converting source IP address binding entries to static MAC address entries.

ip source binding sticky-mac

The function of converting source IP address binding entries to static MAC address entries is disabled by default.

(6) Enable IP Source Guard on an interface.

ip verify source [**port-security**]

IP Source Guard is disabled on an interface by default.

(7) (Optional) Specify an excluded VLAN for IP Source Guard on an interface.

ip verify source exclude-vlan *vlan-id*

The function of specifying excluded VLANs for IP Source Guard on an interface is disabled by default.

Excluded VLANs can be specified on an interface only after IP Source Guard is enabled on the interface. Specified excluded VLANs will be deleted automatically when IP Source Guard is disabled on the interface.

1.5 Enabling IP Source Guard on a VLAN

1.5.1 Overview

When IP Source Guard is enabled on a VLAN, the source IP addresses of IP packets in the VLAN will be checked to filter out invalid IP packets.

1.5.2 Prerequisites

DHCP Snooping is enabled by running the **ip dhcp snooping** command.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Add static user information to the source IP address binding database.

ip source binding *mac-address* **vlan** *vlan-id ipv4-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

No static user information is added by default.

(4) Enter the VLAN configuration mode.

vlan { *vlan-id* | **range** *vlan-range* }

(5) Enable IP Source Guard on a VLAN.

ip verify source [**port-security**]

IP Source Guard is disabled on a VLAN by default.

(6) Return to the global configuration mode.

exit

(7) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(8) (Optional) Configure trusted interfaces of IP Source Guard.

ip verify source trust

No IP Source Guard trusted interface is configured by default.

The IP Source Guard trusted interface function is mutually exclusive with the IP Source Guard interface, port security and Address Resolution Protocol (ARP) check services.

1.6 Enabling the Sole Role of the IP Source Address Binding Database as the Source of DAI Binding Entries

1.6.1 Overview

After the sole role of the source IP address binding database as the source of DAI binding entries is configured, the bound entries are solely used for Dynamic ARP Inspection (DAI) and are not assigned to the hardware. That is, IP Source Guard is not performed.

1.6.2 Procedure (Interface Configuration Mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Add static user information to the source IP address binding database.

ip source binding *mac-address* **vlan** *vlan-id ipv4-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

No static user information is added by default.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(5) Enable the sole role of the source IP address binding database as the source of DAI binding entries.

ip verify source dai-source

The sole role of the source IP address binding database as the source of DAI binding entries is not configured by default.

1.6.3 Procedure (VLAN Configuration Mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Add static user information to the source IP address binding database.

ip source binding *mac-address* **vlan** *vlan-id ipv4-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

No static user information is added by default.

(4) Enter the VLAN configuration mode.

vlan { *vlan-id* | **range** *vlan-range* }

(5) Enable the sole role of the source IP address binding database as the source of DAI binding entries.

ip verify source dai-source

The sole role of the source IP address binding database as the source of DAI binding entries is not configured by default.

1.7 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
show ip verify source [**interface** *interface-type interface-number* | **vlan** *vlan-id*]	Displays user filtering entries of IP Source Guard.
show ip source binding [*ipv4-address*] [*mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**dhcp-snooping** | **static**]	Displays information of the source IP address binding database.
show ip source binding sticky-mac [**interface** *interface-type interface-number*]	Displays information about source IP address binding entries converted to static MAC address entries.

1.8 Common Errors

- IP Source Guard is enabled on a DHCP Snooping trusted interface.

- An excluded VLAN is specified before IP Source Guard is enabled.

1 Configuring IPv6 Source Guard

1.1 Introduction

1.1.1 Overview

The IPv6 Source Guard function enables the hardware to filter IPv6 packets to ensure that only users whose IPv6 packets match information in the database of the hardware can access the network normally, preventing users from privately setting IPv6 addresses or forging IPv6 packets.

1.1.2 Principles

1. Basic Concepts

- Source IPv6 address

  Indicate the source IPv6 address field in IPv6 packets.

- Source MAC address

  Indicate the source media access control (MAC) address field in L2 packets.

- User record binding database

  The user record binding database is the basis for IPv6 Source Guard. Data in the user record binding database comes from the following two sources:

  - Dynamic Host Configuration Protocol version 6 (DHCPv6) and neighbor discovery (ND) Snooping binding databases: After IPv6 Source Guard is enabled, information in the DHCPv6 and ND Snooping binding databases is synchronized to the user binding database of IPv6 Source Guard. In this case, IPv6 packets are filtered strictly through IPv6 Source Guard on devices with DHCPv6 or ND Snooping enabled. DHCPv6 Snooping and ND Snooping are two independent functions. Users can enable both functions or either function.
  - Static user configuration: including static user information bound by running the **ipv6 source binding** command and local link addresses (fe80::/10) and undefined addresses (::/128) released by running the **ipv6 verify source permit link-local** command.

2. Checking the Source Address Fields of Packets

IPv6 packets passing through an interface are checked based on the source IPv6 address or source IPv6 address and MAC address to prevent malicious users from forging packets to launch attacks.

When IPv6 Source Guard is enabled on an interface, the device checks the source addresses of packets passing through the interface, which can be a Layer 2 Ethernet interface, Layer 2 link aggregation or member port of a Layer 2 link aggregation. Only the packets whose source addresses match entries in the user record binding database can pass through the interface. There are two matching methods:

- Filtering based on the source IPv6 address

  The source IPv6 addresses of all IPv6 packets passing through an interface are checked. Only the packets whose source IPv6 addresses match entries in the user record binding database can pass through the interface. It is the default filtering policy of IPv6 Source Guard.

- Filtering based on the source IPv6 address and MAC address

  The source IPv6 addresses and MAC addresses of IPv6 packets passing through an interface are checked. Packets are allowed to pass through the interface only when both the L2 source MAC addresses and L3 source IPv6 addresses of these packets match an entry in the user record binding database.

1.2 Restrictions and Guidelines

- Typically, IPv6 Source Guard needs to work with DHCPv6 Snooping or ND Snooping. Therefore, DHCPv6 Snooping or ND Snooping should also be enabled. DHCPv6 Snooping or ND Snooping can be enabled either before or after IP Source Guard is enabled.
- If DHCPv6 Snooping is enabled on a device, the device does not check DHCPv6 packets.
- If ND Snooping is enabled on a device, the device does not check ND packets.

1.3 Configuration Task Summary

Select any of the following configuration tasks to configure.

- Enabling IPv6 Source Guard on an Interface
- Enabling IPv6 Source Guard on a VLAN

1.4 Enabling IPv6 Source Guard on an Interface

1.4.1 Restrictions and Guidelines

IPv6 Source Guard depends on DHCPv6 Snooping or ND Snooping. Users need to enable IPv6 Source Guard on an untrusted interface of DHCPv6 Snooping or ND Snooping.

1.4.2 Prerequisites

At least DHCPv6 Snooping or DN Snooping is enabled. To enable DHCPv6 Snooping, run the **ipv6 dhcp snooping** command. To enable ND Snooping, run the **ipv6 nd snooping enable** command.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Add static user information to the IPv6 source address binding database.

ipv6 source binding *mac-address* **vlan** *vlan-id ipv6-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

No static user information is added by default.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

interface aggregateport *interface-number*

(5) (Optional) Enable the function of converting IPv6 source address binding entries to static MAC address entries.

ipv6 source binding sticky-mac

The function of converting IPv6 source address binding entries to static MAC address entries is disabled by default.

(6) (Optional) Enable local link address release on an interface.

ipv6 verify source permit link-local

The local link address release function is disabled on an interface by default.

This command can be configured only on a Layer 2 Ethernet interface or link aggregation.

Generally, this command is configured in a DHCPv6-only scenario. In this scenario, fe80::/10 address cannot be obtained through DHCPv6.

(7) Enable IPv6 Source Guard on an interface.

ipv6 verify source [**port-security**]

IPv6 Source Guard is disabled on an interface by default.

1.5 Enabling IPv6 Source Guard on a VLAN

1.5.1 Configuration Tasks

Enabling IPv6 Source Guard on a VLAN includes the following tasks:

(1) Enabling IPv6 Source Guard on a VLAN

(2) Configuring a Trusted Interface

(3) (Optional) Configuring an Untrusted Interface

1.5.2 Enabling IPv6 Source Guard on a VLAN

1. Prerequisites

At least DHCPv6 Snooping or DN Snooping is enabled. To enable DHCPv6 Snooping, run the **ipv6 dhcp snooping** command. To enable ND Snooping, run the **ipv6 nd snooping enable** command.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Add static user information to the IPv6 source address binding database.

ipv6 source binding *mac-address* **vlan** *vlan-id ipv6-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

No static user information is added by default.

(4) Enter the VLAN configuration mode.

vlan { *vlan-id* | **range** *vlan-range* }

(5) Enable IPv6 Source Guard on a VLAN.

ipv6 verify source [**port-security**]

IPv6 Source Guard is disabled on a VLAN by default.

1.5.3 Configuring a Trusted Interface

1. Introduction

To enable IPv6 Source Guard on a VLAN, configure the uplink interface as an IPv6 Source Guard trusted interface. On the IPv6 Source Guard trusted interface, IPv6 Source Guard is not performed.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure the uplink interface as an IPv6 Source Guard trusted interface.

ipv6 verify source trust

No interface is configured as an IPv6 Source Guard trusted interface by default.

1.5.4 Configuring an Untrusted Interface

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) The following configurations are optional. Please configure at least one task.

- Enable the function of converting IPv6 source address binding entries to static MAC address entries.

  ipv6 source binding sticky-mac

The function of converting IPv6 source address binding entries to static MAC address entries is disabled by default.

- Enable local link address release on an interface.

  ipv6 **verify source permit link-local**

  The local link address release function is disabled on an interface by default.

  This command can be configured only on a Layer 2 Ethernet interface or link aggregation.

  Generally, this command is configured in a DHCPv6-only scenario. In this scenario, fe80::/10 address cannot be obtained through DHCPv6.

1.6 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
show ipv6 source binding [*ipv6-address*] [*mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**dhcp-snooping** | **static**]	Displays information of the IPv6 source address binding database.
show ipv6 source binding sticky-mac [**interface** *interface-type interface number*]	Displays information about IPv6 source address binding entries converted to static MAC address entries.

1 Configuring SAVI

1.1 Introduction

1.1.1 Overview

Source Address Validation Improvement (SAVI) establishes a binding list based on the source IPv4/IPv6 addresses, source media access control (MAC) addresses, and access device ports for access devices through Control Packet Snooping (CPS) so as to verify the source addresses of IP packets through a specified port. The binding list sources include neighbor discovery (ND) Snooping, Dynamic Host Configuration Protocol version 6 (DHCPv6) Snooping, and static address configuration. Only packets whose source addresses match binding entries will be forwarded. This ensures the authenticity of source addresses of data packets in the network.

This document mainly describes the application of SAVI in IPv6 networks in stateful address configuration (DHCPv6 generally), stateless address autoconfiguration (SLAAC), and static address configuration scenarios.

1.1.2 Principles

1. Basic Concepts

- Source IPv6 address

  Indicate the source IPv6 address field in IPv6 packets.

- Source MAC address

  Indicate the source MAC address field in L2 packets.

- ND Snooping

  ND Snooping is used to snoop the SLAAC process of clients. The device with ND Snooping enabled extracts a client's IPv6 address and MAC address from a packet and generates a binding entry together with the port ID (interface index) and virtual local area network (VLAN) ID of the client.

- DHCPv6 Snooping

  DHCPv6 Snooping is used to snoop dynamical IPv6 address obtaining of clients through DHCPv6. The device with DHCPv6 Snooping enabled extracts a client's IPv6 address, MAC address, and lease from a packet and generates a binding entry together with the port ID (interface index) and VLAN ID of the client.

2. Checking the Source Address Fields of Packets

IPv6 packets passing through an interface are checked based on source IPv6 address or source IPv6 address and MAC address to prevent malicious users from forging packets to launch attacks.

When SAVI is enabled on an interface, the device checks the source addresses of packets passing through the interface, which can be a Layer 2 Ethernet Interface or link aggregation. Only the packets whose source addresses match SAVI binding entries can pass through the interface. There are two matching methods:

- Filtering based on the source IPv6 address

  The source IPv6 addresses of all IPv6 packets passing through an interface are checked. Only the packets whose source IPv6 addresses match SAVI binding entries can pass through the interface.

- Filtering based on the source IPv6 address and MAC address

The source IPv6 addresses and MAC addresses of all IPv6 packets passing through an interface are checked. Only the packets whose source IPv6 addresses and MAC addresses match SAVI binding entries can pass through the interface.

1.1.3 Protocols and Standards

- RFC 3315: Dynamic Host Configuration Protocol for IPv6 (DHCPv6)
- RFC 4861: Neighbor Discovery for IP version 6
- RFC 4862: IPv6 Stateless Address Autoconfiguration
- RFC 6959: SAVI Threat Scope
- RFC 6620: FCFS SAVI Improvement for Locally Assigned IPv6 Addresses
- RFC 8074: SAVI for Mixed Address Assignment Methods Scenario
- RFC 7039: SAVI Framework
- RFC 7513: Solution for DHCP

1.2 Restrictions and Guidelines

- SAVI-related commands can be configured only after SAVI is enabled globally.
- Typically, SAVI needs to work with DHCPv6 Snooping or ND Snooping. Therefore, DHCPv6 Snooping or ND Snooping should also be enabled. DHCPv6 Snooping or ND Snooping can be enabled either before or after SAVI is enabled.
- If DHCPv6 Snooping is enabled on a device, the device does not check DHCPv6 packets.
- If ND Snooping is enabled on a device, the device does not check ND packets.
- Typically, SAVI is not enabled on DHCPv6 Snooping and ND Snooping trusted interfaces.
- After SAVI is enabled on an interface, the interface will deny all data packets whose source IPv6 addresses are not in the binding list. For control packets, only ICMPv6 packets of types 133, 134, 135, 136, 137, and 143 are permitted.
- After SAVI is enabled on an interface, the permit rules of IPv6 packets are related to the IPv6 address binding mode of global IP address and MAC address binding. The default address binding mode is the strict mode. In this mode, if IPv4 SAVI is enabled but IPv6 SAVI is disabled on an interface, all IPv6 packets through the interface will be intercepted. When IPv4 SAVI is enabled but IPv6 SAVI is disabled on all interfaces, it is recommended that the IPv6 address binding mode of global IP address and MAC address binding be set to the loose mode.

1.3 Configuring SAVI

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Add static user information to the IPv6 source address binding database.

savi ipv6 source binding *mac-address* **vlan** *vlan-id ipv6-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

No static user information is added by default.

(4) (Optional) Configure the data source of SAVI binding entries.

savi ipv6 bind-source add { **slaac** | **dhcp** }

Binding entries generated during the SLAAC and DHCPv6 processes are used as the sources of dynamic binding entries by default. Binding entries can also be statically configured.

(5) (Optional) Configure SAVI to permit local link addresses and undefined addresses.

savi ipv6 check permit link-local

Permitting local link addresses and undefined addresses is not configured by default.

After configuration, SAVI permits all IPv6 packets with fe80::/10 and ::/128 as source addresses.

Generally, this command is configured in a DHCPv6-only scenario. In this scenario, fe80::/10 address cannot be obtained through DHCPv6.

(6) (Optional) Enable binding entry migration.

savi ipv6 station-move

The binding entry migration function is disabled by default.

(7) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(8) Enable IPv6 SAVI.

savi ipv6 check source ip-address [**mac-address**]

IPv6 SAVI is disabled by default.

(9) (Optional) Configure the excluded VLANs for SAVI on an interface.

savi ipv6 check source exclude-vlan *vlan-id*

No excluded VLANs for SAVI are configured on an interface by default.

After SAVI is enabled on an interface, you can run this command to permit IPv6 packets of some VLANs.

1.4 Monitoring

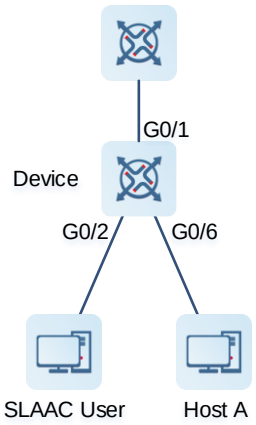
Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
show savi ipv6 source binding [*ipv6-address*] [*mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**type** { **static** | **dhcp** | **slaac** }]	Displays information of the IPv6 source address binding database.

Command	Purpose
show savi ipv6 check source [*ipv6-address* | **interface** *interface-type interface-number*]	Displays effective IPv6 SAVI filtering entries.

1.5 Configuration Examples



1.5.1 Configuring SAVI in an SLAAC-Only Scenario

1. Requirements

Enterprise devices connect to user hosts. No DHCPv6 server is deployed in the network, and hosts can obtain IPv6 addresses only through SLAAC. To prevent attackers from sending invalid IPv6 packets (including ND packets and IPv6 data packets), users need to filter out IPv6 packets with invalid source addresses.

2. Topology

Figure 1-1 Configuring SAVI in an SLAAC-Only Scenario

3. Notes

- Enable ND Snooping.
- Enable SAVI.

4. Procedure

Enable ND Snooping.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet 0/1
Device(config-if-GigabitEthernet 0/1)# ipv6 nd snooping trust
Device(config-if-GigabitEthernet 0/1)# exit
Device(config)# ipv6 nd snooping enable
```

Enable SAVI.

```
Device(config)# interface gigabitethernet 0/2
Device(config-if-GigabitEthernet 0/2)# savi ipv6 check source ip-address mac-address
Device(config-if-GigabitEthernet 0/2)# exit
Device(config)# interface gigabitethernet 0/3
Device(config-if-GigabitEthernet 0/3)# savi ipv6 check source ip-address mac-address
```

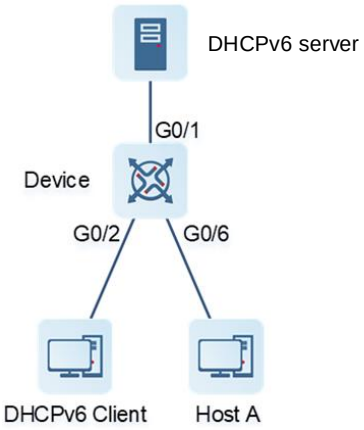
5. Verification

Run the **show savi ipv6 check source** command to check SAVI filtering entries.

```
Device# show savi ipv6 check source
Total entries found: 2
No.    Ipv6 Address                          Mac Address    VLAN Interface Filter
------ ------------------------------------- -------------- ---- --------- --
0     10::f816:3eff:fed7:cfb4                fa16.3ed7.cfb4 1    Gi0/2     IP+MAC
1     fe80::f816:3eff:fed7:cfb4              fa16.3ed7.cfb4 1    Gi0/2     IP+MAC
```

6. Configuration Files

```
!
ipv6 nd snooping enable
!
interface GigabitEthernet 0/1
 ipv6 nd snooping trust
!
interface GigabitEthernet 0/2
 savi ipv6 check source ip-address mac-address
!
interface GigabitEthernet 0/3
 savi ipv6 check source ip-address mac-address
!
end
```



1.5.2 Configuring SAVI in a DHCPv6-Only Scenario

1. Requirements

Enterprise devices connect to user hosts. For unified IPv6 address management, hosts obtain IPv6 addresses through DHCPv6. To prevent attackers from sending invalid IPv6 packets (including DHCPv6 packets and IPv6 data packets), users need to filter out IPv6 packets with invalid source addresses.

2. Topology

Figure 1-2 Configuring SAVI in a DHCPv6-Only Scenario

3. Notes

- Enable DHCPv6 Snooping.
- Enable SAVI.

4. Procedure

Enable DHCPv6 Snooping.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet 0/1
Device(config-if-GigabitEthernet 0/1)# ipv6 dhcp snooping trust
Device(config-if-GigabitEthernet 0/1)# exit
Device(config)# ipv6 dhcp snooping
```

Enable SAVI.

```
Device(config)# savi ipv6 check permit link-local
Device(config)# interface gigabitethernet 0/2
Device(config-if-GigabitEthernet 0/2)# savi ipv6 check source ip-address mac-address
Device(config-if-GigabitEthernet 0/2)# exit
Device(config)# interface gigabitethernet 0/3
Device(config-if-GigabitEthernet 0/3)# savi ipv6 check source ip-address mac-address
```

5. Verification

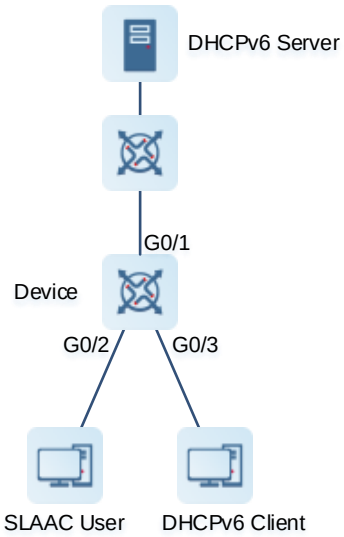
Run the **show savi ipv6 check source** command to check SAVI filtering entries.

```
Device# show savi ipv6 check source
Total entries found: 2
No.    Ipv6 Address                          Mac Address    VLAN Interface Filter
------ ------------------------------------- -------------- ---- --------- ---
0      1001::1                               fa16.3e9b.0b58 1    Gi0/2     IP+MAC
```

```
1     fe80::f816:3eff:fe9b:b58              fa16.3e9b.0b58 1    Gi0/2     IP+MAC
```

6. Configuration Files

```
!
ipv6 dhcp snooping
savi ipv6 check permit link-local
!
interface GigabitEthernet 0/1
 ipv6 nd snooping trust
!
interface GigabitEthernet 0/2
 savi ipv6 check source ip-address mac-address
!
interface GigabitEthernet 0/3
 savi ipv6 check source ip-address mac-address
!
end
```



1.5.3 Configuring SAVI in an SLAAC and DHCPv6 Deployment Scenario

1. Requirements

Enterprise devices connect to user hosts. Some hosts obtain IPv6 addresses through SLAAC, and some hosts obtain IPv6 addresses through DHCPv6. To prevent attackers from sending invalid IPv6 packets (including DHCPv6 packets, ND packets, and IPv6 data packets), users need to filter out IPv6 packets with invalid source addresses.

2. Topology

Figure 1-3 Configuring SAVI in an SLAAC and DHCPv6 Deployment Scenario

3. Notes

- Enable ND Snooping and DHCPv6 Snooping.

- Enable SAVI.

4. Procedure

Enable ND Snooping and DHCPv6 Snooping.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet 0/1
Device(config-if-GigabitEthernet 0/1)# ipv6 nd snooping trust
Device(config-if-GigabitEthernet 0/1)# ipv6 dhcp snooping trust
Device(config-if-GigabitEthernet 0/1)# exit
Device(config)# ipv6 nd snooping enable
Device(config)# ipv6 dhcp snooping
```

Enable SAVI.

```
Device(config)# interface gigabitethernet 0/2
Device(config-if-GigabitEthernet 0/2)# savi ipv6 check source ip-address mac-address
Device(config-if-GigabitEthernet 0/2)# exit
Device(config)# interface gigabitethernet 0/3
Device(config-if-GigabitEthernet 0/3)# savi ipv6 check source ip-address mac-address
```

5. Verification

Run the **show savi ipv6 check source** command to check SAVI filtering entries.

```
Device# show savi ipv6 check source
Total entries found: 4
No.    Ipv6 Address                            Mac Address    VLAN Interface Filter
------ --------------------------------------- -------------- ---- --------- ---
0      1001::1                                 fa16.3e9b.0b58 1    Gi0/3     IP+MAC
1      fe80::f816:3eff:fe9b:b58                fa16.3e9b.0b58 1    Gi0/3     IP+MAC
2      1001::f816:3eff:fed7:cfb4               fa16.3ed7.cfb4 1    Gi0/2     IP+MAC
3      fe80::f816:3eff:fed7:cfb4               fa16.3ed7.cfb4 1    Gi0/2     IP+MAC
```

6. Configuration Files

```
!
ipv6 nd snooping enable
ipv6 dhcp snooping
!
interface GigabitEthernet 0/1
 ipv6 nd snooping trust
 ipv6 dhcp snooping trust
!
interface GigabitEthernet 0/2
 savi ipv6 check source ip-address mac-address
!
interface GigabitEthernet 0/3
 savi ipv6 check source ip-address mac-address
```

```
!
end
```

1.6 Common Errors

SAVI is enabled on a DHCPv6 Snooping/ND Snooping trusted interface.

1.3 Configuring ARP Check 2

1.4 Monitoring 2

1 Configuring ARP Check

1.1 Introduction

1.1.1 Overview

Address Resolution Protocol (ARP) Check is used to filter all ARP packets through a Layer 2 Ethernet interface or link aggregation and discard all invalid ARP packets to prevent ARP spoofing and improve network stability.

On devices supporting ARP check, invalid ARP packets in networks will be filtered out according to the legitimate user information (detection based on IP address or IP address and MAC address) generated by security application modules such as IP Source Guard, global IP address and MAC address binding, 802.1x authentication, web authentication, and port security.

ARP Check uses the information to detect whether the Sender IP fields or the <Sender IP, Sender MAC> fields in all ARP packets through an interface match those in the legitimate user information table. If not, the ARP packets will be discarded.

1.1.2 Principles

1. Compatible Security Modules

ARP Check supports the following security modules:

- Detection of the IP address field only: port security and static configuration of IP Source Guard.
- Detection of the IP address and MAC address fields: IP Source Guard, global IP address and MAC address binding, 802.1x IP authorization, web authentication, and port security.

2. Filtering out Invalid ARP Packets

Enable ARP Check on specified interfaces to filter out invalid ARP packets.

A device matches the source IP and source MAC addresses of the ARP packets received through its interfaces with the valid user information in the database. With successful matching, packets will be transferred, or otherwise they will be discarded.

1.1.3 Protocols and Standards

- RFC 826: An Ethernet Address Resolution Protocol or Converting Network Protocol Addresses

1.2 Restrictions and Guidelines

- When ARP Check is enabled on an interface but IP Source Guard, global IP address and MAC address binding, 802.1x authentication, web authentication, or port security is not enabled on the interface to provide legitimate user information, all ARP packets through the interface will be discarded.
- ARP Check cannot be configured on mirrored destination ports.
- ARP Check cannot be configured on the trusted interfaces of DHCP Snooping.
- ARP Check cannot be configured on excluded interfaces of global IP address and MAC address binding.
- ARP Check can be configured only on a Layer 2 Ethernet interface or link aggregation.

- When ARP Check is enabled, the number of policies or users of related security applications may decrease.
- When the ARP Check and Virtual Router Redundancy Protocol (VRRP) functions are enabled on an interface and the physical IP address and virtual IP address of the interface can be used as the gateway address, the physical IP address and VRRP IP address need to be permitted to pass. Otherwise, ARP packets sent to the gateway will be filtered out.

1.3 Configuring ARP Check

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Enable ARP Check.

arp-check

ARP Check is disabled by default.

1.4 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
show interfaces [*interface-type interface-number*] **arp-check list**	Displays the effective ARP Check entries on an interface.

1 Configuring DAI

1.1 Introduction

1.1.1 Overview

Dynamic ARP Inspection (DAI) is used to check the validity of received Address Resolution Protocol (ARP) packets and discard invalid ARP packets to prevent ARP spoofing and improve network stability. DAI generates ARP filtering information based on the legitimate user information (IP address or IP address and MAC address) generated by security application modules, such as IP Source Guard, global IP address and MAC address binding, 802.1x authentication, web authentication, and port security to filter out invalid ARP packets in the network.

1.1.2 Principles

1. Interface Trust Status

A device processes ARP packets based on the trust status of each interface. It regards ARP packets received through trusted interfaces as valid and does not perform DAI on such packets, and strictly performs DAI on packets received through untrusted interfaces.

In a typical network, L2 interfaces connected to network devices should be set as trusted interfaces, and L2 interfaces connected to hosts should be set as untrusted interfaces.

⚠ Caution

- After DAI is enabled, it is recommended that the uplink interfaces be configured as DAI trusted interfaces. If the uplink interfaces are not DAI trusted interfaces but trusted interfaces of other security functions, ARP packets will be filtered out because the interfaces do not have entries required for DAI.
- If another access security control command is configured on an interface, the interface cannot be configured as a DAI trusted interface. To set the interface as a DAI trusted interface, disable the configured security control command.

2. Filtering out Invalid ARP Packets

Due to defects of ARP, ARP cannot check the validity of received ARP packets. Attackers can easily use vulnerabilities of the protocol to launch ARP spoofing.

When DAI is enabled on a specified virtual local area network (VLAN), a device will intercept all ARP requests and responses transmitted through untrusted interfaces. The device matches the source IP addresses and media access control (MAC) addresses of the ARP packets received through its interfaces with the valid user records in the security database. With successful matching, packets will be transferred, or otherwise they will be discarded.

1.1.3 Protocols and Standards

- RFC 826: An Ethernet Address Resolution Protocol or Converting Network Protocol Addresses

1.2 Configuring DAI

Caution

Before enabling DAI, complete operations of other modules. Otherwise, all ARP packets will be discarded, causing service interruption. Evaluate the service scope that may be affected and perform operations according to the guidelines.

1.2.1 Restrictions and Guidelines

- To enable this command to take effect, enable the ARP Check function first.
- DAI cannot be enabled for Dynamic Host Configuration Protocol (DHCP) snooping trusted interfaces in a VLAN.
- When DAI is disabled, it does not take effect to all interfaces in a VLAN. When ARP Check is still effective on an interface, the device will check ARP packets transmitted through the interface.
- DAI has the same functions as ARP Check. The only difference is that DAI is enabled for VLANs, and ARP Check is enabled for interfaces.

1.2.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable DAI on a VLAN.

ip arp inspection vlan { *vlan-id* | *word* }

DAI is disabled on all VLANs by default.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(5) Configure interfaces as DAI trusted interfaces.

ip arp inspection trust

Interfaces are DAI untrusted interfaces by default.

(6) Configure the ARP packet receiving rate.

For details, see the rate limit command of NFPP.

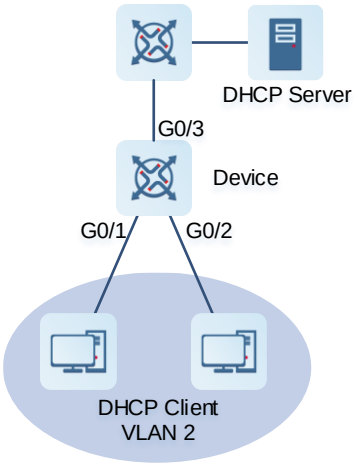
1.3 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
show ip arp inspection vlan [*vlan-id* | *vlan-range*]	Displays whether DAI is enabled for a VLAN.
show ip arp inspection interface	Displays the DAI configuration status on interfaces.

1.4 Configuration Examples



1.4.1 Configuring Dynamic ARP

1. Requirements

Hosts can use only addresses assigned by a legitimate DHCP server to prevent ARP spoofing.

2. Topology

Figure 1-1 Configuring DAI

3. Notes

- Enable DHCP Snooping on the access device and set the interface (GigabitEthernet 0/3 in this example) connected to the legitimate DHCP server as a trusted interface.
- Enable IP Source Guard on the access device.
- Enable DAI after DHCP Snooping and IP Source Guard are enabled.

4. Procedure

Enable DHCP Snooping and IP Source Guard.

```
Device> enable
Device# configure terminal
Device(config)# interface range gigabitEthernet 0/1-2
Device(config-if-range)# switchport access vlan 2
```

```
Device(config-if-range)# ip verify source
Device(config-if-range)# exit
Device(config)# ip dhcp snooping
```

Configure DAI.

```
Device(config)# ip arp inspection vlan 2
```

Configure the trusted interface.

```
Device(config)# interface gigabitethernet 0/3
Device(config-if-GigabitEthernet 0/3)# switchport access vlan 2
Device(config-if-GigabitEthernet 0/3)# ip dhcp snooping trust
Device(config-if-GigabitEthernet 0/3)# ip arp inspection trust
```

5. Verification

Check whether DHCP Snooping, IP Source Guard and DAI are enabled, and whether the trusted interface is correct.

```
Device# show ip dhcp snooping
Switch DHCP snooping status                  :   ENABLE
DHCP snooping verify hardware address status    :   DISABLE
DHCP snooping database write-delay time       :   0 seconds
DHCP snooping option 82 status               :   DISABLE
DHCP snooping Support bootp bind status       :   DISABLE

Interface                   Trusted        Rate limit (pps)
------------------------       -------        ----------------
GigabitEthernet 0/3           YES           unlimited
Default                     No            unlimited
Device# show ip verify source
NO.   INTERFACE              FilterType FilterStatus         IPADDRESS
MACADDRESS    VLAN TYPE
----- ------------------------ ---------- ---------------------  ---------------
-------------- ---- -------------
1    GigabitEthernet 0/1      IP-ONLY    Active              Deny-All
2    GigabitEthernet 0/2      IP-ONLY    Active              Deny-All

Total number of bindings: 2
Device# show ip arp inspection vlan
Vlan Configuration
---- -------------
2   Enable
```

6. Configuration Files

```
hostname Device
!
ip arp inspection vlan 2
ip dhcp snooping
!
```

```
interface GigabitEthernet 0/1
 switchport access vlan 2
 ip verify source
!
interface GigabitEthernet 0/2
 switchport access vlan 2
 ip verify source
!
interface GigabitEthernet 0/3
 switchport access vlan 2
 ip arp inspection trust
 ip dhcp snooping trust
!
end
```

7. Common Errors

An interface configured with security limitations is set as a DAI trusted interface.

1.2 Configuring ARP Spoofing Prevention 2

1.3 Monitoring 2

1.4 Configuration Examples 2

1.4.1 Configuring ARP Spoofing Prevention 2

1 Configuring ARP Spoofing Prevention

1.1 Introduction

1.1.1 Overview

Due to defects of Address Resolution Protocol (ARP), ARP cannot check the validity of received ARP packets. Attackers can easily use vulnerabilities of the protocol to launch ARP spoofing. When a malicious user host is disguised as the gateway to send ARP packets, other user hosts in the network will learn false gateway ARP entries, resulting in ARP spoofing.

The ARP spoofing prevention function is therefore used.

1.1.2 Principles

1. Basic Concepts

- ARP

  ARP is a Transmission Control Protocol (TCP)/IP protocol that obtains physical addresses according to IP addresses. A host broadcasts ARP requests to all hosts in the network and receives the returned packets to determine physical addresses of the target IP addresses, and saves the IP addresses and hardware addresses in the local ARP cache, which can be directly queried in response to future requests. In the same network, all the hosts using ARP are considered as mutually trustful to each other. Each host in the network can independently send ARP response packets, and the other hosts receive the response packets and record them in the local ARP cache without detecting their authenticity. In this way, attackers can send forged ARP response packets to target hosts so that the messages sent from these hosts cannot reach the proper host or reach a wrong host, thereby causing ARP spoofing.

- ARP spoofing

  When host A sends an ARP packet requesting the media access control (MAC) address of a gateway, host B on the same VLAN also receives this packet. Host B can send an ARP response packet, passing off the gateway IP address as the source IP address of the packet and host B's MAC address as the source MAC address. This is called ARP spoofing. After receiving the ARP response, host A regards host B as the gateway. Therefore, all the packets sent from host A to the gateway during communication will be sent to host B. In this way, host A's communications are intercepted, causing ARP spoofing.

2. ARP Spoofing Prevention

ARP spoofing prevention is used to check whether the source IP address of an ARP packet through an access interface is set to the gateway IP address. If yes, the packet will be discarded to prevent hosts from receiving wrong ARP response packets. If not, the packet will not be handled. In this way, only the uplink devices can send ARP packets, and the ARP response packets sent from other PCs which pass for the gateway are filtered out.

1.1.3 Protocols and Standards

- RFC 826: Ethernet Address Resolution Protocol

1.2 Configuring ARP Spoofing Prevention

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Enable ARP spoofing prevention.

anti-arp-spoofing ip *ipv4-address*

ARP spoofing prevention is disabled by default.

ARP spoofing prevention is supported only on Layer 2 Ethernet interfaces or link aggregations.

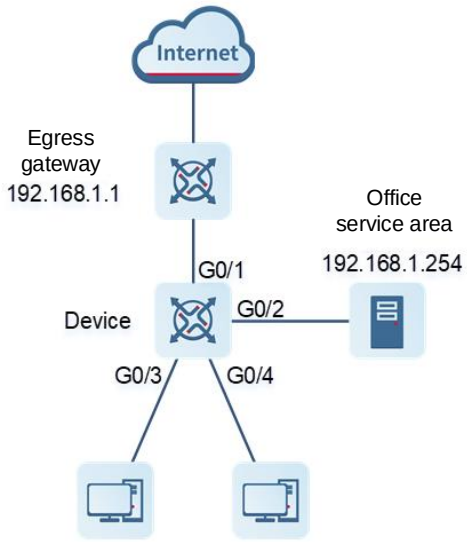
1.3 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
show anti-arp-spoofing	Displays all data on ARP spoofing prevention.

1.4 Configuration Examples



1.4.1 Configuring ARP Spoofing Prevention

1. Requirements

User hosts access the office server through the access device, and connect to external networks through the gateway. If any malicious user hosts use forged gateway IP addresses or server IP addresses to perform ARP spoofing, the other user hosts cannot access the Internet or the server. The ARP spoofing packets with forged gateway addresses and intranet server IP addresses must be blocked so that users can access the Internet.

2. Topology

Figure 1-1 Configuring ARP Spoofing Prevention

3. Notes

Enable ARP spoofing prevention on the access interface.

4. Procedure

Configure ARP spoofing prevention.

```
Device> enable
Device# configure terminal
Device(config)# interface range gigabitEthernet 0/3-4
Device(config-if-range)# anti-arp-spoofing ip 192.168.1.1
Device(config-if-range)# anti-arp-spoofing ip 192.168.1.254
```

5. Verification

Run the **show anti-arp-spoofing** command to check for data on ARP spoofing prevention.

```
Device> enable
Device# show anti-arp-spoofing
NO    PORT      IP              STATUS
----- ---------- ---------------- ----------
1     Gi0/3     192.168.1.1     active
2     Gi0/3     192.168.1.254    active
3     Gi0/4     192.168.1.1     active
4     Gi0/4     192.168.1.254    active
```

6. Configuration Files

```
hostname Device
!
interface GigabitEthernet 0/3
```

```
 anti-arp-spoofing ip 192.168.1.1
 anti-arp-spoofing ip 192.168.1.254
!
interface GigabitEthernet 0/4
 anti-arp-spoofing ip 192.168.1.1
 anti-arp-spoofing ip 192.168.1.254
!
end
```

1 Configuring CPP

1.1 Introduction

1.1.1 Overview

Many malicious attacks exist in the network environment. CPU attack packets significantly increase the CPU usage of a device, which affects the CPU to process and respond to the CPU to normal services and thus causes device function exceptions. CPU protect policy (CPP) protects the CPU of a device. By controlling the traffic of different types of packets sent to the CPU of the device and scheduling their priorities, users can defend against malicious attacks in the network and ensure that the CPU processes normal protocol packets.

1.1.2 Basic Concepts

1. QoS

As a network security mechanism, Quality of Service (QoS) is a technology that is used to solve network delay and congestion.

Differentiated Service (DiffServ) is a typical model of QoS that provides different services to packets by classifying service streams.

2. Bandwidth

Bandwidth specifies the maximum data transmission rate and the rate threshold for packet transmission in this document. When the data transmission rate exceeds the bandwidth, packets beyond the bandwidth are discarded. Therefore, the transmission rates of different types of packets must be equal to or smaller than the bandwidth. Both the bandwidth and data transmission rate use the unit of packets per second (pps).

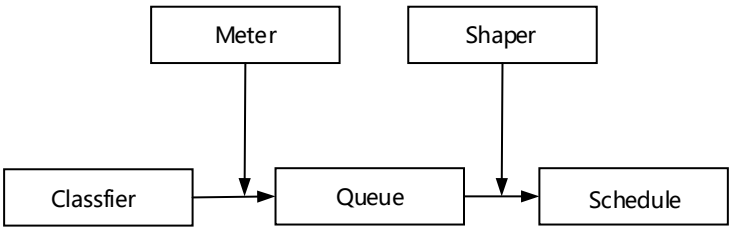
3. L2/L3/L4

L2/L3/L4 means a hierarchical structure of packets based on the TCP/IP model. L2 means layer-2 headers, namely, the Ethernet encapsulation part; L3 means layer-3 headers, namely, the IP encapsulation part; L4 means layer-4 headers, usually, the TCP/UDP encapsulation part.

4. Priority Queue

The strict priority (SP) queue scheduling algorithm is a QoS scheduling algorithm. This scheduling algorithm requires packets to be processed based on the queue priority from high to low. The CPU must process first the packets in a high-priority queue and then those in a low-priority queue.

Packets to be sent to the CPU are cached in the SP queue and scheduled according to the algorithms of the SP queue. Packet scheduling is the process of selecting and transmitting packets in a priority queue to the CPU.



5. CPU Interface

A device caches packets before it sends them to the CPU. Sending the packets to the CPU is similar to a packet output process from the port. The CPU port is a virtual port through which packets are sent to the CPU. The priority queue and SP queue scheduling algorithms apply to only data packets that are transmitted through this CPU port.

1.1.3 Processing Process

The CPP function protects the CPU by using the standard QoS DiffServ model.

Figure 1-1 CPP Implementation Model

1. Classifier

The classifier classifies all packets to be sent to the CPU by the L2, L3 and L4 information of the packets. Classifying packets is the basis for implementing QoS policies. In subsequent actions, CPP can, according to the classification, implement different policies and provide different services. Packets on a device are classified by the supported protocols and management functions, for example, Bridge Protocol Data Unit (BPDU) packets of Spanning Tree Protocol (STP) and packets of Internet Control Message Protocol (ICMP). Packet types cannot be customized.

Note

Packet classification varies with products due to hardware difference. For details, see *Specifications* for details.

2. Meter

The meter limits the rates of different types of packets based on the set rate thresholds. You can set different rate thresholds for various packet types. When the rate of a packet type exceeds the threshold, the packets beyond the threshold are discarded.

By using the meter, you can control the rate of a packet type sent to the to the CPU within a threshold to prevent specific attack packets from exerting great impacts on the CPU resources. This is the level-1 protection of CPP.

3. Queue

Queues are used to classify packets at level 2. You can select the same queue for different packet types; queues cache packets in a device and provide services for the scheduler and shaper.

CPP queues are SP queues. The SPs of the packets are determined based on the time when they are added to a queue. Packets with a larger queue number have a higher priority.

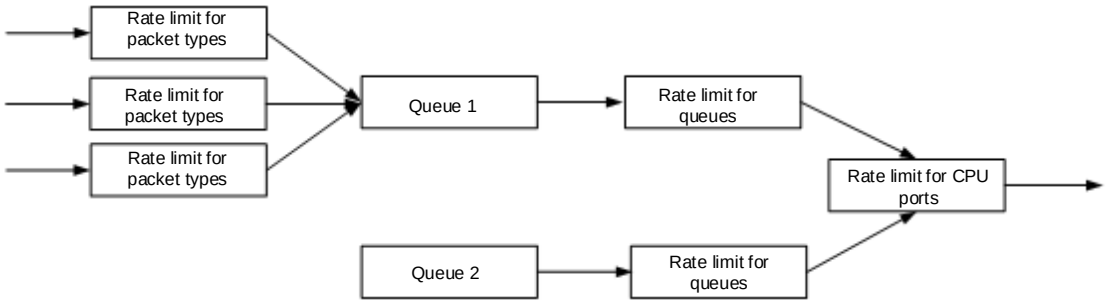
4. Scheduler

The scheduler schedules packets based on SPs of queues. Packets in a high-priority queue are first scheduled.

Before being scheduled, the packets to be sent to the CPU are cached in queues. When being scheduled, the packets are sent to the CPU for processing.

Note

Only the SP scheduling policy is supported and cannot be modified.



5. Shaper

The shaper shapes the packets to be sent to the CPU. When the actual rate of packets is greater than the shaping threshold, the packets must continue to cache in the queue and cannot be scheduled. When packet rates fluctuate, the shaper ensures that the rates of packets sent to the CPU are smooth (not more than the shaping threshold).

When the shaper is available, packets in a low-priority queue may be scheduled before those in a high-priority queue. If the rate of packets in a queue with a priority exceeds the shaping threshold, scheduling of the packets in this queue is stopped temporarily. Therefore, the shaper can prevent only the packets in high-priority queues from being scheduled.

Since the shaper limits the scheduling rates of packets, it provides the rate limit function. The shaper provides level-2 rate limit for priority queues and all packets sent to the CPU (CPU port). The shaper and meter functions provide 3-level rate limit and level-3 protection for the CPU.

Figure 1-2 3-Level Rate Limit of CPP

1.2 Configuration Task Summary

CPP configuration includes the following tasks:

- Configuring Basic Attributes of CPP
- Configuring Alarm Print Function of CPP

1.3 Configuring Basic Attributes of CPP

1.3.1 Overview

The implementation model of CPP includes five basic functional components: classifier, meter, queue, scheduler, and shaper. A device uses fixed classification policies for the classifier and SP scheduling algorithms for the scheduler.

In different network scenarios, users can configure personalized CPPs based on the meter, queue, and shaper to prevent packet attacks and network flapping from affecting normal operation of the CPU of a device.

- Configure a bandwidth for a specific packet type based on the meter to limit the packet transmission rate. Packets beyond the bandwidth are directly discarded.
- Configure a priority queue for a specific packet type based on the queue function. Packets in a high-priority

queue are scheduled first.

- Configure a bandwidth for a CPU port and that for a specific priority queue to limit the packet transmission rate. Packets beyond the bandwidth are directly discarded.

1.3.2 Restrictions and Guidelines

- In one of the following situations, you must adjust the bandwidth for a specific packet type:
  - If a type of packets are discarded though they do not initiate attacks, you must increase the bandwidth for this packet type.
  - If a type of packets initiate attacks and cause CPU running exception, you must decrease the bandwidth for this packet type.
- In one of the following situations, you must adjust the priority queue for a specific packet type:
  - If a type of packets initiate attacks and cause exception in other packets in the same queue, you may put this type of packets into an unused queue.
  - A type of packets may not be discarded, and they are in the same queue with other types of packets in use. To prevent the bandwidth for other types of packets in the same queue from discarding packets, you can put this type of packets into a high-priority queue.
- In one of the following situations, you must adjust the bandwidth for a priority queue:
  - If the bandwidth for a type of packets increases, causing the available bandwidth for other packets in the same priority queue to decrease, you must appropriately increase the bandwidth for this priority queue.
  - If attack packets are put into a priority queue and no other packets in use stay in the same queue, you should decrease the bandwidth for this priority queue.
- When you configure a bandwidth for a specific packet type, note that decreasing the bandwidth may affect the normal service traffic of this packet type. To apply CPP based on users, use the NFPP function. For more information about NFPP configuration, see *Configuring NFPP*.
- The bandwidth configuration for a packet type must match the bandwidth configuration for a priority queue. For the three levels of CPU protection, applying only one level of protection may cause negative effects. For example, if you increase the bandwidth for a packet type, you must also adjust the bandwidth for its priority queue. Otherwise, the other packets in the same priority queue may be affected.
- You are not advised to modify the bandwidth of the CPU port.
- For packets entering the MGMT port, the device applies level-1 rate limit based on the packet type and then applies level-2 rate limit based on the bandwidth of the CPU port. If the rate of the packets entering the MGMT port is three times of the bandwidth specified in the **cpu-protect type bandwidth** command, the device limits the packet rate to 20 PPS for 5 seconds.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the basic attributes of CPP, and configure at least one task.

- Configure a bandwidth for a packet type.

cpu-protect type *packet-type* **bandwidth** *bandwidth-value* [**slot** *slot-number*]

No bandwidth is configured for a specified packet type by default.

Each packet type has a rate threshold (bandwidth) by default, and this rate threshold may be modified, but may not be removed.

- Configure a priority queue for a packet type.

  cpu-protect type *packet-type* **traffic-class** *traffic-class-number*

  Each packet type has a priority queue by default.

  No priority queue is configured for a specified packet type by default.

- Configure a bandwidth for a priority queue.

  cpu-protect traffic-class *traffic-class-number* **bandwidth** *bandwidth-value* [**slot** *slot-number*]

  A shaping threshold (bandwidth) is determined for each priority queue by default, and this shaping threshold may be modified, but may not be removed.

  No bandwidth is configured for a queue by default.

  Configure a bandwidth for the CPU interface.

  cpu-protect cpu bandwidth *bandwidth-value* [**slot** *slot-number*]

  No bandwidth is configured for a CPU interface by default.

1.4 Configuring Alarm Print Function of CPP

1.4.1 Overview

After the alarm print function of CPP is enabled, you can view the alarm logs of lost packets and detect packet attacks to the CPU of the device timely. For the normal service packets that are discarded falsely, you can adjust the CPP configuration to avoid subsequent packet loss.

The configuration effect of the alarm print function is as follows:

- After the alarm print function is enabled for a packet type, the corresponding alarm log is printed if packets of this type are lost.
- After the alarm print function is enabled for a priority queue, the alarm log is printed if packets in this queue are lost.
- After an alarm period is configured, a device periodically detects the lost packets sent to the CPU, and the alarm is printed only once for the packet loss in this specified period.

1.4.2 Restrictions and Guidelines

- You can configure the alarm print function with two methods. Select either of them to validate this function. Commands configured between the configuration methods produce the same function effect. If they are configured, the later configured command takes effect. To facilitate management, you are advised to adopt one configuration method.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an alarm period of CPP. Please configure only one task.

- **cpu-protect alarm period** *period-value*
- **cpp-warn warn-period** *interval*

The default alarm period of CPP is **600** seconds.

(4) Enable the alarm print function for a packet type. Please configure only one task.

- **cpu-protect alarm type** *packet-type* **enable**
- **cpp-warn type** *packet-type* **warn**

The alarm print function for packets is enabled by default.

(5) Enable the alarm print function for a queue. Please configure only one task.

- **cpu-protect alarm traffic-class** *traffic-class-number* **enable**
- **cpp-warn traffic-class** *traffic-class-number* **warn**

The alarm print function for priority queues is enabled by default.

1.5 Monitoring

Run the **show** command to check the configuration.

Run the **clear** command to clear information.

Caution

- During device operation, running the **clear** command may cause service interruption due to key information loss.
- Debugging occupies system resources, so disable it immediately if not required.

Table 1-1 Monitoring

Command	Purpose
clear cpu-protect counters [**slot** *slot-number*]	Clears CPP statistics.
clear cpu-protect counters mboard	Clears the CPP statistics on the master device.
clear cpu-protect statistics [**interface** *interface-type interface-number*]	Clears the CPP statistics on an interface.
show cpu-protect type *packet-type* [**slot** *slot-number*]	Displays the configuration and statistics of a packet type.
show cpu-protect traffic-class *traffic-class-number* [**slot** *slot-number*]	Displays the configuration and statistics of a priority queue.
show cpu-protect cpu	Displays the configuration on the CPU port.

Command	Purpose
show cpu-protect { **mboard** | **summary**}	Displays all the configuration and statistics on the master device.
show cpu-protect [**slot** *slot-number*]	Displays all the configuration and statistics of CPP.
show cpu-protect statistics [**interface** *interface-type interface-number*]	Displays the statistics on a CPP port.
show cpu-protect statistics type *packet-type*	Displays the statistics of a packet type on a CPP port.
show cpu-protect hardware-statistics [**slot** *slot-number*]	Displays the hardware statistics of a CPP packet type.
show cpu-protect linkage summary	Displays the protocol correlation state.

1.6 Configuration Examples

1.6.1 Configuring Basic Functions of CPP

1. Requirements

Address Resolution Protocol (ARP), IP, Open Shortest Path First (OSPF), dot1x, Virtual Router Redundancy Protocol (VRRP), Telnet and ICMP streams are available in the system. In the current configuration, ARP and dot1x streams are in priority queue 2; IP, ICMP and Telnet streams are in priority queue 4; OSPF streams are in priority queue 3; and VRRP streams are in priority queue 6. The bandwidth is 750 pps for the priority queues 0–6, 1000 pps for the priority queue 10, and 2250 pps for the CPU port is 2250 pps. If the device suffers ARP packet attacks, you must enable the CPP function to prevent the packet attacks and network flapping and ensure the normal running of other services on the device.

2. Notes

- Classify ARP attack packets into priority queue 1 and limit the bandwidth for ARP packets or the priority queue.
- Classify OSPF packets into priority queue 5.
- Classify IP attack packets (without the ARP entries) into priority queue 3 and limit the bandwidth for IP packets or the priority queue.

3. Procedure

Configure the basic attributes of CPP.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# cpu-protect type arp traffic-class 1
DeviceA(config)# cpu-protect type arp bandwidth 500
DeviceA(config)# cpu-protect type ospf traffic-class 5
DeviceA(config)# cpu-protect type v4uc-route traffic-class 3
```

```
DeviceA(config)# cpu-protect traffic-class 3 bandwidth 500
DeviceA(config)# end
```

4. Verification

Run the **show cpu-protect** command to view the configuration and statistics.

```
DeviceA# show cpu-protect
%cpu port bandwidth: 2250(pps)
Traffic-class   Bandwidth(pps)  Rate(pps)  Drop(pps)
-------------   --------------  ---------  ---------
 0            750           0         0
 1            750           0         0
 2            750           0         0
 3            500           0         0
 4            750           0         0
 5            750           0         0
 6            750           0         0
 7            1000          0         0
Packet Type           Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)  Total

1 Configuring NFPP

1.1 Introduction

1.1.1 Overview

Many malicious attacks exist in the network environment. If no protection policies are available, attack packets occupy the CPU resources of a device. As a result, the CPU cannot process normal protocol packets and control packets and the device does not normally run. The network foundation protection policy (NFPP) protects devices from attacks and keeps a low CPU load for the devices under attack to ensure normal operation of services and stable operation of the entire network.

1.1.2 Basic Concepts

1. ARP Guard

In a LAN, the Address Resolution Protocol (ARP) can parse an IP address into a MAC address to ensure smooth communication. The Denial of Service (DoS) is a process of sending many invalid ARP packets to a gateway in a network to cause the gateway not to provide services for normal hosts. To avoid this type of attacks, configure a rate limiting threshold for the ARP packets and isolate the source of the attack.

2. IP Guard

Hacking attack and network virus intrusion start at a host that scans network activities. Many scanned packets occupy network bandwidth and thus affect normal communication of the network. To avoid this type of attacks, we configure the IP guard function for a device. This function also reduces the CPU usage of the device. IP attacks include the following two types:

- Scan changes in the destination IP address. This type of attacks consume network bandwidth and increase device load. This indicates most of upcoming hacking attacks.
- Send IP packets to an unconfigured destination IP address. This attack is designed for the CPU of a device. On an L3 device, if a destination IP address is configured, packets are forwarded by the chip without consuming CPU resources. Otherwise, the packets are sent to the CPU and the latter sends ARP requests to request the MAC address of the destination IP address. If too many packets sent to the CPU, this consumes many CPU resources. To avoid this type of attacks, we configure a rate limiting threshold for the IP packets and isolate the source of the attack.

3. ARP Source Suppression

When IP packets are sent to an unconfigured destination IP address at a high rate, they are forwarded to the CPU, triggering the device to send ARP requests to request the MAC address of the destination IP address. If too many packets sent to the CPU, this consumes many CPU resources. To avoid this type of attacks, isolate the source of the attack and enable the function of ARP source suppression. If IP packets that trigger ARP requests exceed the threshold in the specified period, the IP packets out of the threshold are discarded.

4. TCP SYN Guard

TCP-SYN-Flood attack is also called half-open connection attack. An attacker sends SYN packets to the target device without responding to the SYN+ACK packets returned by the target device. If it does not receive the SYN+ACK responses, the target device waits and thus a half-open connection is formed. The attacker allows the target device to generate many half-open connections with this method, forcing the target device to waste resources on the half-open connections.

The available TCP connections of a server are limited. If a malicious attacker sends this type of connection requests consecutively in an attack, the available TCP connections of this server become congested. Thus, the available system resources and available bandwidth drop dramatically, affecting normal network services. Consequently, a DoS occurs.

To avoid the TCP-SYN-Flood attack, configure the TCP SYN guard function on the device to limit the sending rates of TCP SYN packets.

5. ICMP Guard

The Internet Control Message Protocol (ICMP) is a common means of network fault diagnosis. According to the principle of ICMP, when a host sends an ICMP Echo Request packet, the receiver returns an ICMP Echo Reply upon receipt of the packet. This process requires CPU coordination. If an attacker sends many ICMP requests to the target device, many CPU resources are consumed, which may interrupt normal device operation in extreme conditions. This is called an ICMP flood attack. To avoid it, configure a rate limiting threshold for the ICMP packets and isolate the source of the attack.

6. DHCP Guard

The Dynamic Host Configuration Protocol (DHCP) is widely used in a LAN to dynamically assign IP addresses. A DHCP starvation attack is the most popular DHCP attack that broadcasts DHCP requests by using a false MAC address. When a network attacker sends enough DHCP requests, it can exhaust the address space of the DHCP server within a period. In this case, the legal host fails to request IP addresses from the DHCP server and thus cannot access a network. To avoid this type of attacks, configure a rate limiting threshold for the DHCP packets and isolate the detected source of the attack.

7. DHCPv6 Guard

DHCPv6 is widely used in a LAN to dynamically assign IPv6 addresses. Like DHCPv4, DHCPv6 has security problems. Therefore, the attack methods of DHCPv4 are applicable to DHCPv6. When a network attacker sends enough DHCPv6 requests, it can exhaust the address space of the DHCPv6 server within a period. In this case, the legal host fails to request IPv6 addresses from the DHCP server and thus cannot access a network. To avoid this type of attacks, configure a rate limiting threshold for DHCPv6 packets and isolate the detected source of the attack.

8. ND Guard

Neighbor discovery (ND) parses addresses, discovers routes and prefixes, and redirects routes in an IPv6 network. A ND process involves five types of packets: Neighbor Solicitation (NS), Neighbor Advertisement (NA), Router Solicitation (RS), Router Advertisement (RA), and Redirect packets. The five types of packets are called ND packets collectively.

ND Snooping listens to ND packets in a network, filters out invalid ND packets, and monitors IPv6 users and binds these users to ports to avoid theft of IPv6 addresses. ND Snooping requires ND packets to be sent to the

CPU. If they are sent at a high rate, this initiates an attack on the CPU. Therefore, we must configure ND guard to limit the rates of ND packets.

9. Customized Guard

There are many types of network protocols, including routing protocols such as OSPF, BGP, and RIP. To exchange packets between devices running different protocols, the packets must be sent to the CPU and processed by the protocol. Each protocol running on a device gives attackers a chance to initiate attacks. If an attacker sends many protocol packets to a network device, this consumes many CPU resources of the device, even affecting device operation.

Network protocols are diverse and grow constantly. Different protocols are demanded in different user environments. Therefore, protocol-specific guard functions have some limitations. To avoid this type of attacks, configure the customized guard function for the device to allow users to flexibly define and configure guard types to meet guard requirements in different user environments.

1.1.3 Rate Limiting Threshold and Attack Identification for Hosts

By configuring a rate limiting threshold for attack packets of hosts, a device can identify different attack scenarios such as host attacks, ARP scanning, and IP scanning. Host attacks can be identified in the following ways:

- Identify hosts according to the source IP address, VLAN ID, and port.
- Identify hosts according to the source MAC address, VLAN ID, and port on the link layer.

Each host is configured with a rate limiting threshold and an attack or attack threshold. The rate limiting threshold must be smaller than the attack threshold.

- If a single host sends attack packets at a rate higher than the rate limiting threshold, packets out of the threshold are discarded.
- If a single host sends attack packets at a rate higher than the attack threshold, the host behavior is identified as an attack and recorded into the log. Meanwhile, a Trap message is sent.
- If the received ARP packets exceed the scanning threshold in the configured period, the source MAC address in the packets is unchanged and the source IP address is changing on the link layer, or the source MAC address and source IP address on the link layer are unchanged but the destination IP address is changing, an ARP scanning attack is suspected.
- If the received IP packets exceed the scanning threshold in the configured period and the source IP address in the packets is unchanged and the destination IP address is changing, an IP scanning attack is suspected.

Note

- When NFPP detects attacks of a specific packet type, NFPP can send an alarm message to users. To avoid frequent alarm messages, NFPP does not resend an alarm within 60 seconds running after the message is generated.
- To prevent frequent log printing from consuming CPU resources, NFPP writes attacks related log content into the buffer and prints the log content from the buffer at the specified rate. NFPP does not limit the rates of Trap messages.
- Only ARP guard and IP scanning guard support the scanning prevention function.

1.1.4 Rate Limiting and Attack Identification for Ports

Each port is configured with a rate limiting threshold and an attack threshold. The rate limiting threshold must be smaller than the attack threshold.

- If a single port sends packets at a rate higher than the rate limiting threshold, packets out of the threshold are discarded.
- If a single port sends packets at a rate higher than the attack threshold, the port behavior is recorded into the log. Meanwhile, a Trap message is sent.

1.1.5 Hardware Isolation

Hardware is isolated by the guard policy after an attack is detected. Isolation requires a filter of hardware. Attack packets from an isolated device are not sent to the CPU for processing to ensure normal operation of the device.

Hardware isolation falls into host based isolation and port-based isolation. The port-based isolation configures a rate limit for physical ports. Only ARP guard and ND guard support hardware isolation based on physical ports.

To isolate attackers, you must configure policies for hardware entries. Because hardware resources are limited, a log is printed to remind users when such resources are exhausted.

Note

Only ARP guard can be configured with the global isolation and forwarding function and the rate limit function for port-based isolation and forwarding.

1.1.6 Monitoring Time

Monitoring hosts can detect attacks in the system. If the isolation time is 0 (indicating no isolation), the guard module automatically monitors attackers through software based on the configured monitoring time. If the isolation time is not 0, the guard module isolates attackers through hardware.

During software monitoring, when the isolation time is configured as a non-zero value, the guard module automatically isolates the attackers under software monitoring through hardware and configures the timeout time of the software monitoring as the isolation time. The monitoring time takes effect only when the isolation time is 0.

1.1.7 Trust Host

To stop monitoring a host is to trust the host. You can configure the host as a trusted host to allow it to send packets to the CPU.

1.2 Configuration Task Summary

NFPP configuration includes the following tasks:

(1) Configuring ARP Guard

(2) Configuring IP Guard

(3) Configuring TCP-SYN Guard

(4) Configuring ICMP Guard

(5) Configuring DHCP Guard

(6) Configuring DHCPv6 Guard

(7) Configuring ND Guard

(8) Customizing Guard

(9) Disabling Guard

(10) Configuring NFPP Logs

1.3 Configuring ARP Guard

1.3.1 Overview

ARP guard is used to detect, process, and prevent ARP based packet attacks. It includes the following functions:

- Identify ARP attacks based on hosts or physical ports. This function can determine an attack host based on the source IP address/MAC address (link layer), VLAN ID, and physical port. A rate limiting threshold and an attack threshold can be configured for each attack identification method. When the ARP packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the ARP packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent to remind users of ARP attacks.
- Identify ARP scanning attacks. For the ARP packets received within 10 seconds, if the source MAC address is unchanged and the source IP address is changing on the link layer, or the former and source IP address on the link layer are unchanged but the destination IP address is changing more than the specified scanning threshold of times, an ARP scanning attack is suspected and an alarm is printed to remind users.
- Suppress the ARP source. In this type of attacks, ARP requests are triggered through IP packets to consume CPU resources. If the number of IP packets with inexistent destination IP address exceeds the threshold in the specified period, the IP packets out of the threshold are discarded.
- Isolate the source of ARP attacks based on hosts or ports.
  - This function configures hardware entries to isolate the identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
  - After isolation takes effect, you can enable the isolation forwarding function to limit the isolation range so that only the management plane of the target CPU is isolated and packets on the data plane are still forwarded.
  - If the port-based isolation entries take effect, the default action is to discard all attack packets. After you enable the function of port-based rate limit forwarding, you can allow some of packets to pass through by changing the isolation action.
- Monitor host attacks through software. After this function guard identifies any attacks, it can monitor the attack host through software in the configured monitoring time.

1.3.2 Restrictions and Guidelines

- ARP guard is to solve the ARP DoS attacks on a device. This function can reduce the impact of this type of attacks on the device, but does not cope with ARP spoofing attacks or ARP attacks in a network.
- If this function is configured in global configuration mode and interface configuration mode, the interface

configuration prevails. For example, if the ARP guard function is enabled on an interface and then disabled in global configuration mode, the function remains effective on this interface.

- After the ARP guard function is disabled, the system automatically clears the entries related to the monitored hosts, scanning hosts, and isolated ports.
- The rate limiting threshold configured based on a MAC address has a higher priority than that configured based on an IP address, and the rate limiting threshold configured based on an IP address has a higher priority than that configured based on a port. To optimize the ARP guard effect, users are advised to configure rate limiting thresholds and attack thresholds for hosts based on the following rules:
  Attack threshold based on source MAC address > Rate limiting threshold based on source MAC address > Attack threshold based on IP address > Rate limiting threshold based on IP address
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- An ARP scanning table can store only 256 latest records. When the ARP scanning table is full, new records overwrite old ones. ARP scanning attacks may be misjudged. Therefore, when ARP guard does not isolate a detected host that is suspected to initiate an ARP scanning attack, this function only provides some information for the reference of users.
- ARP source suppression conflicts with the isolation function of IP guard scan. If the latter is enabled, you cannot enable the function of ARP source suppression.
- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:
  - If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
  - If you change the isolation time to 0 from a non-zero value, entries of the isolated attacker are directly deleted without monitoring the attacker through software.
- After you enable the isolation function, the recorded attack host occupies the security module entry.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.
  - When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.

1.3.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the function of global ARP guard.

arp-guard enable

The function of global ARP guard is enabled by default.

(5) (Optional) Configure the global isolation time of ARP guard.

arp-guard isolate-period { *interval* | **permanent** }

The default global isolation time of ARP guard is **0**, and the isolation function is disabled by default.

(6) (Optional) Enable the function of global isolation forwarding of ARP guard.

arp-guard isolate-forwarding enable

The function of global isolation forwarding of ARP guard is enabled by default.

(7) (Optional) Enable the function of port-based rate limit forwarding of ARP guard.

arp-guard ratelimit-forwarding enable

The function of port-based rate limit forwarding of ARP guard is disabled by default.

(8) Configure the monitoring time of ARP guard.

arp-guard monitor-period *interval*

The default monitoring time of ARP guard is **600** seconds.

(9) Configure the maximum number of monitored hosts of ARP guard in global configuration mode.

arp-guard monitored-host-limit *limit-number*

The maximum number of monitored hosts of ARP guard in global configuration mode is **20000** by default.

(10) Configure a global rate limiting threshold of ARP guard.

arp-guard rate-limit { **per-port** *rate-limit* | **per-src-ip** *rate-limit* | **per-src-mac** *rate-limit* }

The default configuration of this command depends on the product version.

(11) Configure a global attack threshold of ARP guard.

arp-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* | **per-src-mac** *attack-threshold* }

The default configuration of this command depends on the product version.

(12) Configure a global scanning threshold of ARP guard.

arp-guard scan-threshold *scan-threshold*

The default configuration of this command depends on the product version.

(13) Enable the function of ARP source suppression.

arp-guard suppress-mode enable

The function of ARP source suppression is disabled by default.

(14) Configure a threshold of ARP source suppression.

arp-guard suppress-threshold *suppress-threshold*

The default threshold of ARP source suppression is **5** pps.

(15) Configure the period of ARP source suppression.

arp-guard suppress-period *interval*

No period of ARP source suppression is configured by default.

1.3.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the ARP guard function on an interface.

nfpp arp-guard enable

The ARP guard function is disabled on an interface by default.

(5) Configure the isolation time of ARP guard on an interface.

nfpp arp-guard isolate-period { *interval* | **permanent** }

No isolation time of ARP guard is configured on an interface by default. The global isolation time of ARP guard is used.

(6) Configure a rate limiting threshold and an attack threshold of ARP guard on an interface.

nfpp arp-guard policy { **per-port** *rate-limit attack-threshold* | **per-src-ip** *rate-limit attack-threshold* | **per-src-mac** *rate-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of ARP guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of ARP guard are used.

(7) Configure a local scanning threshold of ARP guard on an interface.

nfpp arp-guard scan-threshold *scan-threshold*

No local scanning threshold of ARP guard is configured on an interface by default. The global scanning threshold of ARP guard is used.

1.4 Configuring IP Guard

1.4.1 Overview

After the IP guard function is enabled, a device can detect several common types of IP attacks timely, and ensure its stable operation by rate limit and host isolation. IP guard includes the following functions:

- Identify IP attacks based on hosts or physical ports. This function can determine an attack host based on the source IP address, VLAN ID, and physical port. A rate limiting threshold and an attack threshold can be configured for each attack identification method. When the IP packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the IP packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent to remind users of IP attacks.
- Identify IP scanning attacks. For the IP packets received within 10 seconds, if the source IP address is

unchanged and the destination IP address (not the local address) is changing more than the specified scanning threshold of times, an IP scanning attack is suspected and an alarm is printed to remind users.

- Isolate IP attackers based on hosts. This function configures hardware entries to isolate identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
- Monitor attack hosts through software.
  - After this function identifies any attacks, it can monitor the attack host through software in the configured monitoring time.
  - This function can configure a specified host as a trusted host based on its IP address so that the host is free from software monitoring and allowed to send packets to the CPU.

1.4.2 Restrictions and Guidelines

- IP guard is to solve IP attacks whose destination IP address is not a local IP address. If the destination IP address is a local IP address, the rates of IP packets are limited by the function of CPU protect policy (CPP).
- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails. For example, if the IP guard function is enabled on an interface and then disabled in global configuration mode, the function is still enabled on this interface.
- After the IP guard function is disabled, the system automatically clears the entries related to the monitored hosts.
- The rate limiting threshold configured based on a source IP address has a higher priority than that configured based on a port.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- The isolation function of IP guard conflicts with the function of ARP source suppression. Therefore, you cannot configure the two functions at the same time.
  - If you enable them at the same time, you cannot configure the isolation time of IP guard.
  - If you enable the function of ARP source suppression and configure the global or local isolation time for IP guard, you cannot enable the IP guard function.

  To configure the isolation function of IP guard, make sure to disable the function of ARP source suppression.
- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:
  - If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
  - If you change the isolation time to 0 from a non-zero value, entries related to the isolated attacker are directly deleted without monitoring the attacker through software.
- After you enable the isolation function, the recorded attack host occupies the security module entry.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the

existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.

- When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.

- IP guard can be configured with trusted hosts. When entries in the table of monitored hosts match the trusted hosts (their IP addresses are the same), the system automatically deletes the entries of the IP addresses. IP guard can be configured with a maximum of 500 trusted hosts.

1.4.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the global IP guard function.

ip-guard enable

The global IP guard function is enabled by default.

(5) (Optional) Configure the global isolation time of IP guard.

ip-guard isolate-period { *interval* | **permanent** }

The default global isolation time of IP guard is **0**, and the isolation function is disabled by default.

If the isolation function is enabled, attack host information occupies a hardware entry of the security module.

(6) Configure the monitoring time of IP guard.

ip-guard monitor-period *interval*

The default monitoring time of IP guard is **600** seconds.

(7) Configure the maximum number of monitored hosts of IP guard.

ip-guard monitored-host-limit *number*

The maximum number of monitored hosts of IP guard is **20000** by default.

(8) (Optional) Configure a global rate limiting threshold of IP guard.

ip-guard rate-limit { **per-port** *rate-limit* | **per-src-ip** *rate-limit* }

The default configuration of this command depends on the product version.

(9) Configure a global attack threshold of IP guard.

ip-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* }

The default configuration of this command depends on the product version.

(10) Configure a global scanning threshold of IP guard.

ip-guard scan-threshold *scan-threshold*

The default configuration of this command depends on the product version.

(11) (Optional) Configure the trusted hosts of IP guard.

ip-guard trusted-host { *ipv4-address mask* | *ipv6-address/prefix-length* }

No host is configured as a trusted host of IP guard by default.

1.4.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the IP guard function on an interface.

nfpp ip-guard enable

The IP guard function is disabled on an interface by default.

(5) Configure the local isolation time of IP guard on an interface.

nfpp ip-guard isolate-period { *interval* | **permanent** }

No isolation time of IP guard is configured by default.

(6) Configure a local rate limiting threshold and a local attack threshold of IP guard on an interface.

nfpp ip-guard policy { **per-port** *rate-limit attack-threshold* | **per-src-ip** *rate-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of IP guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of IP guard are used.

(7) Configure a scanning threshold of IP guard on an interface.

nfpp ip-guard scan-threshold *scan-threshold*

No local scanning threshold of IP guard is configured on an interface by default. The global scanning threshold of IP guard is used.

1.5 Configuring TCP-SYN Guard

1.5.1 Overview

An attacker can launch an attack against the device connected through TCP connections. To detect and prevent the TCP-SYN flooding attacks, you can enable the TCP-SYN guard function on the devices. TCP-SYN guard includes the following functions:

- Identify TCP-SYN attacks based on hosts or physical ports. This function can determine an attack host based on the source IP address, VLAN ID, and physical port. A rate limiting threshold and an attack threshold can be configured for each attack identification method. When the TCP-SYN packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the

TCP-SYN packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent.

- Isolate TCP-SYN attackers based on hosts. This function configures hardware entries to isolate identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
- Monitor attack hosts through software.
  - After this function identifies any attacks, it can monitor the attack host through software in the configured monitoring time.
  - This function can configure a specified host as a trusted host of TCP-SYN guard based on its IP address so that it is free from software monitoring and allowed to send packets to the CPU.

1.5.2 Restrictions and Guidelines

- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- The rate limiting threshold configured based on a source IP address has a higher priority than that configured based on a port.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:
  - If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
  - If you change the isolation time to 0 from a non-zero value, entries related to the isolated attacker are directly deleted without monitoring the attacker through software.
- After you enable the isolation function, the recorded attack host occupies the security module entry.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.
  - When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.
- TCP-SYN guard can be configured with trusted hosts. When entries in the table of monitored hosts match the trusted hosts (their IP addresses are the same), the system automatically deletes the entries of the IP addresses. TCP-SYN guard can be configured with a maximum of 500 trusted hosts.

1.5.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the global TCP-SYN guard function.

tcp-syn-guard enable

By default, the global TCP-SYN guard function is enabled.

(5) (Optional) Configure the global isolation time of TCP-SYN guard.

tcp-syn-guard isolate-period { *interval* | **permanent** }

The default global isolation time of TCP-SYN guard is **0**, and the isolation function is disabled by default.

(6) Configure the monitoring time of TCP-SYN guard.

tcp-syn-guard monitor-period *interval*

The default monitoring time of TCP-SYN guard is **600** seconds.

(7) Configure the maximum number of monitored hosts of TCP-SYN guard.

tcp-syn-guard monitored-host-limit *number*

The maximum number of monitored hosts of TCP-SYN guard is **20000** by default.

(8) Configure a global rate limiting threshold of TCP-SYN guard.

tcp-syn-guard rate-limit { **per-port** *rate-limit* | **per-src-ip** *rate-limit* }

The default configuration of this command depends on the product version.

(9) Configure a global attack threshold of TCP-SYN guard.

tcp-syn-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* }

The default configuration of this command depends on the product version.

(10) (Optional) Configure the trusted hosts of TCP-SYN guard.

tcp-syn-guard trusted-host { *ipv4-address mask* | *ipv6-address/prefix-length* }

No host is configured as a trusted host of TCP-SYN guard by default.

1.5.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the TCP-SYN guard function on an interface.

nfpp tcp-syn-guard enable

The TCP-SYN guard function is not configured on an interface by default. The global TCP-SYN guard function is used.

(5) Configure the isolation time of TCP-SYN guard on an interface.

nfpp tcp-syn-guard isolate-period { *interval* | **permanent** }

No local isolation time of TCP-SYN guard is configured by default. The global isolation time of TCP-SYN guard is used.

(6) Configure the local rate limiting threshold and local attack threshold of TCP-SYN guard on an interface.

nfpp tcp-syn-guard policy { **per-port** *rate-limit attack-threshold* | **per-src-ip** *rate-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of TCP-SYN guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of TCP-SYN guard are used.

1.6 Configuring ICMP Guard

1.6.1 Overview

The ICMP guard function configured for a device is used to prevent an attacker from consuming system resources by sending many ICMP requests. ICMP guard includes the following functions:

- Identify ICMP attacks based on hosts or physical ports. This function can determine an attack host based on the source IP address, VLAN ID, and port. A rate limiting threshold and an attack threshold can be configured for each attack identification method. When the ICMP packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the ICMP packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent.
- Isolate ICMP attackers based on hosts. This function configures hardware entries to isolate identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
- Monitor attack hosts through software.
  - After this function identifies any attacks, it can monitor the attack host through software in the configured monitoring time.
  - This function can configure a specified host as a trusted host of ICMP guard based on its IP address so that it is free from software monitoring and allowed to send packets to the CPU.

1.6.2 Restrictions and Guidelines

- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- After the ICMP guard function is disabled, the system automatically clears the entries related to the monitored hosts.
- The rate limiting threshold configured based on a source IP address has a higher priority than that configured based on a port.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:

- If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
- If you change the isolation time to 0 from a non-zero value, entries related to the isolated attacker are directly deleted without monitoring the attacker through software.

- After you enable the isolation function, the recorded attack host occupies the security module entry.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.
  - When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.
- ICMP guard can be configured with trusted hosts. When entries in the table of monitored hosts match the trusted hosts (their IP addresses are the same), the system automatically deletes the entries of the IP addresses. ICMP guard can be configured with a maximum of 500 trusted hosts.

1.6.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the function of global ICMP guard.

icmp-guard enable

The function of global ICMP guard is enabled by default.

(5) (Optional) Configure the global isolation time of ICMP guard.

icmp-guard isolate-period { *interval* | **permanent** }

The default global isolation time of ICMP guard is **0**, and the isolation function is disabled by default.

(6) Configure the monitoring time of ICMP guard.

icmp-guard monitor-period *interval*

The default monitoring time of ICMP guard is **600** seconds.

(7) Configure the maximum number of monitored hosts.

icmp-guard monitored-host-limit *number*

The maximum number of monitored hosts is **20000** by default.

(8) Configure the global rate limiting threshold of ICMP guard.

icmp-guard rate-limit { **per-port** *rate-limit* | **per-src-ip** *rate-limit* }

The default configuration of this command depends on the product version.

(9) Configure the global attack threshold of ICMP guard.

icmp-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* }

The default configuration of this command depends on the product version.

(10) (Optional) Configure the trusted hosts of ICMP guard.

icmp-guard trusted-host { *ipv4-address mask* | *ipv6-address/prefix-length* }

No host is configured as a trusted host by default.

1.6.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the ICMP guard function on an interface.

nfpp icmp-guard enable

The ICMP guard function is not configured on an interface by default. The global ICMP guard function is used.

(5) Configure the local isolation time of ICMP guard on an interface.

nfpp icmp-guard isolate-period { *interval* | **permanent** }

No local isolation time of ICMP guard is configured on an interface by default. The global isolation time of ICMP guard is used.

(6) Configure the local rate limiting threshold and local attack threshold of ICMP guard on an interface.

nfpp icmp-guard policy { **per-port** *rate-limit attack-threshold* | **per-src-ip** *rate-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of ICMP guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of ICMP guard are used.

1.7 Configuring DHCP Guard

1.7.1 Overview

In a DHCP starvation attack, all IP addresses of a DHCP server are exhausted. As a result, the DHCP server fails to provide the address assignment service, thus affecting the network access of legal users. To address this type of attacks, you must deploy the DHCP guard function on a device.

DHCP guard includes the following functions:

- Identify DHCP attacks based on hosts or physical ports. This function can determine an attack host based on the source MAC address, VLAN ID, and port on the link layer. A rate limiting threshold and an attack

threshold can be configured for each attack identification method. When the DHCP packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the DHCP packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent.

- Isolate DHCP attackers based on hosts. This function configures hardware entries to isolate identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
- Monitor attack hosts through software. After an attack is identified, this function monitors the attack host through software in the configured monitoring time.

1.7.2 Restrictions and Guidelines

- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- After the DHCP guard function is disabled, the system automatically clears the entries related to the monitored hosts.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:
  - If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
  - If you change the isolation time to 0 from a non-zero value, entries related to the isolated attacker are directly deleted without monitoring the attacker through software.
- After you enable the isolation function, the recorded attack host occupies the security module entry.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.
  - When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.
- If a port is configured as trusted by the DHCP Snooping function, the DHCP guard function becomes invalid to avoid misjudging DHCP traffic on the trusted port. For trusted port configuration in DHCP Snooping, see *Configuring DHCP Snooping*.

1.7.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the function of global DHCP guard.

dhcp-guard enable

The function of global DHCP guard is enabled by default.

(5) (Optional) Configure the global isolation time of DHCP guard.

dhcp-guard isolate-period { *interval* | **permanent** }

The default global isolation time of DHCP guard is **0**, and the isolation function is disabled by default.

(6) Configure the monitoring time of DHCP guard.

dhcp-guard monitor-period *interval*

The default monitoring time of DHCP guard is **600** seconds.

(7) Configure the maximum number of monitored hosts.

dhcp-guard monitored-host-limit *number*

The maximum number of monitored hosts of DHCP guard is **20000** by default.

(8) Configure the global rate limiting threshold of DHCP guard.

dhcp-guard rate-limit { **per-port** *rate-limit* | **per-src-mac** *rate-limit* }

The default configuration of this command depends on the product version.

(9) Configure the global attack threshold of DHCP guard.

dhcp-guard attack-threshold { **per-port** *attack-threshold* | **per-src-mac** *attack-threshold* }

The default configuration of this command depends on the product version.

1.7.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the DHCP guard function on an interface.

nfpp dhcp-guard enable

The DHCP guard function is disabled on an interface by default. The global DHCP guard function is enabled.

(5) Configure isolation time of DHCP guard on an interface.

nfpp dhcp-guard isolate-period { *interval* | **permanent** }

No local isolation time of DHCP guard is configured on an interface by default. The global isolation time of DHCP guard is used.

(6) Configure the local rate limiting threshold and local attack threshold of DHCP guard on an interface.

nfpp dhcp-guard policy { **per-port** *rate-limit attack-threshold* | **per-src-mac** *rate-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of DHCP guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of DHCP guard are used.

1.8 Configuring DHCPv6 Guard

1.8.1 Overview

Like DHCPv4, DHCPv6 has security problems. Therefore, the attack methods of DHCPv4 are applicable to DHCPv6. To prevent this type of attacks, we must also deploy the DHCPv6 guard policy. DHCPv6 guard includes the following functions:

- Identify DHCPv6 attacks based on hosts or physical ports. This function can determine an attack host based on the source MAC address, VLAN ID, and port on the link layer. A rate limiting threshold and an attack threshold can be configured for each attack identification method.
- Isolate DHCPv6 attackers based on hosts. This function configures hardware entries to isolate identified attack hosts. Thus, attack packets are not sent to the CPU or forwarded.
- Monitor attack hosts through software. After an attack is identified, this function monitors the attack host through software in the configured monitoring time.

1.8.2 Restrictions and Guidelines

- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- After the DHCPv6 guard function is disabled, the system automatically clears the entries related to the monitored hosts.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- When host attack packets are sent at a rate higher than the rate limiting threshold of CPP, you can configure isolation time to discard the packets and prevent them from occupying bandwidth. When you configure isolation time, you must note that:
  - If you change the isolation time to a non-zero value from 0, attack hosts under software monitoring are automatically isolated by hardware, and the configured monitoring time becomes invalid.
  - If you change the isolation time to 0 from a non-zero value, entries related to the isolated attacker are directly deleted without monitoring the attacker through software.
- After you enable the isolation function, the recorded attack host occupies the security module entry.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.
  - When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.

- If a port is configured as trusted by the DHCPv6 Snooping function, the DHCPv6 guard function becomes invalid to avoid misjudging DHCPv6 traffic on the trusted port. For trusted port configuration in DHCPv6 Snooping, see *Configuring DHCPv6 Snooping*.

1.8.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the function of global DHCPv6 guard.

dhcpv6-guard enable

The function of global DHCPv6 guard is enabled by default.

(5) Configure the monitoring time of DHCPv6 guard.

dhcpv6-guard monitor-period *interval*

The default monitoring time of DHCPv6 guard is **600** seconds.

(6) Configure the maximum number of monitored hosts.

dhcpv6-guard monitored-host-limit *number*

The maximum number of monitored hosts of DHCPv6 guard is **20000** by default.

(7) Configure the global rate limiting threshold of DHCPv6 guard.

dhcpv6-guard rate-limit { **per-port** *rate-limit* | **per-src-mac** *rate-limit* }

The default configuration of this command depends on the product version.

(8) Configure the global attack threshold of DHCPv6 guard.

dhcpv6-guard attack-threshold { **per-port** *attack-threshold* | **per-src-mac** *attack-threshold* }

The default configuration of this command depends on the product version.

1.8.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the DHCPv6 guard function on an interface.

nfpp dhcpv6-guard enable

The DHCPv6 guard function is disabled on an interface by default. The global DHCPv6 guard function is used.

(5) Configure the local rate limiting threshold and local attack threshold of DHCPv6 guard on an interface.

nfpp dhcpv6-guard policy { **per-port** *rate-limit attack-threshold* | **per-src-mac** *rate-limit attack-threshold* }

No local rate limiting threshold is local attack threshold of DHCPv6 guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of DHCPv6 guard are used.

1.9 Configuring ND Guard

1.9.1 Overview

ND packets of ND guard fall into three types by use:

- Type 1: Neighbor requests and neighbor advertisements, which are used to parse addresses.
- Type 2: Route requests, which are used to discover gateways for hosts.
- Type 3: Route advertisements, which are used to advertise gateways and prefixes; and redirection packets, which are used to advertise better next hops.

ND guard identifies ND packets based on physical ports. This function prevents attacks by configuring rate limiting thresholds for attack ports and isolating the ports.

1.9.2 Restrictions and Guidelines

- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- After you enable the ND Snooping function by running the **ipv6 nd snooping enable** command, all ND packets are NDSNP packets. In this case, you must configure rate limiting thresholds and attack thresholds for the NDSNP packets to validate the guard.
- After you enable the isolation function, the recorded attack host occupies the security module entry. If the port-based isolation entries take effect, the default action is to discard all attack packets. After you enable the function of port-based rate limit forwarding, you can allow some of packets to pass through by changing the isolation action.
- Rate limit by hardware is ineffective to NDSNP packets.

1.9.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Enable the global ND guard function.

nd-guard enable

The function of global ND guard is enabled by default.

(5) Enable the function of port-based rate limit forwarding of ND guard.

nd-guard ratelimit-forwarding enable

The function of port-based rate limit forwarding of ND guard is enabled by default.

(6) Configure the global rate limiting threshold of ND guard.

nd-guard rate-limit per-port { **ndsnp** *rate-limit* | **ns-na** *rate-limit* | **ra-redirect** *rate-limit* | **rs** *rate-limit* }

The default configuration of this command depends on the product version.

(7) Configure the global attack threshold of ND guard.

nd-guard attack-threshold per-port { **ndsnp** *attack-threshold* | **ns-na** *attack-threshold* | **ra-redirect** *attack-threshold* | **rs** *attack-threshold* }

The default configuration of this command depends on the product version.

1.9.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the ND guard function on an interface.

nfpp nd-guard enable

The ND guard function is disabled on an interface by default. The global ND guard function is enabled.

(5) Configure the local rate limiting threshold and local attack threshold of ND guard on an interface.

nfpp nd-guard policy per-port { **ndsnp** *rate-limit attack-threshold* | **ns-na** *rate-limit attack-threshold* | **ra-redirect** *rate-limit attack-threshold* | **rs** *rate-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of ND guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of ND guard are used.

1.10 Customizing Guard

1.10.1 Overview

Users can customize guard types and guard policies to solve network attacks in special application scenarios.

Customized guard includes the following functions:

- Allow users to combine packet type fields and use them as packet types of customized guard to meet requirements of guard scenarios.
- Configure guard policies based on hosts and ports. Host guard policies include those based on the source IP address, VLAN ID and port, or those based on the source MAC address, VLAN ID and port on the link layer. A rate limiting threshold and an attack threshold can be configured for each guard policy. When the packets are sent at a rate higher than the rate limiting threshold, the packets out of the threshold are discarded. When the packets are sent at a rate higher than the attack threshold, an alarm is printed and a Trap message is sent.
- Monitor attack hosts through software.
  - After this function identifies any attacks, it can monitor the attack host through software in the configured monitoring time.
  - This function can configure a specified host as a trusted host based on its IPv4, IPv6, or MAC address so that it is free from software monitoring and allowed to send packets to the CPU without rate limit and processing.

1.10.2 Restrictions and Guidelines

- Customized guard allows users to combine packet type fields to include most existing protocol types and expand new protocol types. Improper configuration of the packet type fields may cause a network exception. Therefore, users must well understand network protocols before they configure this function.
- Customized guard has a higher packet detection priority than basic guard types. When packets match the customized guard policy and the policy of a basic guard type, they preferentially undergo rate limit and attack identification according to the customized guard policy. To ensure the configuration effect of basic guard types, try to refer to the configuration guide when you configure the packet type fields of customized guard.
- Customized guard policies must be configured with different type names and packet types. Matched packet types must differ from the packet types of existing guard types, including those of basic guard types such as ARP guard, IP guard, ICMP guard, TCP-SYN guard, DHCP guard, DHCPv6 guard, and ND guard.
- You can configure packet types of customized guard by combining the following fields. These fields include Ethernet link layer type (etype), source MAC address (src-mac), destination MAC address (dst-mac), IPv4 or IPv6 protocol number (protocol), source IPv4 or IPv6 address (src-ip/src-ipv6), destination IPv4 or IPv6 address (dst-ip/dst-ipv6), source port on the transport layer (src-port), and destination port on the transport layer (dst-port).

  To configure the matched fields of packet fields, conform with the following limit rules. Otherwise, the configuration fails:

  - The IPv4 or IPv6 protocol number (protocol) is configurable only when the Ethernet link layer type (etype) is IPv4 or IPv6.
  - The source IPv4 address (src-ip) and destination IPv4 address (dst-ip) are configurable only when the Ethernet link layer type (etype) is IPv4.
  - The source IPv6 address (src-ipv6) and destination IPv6 address (dst-ipv6) are configurable only when the Ethernet link layer type (etype) is IPv6.
  - The source port on the transport layer (src-port) and destination port on the transport layer (dst-port) are configurable only when the IPv4 or IPv6 protocol number (protocol) is TCP or UDP.

- For the three types of customized guard policies that are based on the source IP address, source MAC address, and port, you must configure at least one type. That is, you must configure the global rate limiting threshold and global attack threshold of customized guard. Otherwise, the customized guard function does not take effect. You can configure a host policy based on the source IP address, VLAN ID, and port only when the specified Ethernet link layer type (etype) is IPv4 or IPv6.
- The rate limiting threshold based on a source MAC address has a higher priority than that based on a source IP address. The configured attack threshold must be greater than the rate limiting threshold. Otherwise, the configuration fails.
- Only after you configure packet types and guard policies can you enable the customized guard function. If you do not complete any configuration, you are reminded that the current customized guard is not completely configured and the configuration fails.
- The host policy of customized guard on an interface must be consistent with the global host policy configuration. For example, if no global rate limiting threshold and global attack threshold are configured based on the source IP address, you cannot configure the local rate limiting threshold and local attack threshold on an interface.
- If this function is configured in global configuration mode and interface configuration mode, the interface configuration prevails.
- After the customized guard function is disabled, the system automatically clears the entries related to the monitored hosts.
- When you configure the maximum number of monitored hosts, you must note that:
  - As monitored hosts increase, processing them occupies more CPU resources.
  - If the configured maximum number of hosts is smaller than that of the actually monitored hosts, the existing monitored hosts are not automatically deleted. An alarm is printed to remind users of configuration failure. In this case, users must manually clear some monitored hosts.
  - When the monitored hosts reach the threshold, a log is printed to remind users. In this case, you must manually clear some monitored hosts.
- When you configure trusted hosts, note that:
  - You must configure matched packet types before you configure trusted hosts.
  - The trusted hosts of customized guard must be consistent with the matched packet types. For example, only when the Ethernet link layer type (etype) is IPv4, can you add IPv4 addresses as trusted IP addresses. Similarly, when the matched packet type is IPv4, IPv6 addresses cannot be added as trusted IP addresses.
  - You can configure all hosts in a network segment as trusted hosts by configuring masks.
  - When entries in the table of monitored hosts match the trusted hosts, the system automatically deletes the entries of the IP addresses.
  - ICMP guard can be configured with a maximum of 500 trusted hosts.

1.10.3 Procedure (Global Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Customize a guard type, and enter the configuration mode of the NFPP customized guard type.

define *define-name*

(5) Configure the matched packet types of the customized guard type.

match { **dst-ip** *destination-ipv4-address* [**dst-ip-mask** *mask*] | **dst-ipv6** *destination-ipv6-address* [**dst-ipv6-masklen** *prefix-length*] | **dst-mac** *destination-mac* [**dst-mac-mask** *destination-mac-mask*] | **dst-port** *port-number* | **etype** *type* | **protocol** *protocol* | **src-ip** *source-ipv4-address* [**src-ip-mask** *mask*] | **src-ipv6** *source-ipv6-address* [**src-ipv6-masklen** *prefix-length*] | **src-mac** *source-mac-address* | **src-port** *port-number* }*

(6) Configure the global rate limiting threshold and global attack threshold of the customized guard type.

global-policy { **per-port** *rate-limit attack-threshold* | **per-src-ip** *rate-limit attack-threshold* | **per-src-mac** *rate-limit attack-threshold* }

No global rate limiting threshold or global attack threshold of the customized guard type is configured by default.

They must be configured. Otherwise, you cannot enable the customized guard function.

(7) Configure the monitoring time of the customized guard type.

monitor-period *interval*

The default monitoring time of a customized guard type is **600** seconds.

(8) Configure the maximum number of monitored hosts of the customized guard type.

monitored-host-limit *number*

The maximum number of monitored hosts is **20000** by default.

(9) Configure the trusted hosts of the customized guard type.

trusted-host { *ipv4-address mask* | *ipv6-address/prefix-length* | *mac-address mask* }

No host is configured as a trusted host of the customized guard type by default.

(10) Enable the function of global customized guard.

define *define-name* **enable**

The function of global customized guard is disabled by default.

1.10.4 Procedure (Interface Configuration)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the configuration mode of the L2 Ethernet interface.

  interface *ethernet-type interface-number*

- Enter the configuration mode of the L3 Ethernet interface.

  interface *ethernet-type interface-number*

(4) Enable the customized guard function on an interface.

nfpp define *define-name* **enable**

The customized guard function is disabled on an interface by default. The global customized guard function is used.

(5) Configure the local rate limiting threshold and local attack threshold of the customized guard type on an interface.

nfpp define *define-name* **policy** { **per-port** *rate-limit attack-threshold* | **per-src-ip** *rate-limit attack-threshold* | **per-src-mac** *rate-limit attack-threshold* }

No local rate limiting threshold or local attack threshold of the customized guard type is configured on an interface by default. The global rate limiting threshold and global attack threshold of the customized guard type are used.

1.11 Disabling Guard

1.11.1 Overview

Users can disable or enable all basic types of global guard function by running one command. Basic guard types supported by this function include ARP guard, IP guard, ICMP guard, TCP-SYN guard, DHCP guard, DHCPv6 guard, and ND guard.

1.11.2 Restrictions and Guidelines

- This function applies to only basic guard types and does not affect the customized guard types.
- This function applies to the guard functions in global configuration mode and does not affect the guard functions in interface configuration mode.
- After you run the one-click enabling/disabling command, the configuration of this command cannot be displayed by running the **show running-config** command.
- The one-click enabling/disabling command is to actually enable or disable basic guard types in global configuration mode. After you run this command to disable basic guard types, the **show running-config** command allows you to display the global disabling command of each basic guard function. After you run this command to enable basic guard types, the **show running-config** command allows you to display the default configuration.
- This command cannot be saved, but its running result can be saved and take effect after device restart.

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Disable all the basic types of global guard of NFPP.

no all-guard enable

1.12 Configuring NFPP Logs

1.12.1 Overview

When many attacks are launched to a device, the generated prompts may affect user experience. You can configure the size of a log buffer, system message rate, and filtering conditions to restrictively record and displaylogs.

- NFPP retrieves logs from a special buffer at a rate, uses them to generate system messages, and clears the logs from the buffer. Therefore, you can configure the rate of generating system messages from logs of the log buffer through NFPP to control the message report frequency and avoid log spamming.
- You can also configure filtering conditions to obtain required log information accurately and filter out logs that do not complywith the filtering rules.
- To monitor whether an attack occurs, you can print logs on a screen in real time.

1.12.2 Restrictions and Guidelines

- After active/standby switchover of a device, the device will clear logs in a buffer and record new logs again.
- Even if a device does not suffer an attack, logs are continuously retrieved from the buffer to generate system messages.
- When the log buffer overflows, new logs overwrite the stale logs, and the log buffer displays an entry with attributes being "-". In this case, you must increase the log buffer size or improve the generation rate of system messages.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the NFPP configuration mode.

nfpp

(4) Configure the size of a log buffer.

log-buffer entries *number*

The default size of the NFPP log buffer is **256** entries.

(5) Configure the rate of generating system messages from logs of the log buffer through NFPP.

log-buffer logs *message-number* **interval** *interval*

No rate of generating system messages from logs of the log buffer is configured through NFPP and NFPP logs are not written into the buffer by default.

If the values of the *message-number* and *interval* parameters are **0**, logs are used by NFPP to immediately generate system messages without being written into the buffer.

(6) Configure NFPP to record the logs of a specified VLAN and a specified interface.

logging { **interface** *interface-type interface-number* | **vlan** *vlan-range* }

NFPP records the logs of all VLANs and interfaces by default.

(7) Enable the function of screen log output.

log-buffer enable

The function of screen log output is disabled by default and logs are saved in the buffer.

1.13 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

Caution

Running the **clear** command may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
clear nfpp arp-guard scan	Clears the scanning table of ARP guard.
clear nfpp arp-guard hosts	Clears the monitored hosts of ARP guard.
clear nfpp ip-guard hosts	Clears the monitored hosts of IP guard.
clear nfpp tcp-syn-guard hosts	Clears the monitored hosts of TCP-SYN guard.
clear nfpp nd-guard hosts	Clears the monitored hosts of ND guard.
clear nfpp icmp-guard hosts	Clears the monitored hosts of ICMP guard.
clear nfpp dhcp-guard hosts	Clears the monitored hosts of DHCP guard.
clear nfpp dhcpv6-guard hosts	Clears the monitored hosts of DHCPv6 guard.
clear nfpp define *define-name* **hosts**	Clears the monitored hosts of customized guard.
clear nfpp log	Clears NFPP log buffer.
show nfpp arp-guard summary	Displays ARP guard configuration.
show nfpp arp-guard hosts	Displays the monitored hosts of ARP guard.
show nfpp arp-guard scan	Displays the scanning table of ARP guard.
show nfpp ip-guard summary	Displays the IP guard configuration.
show nfpp ip-guard hosts	Displays the monitored hosts of IP guard.
show nfpp ip-guard trusted-host	Displays the trusted hosts of IP guard.

Command	Purpose
show nfpp tcp-syn-guard summary	Displays the configuration parameters of TCP-SYN guard.
show nfpp tcp-syn-guard hosts	Displays the monitored hosts of TCP-SYN guard.
show nfpp tcp-syn-guard trusted-host	Displays the scanning table of TCP-SYN guard.
show nfpp icmp-guard summary	Displays the configuration parameters of ICMP guard.
show nfpp icmp-guard hosts	Displays the monitored hosts of ICMP guard.
show nfpp icmp-guard trusted-host	Displays the trusted hosts of ICMP guard.
show nfpp dhcp-guard summary	Displays the configuration parameters of DHCP guard.
show nfpp dhcp-guard hosts	Displays the monitored hosts of DHCP guard.
show nfpp dhcpv6-guard summary	Displays the DHCPv6 guard configuration.
show nfpp dhcpv6-guard hosts	Displays the monitored hosts of DHCPv6 guard.
show nfpp nd-guard summary	Displays the ND guard configuration.
show nfpp nd-guard hosts	Displays the trusted hosts of ND guard.
show nfpp define summary [*name*]	Displays the customized guard configuration.
show nfpp define hosts *name*	Displays the monitored hosts of the customized guard.
show nfpp define trusted-host *name*	Displays the trusted hosts of the customized guard.
show nfpp log summary	Displays the statistics of the NFPP log buffer.
show nfpp log buffer [**statistics**]	Displays the log buffer of NFPP.

1.14 Configuration Examples

1.14.1 Configuring CPU Guard

1. Requirements

In a network system, protocols such as ARP, IP, TCP-SYN, ICMP, DHCP, DHCPv6, and ND are popular targets of attacks. This may cause packet forwarding failure and high CPU usage. You can enable guard policies to ensure the stable running of devices.

2. Notes

- Configure the rate limiting threshold, attack threshold and isolation time of ARP guard.
- Configure the rate limiting threshold, attack threshold and isolation time of IP guard.
- Configure the rate limiting threshold, attack threshold and isolation time of TCP-SYN guard.
- Configure the rate limiting threshold, attack threshold and isolation time of ICMP guard.

- Configure the rate limiting threshold, attack threshold and isolation time of DHCP guard.
- Configure the rate limiting threshold and attack threshold of DHCPv6 guard.
- Configure the rate limiting threshold and attack threshold of ND guard.

3. Procedure

Configure ARP guard on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# nfpp
DeviceA(config-nfpp)# arp-guard rate-limit per-src-mac 5
DeviceA(config-nfpp)# arp-guard attack-threshold per-src-mac 10
DeviceA(config-nfpp)# arp-guard isolate-period 180
```

Configure IP guard on Device A.

```
DeviceA(config-nfpp)# ip-guard rate-limit per-src-ip 20
DeviceA(config-nfpp)# ip-guard attack-threshold per-src-ip 30
DeviceA(config-nfpp)# ip-guard isolate-period 180
DeviceA(config-nfpp)# ip-guard trusted-host 192.168.201.46 255.255.255.255
```

Configure TCP-SYN guard on Device A.

```
DeviceA(config-nfpp)# tcp-syn-guard rate-limit per-src-ip 20
DeviceA(config-nfpp)# tcp-syn-guard attack-threshold per-src-ip 30
DeviceA(config-nfpp)# tcp-syn-guard isolate-period 180
DeviceA(config-nfpp)# tcp-syn-guard trusted-host 192.168.201.46 255.255.255.255
```

Configure ICMP guard on Device A.

```
DeviceA(config-nfpp)# icmp-guard rate-limit per-src-ip 20
DeviceA(config-nfpp)# icmp-guard attack-threshold per-src-ip 30
DeviceA(config-nfpp)# icmp-guard isolate-period 180
DeviceA(config-nfpp)# icmp-guard trusted-host 192.168.201.46 255.255.255.255
```

Configure DHCP guard on Device A.

```
DeviceA(config-nfpp)# dhcp-guard rate-limit per-port 20
DeviceA(config-nfpp)# dhcp-guard attack-threshold per-port 30
DeviceA(config-nfpp)# dhcp-guard isolate-period 180
DeviceA(config-nfpp)# dhcp-guard trusted-host 192.168.201.46 255.255.255.255
```

Configure DHCPv6 guard on Device A.

```
DeviceA(config-nfpp)# dhcpv6-guard rate-limit per-port 20
DeviceA(config-nfpp)# dhcpv6-guard attack-threshold per-port 30
DeviceA(config-nfpp)# dhcpv6-guard trusted-host 192.168.201.46 255.255.255.255
```

Configure ND guard on Device A.

```
DeviceA (config-nfpp)# nd-guard rate-limit per-port ns-na 30
DeviceA (config-nfpp)# nd-guard attack-threshold per-port ns-na 50
```

4. Verification

Run the **show nfpp arp-guard summary** command to display the configuration.

```
DeviceA# show nfpp arp-guard summary
(Format of column Rate-limit and Attack-threshold is
per-src-ip/per-src-mac/per-port.)
Interface Status  Isolate-period Rate-limit     Attack-threshold Scan-threshold
Global    Enable  180          30/5/128       100/10/200      100

Maximum count of monitored hosts: 20000
Monitor period: 600s
Suppress-mode: disable
Suppress-threshold: 5pps
Suppress-period: 5s
```

Run the **show nfpp arp-guard hosts** command to display the monitored hosts.

```
DeviceA# show nfpp arp-guard hosts
If col_filter 1 shows '*', it means "hardware do not isolate host".
 VLAN    interface   IP address       MAC address    remain-time(s)
 ----    ---------   ----------       -----------    --------------
 1      Gi0/43     5.5.5.16        -            175
Total: 1 host
```

Run the **show nfpp arp-guard scan** command to display the scanned hosts.

```
DeviceA# show nfpp arp-guard scan
VLAN  interface      IP address       MAC address    timestamp
----  ---------      ----------       -----------    ---------
1     Gi0/5          -              001a.a9c2.4609  2013-4-30 23:50:32
1     Gi0/5          192.168.206.2    001a.a9c2.4609  2013-4-30 23:50:33
1     Gi0/5          -              001a.a9c2.4609  2013-4-30 23:51:33
1     Gi0/5          192.168.206.2    001a.a9c2.4609  2013-4-30 23:51:34
Total: 4 record(s)
```

Note

If attack traffic carries the VLAN ID 0, NFPP may consider the corresponding host as an attack host and configure a rate limiting threshold for the attack traffic. Run the **show nfpp arp-guard host** command to display the attack hosts. The VLAN ID field may be displayed as a port PVID or hidden.

Run the **show nfpp ip-guard summary** command to display the configuration.

```
DeviceA# show nfpp ip-guard summary
(Format of column Rate-limit and Attack-threshold is
per-src-ip/per-src-mac/per-port.)
Interface Status  Isolate-period Rate-limit     Attack-threshold Scan-threshold
Global    Disable 180          20/-/100       30/-/200        100

Maximum count of monitored hosts: 1000
Monitor period: 600s
```

Run the **show nfpp ip-guard hosts** command to display the monitored hosts.

```
DeviceA# show nfpp ip-guard hosts
```

```
If col_filter 1 shows '*', it means "hardware do not isolate host".
 VLAN    interface   IP address       Reason    remain-time(s)
 ----    ---------   ----------       ------    --------------
  1      Gi0/5       192.168.201.47   ATTACK    160
Total: 1 host
```

Run the **show nfpp ip-guard trusted-host** command to displaythe trusted hosts.

```
DeviceA# show nfpp ip-guard trusted-host
IP address         mask
----------         ----
192.168.201.46     255.255.255.255
Total: 1 record(s)
```

Note

If attack traffic carries the VLAN ID 0, NFPP may consider the corresponding host as an attack host and configure a rate limiting threshold for the attack traffic. Run the **show nfpp ip-guard host** command to display the attack hosts. The VLAN ID field may be displayed as a port PVID or hidden.

Run the **show nfpp tcp-syn-guard summary** command to displaythe configuration.

```
DeviceA# show nfpp tcp-syn-guard summary
(Format of column Rate-limit and Attack-threshold is
per-src-ip/per-src-mac/per-port.)
Interface Status  Isolate-period Rate-limit     Attack-threshold Scan-threshold
Global    Disable 180           20/-/100       30/-/200         100

Maximum count of monitored hosts: 1000
Monitor period: 600s
```

Run the **show nfpp tcp-syn-guard hosts** command to displaythe monitored hosts.

```
DeviceA# show nfpp tcp-syn-guard hosts
If col_filter 1 shows '*', it means "hardware do not isolate host".
 VLAN    interface   IP address       Reason    remain-time(s)
 ----    ---------   ----------       ------    --------------
  1      Gi0/5       192.168.201.47   ATTACK    160
Total: 1 host
```

Run the **show nfpp tcp-syn-guard trusted-host** command to displaythe trusted hosts.

```
DeviceA# show nfpp tcp-syn-guard trusted-host
IP address         mask
----------         ----
192.168.201.46     255.255.255.255
Total: 1 record(s)
```

Note

If attack traffic carries the VLAN ID 0, NFPP may consider the corresponding host as an attack host and configure a rate limiting threshold for the attack traffic. Run the **show nfpp tcp-syn-guard host** command to displaythe attack hosts. The VLAN ID field may be displayed as a port PVID or hidden.

Run the **show nfpp icmp-guard summary** command to displaythe configuration.

```
DeviceA# show nfpp icmp-guard summary
(Format of column Rate-limit and Attack-threshold is
per-src-ip/per-src-mac/per-port.)
Interface Status  Isolate-period Rate-limit     Attack-threshold Scan-threshold
Global    Disable 180           20/-/100       30/-/200         100

Maximum count of monitored hosts: 1000
Monitor period: 600s
```

Run the **show nfpp icmp-guard hosts** command to displaythe monitored hosts.

```
DeviceA# show nfpp icmp-guard hosts
If col_filter 1 shows '*', it means "hardware do not isolate host".
 VLAN    interface   IP address       Reason    remain-time(s)
 ----    ---------   ----------       ------    --------------
  1      Gi0/5       192.168.201.47   ATTACK    160
Total: 1 host
```

Run the **show nfpp icmp-guard trusted-host** command to displaythe trusted hosts.

```
DeviceA# show nfpp icmp-guard trusted-host
IP address         mask
----------         ----
192.168.201.46      255.255.255.255
Total: 1 record(s)
```

Note

If attack traffic carries the VLAN ID 0, NFPP may consider the corresponding host as an attack host and configure a rate limiting threshold for the attack traffic. Run the **show nfpp icmp-guard host** command to displaythe attack hosts. The VLAN ID field may be displayed as a port PVID or hidden.

Run the **show nfpp dhcp-guard summary** command to displaythe configuration.

```
DeviceA# show nfpp dhcp-guard summary
(Format of column Rate-limit and Attack-threshold is
per-src-ip/per-src-mac/per-port.)
Interface Status  Isolate-period Rate-limit     Attack-threshold Scan-threshold
Global    Disable 180           20/-/100       30/-/200         100

Maximum count of monitored hosts: 1000
Monitor period: 600s
```

Run the **show nfpp dhcp-guard hosts** command to displaythe monitored hosts.

```
DeviceA# show nfpp dhcp-guard hosts
If col_filter 1 shows '*', it means "hardware do not isolate host".
 VLAN    interface   IP address       Reason    remain-time(s)
 ----    ---------   ----------       ------    --------------
```

```
  1     Gi0/5      192.168.201.47    ATTACK    160
Total: 1 host
```

Run the **show nfpp dhcp-guard trusted-host** command to displaythe trusted hosts.

```
DeviceA#  show nfpp  dhcp-guard trusted-host
IP address         mask
----------         ----
192.168.201.46     255.255.255.255
Total: 1 record(s)
```

Note

If attack traffic carries the VLAN ID 0, NFPP may consider the corresponding host as an attack host and configure a rate limiting threshold for the attack traffic. Run the **show nfpp dhcp-guard host** command to displaythe attack hosts. The VLAN ID field may be displayed as a port PVID or hidden.

Run the **show nfpp dhcpv6-guard summary** command to displaythe configuration.

```
DeviceA# show nfpp dhcpv6-guard summary
(Format of column Rate-limit and Attack-threshold is
per-src-ip/per-src-mac/per-port.)
Interface Status  Isolate-period Rate-limit     Attack-threshold Scan-threshold
Global    Disable 180           20/-/100       30/-/200         100

Maximum count of monitored hosts: 1000
Monitor period: 600s
```

Run the **show nfpp dhcpv6-guard hosts** command to displaythe monitored hosts.

```
DeviceA# show nfpp dhcpv6-guard hosts
If col_filter 1 shows '*', it means "hardware do not isolate host".

1 Configuring Storm Control

1.1 Introduction

1.1.1 Overview

When a local area network (LAN) has excess broadcast, multicast, or unknown unicast data flows, the network speed will slow down and packet transmission will have an increased timeout probability. This situation is called a LAN storm. A storm may occur when topology protocol execution or network configuration is incorrect.

Storm control can be implemented to limit broadcast, multicast, or unknown unicast data flows. When the rate of broadcast, multicast, or unknown unicast data flows received over a device port exceeds the specified range, the device transmits only packets in the specified range and discards packets beyond the range until the packet rate falls within the range. This prevents flooded data from entering the LAN and causing a storm.

1.1.2 Principles

1. Storm Control Based on the Percentage-based Bandwidth Threshold

If the rate of data flows received over a device port exceeds the specified bandwidth, excess data flows are discarded until the rate falls within the threshold.

Note

When the storm suppression threshold is set to the percentage-based bandwidth, products may convert the configured value to a multiple of the step supported by the product. Therefore, the actual effective suppression threshold on a port may be smaller than the configured suppression threshold.

2. Storm Control Based on the Packets-per-Second Threshold

If the rate of data flows received over a device port exceeds the configured packets-per-second threshold, excessive data flows are discarded until the rate falls within the threshold.

3. Storm Control Based on the Kilobits-per-Second Threshold

If the rate of data flows received over a device port exceeds the configured kilobits-per-second threshold, excessive data flows are discarded until the rate falls within the threshold.

Note

When the storm suppression threshold is set to kilobits-per-second, products may convert the configured value to a multiple of the step supported by the product. Therefore, the actual effective suppression threshold on a port may be smaller than the configured suppression threshold.

4. Storm Control Actions.

Storm control actions are performed on a port when the device detects that the incoming data flow rate on the port exceeds the configured storm control threshold.

After the storm control action is configured, the storm control detection is performed based on the default or configured interval (10s by default). When the average rate of broadcast, multicast, or unknown unicast packets received by the port is greater than the specified maximum threshold, the configured storm control action is performed on the port.

1.2 Configuring Storm Control

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Enable packet storm control.

storm-control { **broadcast** | **multicast** | **unicast** } [**level** *percent* | **pps** *packets* | *rate*] [**min-rate** *min-rate*]

Packet storm control is disabled by default.

(5) (Optional) Configure the storm control action.

storm-control action { **block** | **shutdown** | **trap** }

No storm control action is configured by default.

(6) (Optional) Enable the function of recording storm control logs.

storm-control enable log

The logging function is disabled during storm control by default.

(7) (Optional) Configure the storm control detection interval.

storm-control interval *interval-value*

The default storm control detection interval is 10s.

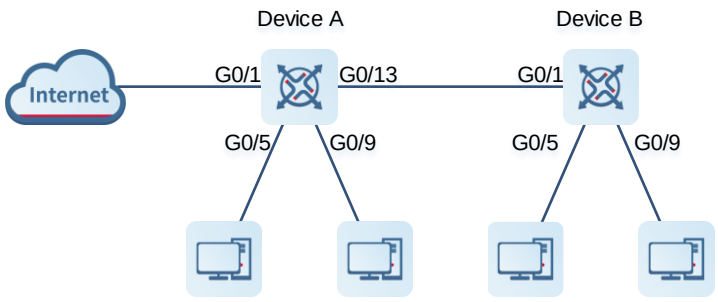
1.3 Monitoring

Run the **show** command to check the configuration.

Table 1-1 Monitoring

Command	Purpose
show storm-control [*interface-type interface-number*]	Displays storm control information.

1.4 Configuration Examples



1.4.1 Configuring Storm Control

1. Requirements

Enable storm control to prevent excessive broadcast, multicast, or unknown unicast data flows in a LAN, which will cause the network speed to slow down.

2. Topology

Figure 1-1 Topology of Configuring Storm Control

3. Notes

Enable storm control on access devices A and B.

4. Procedure

(1) Enable storm control on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface range gigabitethernet 0/5,0/9,0/13
DeviceA(config-if-range)# storm-control broadcast
DeviceA(config-if-range)# storm-control multicast
DeviceA(config-if-range)# storm-control unicast
```

(2) Enable storm control on Device B.

```
DeviceA> enable
DeviceA# configure terminal
DeviceB(config)# interface range gigabitethernet 0/1,0/5,0/9
DeviceB(config-if-range)# storm-control broadcast
DeviceB(config-if-range)# storm-control multicast
DeviceB(config-if-range)# storm-control unicast
```

5. Verification

(1) Check whether storm control is enabled on Device A.

```
DeviceA# show storm-control
Interface              Broadcast Control Multicast Control Unicast Control Action
------------------------ ----------------- ----------------- ---------------
--------
     GigabitEthernet 0/1         Disabled         Disabled       Disabled
none
     GigabitEthernet 0/5          default          default        default
none
     GigabitEthernet 0/9          default          default        default
none
     GigabitEthernet 0/13         default          default        default
none
```

(2) Check whether storm control is enabled on Device B.

```
DeviceA# show storm-control
Interface              Broadcast Control Multicast Control Unicast Control Action
------------------------ ----------------- ----------------- ---------------
--------
     GigabitEthernet 0/1          default          default        default
none
     GigabitEthernet 0/5          default          default        default
none
     GigabitEthernet 0/9          default          default        default
none
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/5
 storm-control broadcast
 storm-control multicast
 storm-control unicast
!
interface GigabitEthernet 0/9
 storm-control broadcast
 storm-control multicast
 storm-control unicast
!
interface GigabitEthernet 0/13
 storm-control broadcast
 storm-control multicast
 storm-control unicast
!
```

```
End
```

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 storm-control broadcast
 storm-control multicast
 storm-control unicast
!
interface GigabitEthernet 0/5
 storm-control broadcast
 storm-control multicast
 storm-control unicast
!
interface GigabitEthernet 0/9
 storm-control broadcast
 storm-control multicast
 storm-control unicast
!
end
```

1 Configuring uRPF

1.1 Introduction

1.1.1 Overview

Unicast Reverse Path Forwarding (uRPF) is a function that protects the network against source address spoofing.

uRPF obtains the source address and inbound interface of a received packet and searches for a forwarding entry in the forwarding table based on the source address. If no entry is configured, the packet is discarded. In uRPF strict mode, if the outbound interface of the forwarding entry does not match the inbound interface of the packet, the packet is also discarded.

1.1.2 Principles

1. Basic Concepts

- uRPF strict mode

  uRPF obtains the source address and inbound interface of a received packet and searches for a forwarding entry in the forwarding table based on the source address. If the entry does not exist, the packet is discarded. If the outbound interface of the forwarding entry does not match the inbound interface of the packet, the packet is also discarded. The strict mode requires that the inbound interface of a received packet must be the outbound interface of the route entry to the source address of the packet.

  The uRPF strict mode is often deployed on a point-to-point (P2P) interface, and inbound and outbound data streams must go through the network of the P2P interface. uRPF blocks the packets with spoofed source addresses at the access layer or aggregation layer to prevent sending such packets from PCs to the core network.

- uRPF loose mode

  uRPF reversely searches for a route based on the source IP address of a received packet. The outbound interface of the next hop on the route does not need to be the inbound interface of the received packet. However, the route cannot be a route of a host on the local network.

  The loose mode is applicable to asymmetric routes or multi-homed networks with asymmetric traffic. On a multi-homed network, the user network is connected to multiple Internet service providers (ISPs), and the inbound and outbound traffic is not symmetric. To prevent invalid packets from attacking the user network, deploy the uRPF loose mode on the outbound interface connected to ISPs.

- uRPF packet loss rate

  The uRPF packet loss rate is the number of packets discarded due to the uRPF check per second. The unit is packets/second, that is, pps.

- Interval for calculating the uRPF packet loss rate

  It refers to the interval from the previous time the packet loss rate is calculated to the current time the packet loss rate is calculated.

- Sampling interval of the uRPF packet loss rate

It refers to the interval at which the number of lost packets is collected for calculating the packet loss rate. This interval must be greater than or equal to the interval for calculating the packet loss rate.

- Threshold of the uRPF packet loss rate

  It refers to the maximum packet loss rate that is acceptable. When the packet loss rate exceeds the threshold, alarms can be sent to users through syslogs or trap messages. You can adjust the threshold of the packet loss rate based on the actual network conditions.

- Alarm interval of the uRPF packet loss rate

  It refers to the interval at which alarms are sent to users. You can adjust the alarm interval based on the actual network conditions to prevent frequent output of logs or trap messages.

2. Enabling uRPF

Enable uRPF to perform a uRPF check on IP packets, thus protecting the device against source address spoofing.

uRPF can be configured in global or interface configuration mode.

Caution

uRPF cannot be configured in global configuration mode and interface configuration mode simultaneously.

- Global configuration mode

  After uRPF is enabled in global configuration mode, a device will perform a uRPF check for packets received over all interfaces of the device.

- Interface configuration mode

  uRPF is performed for packets received on the configured interface.

3. Notifying the uRPF Packet Loss Rate

To conveniently monitor lost packets after uRPF is enabled, the device uses syslogs or trap messages to proactively notify users of the packet loss information detected in the uRPF check.

In the period from the time when uRPF is enabled to the time when the sampling interval arrives, the packet loss rate is the number of lost packets measured within the sampling interval divided by the uRPF enabling time. After that, the packet loss rate is calculated as follows:
Current packet loss rate = (Current number of lost packets measured at the calculation interval – Number of lost packets measured before the sampling interval)/Sampling interval

1.1.3 Protocols and Standards

- RFC 2827: Network Ingress Filtering: DDOS Attacks which employ IP Source Address Spoofing
- RFC 3704: Ingress Filtering for Multi-homed Networks

1.2 Restrictions and Guidelines

- uRPF is implemented with the help of existing unicast routes in the network. Therefore, unicast routes must be configured in the network.
- uRPF checks only source addresses of packets whose destination addresses are unicast addresses and does not check packets whose destination addresses are multicast or IPv4 broadcast addresses.

- uRPF cannot be enabled on a range of interfaces.
- uRPF does not check DHCP/BOOTP packets whose source IP address is 0.0.0.0 and destination IP address is 255.255.255.255.
- uRPF does not check IPv6 packets whose source IP addresses are local link addresses.
- uRPF does not check loopback packets sent by the local device to itself.

1.3 Configuration Task Summary

uRPF configuration includes the following tasks:

(1) Enabling uRPF. Please configure only one task.

- Enabling uRPF on an Interface

(2) (Optional) Configuring uRPF Packet Loss Rate Advertisement. Configure at least one of the tasks.

- Configuring Global Packet Loss Rate Parameters
- Configuring Packet Loss Rate Parameters on an Interface

1.4 Enabling uRPF on an Interface

1.4.1 Overview

uRPF is performed for packets received on the configured interface to prevent source address spoofing.

1.4.2 Restrictions and Guidelines

- Both the uRPF strict mode and loose mode can be configured on an interface.
- The default route is not used for a uRPF check by default. You can configure **allow-default** to use the default route for a uRPF check if necessary.
- After the uRPF IPv4 command is configured, a switch will perform a uRPF check on both IPv4 and IPv6 packets. Currently, switches do not support the uRPF IPv6 command.
- Packets that fail in a uRPF check will be discarded by default. If an access control list (ACL) (*acl-name*) is configured, the packet is matched against the ACL after it fails in the uRPF check. If no ACL is configured or a packet matches a deny ACE, the packet will be discarded. If the packet matches a permit ACE, the packet will be forwarded.
- The uRPF strict mode supports matching of equal-cost routes. If a packet received on an interface matches an equal-cost route during the uRPF check, the packet will be processed according to the uRPF loose mode.
- After uRPF is enabled, the route forwarding capacity of a device will be reduced by half.
- After uRPF is enabled on interfaces, a uRPF check is performed for all packets received on physical ports corresponding to these interfaces, which increases the scope of packets checked by uRPF. If a packet received on a tunnel port is also received on the preceding physical ports, the packet is also checked by uRPF. In such a scenario, be cautious in enabling uRPF.
- uRPF does not support the use of IPv6 routes with a 65- to 127-bit prefix for a uRPF check.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the *SVI configuration mode.*

  interface vlan *vlan-id*

(4) Enable uRPF for an interface.

ip verify unicast source reachable-via { **any** | **rx** } [**allow-default**]

IPv4 uRPF is disabled for an interface by default.

1.5 Configuring uRPF Packet Loss Rate Advertisement

1.5.1 Overview

After uRPF packet loss information monitoring is enabled, a device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the uRPF check so that the users can monitor the network status conveniently.

1.5.2 Restrictions and Guidelines

uRPF must be enabled.

1.5.3 Configuration Tasks

Configure at least one of the tasks.

- Configuring Global Packet Loss Rate Parameters
- Configuring Packet Loss Rate Parameters on an Interface

1.5.4 Configuring Global Packet Loss Rate Parameters

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure global packet loss rate parameters. Configure at least one of the tasks.

- Configure the interval of calculating the uRPF IPv4/IPv6 packet loss rate.

  ip verify urpf drop-rate compute interval *interval*

The default interval for calculating the uRPF IPv4/IPv6 packet loss rate is **30** seconds.

- Configure the alarm interval for the uRPF IPv4/IPv6 packet loss rate.

  ip verify urpf drop-rate notify hold-down *hold-down-time*

  The default alarm interval for the uRPF IPv4/IPv6 packet loss rate is **300** seconds.

1.5.5 Configuring Packet Loss Rate Parameters on an Interface

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure packet loss rate parameters on an interface. Configure at least one of the tasks.

- Enable uRPF packet loss information monitoring.

  ip verify urpf drop-rate notify

  uRPF packet loss information monitoring is disabled by default.

- Configure the threshold of the uRPF packet loss rate.

  ip verify urpf notification threshold *rate-value*

  The default threshold of the uRPF packet loss rate is **1000** packets per second.

  If the threshold is **0**, a notification is sent for every packet that is discarded because it fails in the uRPF check.

1.6 Monitoring

Run the **show** command to check the configuration.

Run the **debug** command to output debugging information.

Caution

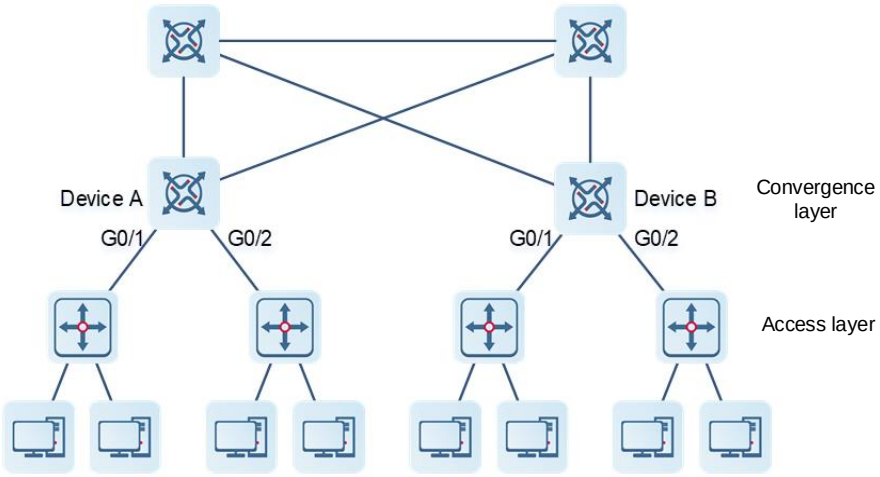
Debugging occupies system resources, so disable it immediately if not required.

Table 1-1 Monitoring

Command	Purpose
show ip urpf [**interface** *interface-type interface-number*]	Displays the IPv4 uRPF configurations and statistics.

Command	Purpose
show ip urpf hide [**global** | **interface** *interface-type interface-number*]	Displays IPv4 uRPF packet loss information.
show ip urpfk	Displays IPv4 uRPF information in fast forwarding.
show urpf ability-notify	Displays the uRPF capability value.
show urpf debug-logging	Displays the content of the uRPF log file.
show urpf client [**brief** | **index** *client-id* [**brief**]]	Displays information about clients connected to the uRPF-enabled device.
show urpf memory	Displays memory information about the uRPF process.
show urpf mom	Displays interaction information between uRPF and MOM.
show urpf msg error	Displays statistics on uRPF error messages.
show urpf statistic	Displays uRPF statistics.
show urpfk memory	Displays memory information of uRPF in fast forwarding.
show urpfk packet-log	Displays uRPF packet logs in fast forwarding.
clear ip urpf [**interface** *interface-type interface-number*]	Clears IPv4 uRPF packet loss statistics.
clear urpf client [**index** *client-id*]	Clears uRPF client statistics.
clear urpfk packet-log	Clears uRPF logs in fast forwarding.
debug urpf event	Debugs uRPF events.
debug urpf timer	Debugs uRPF timers.

1.7 Configuration Examples



1.7.1 Configuring the uRPF Strict Mode

1. Requirements

In uRPF strict mode, packets with spoofed source addresses are blocked at the access layer or aggregation layer to prevent sending such packets from PCs to the core network.

2. Topology

Figure 1-1 Configuring the uRPF Strict Mode

3. Notes

Enable the uRPF strict mode on the aggregation devices, including Devices Aand B.

4. Procedure

(1) Configure Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip address 195.52.1.1 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# ip verify unicast source reachable-via rx
DeviceA(config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface gigabitethernet0/2
DeviceA(config-if-GigabitEthernet 0/2)# ip address 195.52.2.1 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/2)# ip verify unicast source reachable-via rx
DeviceA(config-if-GigabitEthernet 0/2)# ip verify urpf drop-rate notify
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

(2) Configure Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# interface gigabitethernet0/1
DeviceB(config-if-GigabitEthernet 0/1)# ip address 195.52.3.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# ip verify unicast source reachable-via rx
DeviceB(config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify
DeviceB(config-if-GigabitEthernet 0/1)# exit
DeviceB(config)# interface gigabitethernet0/2
DeviceB(config-if-GigabitEthernet 0/2)# ip address 195.52.4.1 255.255.255.0
```

```
DeviceB(config-if-GigabitEthernet 0/2)# ip verify unicast source reachable-via rx
DeviceB(config-if-GigabitEthernet 0/2)# ip verify urpf drop-rate notify
DeviceB(config-if-GigabitEthernet 0/2)# exit
```

5. Verification

If source address spoofing exists on the network, run the **show ip urpf** command to display the number of spoofing packets discarded byuRPF.

Displaythe number of spoofing packets discarded byuRPF on GigabitEthernet 0/1 of Device A.

```
DeviceA# show ip urpf interface gigabitethernet 0/1
IP verify source reachable-via RX
IP verify URPF drop-rate notify is enabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 124
Number of drop-rate notification counts in this interface is 0
```

Displaythe number of spoofing packets discarded byuRPF on GigabitEthernet 0/2 of Device A.

```
DeviceA# show ip urpf interface gigabitethernet 0/2
IP verify source reachable-via RX
IP verify URPF drop-rate notify is enabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 133
Number of drop-rate notification counts in this interface is 0
```

Displaythe number of spoofing packets discarded byuRPF on GigabitEthernet 0/1 of Device B.

```
DeviceB# show ip urpf interface gigabitethernet 0/1
IP verify source reachable-via RX
IP verify URPF drop-rate notify is enabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 124
Number of drop-rate notification counts in this interface is 0
```

Displaythe number of spoofing packets discarded byuRPF on GigabitEthernet 0/2 of Device B.

```
DeviceB# show ip urpf interface gigabitethernet 0/2
IP verify source reachable-via RX
IP verify URPF drop-rate notify is enabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 250
Number of drop-rate notification counts in this interface is 0
```

6. Configuration Files

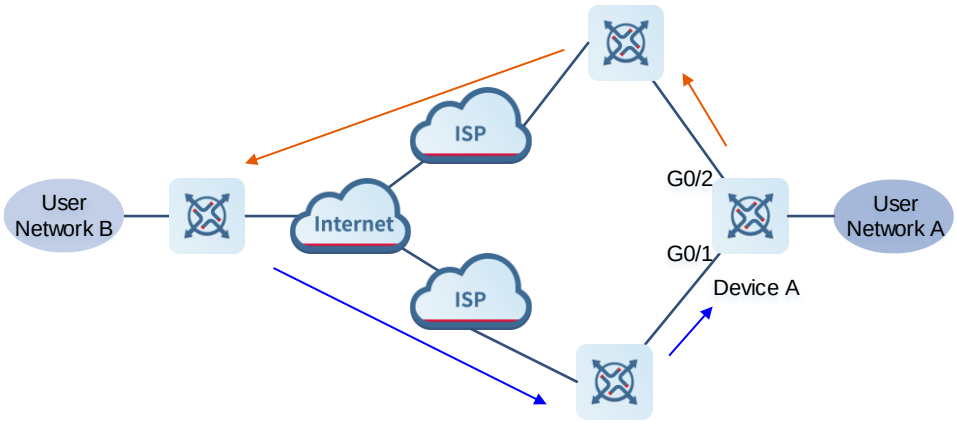
- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 ip address 195.52.1.1 255.255.255.0
 ip verify unicast source reachable-via rx
 ip verify urpf drop-rate notify
```

```
!
interface GigabitEthernet 0/2
 ip address 195.52.2.1 255.255.255.0
 ip verify unicast source reachable-via rx
 ip verify urpf drop-rate notify
!
end
```

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 ip address 195.52.3.1 255.255.255.0
 ip verify unicast source reachable-via rx
 ip verify urpf drop-rate notify
!
interface GigabitEthernet 0/2
 ip address 195.52.4.1 255.255.255.0
 ip verify unicast source reachable-via rx
 ip verify urpf drop-rate notify
!
end
```



1.7.2 Configuring the uRPF Loose Mode

1. Requirements

To prevent invalid packets from attacking the user network, deploythe uRPF loose mode.

2. Topology

Figure 1-2 Configuring the uRPF Loose Mode

3. Notes

Configure the uRPF loose mode on the outbound interfaces connected to ISPs.

4. Procedure

Enable the uRPF loose mode on GigabitEthernet 0/1 and GigabitEthernet 0/2.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet0/1
DeviceA(config-if-GigabitEthernet0/1)# ip address 195.52.1.2 255.255.255.252
DeviceA(config-if-GigabitEthernet0/1)# ip verify unicast source reachable-via any
DeviceA(config-if-GigabitEthernet0/1)# ip verify urpf drop-rate notify
DeviceA(config-if-GigabitEthernet0/1)# exit
DeviceA(config)# interface gigabitethernet0/2
DeviceA(config-if-GigabitEthernet0/2)# ip address 152.95.1.2 255.255.255.252
DeviceA(config-if-GigabitEthernet0/2)# ip verify unicast source reachable-via any
DeviceA(config-if-GigabitEthernet0/2)# ip verify urpf drop-rate notify
DeviceA(config-if-GigabitEthernet0/2)# end
```

5. Verification

If source address spoofing exists on the network, run the **show ip urpf** command to display the number of spoofing packets discarded by uRPF.

```
DeviceA# show ip urpf
IP verify URPF drop-rate compute interval is 30s
IP verify URPF drop-rate notify hold-down is 300s
Interface gigabitEthernet0/1
IP verify source reachable-via ANY
IP verify URPF drop-rate notify is enabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 4121
Number of drop-rate notification counts in this interface is 2
Interface gigabitEthernet0/2
IP verify source reachable-via ANY
IP verify URPF drop-rate notify is enabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 352
Number of drop-rate notification counts in this interface is 0
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 ip address 195.52.1.2 255.255.255.252
 ip verify unicast source reachable-via any
 ip verify urpf drop-rate notify
!
interface GigabitEthernet 0/2
 ip address 152.95.1.2 255.255.255.252
```

```
 ip verify unicast source reachable-via any
 ip verify urpf drop-rate notify
!
end
```

1 Configuring DoS Protection

1.1 Introduction

1.1.1 Overview

Denial-of-service (DoS) attacks aim to put computers or networks out of service.

DoS attacks are diversified in types and can be implemented in many ways but have one common purpose, that is, prevent victim hosts or networks from receiving, processing, or responding to external requests in time. In particular, in an L2 network, DoS attack packets can be spread in the entire broadcast domain. If hackers maliciously initiate DoS attacks, some operating systems (OSs) may collapse. Ruijie products support the following anti-DoS attack functions:

- Denying land attacks
- Denying invalid Transmission Control Protocol (TCP) packets
- Denying invalid L4 ports
- Denying null scan attacks
- Denying Internet Control Message Protocol (ICMP) flood packets
- Denying TCP synchronization (SYN) flood packets

1.1.2 Principles

1. Denying Land Attacks

In a land attack, the attacker sets the source and destination IP addresses in an SYN packet to the same address of the target host. Consequently, the attacked host will be trapped in an infinite loop or even collapse when attempting to set up a TCP connection with itself.

When the function of denying land attacks is enabled, the device checks packets based on characteristics of land packets (that is, SYN packets with the same source and destination IP addresses), and discards invalid packets.

2. Denying Invalid TCP Packets

There are several flag fields in the TCP packet header:

- SYN: Connection establishment flag. A TCP SYN packet sets this flag to **1** to request establishment of a connection.
- ACK: Acknowledgment flag. In a TCP connection, this field must be available in every packet (except the first packet, that is, the TCP SYN packet) as the acknowledgment of the previous packet.
- FIN: Finish flag. When a host receives the TCP packet with the FIN flag, the host disconnects the TCP connection.
- RST: Reset flag. When the IP protocol stack receives a TCP packet that contains a non-existent destination port, it responds with a packet carrying the RST flag.
- PSH: This flag notifies the protocol stack to submit TCP data to the upper-layer program for processing as soon as possible.

In invalid TCP packets, flag fields are set improperly to consume processing resources of hosts or even collapse the system. The following lists several common methods for setting flag fields in invalid TCP packets:

- TCP packets with both the SYN and FIN flags

  Normally, a TCP packet cannot contain both the SYN and FIN flags. In addition, RFC does not stipulate how the IP protocol stack should process such invalid packets containing both the SYN and FIN flags. The protocol stack of each OS may process such packets in different ways. Attackers can use this feature to send packets containing both the SYN and FIN flags to identify the OS type and initiate attacks on this OS.

- TCP packets without any flag

  Normally, a TCP packet contains at least one of the five flags, including SYN, FIN, ACK, RST, and PSH. The first TCP packet (TCP SYN packet) must contain the SYN flag, and the subsequent packets contain the ACK flag. Based on such assumptions, some protocol stacks do not specify the method for processing TCP packets without any flag and may collapse if such TCP packets are received. Attackers use this feature to initiate attacks on target hosts.

- TCP packets with the FIN flag but without the ACK flag

  Normally, except the first packet (TCP SYN packet), all other packets, including the packets with the FIN flag, contain the ACK flag. Some attackers may send TCP packets with the FIN flag but without the ACK flag to the target hosts, causing breakdown of the target hosts.

- TCP packets with the SYN flag and the source port ID set to a value between 0 and 1023

  Port IDs 0 to 1023 are known port IDs allocated by the Internet Assigned Numbers Authority (IANA). In most systems, these port IDs can be used only by the system (or root) processes or programs run by privileged users. These ports (0–1023) cannot be used as the source ports in the first TCP packets (with the SYN flag) sent by clients.

  When the function of denying invalid TCP packets is enabled, the device checks packets based on characteristics of invalid TCP packets and discards invalid TCP packets.

3. Denying Invalid L4 Ports

Attackers send packets in which the IP address and L4 port ID are the same as those of the target host to the target host. As a result, the target host sends TCP connection setup requests to itself. Under such attacks, resources of the target host will soon be exhausted and the system will collapse.

When the function of denying invalid L4 ports is enabled, the device checks the L4 source port ID and destination port ID in the packets. If they are the same, the device discards the packets.

1.2 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Function of Denying Land Attacks
- Configuring the Function of Denying Invalid TCP Packets
- Configuring the Function of Denying Invalid L4 Ports

1.3 Configuring the Function of Denying Land Attacks

1.3.1 Overview

If the function of denying land attacks is enabled, the device checks packets based on characteristics of land packets (that is, SYN packets with the same source and destination IP addresses), and discards invalid packets.

1.3.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of denying land attacks.

ip deny land

The function of denying land attacks is disabled by default.

1.4 Configuring the Function of Denying Invalid TCP Packets

1.4.1 Overview

When the function of denying invalid TCP packets is enabled, the device checks packets based on characteristics of invalid TCP packets and discards invalid TCP packets.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of denying invalid TCP packets.

ip deny invalid-tcp

The function of denying invalid TCP packets is disabled by default.

1.5 Configuring the Function of Denying Invalid L4 Ports

1.5.1 Overview

When the function of denying invalid L4 ports is enabled, the device checks the L4 source port ID and destination port ID in the packets. If they are the same, the device discards the packets.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of denying invalid L4 ports.

ip deny invalid-l4port

The function of denying invalid L4 ports is disabled by default.

1.6 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
show ip deny land	Displays the status of the function of denying land attacks.
show ip deny invalid-tcp	Displays the status of the function of denying invalid TCP packets.
show ip deny invalid-l4port	Displays the status of the function of denying invalid L4 ports.
show ip deny	Displays the status of all anti-DoS attack functions.

1 Configuring Security Log Auditing

1.1 Introduction

1.1.1 Overview

Security log auditing is used to record key operations on a device and audit and backtrack these operations afterwards to improve the device security and meet the national security standards.

Note

The following sections describe content related to security log auditing only.

1.1.2 Principles

1. Basic Concepts

- Key operation

  After enabling the security log auditing function, the device records logs for key operations, including account management, login events, system events, configuration file changes, and security log events. Key operations include:

  - Adding/deleting accounts
  - Editing authentication information
  - Modifying configurations (such as the DNS address and IP address)
  - User login/logout
  - Restarting/Stopping the device
  - Uploading/downloading files (when supported)
  - Editing user permissions (when supported)
  - Enabling/disabling log auditing and deleting logs

2. Enabling Security Log Auditing

After the security log auditing function is enabled, the device can record logs for key operations and locally store the logs.

When a user performs a key operation, such as account management, login/logout, system restart, configuration file change, or log auditing function enabling/disabling, the corresponding service module will collect information (such as time, username, IP address, operation log content, and operation result), generate a log, and write the log to the local database through the log auditing framework.

At 03:00:00 a.m. each day, the system checks whether any logs for key operations exceed the storage time. If yes, the logs will be deleted.

A maximum of 10,000 logs can be stored by default. After the number of stored logs exceeds the storage limit, new logs will overwrite the earliest ones.

3. Enabling the Function of Sending Security Logs to the Syslog Server

After a device is configured with the functions of syslog, and the security log auditing and sending functions are enabled, the log auditing framework will send generated logs to the syslog server to store.

1.2 Restrictions and Guidelines

- To protect the flash storage chip, newly generated logs will be cached in the memory and written to a file every 1 hour. When a restart command, such as **reload**, is executed, logs will be written to a file. If many logs are generated in this hour and some logs are not written to the file in 1 hour, the logs will be lost.
- When logs are exported to a file, download the file in time. The file will be automatically deleted after 1 hour.

1.3 Configuration Task Summary

Configuration of security log auditing includes the following tasks:

(1) Enabling Security Log Auditing

(2) (Optional) Configuring the Local Storage Time for Security Logs

(3) (Optional) Configuring the Handling Time of Aged Security Logs

(4) (Optional) Configuring the Local Storage Capacity for Security Logs

(5) Enabling the Function of Sending Security Logs to the Syslog Server

1.4 Configuring Security Log Auditing

1.4.1 Overview

The security log auditing function can record logs for key operations on a device and locally store the logs. Log query and export are supported.

1.4.2 Enabling Security Log Auditing

1. Overview

After the security log auditing function is enabled, the device will record logs for key operations, including account management, login events, system events, configuration file changes and security log events, and store the logs to the local database.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable security log auditing.

security-log audit-enable

Security log auditing is enabled by default.

1.4.3 Configuring the Local Storage Time for Security Logs

1. Overview

After the local storage time is configured for security logs, the logs that have exceeded the storage time will be deleted.

2. Restrictions and Guidelines

Security logs that have exceeded the storage time will be deleted.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the local storage time for security logs.

security-log data-store-days *data-store-time*

The default local storage time for security logs is **65535** days.

1.4.4 Configuring the Handling Time of Aged Security Logs

1. Overview

After the handling time of aged security logs is configured, the system checks whether any logs have exceeded the storage time at the configured handling time (deviation: 5 minutes) and deletes expired logs.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the handling time of aged security logs.

security-log auto-vacuum-time *hh*:*mm*:*ss*

The default handling time of aged security logs is **03:00:00** every day.

1.4.5 Configuring the Local Storage Capacity for Security Logs

1. Overview

After the local storage capacity for security logs is configured, new logs will overwrite earliest ones when the capacity of locally stored logs exceeds the storage limit.

2. Restrictions and Guidelines

If flash space is limited, you can run this command to decrease the storage capacity for security logs.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the local storage capacity for security logs.

security-log data-store-items *log-number*

The default local storage capacity for security logs is **10000**.

1.4.6 Enabling the Function of Sending Security Logs to the Syslog Server

1. Overview

After the function of sending security logs to the syslog server is enabled, a syslog is generated for each security log.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of sending security logs to the syslog server.

security-log send-syslog

The function of sending security logs to the syslog server is enabled by default.

1.5 Monitoring

Run the **delete** commands to clear information.

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** commands to output debugging information.

⚠ Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
debug security-log errors	Debugs log auditing.
debug security-log recv-info	Debugs received logs.
debug security-log sql-info	Debugs the log database.
show security-log	Displays all logs.

Command	Purpose
show security-log config	Displays configurations.
show security-log detail { **all** | **from** *year month day hh:mm:ss* **to** *year month day hh:mm:ss* } [**hostname** *hostname* | **log-type** { **acc_mnt** | **config** | **login** | **other** | **sec_log** | **sys** } | **peerinfo** *peerinfo* | **user** *username*] * [**order-by** { **log-type** | **time** } { **asc** | **desc** } [**start-item** *start-item* **end-item** *end-item*]]	Displays the detailed log information, which can be filtered by time, log type, username, host name, and terminal information.
show security-log detail export { **all** | **from** *year month day hh:mm:ss* **to** *year month day hh:mm:ss* } [**hostname** *hostname* | **log-type** { **acc_mnt** | **config** | **login** | **other** | **sec_log** | **sys** } | **peerinfo** *peerinfo* | **user** *username*] * [**order-by** { **log-type** | **time** } { **asc** | **desc** } [**start-item** *start-item* **end-item** *end-item*]]	Exports the detailed log information, which can be filtered by time, log type, username, host name, and terminal information.
show security-log detail stat { **all** | **from** *year month day hh:mm:ss* **to** *year month day hh:mm:ss* } [**hostname** *hostname* | **log-type** { **acc_mnt** | **config** | **login** | **other** | **sec_log** | **sys** } | **peerinfo** *peerinfo* | **user** *username*] *	Displays the log statistics, which can be filtered by time, log type, username, host name, and terminal information.
show security-log info	Displays the statistics during log processing.
show security-log statistics	Displays the statistics.
security-log delete all	Deletes all logs.

1.6 Configuration Examples

1.6.1 Configuring Security Log Auditing

1. Requirements

To improve device security and audit and backtrack exceptions (such as key configurations being tampered) afterwards, key operations on a device need to be recorded. After the security log auditing function is enabled, the device records key operations, including account management, login events, system events, configuration file changes, and security log events. After logging in to the device, the administrator can monitor recent user behaviors through the records.

2. Topology

Figure 1-1 Configuring Security Log Auditing

3. Notes

- Enable security log auditing.
- Configure parameters related to security log auditing.

4. Procedure

Enable security log auditing.

```
Device> enable
Device# configure terminal
Device(config)# security-log audit-enable
```

Set the local storage time of security logs to **300** days.

```
Device(config)# security-log data-store-days 300
```

Set the handling time of aged security logs to **05:05:00** every day.

```
Device(config)# security-log auto-vacuum-time 05:05:00
```

Set the local storage capacity for security logs to **1000**.

```
Device(config)# security-log data-store-items 1000
```

5. Verification

Log in to the device, perform key operations, and run **show security-log detail all** 30s later to check the log auditing records.

```
Device# show security-log detail all
time, username, peerinfo, hostname, log-type: content
2019-10-22 10:00:02, admin, vty0(192.168.111.111), Device, SEC_LOG: SECURITY_LOG
deleted all security log successfully
2019-10-22 10:00:02, admin, vty0(192.168.111.111), Device, SEC_LOG: SECURITY_LOG
disabled security log audit configuration unsuccessfully
2019-10-22 10:00:03, ---, console, Device, SEC_LOG: SECURITY_LOG enabled security log
audit configuration successfully
```

Run the **show security-log config** command to verify that the local storage time of security logs is 300 days, the handling time of aged security logs is 05:05:00 every day, and the local storage capacity for security logs is 1000.

```
Device# show security-log config
Security-log audit: enable
Limit number: 1000
Store days: 300
Auto vacuum time: 05:05:00
Security-log send to syslog: enable
```

6. Configuration Files

```
hostname Device
!
security-log data-store-days 300
security-log data-store-items 1000
```

```
security-log auto-vacuum-time 05:05:00
!
end
```

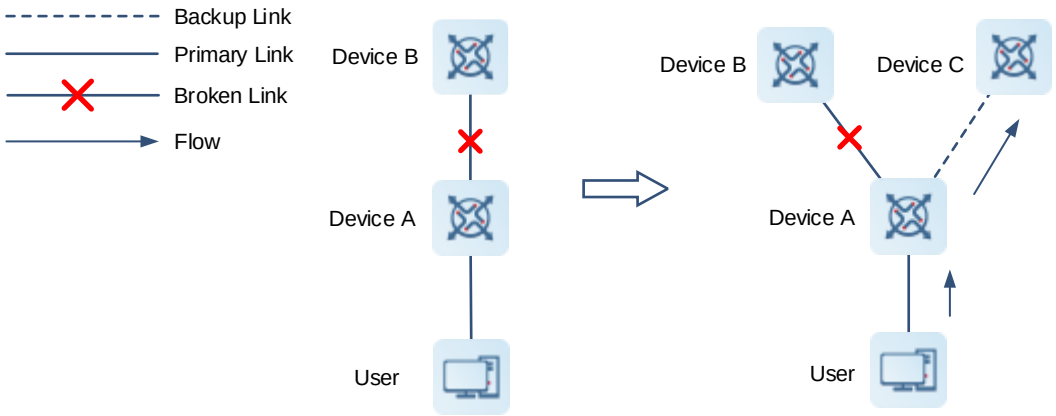
1 Configuring REUP

Rapid Ethernet Uplink Protection (REUP) provides a rapid uplink protection function. In the dual uplink networking, REUP is used to ensure normal communication between links, block redundant links, avoid link loops, and implement fast backup.



1.1 Introduction

1.1.1 Topology

The left topology in Figure 1-1 shows single uplink networking, where there is only one link between the user and the distribution switch to implement communication. When the link between access Device A and distribution Device B fails, the link between the user and Device B is disconnected, which interrupts all external services of the user.

The topology can be transformed into REUP dual uplink deployment topology, as shown in the right topology in Figure 1-1. In this topology, one link functions as the active link for normal communication, and the other link functions as a backup link and is not used for communication. When the active link fails, traffic is switched to the backup link. This helps reduce the impact of a single link failure on the network and improve reliability.

Figure 1-1 REUP Topology

REUP and the Spanning Tree Protocol (STP) are mutually exclusive on ports. Generally, a device runs STP in the downlink direction and runs REUP in the uplink direction to implement uplink backup and data protection in the case of faults. REUP can still provide basic link redundancy when STP is disabled. It also provides millisecond-level fault recovery faster than STP. Its main features are as follows.

- The uplink ports of REUP are configured in pairs, namely, an uplink port pair includes a forward port and a standby port. The standby port does not forward data packets. When the forward port fails, the standby port immediately becomes the forward port to forward data.
- REUP sends an address update packet to the upstream device so that the upstream device can update the MAC address information immediately. This function ensures that L2 data streams are restored rapidly after a link gets faulty.

1.1.2 Basic Concepts

1. REUP Pair

You can specify a port as the backup port of another port to configure an REUP pair, in which one port is the active port and the other is the backup port. When both ports are normal, one port is configured as the forward port and the other as the standby port.

2. MAC Address Update Message

According to the MAC address learning principle, before L2 link switching a user's MAC address entry exists on the forwarding link, and no packet is forwarded by the blocked link, so there is no user's MAC address entry on the blocked link. After switching, packets cannot be forwarded because they are still forwarded according to the existing MAC address entry of the user. MAC address update messages refer to FLUSH packets sent to an uplink device through private multicast packets. When an uplink device, on which the function of receiving MAC address update messages is enabled, receives a MAC address update message, the device updates the MAC entry on the relevant interface.

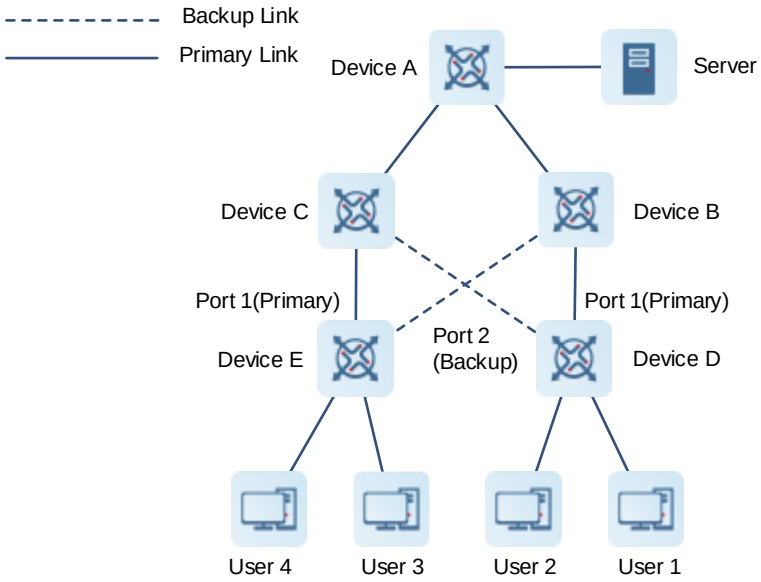
3. MAC Address Update Group

Multiple ports can be added to a group. If one port in the group receives a MAC address update message, the MAC address entries on other ports in the group are updated at the same time. In this case, the group is called a MAC address update group.

4. MAC Address Update Packet

MAC address update packets are sent to uplink devices of other manufacturers to ask them to update their MAC address entries, so as to implement compatibility with them.

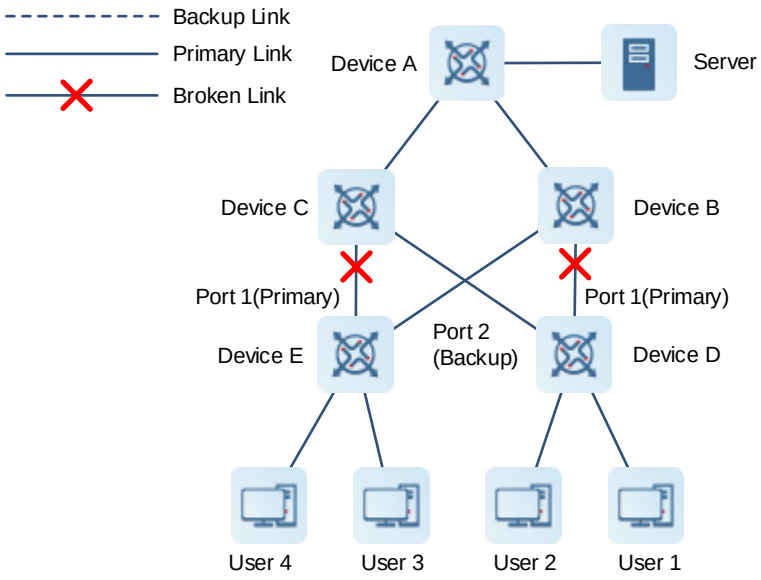
5. Link State Tracking Group



The uplink and downlink ports of a device can be added to a group at the same time, which is called a link state tracking group. If all uplink ports in the group are down, all downlink ports in this group are forced down.

1.1.3 Dual-Link Backup

When an active link is faulty, the link in the backup state will rapidly switch to the forward state and start to forward data, to minimize the service interruption caused by the link failure.



- You can specify a port as the backup port of another port to configure an REUP pair. When the two ports are normal, one link is in the forwarding state (forwarding data packets) and the other link is in the backup state (not forwarding data packets).
- When the active link is faulty, the link in the backup state rapidly switches to the forwarding state and starts to forward data.
- When the faulty link recovers, it enters the backup state and does not forward data packets.
- The preemption mode can be configured to specify whether the link recovering from a fault preempts to become the link in the forwarding state.

Figure 1-2 Topology with Two Normal Links

As shown in Figure 1-2, ports 1 and 2 of Device D (Device E) are connected to uplink switches B and C (Devices C and B) respectively, and REUP is configured on ports 1 and 2. When the links are normal, port 1 is in the forwarding state and forwards data packets and port 2 is in the backup state and does not forward data packets.

Figure 1-3 Topology with Faulty Port 1 of Device D and Device E

As shown in Figure 1-3, once port 1 fails, port 2 immediately starts to forward data packets and restores uplink transmission of the switch. In the non-preemption mode, when the link of port 1 recovers, port 1 is in the backup state and does not forward data packets, and port 2 continues forwarding data packets. You must enable the REUP dual-link backup function on a port so that the port undertakes the REUP link switching when the port is faulty.

Note

- REUP, Ethernet Ring Protection Switching (ERPS), and Rapid Ethernet Ring Protection (RERP) do not share ports.
- On devices enabled with REUP, the storm control function must be disabled on all L2 ports.

1.1.4 MAC Address Update

During link switching, the MAC address entries on a port are updated to speed up packet convergence. As shown in Figure 1-2, the MAC address update process is analyzed as follows:

- Ports 1 and 2 of Device D (Device E) have the REUP dual-link backup enabled. Port 1 works as the active port. During normal communication, Device A learns the MAC addresses of users 1 and 2 (users 3 and 4) from the port connecting to Device B (Device C).
- When port 1 of Device D (Device E) fails, port 2 quickly changes to the forwarding state and starts to forward data packets. In this case, Device A has not learned the MAC addresses of users 1 and 2 (users 3 and 4) from the port connecting to Device B (Device C). The data packets sent by the server to users 1 and 2 (users 3 and 4) are forwarded to Device C (B) by Device A, causing loss of the packets from the server to users 1 and 2 (users 3 and MAC 4).

The following measures can be taken to avoid the above problem:

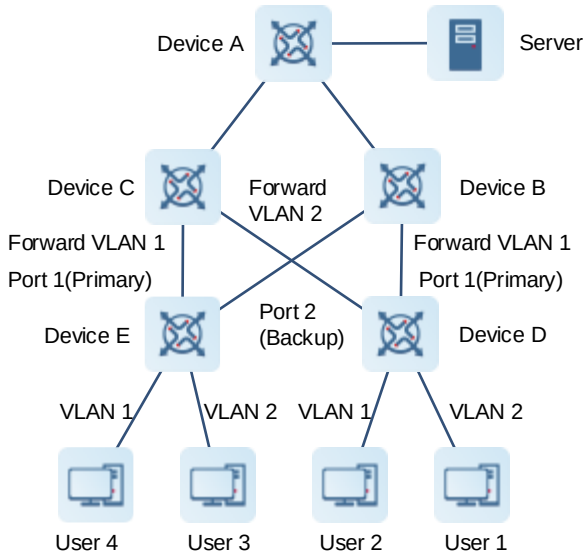
- Enable the MAC address update function on Device D (Device E). When port 2 starts to forward packets, Device D (Device E) sends a MAC address update message to port 2.
- After receiving the MAC address update message from port 2, Device A updates the MAC address entries on the port of Device A. In this way, Device A forwards the packets sent by the server to the users, to the port connecting to Device C (Device B) to speed up packet transmission convergence.
- In addition, a MAC address update group can be configured, that is, multiple ports can be classified into the same group. When a port in this group receives a MAC address update message, the MAC address entries on other ports in the group are updated, to reduce the side effect of flooding caused by MAC address update.
- To be compatible with upstream devices not supporting MAC address update messages, Device D (Device E) sends MAC address update packets for users 1 and user 2 (users 3 and 4) upstream when port 2 DeviceEs to the forwarding state. In this way, Device A updates the MAC addresses of users 1 and 2 (users 3 and 4) to the corresponding port and the downstream data transmission of Device A is restored.

Based on the above process analysis, the relevant configuration to be involved includes the following items:

Table 1-1 Description of MAC Address Update Configuration Items

Configuration Item	Description
Sending MAC address updates	If the function of sending MAC address update messages is not enabled, no MAC address update message is sent when REUP dual-link backup switching is performed.

Configuration Item	Description
Receiving MAC address updates	If the function of receiving MAC address update messages is not enabled, a device cannot receive MAC address update messages from downlink devices during REUP dual-link backup switching and will not update the MAC addresses.
Specifying a VLAN for sending MAC address updates	If the VLAN in which an interface sends MAC address update messages is configured, the messages are sent in the configured VLAN; otherwise, the messages are sent in the default VLAN to which the interface belongs.
Specifying a VLAN for receiving MAC address updates	If no VLAN in which an interface receives MAC address update messages is configured, MAC address update messages are received in all the configured VLANs; otherwise, MAC address update messages are received in the specified VLAN.
MAC address update group	If no MAC address update group is configured, MAC address update is not performed when MAC address update packets are received.
Maximum number of MAC address update messages sent per second	A greater number of messages configured indicates more CPU time used for sending messages and fewer downstream packets to be lost.



1.1.5 VLAN Load Balancing

The VLAN load balancing function allows the two ports of a REUP pair to forward data packets of mutually exclusive VLANs so as to make full use of the link bandwidth.

As shown in Figure 1-4, the MAC address update process is analyzed as follows:

- Configure REUP dual-link backup and enable the VLAN load balancing of REUP on ports 1 and 2 of Device D, and map VLAN 1 to instance 1 and VLAN 2 to instance 2. Data of VLAN 1 (instance 1) is transmitted through port 1 and data of VLAN 2 (instance 2) is transmitted through port 2. Perform the same configuration on Device E.
- When a port is faulty, the other port takes over the transmission of all VLAN data.
- When the faulty port recovers and works properly within the preemption delay, the transmission of VLAN data in the charge of the faulty port is switched back to the recovered port.

Figure 1-4 VLAN load balancing topology

Therefore, the VLAN load balancing function needs to be enabled on the ports to make full use of the link bandwidth for packet forwarding when both links are normal.

Caution

- The instance mapping of REUP VLAN load balancing is controlled by the Multiple Spanning Tree Protocol (MSTP) module in a unified manner. For details about how to configure the instances, see *Configuring MSTP*.
- The VLAN load balancing function can be configured only on trunk, uplink, or hybrid ports.

1.1.6 Link State Tracking

Link state tracking means that, when an uplink is faulty, the downlink switches services to the backup uplink so that the backup interface can continue to forward packets. By configuring the uplink and downlink interfaces of the link state tracking group, the state of multiple downlink interfaces can be bound to multiple uplink ports. When all the downlink interfaces in a tracking group are faulty, the device forcibly disables the uplink interface to switch services of the uplink.

As shown in Figure 1-5, when the uplink of Device B is faulty, link state tracking rapidly shuts down the downstream port of Device B so that the upstream transmission of Device D is switched to Device C.

Figure 1-5 Topology with the Faulty Active Uplink

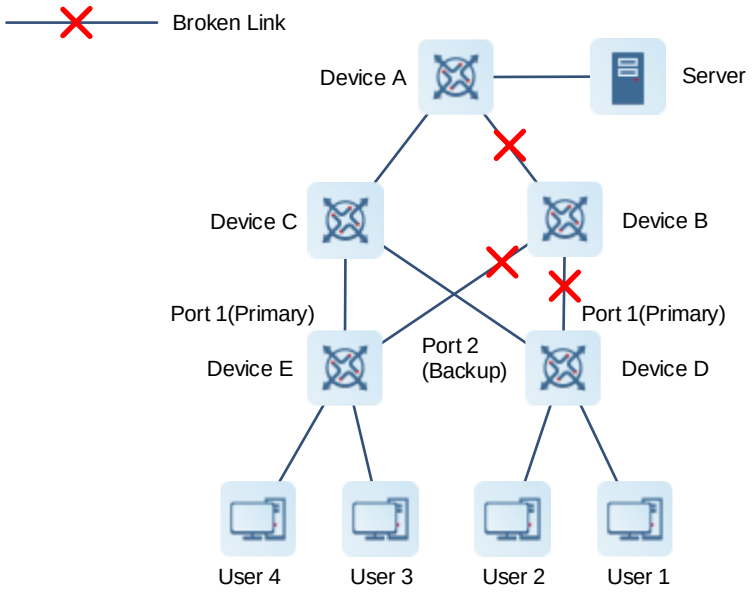


Table 1-2 Description of Link State Tracking Configuration Items

Configuration Item	Description
Link state tracking	If the link state tracking function is not enabled, the state of a corresponding uplink port cannot be detected and packet forwarding switching cannot be implemented in time.
Downlink up delay function for a link state tracking group	By enabling the downlink up delay function, you can avoid frequent downlink switching caused by uplink flapping in a link state tracking group. That is, when the uplink becomes up, the downlink becomes up after a delay.
Adding a port to a link state tracking group	If a port is not added to a link state tracking group, the state of a corresponding uplink port cannot be detected and packet forwarding switching cannot be implemented in time.

1.2 Configuration Task Summary

REUP configuration includes the following tasks:

(1) Configuring Basic Features of REUP

(2) (Optional) Configuring the Preemption Function of REUP

(3) Configuring the MAC Address Update Function

(4) (Optional) Configuring VLAN Load Balancing

(5) Configuring Link State Tracking

1.3 Configuring Basic Features of REUP

1.3.1 Overview

When a link is faulty, another normal link switches to the forward state immediately to forward packets.

1.3.2 Restrictions and Guidelines

- One port belongs to only one REUP pair. Each active link has only one backup link. A backup link can be used as the backup link of only one active link. The active and backup links must use different ports.
- REUP supports Layer 2 physical ports and link aggregations, but does not support member ports of a link aggregation.
- The active and backup ports may be of different types and have different rates. For example, an AP can be used as the active port and a physical port can be configured as the backup port.
- Ports configured with REUP are not involved in STP calculation.
- Each device can be configured with a maximum of 16 REUP pairs.
- Ports successfully configured with REUP cannot be configured as Layer 3 interfaces or added to a link aggregation.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the Layer 2 Ethernet interface configuration mode.

interface *interface-type interface-number*

(4) Configure a REUP dual-link backup port.

switchport backup interface *interface-type interface-number*

No REUP dual-link backup port is configured by default.

1.4 Configuring the Preemption Function of REUP

1.4.1 Overview

- You can configure the preemption mode to determine the link to use. If the active link needs to always forward packets or the link for forwarding packets needs to be determined based on the link bandwidth, the preemption mode and delaytime must be configured.
- The preemption mode can be set to three modes: forced, bandwidth, and off. In the bandwidth mode, a port with a greater bandwidth is selected to transmit data; in the forced mode, the active port is selected to transmit data; in the off mode, no preemption is performed. If the preemption mode is set to bandwidth mode, a link with a greater bandwidth is used. The value of the bandwidth attribute of a link aggregation is the actual bandwidth of the link aggregation, equal to the number of link up member ports of the link aggregation multiplied by the speed attribute value of a member port. You can also set the preemption mode to forced mode to select a stable and reliable link forcibly.

- To avoid frequent active/backup link switching caused by faults, REUP provides a preemption delay function. After the two links recover, link switching is delayed (**35** seconds by default) for the faulty link to become stable. A smaller delay means more frequent preemption switching after the faulty link recovers. When STP is enabled on an uplink, the preemption delay time of REUP should be greater than 35 seconds.

1.4.2 Restrictions and Guidelines

REUP dual-link backup must be configured.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(4) Configure the preemption mode of REUP.

switchport backup interface *interface-type interface-number* **preemption mode** { **bandwidth** | **forced** | **off** }

The default link preemption mode of REUP is off mode.

(5) Configure the preemption delay time of REUP.

switchport backup interface *interface-type interface-number* **preemption delay** *interval*

The default preemption delay time of REUP is **35** seconds.

1.5 Configuring the MAC Address Update Function

1.5.1 Overview

- The MAC address update function can rapidly delete and update MAC address information on interfaces during link switching to make packet convergence faster.
- When dual-link backup switching occurs, downstream data streams may be lost because the MAC address table of the uplink switch is not updated in time. In order to reduce loss of L2 data streams, you need to update the MAC address table of the uplink switch. To update the MAC address table of the uplink switch, enable the function of sending MAC address update messages on the device where link switching occurs, and enable the function of receiving MAC address update messages on the uplink device. During link switching, if the function of sending MAC address update messages is enabled, REUP sends a certain number of MAC address update packets to an uplink device per second to recover the downstream data transmission of the uplink device. For a VLAN in which the function of processing MAC address update messages is disabled, the device can still recover the downlink transmission of uplink devices based on the MAC address update packets; however, the convergence performance will be degraded in the case of link

faults.

- Massive flooding caused by MAC address update may affect normal data transmission of the switch. Flooding packets can be reduced by configuring MAC address update groups to quickly recover data transmission. Transmission of downstream data can be rapidly recovered only after all ports in a switching path are added to the same MAC address update group.

1.5.2 Restrictions and Guidelines

- REUP dual-link backup must be configured.
- A maximum of eight address update groups can be configured on each device. Each address update group can contain a maximum of eight member ports and a port can belong to multiple address update groups.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of sending MAC address update private multicast messages.

mac-address-table move update transit

No MAC address update private multicast message is sent by default.

(4) (Optional) Configure the maximum rate for sending MAC address update broadcast packets.

mac-address-table move update max-update-rate *packet-per-second*

The default maximum rate for sending MAC address update broadcast packets is **150** packets/second.

(5) On an uplink device, enable the function of receiving MAC address update private multicast messages.

mac-address-table move update receive

No MAC address update private multicast message is received by default.

(6) (Optional) On an uplink device, configure the VLAN ID range, in which MAC address update private multicast messages are received.

mac-address-table move update receive vlan *vlan-range*

The MAC address update private multicast messages in all the VLAN ID ranges are received by default.

(7) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(8) Configure the MAC address update group ID for the interface.

mac-address-table update group [*group-id*]

No MAC address update group is configured by default.

(9) (Optional) Configure the ID of a VLAN, in which a port sends MAC address update private multicast messages.

mac-address-table move update transit vlan *vlan-id*

By default, the ID of the VLAN, in which a port sends MAC address update private multicast messages is the local default VLAN of the port.

1.6 Configuring VLAN Load Balancing

1.6.1 Overview

- This function is used to maximize the utilization of link bandwidth.
- You can modify the mapping between instances and VLANs by using the instance mapping function of MSTP.
- The VLAN load balancing function allows the two ports of a REUP pair to forward data packets of mutually exclusive VLANs so as to make full use of the link bandwidth. That is, it allows some VLAN data packets to be forwarded through the backup link, but the active link does not forward these VLAN data packets. In this way, the active link and backup link forward different VLAN data packets and achieve load sharing.
- The VLAN load balancing of REUP relies on the mappings between VLANs and MSTP instances, and the instance mappings are controlled by the MSTP module in a unified manner. You can modify the mappings between instances and VLANs by using the instance mapping function of MSTP. For details about how to configure the instances, see the description in "Configuring MSTP."

1.6.2 Restrictions and Guidelines

- REUP dual-link backup must be configured.
- VLAN load balancing cannot be configured on an access port but can share a port with STP.
- For ports successfully configured with VLAN load balancing, you cannot modify the port attributes but can modify the VLAN attributes of the ports.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a group of VLANs.

vlan { *vlan-id* | **range** *vlan-range* }

Only VLAN 1 exists by default.

(4) Return to the global configuration mode.

exit

(5) Enter the MST configuration mode.

spanning-tree mst configuration

(6) Configure the mappings between instances and VLANs, and add the VLAN group to one MST instance.

instance *instance-id* **vlan** *vlan-range*

Only instance **0** exists and all VLANs belong to instance **0** by default.

(7) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(8) Configure the VLAN load balancing function.

switchport backup interface *interface-type interface-number* **prefer instance** *instance-range*

The VLAN load balancing function is not configured by default.

1.7 Configuring Link State Tracking

1.7.1 Overview

After detecting that the uplink is disconnected, REUP forcibly disconnects the downlink so that link switching can be performed.

1.7.2 Restrictions and Guidelines

- REUP dual-link backup must be configured.
- For the link state tracking function, each port belongs to only one link state tracking group and each device can be configured with up to two link state tracking groups. Each link state tracking group can have 10 upstream ports and 256 downstream ports.
- You must enable the delay function so that the downlink can be Up after the delay.
- You must create a link state tracking group first and then add a port to the tracking group.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable a link state tracking group.

link state track [*track-number*]

All the link state tracking groups are disabled by default.

(4) Configure the downlink recovery delay time for the link state tracking group.

link state track *track-number* **up-delay** *interval*

By default, downlink recovery of the link state tracking group is not delayed, and the downlink tracks the uplink.

(5) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

interface *interface-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 aggregate interface configuration mode \.

  interface aggregateport *interface-number*

(6) Add a port to the link state tracking group, and specify it as the uplink port of the group.

link state group [*track-number*] **upstream**

No port is added to a link state tracking group by default.

(7) Add a port to the link state tracking group and specify it as the downlink port of the group.

link state group [*track-number*]**downstream**

No port is added to a link state tracking group by default.

1.8 Monitoring

Run the **show** command to check the configuration.

Run the **debug** command to output debugging information.

Caution

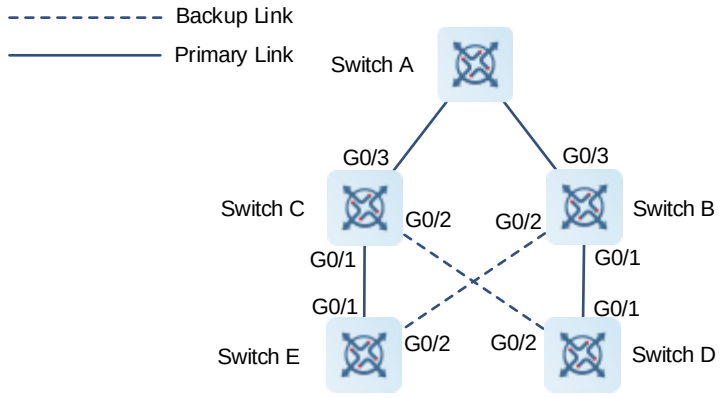
Debugging occupies system resources, so disable it immediately if not required.

Table 1-3 REUP Monitoring

Command	Purpose
show interfaces [*interface-type interface-number*] **switchport** [**backup** [**detail**]]	Displays the REUP dual-link backup information.
show mac-address-table update group [**detail**]	Displays the configurations of a MAC address update group.
show mac-address-table move update	Displays the statistics on MAC address update messages sent by an REUP pair.
show link state group [*track-number*]	Displays the information about a link state tracking group.
debug reup all	Debugs all functions of REUP.
debug reup process	Debugs the normal running process of REUP.
debug reup packet	Debugs MAC address update messages of REUP.
debug reup macupdt	Debugs MAC address update packets of REUP.
debug reup ha	Debugs hot backup.
debug reup error	Debugs errors occurring in REUP running.

Command	Purpose
debug reup event	Debugs received events.
debug reup status	Debugs statistics displayed when a show command is executed.

1.9 Configuration Examples



1.9.1 Configuring Basic Features of REUP

1. Requirements

To improve network reliability and ensure continuity of services between the access device and the core device, two links are deployed between core device A and each of the access devices D and E, as shown in Figure 1-6. REUP dual-link backup must be configured on the access devices. When the two links are normal, one is in the active state and forwards packets while the other is in the standby state. When the active link becomes faulty, the link in standby state is quickly switched to the active state and starts to forward data.

2. Topology

Figure 1-6 Topology for Configuring Basic Features of REUP

3. Notes

- Configure REUP dual-link backup (GigabitEthernet 0/1 is the active port and GigabitEthernet 0/2 is the backup port) on access Device D (Device E).

4. Procedure

Perform the following configuration on Device D.

```
DeviceD> enable
DeviceD# configure terminal
DeviceD(config)# interface gigabitethernet 0/1
DeviceD(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceD(config-if-GigabitEthernet 0/1)# switchport backup interface gigabitethernet
0/2
```

```
DeviceD(config-if-GigabitEthernet 0/1)# exit
```

Perform the following configuration on Device E.

```
DeviceE> enable
DeviceE# configure terminal
DeviceE(config)# interface gigabitethernet 0/1
DeviceE(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceE(config-if-GigabitEthernet 0/1)# switchport backup interface gigabitethernet
0/2
DeviceD(config-if-GigabitEthernet 0/1)# exit
```

5. Verification

Run the **show interfaces switchport backup detail** command to verify that the configuration is correct.

Check the configuration of Device D.

```
DeviceD#show interfaces switchport backup detail
Switch Backup Interface Pairs:
Active Interface        Backup Interface        State
------------------------------------------------------------------------
Gi0/1                Gi0/2                Active Up/Backup Standby

Interface Pair : Gi0/1, Gi0/2
Preemption Mode : off
Preemption Delay : 35 seconds
Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)
```

Check the configuration of Device E.

```
DeviceE#show interfaces switchport backup detail
Switch Backup Interface Pairs:
Active Interface        Backup Interface        State
------------------------------------------------------------------------
Gi0/1                Gi0/2                Active Up/Backup Standby

Interface Pair : Gi0/1, Gi0/2
Preemption Mode : off
Preemption Delay : 35 seconds
Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)
```

6. Configuration Files

- Device D configuration file

```
hostname DeviceD
!
interface GigabitEthernet 0/1
 switchport mode trunk
 switchport backup interface GigabitEthernet 0/2
!
```

```
end
```

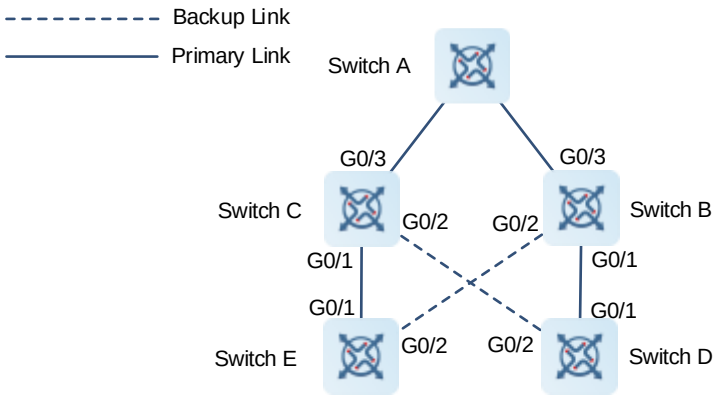
- Device E configuration file

```
hostname DeviceE
!
interface GigabitEthernet 0/1
 switchport mode trunk
 switchport backup interface GigabitEthernet 0/2
!

end
```

7. Common Errors

- When a port is added to an REUP pair, the port has been configured to belong to another REUP pair.
- A configured port is not a Layer 2 physical port or link aggregation.



1.9.2 Configuring the MAC Address Update Function

1. Requirements

To improve network reliability and ensure continuity of services between the access device and the core device, two links are deployed between core device A and each of the access devices D and E, as shown in Figure 1-7. To accelerate packet convergence during link switch, the MAC address update function must be configured on the device.

2. Topology

Figure 1-7 Topology for Configuring the MAC Address Update Function

3. Notes

- Enable the function of sending MAC address update messages on access Device D (Device E).
- Enable the function of receiving MAC address update packets on Device B (Device C).
- Add all ports in the REUP switching path to the same MAC address update group.
- GigabitEthernet 0/1 and GigabitEthernet 0/3 of Device B are the ports in the uplink switching path of Device D, and GigabitEthernet 0/3 and GigabitEthernet 0/2 are the ports in the uplink switching path of Device E. You can add ports GigabitEthernet 0/1, GigabitEthernet 0/2, and GigabitEthernet 0/3 to the same address

update group. Similarly, you can perform the configuration on Device C.

- Enable the function of receiving MAC address update packets on Device A.
- Add all ports in the REUP switching path of Device A to the same MAC address update group.

4. Procedure

Perform the following configuration on Device D.

```
DeviceD> enable
DeviceD# configure terminal
DeviceD(config)# mac-address-table move update transit
```

Perform the following configuration on Device E.

```
DeviceE> enable
DeviceE# configure terminal
DeviceE((config)# mac-address-table move update transit
```

Perform the following configuration on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# mac-address-table move update receive
DeviceB(config)# interface range gigabitethernet 0/1-3
DeviceB(config-if-range)# switchport mode trunk
DeviceB(config-if-range)# mac-address-table update group 1
```

Perform the following configuration on Device C.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# mac-address-table move update receive
DeviceC(config)# interface range gigabitethernet 0/1-3
DeviceC(config-if-range)# switchport mode trunk
DeviceC(config-if-range)# mac-address-table update group 1
```

Perform the following configuration on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# mac-address-table move update receive
DeviceA(config)# interface range gigabitethernet 0/1-2
DeviceA(config-if-range)# switchport mode trunk
DeviceA(config-if-range)# mac-address-table update group 1
```

5. Verification

Displaythe configurations of the MAC address update group on device B.

```
DeviceB# show mac-address-table update group detail
show mac-address-table update group detailMac-address-table Update Group:1
Received mac-address-table update message count:0
Group member        Receive Count    Last Receive Switch-ID      Receive Time
-------------------------------------------------------------------------------
Gi0/1              0              0000.0000.0000
```

```
Gi0/2              0              0000.0000.0000
Gi0/3              0              0000.0000.0000
```

Displaythe configurations of the MAC address update group on device C.

```
DeviceC# show mac-address-table update group detail
Mac-address-table Update Group:1
Received mac-address-table update message count:0
Group member        Receive Count    Last Receive Switch-ID      Receive Time
-------------------------------------------------------------------------------
Gi0/1              0              0000.0000.0000
Gi0/2              0              0000.0000.0000
Gi0/3              0              0000.0000.0000
```

Displaythe configurations of the MAC address update group on device A.

```
DeviceA# show mac-address-table update group detail
Mac-address-table Update Group:1
Received mac-address-table update message count:0
Group member        Receive Count    Last Receive Switch-ID      Receive Time
-------------------------------------------------------------------------------
Gi0/1              0              0000.0000.0000
Gi0/2              0              0000.0000.0000
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 switchport mode trunk
 mac-address-table update group 1
!
interface GigabitEthernet 0/2
 switchport mode trunk
 mac-address-table update group 1
!
mac-address-table move update receive

end
```

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 switchport mode trunk
 mac-address-table update group 1
!
interface GigabitEthernet 0/2
 switchport mode trunk
```

```
 mac-address-table update group 1
!
interface GigabitEthernet 0/3
 switchport mode trunk
 mac-address-table update group 1
!
mac-address-table move update receive

end
```

- Device C configuration file

```
hostname DeviceC
!
interface GigabitEthernet 0/1
 switchport mode trunk
 mac-address-table update group 1
!
interface GigabitEthernet 0/2
 switchport mode trunk
 mac-address-table update group 1
!
interface GigabitEthernet 0/3
 switchport mode trunk
 mac-address-table update group 1
!
mac-address-table move update receive

end
```

- Device D configuration file

```
hostname DeviceD
!
mac-address-table move update transit

end
```

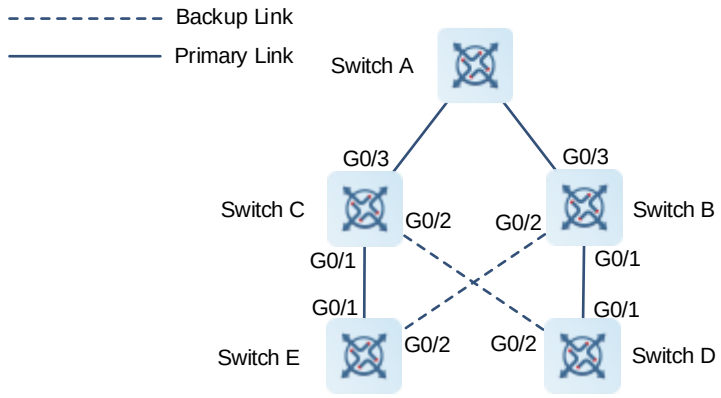
- Device E configuration file

```
hostname DeviceE
!
mac-address-table move update transit

end
```

7. Common Errors

- A configured port is not a Layer 2 physical port or link aggregation.



1.9.3 Configuring VLAN Load Balancing

1. Requirements

To improve network reliability and ensure continuity of services between the access device and the core device, two links are deployed between core device A and each of the access devices D and E, as shown in Figure 1-8. To make full use of the link bandwidth, the VLAN load balancing function must be enabled.

2. Topology

Figure 1-8 Topology for Configuring VLAN Load Balancing

3. Notes

- Configure instance mappings on Device D (Device E) to map VLAN 1 to instance 1, VLAN 2 to instance 2, VLAN 3 to instance 3, and VLAN 4 to instance 4. For details about how to configure the mappings, see "Configuring MSTP" in *Ethernet Switching Configuration Guide*.
- Configure the VLAN load balancing function on Device D (Device E).

4. Procedure

Perform the following configuration on Device D.

```
DeviceD> enable
DeviceD# configure terminal
DeviceD(config)# interface gigabitethernet 0/1
DeviceD(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceD(config-if-GigabitEthernet 0/1)# switchport backup interface gigabitethernet
0/2 prefer instance 2
DeviceD(config-if-GigabitEthernet 0/1)# exit
```

Perform the following configuration on Device E.

```
DeviceE> enable
DeviceE# configure terminal
DeviceE(config)# interface gigabitethernet 0/1
DeviceE(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceD(config-if-GigabitEthernet 0/1)# switchport backup interface gigabitethernet
0/2 prefer instance 4
DeviceD(config-if-GigabitEthernet 0/1)# exit
```

5. Verification

Run the **show interfaces switchport backup detail** command to check the dual-link backup information configured on Device D.

```
DeviceD# show interfaces switchport backup detail
Switch Backup Interface Pairs:
Active Interface        Backup Interface        State
------------------------------------------------------------------------
Gi0/1                Gi0/2                Active Up/Backup Up

Instances Preferred on Active Interface: Instance 0-1,3-64
       Mapping VLAN 1,3-4094

Instances Preferred on Backup Interface: Instance 2
       Mapping VLAN 2

Interface Pair : Gi0/1, Gi0/2
Preemption Mode : balance
Preemption Delay : 35 seconds
Bandwidth : Gi0/1(800 kbits), Gi0/2(100000 kbits)
```

Run the **show interfaces switchport backup detail** command to check the dual-link backup information configured on Device E

```
DeviceE# show interfaces switchport backup detail
Switch Backup Interface Pairs:
Active Interface        Backup Interface        State
------------------------------------------------------------------------
Gi0/1                Gi0/2                Active Up/Backup Up

Instances Preferred on Active Interface: Instance 0-3,5-64
       Mapping VLAN 1-3,5-4094

Instances Preferred on Backup Interface: Instance 4
       Mapping VLAN 4

Interface Pair : Gi0/1, Gi0/2
Preemption Mode : balance
Preemption Delay : 35 seconds
Bandwidth : Gi0/1(800 kbits), Gi0/2(100000 kbits)
```

6. Configuration Files

- Device D configuration file

```
hostname DeviceD
!
interface GigabitEthernet 0/1
 switchport mode trunk
 switchport backup interface gigabitethernet 0/2 prefer instance 2
```

```
!

end
```

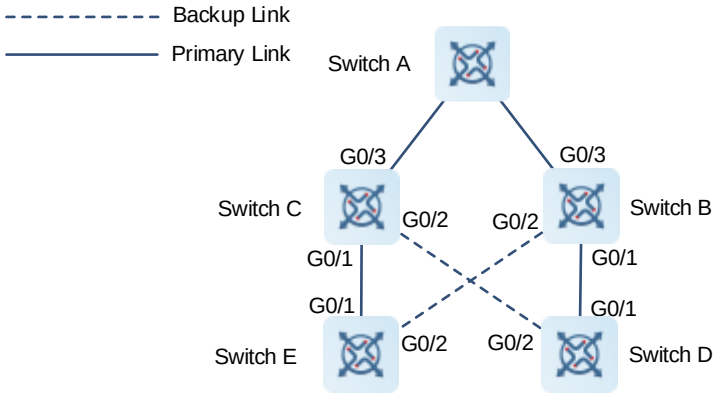
- Device E configuration file

```
hostname DeviceE
!
interface GigabitEthernet 0/1
 switchport mode trunk
 switchport backup interface gigabitethernet 0/2 prefer instance 2
!

end
```

7. Common Errors

- The mappings between VLAN IDs and instances are not configured.



1.9.4 Configuring Link State Tracking

1. Requirements

To improve network reliability and ensure continuity of services between the access device and the core device, two links are deployed between core device A and each of the access devices D and E, as shown in Figure 1-9To forcibly switch downlink transmission upon uplink faults and ensure normal transmission of service packets, the link tracking function must be enabled on devices B and C.

2. Topology

Figure 1-9 Topology for Configuring Link State Tracking

3. Notes

- Create link state tracking group 1 on Device B (Device C).
- On Device B (Device C), add the ports GigabitEthernet 0/1 and GigabitEthernet 0/2 as downlink ports of the link state tracking group and add the port GigabitEthernet 0/3 as an uplink port of the link state tracking group.

4. Procedure

Perform the following configuration on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# link state track 1
DeviceB(config)# interface GigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# link state group 1 downstream
DeviceB(config-if-GigabitEthernet 0/1)# exit
DeviceB(config)# interface GigabitEthernet 0/2
DeviceB(config-if-GigabitEthernet 0/2)# link state group 1 downstream
DeviceB(config-if-GigabitEthernet 0/2)# exit
DeviceB(config)# interface GigabitEthernet 0/3
DeviceB(config-if-GigabitEthernet 0/3)# link state group 1 upstream
```

Perform the following configuration on Device C.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# link state track 1
DeviceC(config)# interface GigabitEthernet 0/1
DeviceC(config-if-GigabitEthernet 0/1)# link state group 1 downstream
DeviceC(config-if-GigabitEthernet 0/1)# exit
DeviceC(config)# interface GigabitEthernet 0/2
DeviceC(config-if-GigabitEthernet 0/2)# link state group 1 downstream
DeviceC(config-if-GigabitEthernet 0/2)# exit
DeviceC(config)# interface GigabitEthernet 0/3
DeviceC(config-if-GigabitEthernet 0/3)# link state group 1 upstream
```

5. Verification

Run the **show link state group** command to check whether the link tracking group is created on Device B.

```
DeviceB# show link state group
Link State Group:1  Status: enabled, Down Mode: upstream
Upstream Interfaces :Gi0/3(Down)
Downstream Interfaces : Gi0/1(Down) Gi0/2(Down)

Link State Group:2  Status: Disabled, Down Mode: upstream
Upstream Interfaces :
Downstream Interfaces :

(Up):Interface up   (Down):Interface Down   (Dis):Interface disabled
```

Run the **show link state group** command to check whether the link tracking group is created on Device C.

```
DeviceC# show link state group
Link State Group:1  Status: enabled, Down Mode: upstream
Upstream Interfaces :Gi0/3(Down)
Downstream Interfaces : Gi0/1(Down) Gi0/2(Down)
```

```
Link State Group:2  Status: Disabled, Down Mode: upstream
Upstream Interfaces :
Downstream Interfaces:

(Up):Interface up   (Down):Interface Down   (Dis):Interface disabled
```

6. Configuration Files

- Device B configuration file

```
hostname DeviceB
!
link state track 1
interface GigabitEthernet 0/1
 link state group 1 downstream
!
interface GigabitEthernet 0/2
 link state group 1 downstream
!
interface GigabitEthernet 0/3
 link state group 1 upstream
!

end
```

- Device C configuration file

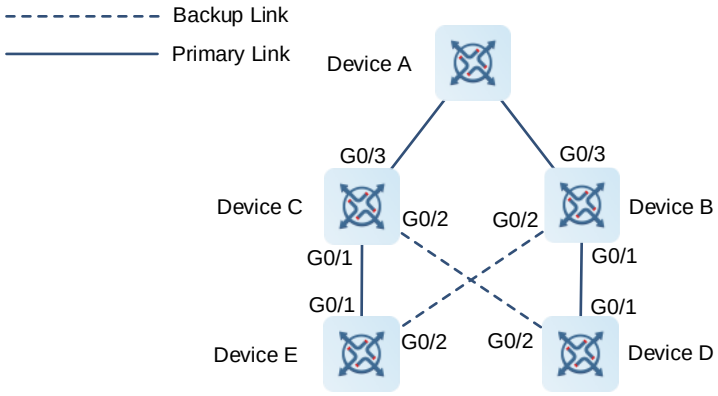
```
hostname DeviceC
!
link state track 1
interface GigabitEthernet 0/1
 link state group 1 downstream
!
interface GigabitEthernet 0/2
 link state group 1 downstream
!
interface GigabitEthernet 0/3
 link state group 1 upstream
!

end
```

7. Common Errors

- Ports are added to a link state tracking group before the link state tracking group is enabled.

1.9.5 Configuring Bidirectional Tracking



1. Requirements

As shown in Figure 1-10, to improve network reliability and ensure continuity of services between the access device and the core device when one link fails, deploy two links between core device A and each of access

devices D and E. To forcibly switch the uplink and downlink when the uplink and downlink fail respectively, and to ensure service packet transmission, configure bidirectional link tracking on Device B and Device C.

2. Topology

Figure 1-10 Topology of Link Tracking Configuration

3. Notes

- On Device B (C), create link state tracking group 1 and set the link tracking mode to bidirectional.
- On Device B (C), add GigabitEthernet 0/1, GigabitEthernet 0/2, and GigabitEthernet 0/3 to the link state tracking group.

4. Procedure

Perform the following configuration on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# link state track 1 mode bidirectional
DeviceB(config)# interface GigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# link state group 1 downstream
DeviceB(config-if-GigabitEthernet 0/1)# exit
DeviceB(config)# interface GigabitEthernet 0/2
DeviceB(config-if-GigabitEthernet 0/2)# link state group 1 downstream
DeviceB(config)# interface GigabitEthernet 0/3
DeviceB(config-if-GigabitEthernet 0/3)# link state group 1 upstream
```

Perform the following configuration on Device C.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# link state track 1 mode bidirectional
DeviceC(config)# interface GigabitEthernet 0/1
DeviceC(config-if-GigabitEthernet 0/1)# link state group 1 downstream
DeviceC(config-if-GigabitEthernet 0/1)# exit
```

```
DeviceC(config)# interface GigabitEthernet 0/2
DeviceC(config-if-GigabitEthernet 0/2)# link state group 1 downstream
DeviceC(config)# interface GigabitEthernet 0/3
DeviceC(config-if-GigabitEthernet 0/3)# link state group 1 upstream
```

5. Verification

Run the **show link state group** command to check whether the link state tracking group is correctly configured on Device B.

```
DeviceB# show link state group
Link State Group:1  Status: enabled, Down  Mode:bidirectional
Upstream Interfaces : Gi0/3(Down)
Downstream Interfaces : Gi0/1(Down) Gi0/2(Down)

Link State Group:2  Status: Disabled, Down  Mode:upstream
Upstream Interfaces :
Downstream Interfaces :

(Up):Interface up   (Down):Interface Down   (Dis):Interface disabled
```

Run the **show link state group** command to check whether the link state tracking group is correctly configured on Device C.

```
DeviceC# show link state group
Link State Group:1  Status: enabled, Down  Mode:bidirectional
Upstream Interfaces : Gi0/3(Down)
Downstream Interfaces : Gi0/1(Down) Gi0/2(Down)

Link State Group:2  Status: Disabled, Down Mode:upstream
Upstream Interfaces :
Downstream Interfaces :

(Up):Interface up   (Down):Interface Down   (Dis):Interface disabled
```

6. Configuration Files

- Device B configuration file

```
hostname DeviceB
!
link state track 1 mode bidirectional
interface GigabitEthernet 0/1
 link state group 1 downstream
!
interface GigabitEthernet 0/2
```

```
 link state group 1 downstream
!
interface GigabitEthernet 0/3
 link state group 1 upstream
!

end
```

- Device C configuration file

```
hostname DeviceC
!
link state track 1 mode bidirectional
interface GigabitEthernet 0/1
 link state group 1 downstream
!
interface GigabitEthernet 0/2
 link state group 1 downstream
!
interface GigabitEthernet 0/3
 link state group 1 upstream
!
end
```

7. Common Errors

Interfaces are added to a link state tracking group before the link state tracking group is enabled.

1.4.3 Configuring Bidirectional Link Detection 12

1 Configuring RLDP

1.1 Introduction

The Rapid Link Detection Protocol (RLDP) is an Ethernet link failure detection protocol, which is used to rapidly detect unidirectional link failures, bidirectional link failures, and downlink loop failures. When a failure is found, RLDP automatically shuts down relevant ports or asks users to manually shut down the ports according to the configured failure handling methods, to avoid wrong forwarding of traffic or Ethernet L2 loops.

1.1.1 Basic Concepts

1. Unidirectional Link Failure

A unidirectional link failure occurs when one end of the receiving or transmission link in an optical fiber is disconnected or not connected, one line in a twisted-pair cable is disconnected, or unidirectional disconnection occurs on an intermediate device between two devices. A unidirectional link failure can lead to wrong forwarding of traffic or the failure of a loop protection protocol such as Spanning Tree Protocol (STP).

2. Bidirectional Link Failure

A bidirectional link failure occurs when two optical fibers are disconnected, two lines in a twisted-pair cable are disconnected, or bidirectional disconnection occurs on an intermediate device between two devices. A bidirectional link failure can lead to the wrong forwarding of traffic.

3. Loop Failure

A loop failure occurs when a downlink port of a device is wrongly connected to another device and a loop forms. A loop failure can result in a broadcast storm.

4. VLAN Loop Failure

A VLAN loop failure occurs when all the interfaces in a link loop belong to the same VLAN, forming a loop on the VLAN and causing a broadcast storm. Because the allowed VLAN varies on different device interfaces, a VLAN loop failure may occur within certain VLANs, while traffic can be forwarded normally among other VLANs.

5. Protocol Packets

RLDP defines the following four types of packets:

- Probe packets: L2 multicast packets used for neighbor negotiation, and unidirectional or bidirectional link detection. The default encapsulation format of the packets is of the Subnetwork Access Protocol (SNAP) type, which automatically changes to EthernetII if a neighbor sends EthernetII packets.
- Echo packets: L2 unicast packets in response to probe packets and used for unidirectional or bidirectional link detection. The default encapsulation format is of the SNAP type, which automatically changes to EthernetII if a neighbor sends EthernetII packets.
- Loop packets: L2 multicast packets for downlink loop detection. They can only be received by senders. The default encapsulation format of the packets is of the SNAP type.
- VLAN loop packets (VLAN LOOP): RLDP VLAN loop packets are Layer 2 multicast packets used for VLAN loop detection. Such packets are received only by the sender and are encapsulated in the SNAP format. To

distinguish them from Loop packets, VLAN loop packets carry the VLAN tag.

6. Detection Interval

A detection interval and the maximum detection count can be configured for RLDP. A detection interval determines the period of sending probe packets and loop packets. When a device receives a probe packet, it replies with an echo packet immediately. A detection interval and the maximum detection count determine the maximum detection time (Detection interval x Maximum detection count + 1) for unidirectional or bidirectional link detection. If neither a probe nor an echo packet from a neighbor is correctly received within the maximum detection time, the handling of unidirectional or bidirectional failures is triggered. The timers involved are described in Table 1-1.

Table 1-1 Description of RLDP Timers

Timer Name	Timer Description
Send timer	After the link detection function is enabled, the send timer is started and the probe packets or loop packets are sent regularly. The time interval of the send timer is the configured detection interval.
Timeout timer	● If a unidirectional or bidirectional link failure is detected, the timeout timer is started after the probe packet is sent, and the timeout time is the maximum detection time (Detection interval x Maximum detection count + 1). ● In unidirectional link detection, when the detection timeout time expires and a port can only receive the probe packet or response packet from the neighbor, it is considered that a unidirectional link failure occurs. ● In bidirectional link detection, when the detection timeout time expires and a port fails to receive the probe packet and response packet from the neighbor, it is considered that a bidirectional link failure occurs.

7. Neighbor Negotiation

When configured with unidirectional or bidirectional link detection, a port can learn a peer device as its neighbor. One port can learn only one neighbor, which is changeable. If the negotiation function is enabled, unidirectional or bidirectional link detection starts after a port finds a neighbor through negotiation. Negotiation is considered successful if the port receives a probe packet from the neighbor. However, if RLDP is enabled on a port after a failure already occurs, the port fails to learn a neighbor and detection fails to be started. In this case, you are advised to rectify the link failure first.

8. Associated Actions

The associated actions and recovery methods after a RLDP port failure are described in Table 1-2.

Table 1-2 Description of RLDP Port Failure Handling

Type	Associated Action/ Recovery Method	Description
Associated actions after a	warning	Only the relevant system log is printed to indicate the failed port and the failure type.

Type	Associated Action/ Recovery Method	Description
failure	Shutdown SVI	A system log is printed. If the failed port is a Layer 2 Ethernet interface or member port of a Layer 2 link aggregation, a switch virtual interface (SVI) is queried based on the access VLAN or native VLAN of the port, and then the SVI is shut down.
	Port errdisable	A system log is printed, the failed port is set in errdisable state, and the port enters the linkdown state physically.
	Block	A system log is printed, the forwarding state of the failed port is set to blocked, and the port does not forward received packets.
	isolate-vlan	The loop VLAN is isolated in addition to printing a syslog, and the interface does not forward packets received from the isolated VLAN.
Recovery methods after a failure	Manual reset	Manually reset all the failed ports to the initialized state to restart link detection.
	Manual or automatic errdisable recovery	Recover all the failed ports to the initialized state manually or regularly (**30** seconds by default and configurable) and restart link detection.
	Automatic recovery	Under unidirectional or bidirectional link detection, if the handling method specified for failed ports does not enable the ports to enter the errdisable state, the ports can automatically recover to the initialized state based on probe packets exchanged with the neighbor, and link detection is restarted.

9. RLDP Port State

RLDP ports can be in two states:

- Normal: Indicates the state of a port, on which link detection is enabled.
- Error: Indicates the state of a port, on which a unidirectional or bidirectional link failure or a loop failure is detected.

1.1.2 Detection Principles

A typical Ethernet link detection mechanism detects physical link connectivity through auto-negotiation at the physical layer. However, this detection mechanism has limitations. In some cases, devices are connected and work normally at the physical layer but L2 link communication fails or is abnormal. RLDP recognizes a neighbor device and detects whether a link failure exists by exchanging probe packets, echo packets, or loop packets with the neighbor device. Figure 1-1 shows the protocol states.

Figure 1-1 RLDP Protocol State Diagram

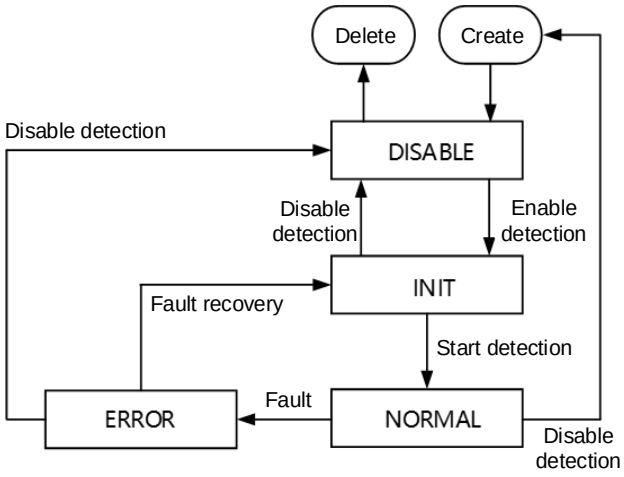

Figure 1-1 shows the detection logic of RLDP, which can be mainly in four states. The four states are described in Table 1-3.

Table 1-3 Description of RLDP States

State	Description
DISABLE	After the global RLDP function is enabled, all ports enter the disable state. Now, unidirectional link detection, bidirectional link detection, or downlink loop detection is not enabled on the ports. If the RLDP is disabled in any state, a port enters this state.
INIT	It refers to the initialized state after RLDP is just configured and enabled or a failure is rectified. Now, unidirectional link detection, bidirectional link detection, or downlink loop detection is enabled on ports, and the corresponding link failure handling methods are specified, or the links can recover from unidirectional failures, bidirectional failures, or loop failures automatically.
NORMAL	It refers to the state after detection is enabled for RLDP. For downlink loop detection, RLDP enters the state directly after enabled. For unidirectional or bidirectional link detection, RLDP enters the state directly or enters the state only after negotiation with a specified neighbor succeeds.
ERROR	It refers to the state after RLDP detects a failure. In this case, a unidirectional link failure or bidirectional link failure is detected on a port. The failure will be handled according to the specified failure handling method.

1.1.3 RLDP Detection

The RLDP link detection mode includes unidirectional and bidirectional link detection, downlink detection, and VLAN loop detection.

1. Unidirectional Link Detection

After unidirectional link detection is enabled, a port sends probe packets and receives echo packets from a neighbor regularly. It also receives probe packets from the neighbor and replies with echo packets to the neighbor. If the port receives only probe packets but no echo packets, or none of them from the neighbor within the maximum detection time, handling of a unidirectional failure is triggered and the detection stops.

2. Bidirectional Link Detection

After bidirectional link detection is enabled, a port sends probe packets and receives echo packets from a neighbor regularly. It also receives probe packets from the neighbor and replies with echo packets to the neighbor. If the port receives neither probe packets nor echo packets from the neighbor within the maximum detection time, handling of a bidirectional failure is triggered and the detection stops.

3. Downlink Loop Detection

After downlink loop detection is enabled, a port sends loop packets regularly. After the same port or different ports on a device receive loop packets, a loop failure is triggered if any of the following cases occurs: The transmission and receiving ports of the packets are the same Layer 3 Ethernet interfaces or member ports of a Layer 3 link aggregation; the transmission and receiving ports of packets are Layer 2 interfaces or member ports of a Layer 2 link aggregation, the default VLANs of the ports are the same, and forwarding states of the ports are forward. The failure is handled according to the corresponding method and the detection stops.

4. RLDP VLAN Loop Detection

After VLAN loop detection is enabled, the interface periodically sends loop detection packets. Different from RLDP downlink loop detection, this function periodically sends packets with a tag within the VLAN of the interface to check whether the packet returns to the device (the sending interface and receiving interface can be different) to determine whether there is a loop between the interface and the downstream network or device or between the two interfaces of the device. If a loop is detected in a VLAN, RLDP sets the interface into controlled state based on the user configuration and stops loop detection in this VLAN to lower the impact on the device and the network.

1.2 Configuring Basic Features of RLDP

1.2.1 Overview

- You can enable RLDP unidirectional link detection, bidirectional link detection, or downlink loop detection to discover unidirectional, bidirectional, or loop failures.
- After global RLDP detection is enabled, the RLDP detection is started on each port normally.
- After the function is enabled in global configuration mode, RLDP detection on a port is started after successful neighbor negotiation.
- If loop detection latency interval is configured in global configuration mode, the downlink port loop cannot be detected in this period of time.
- You can configure the RLDP function for interfaces, choose unidirectional, bidirectional, downlink loop detection, or VLAN loop detection, and specify the failure handling method.
- You can restore all the failed ports and restart detection.

1.2.2 Restrictions and Guidelines

- Loop detection configured on an aggregate interface member takes effect on all the members of the aggregate interface. Unidirectional link detection and bidirectional link detection take effect on an aggregate interface member interface directly.
- The loop detection configuration of a physical port added to an aggregate interface must be the same as that of the other member interfaces of the aggregate interface.
  - If loop detection is not configured on the new member interface but on the existing member interfaces, the new port adopts the configuration and detection results of the existing ports.
  - If the new member interface is configured with loop detection but the existing member interfaces are not configured with loop detection, the loop detection configuration of the new member interface will be deleted.
  - If the new member interface and the existing member interfaces have different loop detection configurations, the new interface adopts the configuration and detection results of the existing interfaces.
  - If the new member interface is configured with loop detection and the aggregate interface has no existing members, the loop detection configuration of the new member interface is retained.
- When configuring the RLDP on an aggregate interface member, you can configure only the "shutdown-port" and "warning" handling methods. If the failure handling method is not set to "shutdown-port" or "warning", it is modified to "shutdown-port" and takes effect.
- After the "shutdown-port" handling method is configured on a port, the port cannot resume RLDP detection in the case of a failure. After confirming that the failure is rectified, you can run the **rldp reset** or **errdisable recovery** command to restore the port and restart detection. For the description and configuration of **errdisable recovery**, see *Configuring Ethernet Interface*.
- After VLAN loop detection of RLDP is enabled on a switching port, the detection does not take effect on the native VLAN because the native VLAN usually carries service traffic.

1.2.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the global RLDP detection function.

rldp enable

The global RLDP detection function is disabled by default.

(4) (Optional) Configure global neighbor negotiation.

rldp neighbor-negotiation

The neighbor negotiation function is disabled by default.

(5) (Optional) Configure the global RLDP detection interval.

rldp detect-interval *interval*

The default interval for sending RLDP packets by a port is **3** seconds.

(6) (Optional) Configure a time interval for RLDP to recover failed ports.

rldp error-recover interval *interval*

No time interval for RLDP to recover failed ports regularly is configured by default.

(7) (Optional) Configure the maximum detection count of RLDP.

rldp detect-max *max-detect-num*ber

The default maximum detection count of RLDP is **2**.

(8) (Optional) Configure the global loop detection latency interval.

rldp detect-latency *interval*

The default latency interval for global RLDP loop detection is **0** seconds.

(9) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode

  interface aggregateport *interface-number*

- Enter the Layer 3 aggregate interface configuration mode

  interface aggregateport *interface-number*

(10) Configure RLDP detection on the port.

rldp port { **bidirection-detect** | **loop-detect** | **unidirection-detect** } { **block** | **shutdown-port** | **shutdown-svi** | **warning** }

RLDP detection is not configured on a port by default.

(11) Configure RLDP VLAN loop detection for the port.

rldp port vlan-loop-detect { **isolate-vlan** | **warning** } **vlan** *vlan-list*

RLDP VLAN loop detection is not configured for the port by default.

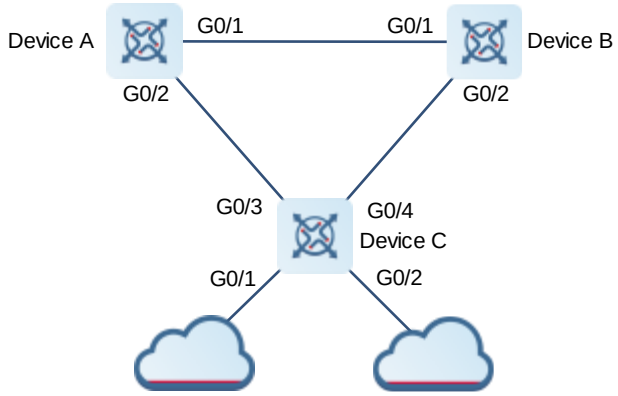
1.3 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-4 RLDP Monitoring

Command	Purpose
show rldp [**interface** *interface-type interface-number*]	Displays the RLDP running state.

1.4 Configuration Examples



1.4.1 Configuring Basic Features of RLDP

1. Requirements

Aggregation and access use a ring network topology. STP is enabled for all devices on the ring network to prevent loops and provide redundancy protection. To prevent unidirectional or bidirectional link faults in the loop which may invalidate the STP protocol, enable unidirectional and bidirectional RLDP detection between aggregation devices and between aggregation devices and access devices. To prevent loops caused by incorrect downlink connections of aggregation devices, enable RLDP downlink loop detection or VLAN-based loop detection for the downlink interfaces of aggregation and access devices. To prevent loops caused by incorrect downlink connections of access devices, enable RLDP downlink loop detection or VLAN-based loop detection for the downlink interfaces of access devices.

2. Topology

Figure 1-2 Topology for Configuring Basic Features of RLDP

3. Notes

- Devices A and B are aggregation devices, and device C is an access device. User devices can be connected to downlink ports of device C. Devices A, B, and C are structured in a ring topology, and STP is enabled on each of them. For STP configuration, refer to the relevant configuration guide.
- Enable RLDP on device A, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port.
- Enable RLDP on device B, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port.
- Enable RLDP on device C, enable unidirectional and bidirectional link detection on the two uplink ports, and enable loop detection on the two downlink ports.

4. Procedure

Perform the following configuration on device A.

```
DeviceA# configure terminal
DeviceA(config)# rldp enable
DeviceA(config)# interface GigabitEthernet 0/1
```

```
DeviceA(config-if-GigabitEthernet 0/1)# rldp port unidirection-detect shutdown-port
DeviceA(config-if-GigabitEthernet 0/1)# rldp port bidirection-detect shutdown-port
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface GigabitEthernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# rldp port unidirection-detect shutdown-port
DeviceA(config-if-GigabitEthernet 0/2)# rldp port bidirection-detect shutdown-port
DeviceA(config-if-GigabitEthernet 0/2)# rldp port loop-detect shutdown-port
```

Perform the following configuration on device B.

```
DeviceB# configure terminal
DeviceB(config)# rldp enable
DeviceB(config)# interface GigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# rldp port unidirection-detect shutdown-port
DeviceB(config-if-GigabitEthernet 0/1)# rldp port bidirection-detect shutdown-port
DeviceB(config-if-GigabitEthernet 0/1)# exit
DeviceB(config)# interface GigabitEthernet 0/2
DeviceB(config-if-GigabitEthernet 0/2)# rldp port unidirection-detect shutdown-port
DeviceB(config-if-GigabitEthernet 0/2)# rldp port bidirection-detect shutdown-port
DeviceB(config-if-GigabitEthernet 0/2)# rldp port loop-detect shutdown-port
```

Perform the following configuration on device C.

```
DeviceC# configure terminal
DeviceC(config)# rldp enable
DeviceC(config)# interface GigabitEthernet 0/3
DeviceC(config-if-GigabitEthernet 0/3)# rldp port unidirection-detect shutdown-port
DeviceC(config-if-GigabitEthernet 0/3)# rldp port bidirection-detect shutdown-port
DeviceC(config-if-GigabitEthernet 0/3)# exit
DeviceC(config)# interface GigabitEthernet 0/4
DeviceC(config-if-GigabitEthernet 0/4)# rldp port unidirection-detect shutdown-port
DeviceC(config-if-GigabitEthernet 0/4)# rldp port bidirection-detect shutdown-port
DeviceC(config-if-GigabitEthernet 0/4)# exit
DeviceC(config)# interface GigabitEthernet 0/1
DeviceC(config-if-GigabitEthernet 0/1)# rldp port loop-detect shutdown-port
DeviceC(config-if-GigabitEthernet 0/1)# exit
DeviceC(config)# interface GigabitEthernet 0/2
DeviceC(config-if-GigabitEthernet 0/2)# rldp port loop-detect shutdown-port
```

5. Verification

Check the RLDP state information on devices, A, B, and C. Device A is taken as an example. Run the **show rldp** command to check whether the configuration is correct.

```
DeviceA# show rldp
rldp state         : enable
rldp hello interval: 3
rldp max hello     : 2
rldp local bridge  : 00d0.f822.33aa
------------------------------------
Interface GigabitEthernet 0/1
```

```
port state      : normal
neighbor bridge : 00d0.f800.51b1
neighbor port   : GigabitEthernet 0/1
unidirection detect information:
    action: shutdown-port
    state : normal
bidirection detect information:
    action: shutdown-port
    state : normal

Interface GigabitEthernet 0/2
port state      : normal
neighbor bridge : 00d0.f800.41b0
neighbor port   : GigabitEthernet 0/3
unidirection detect information:
    action: shutdown-port
    state : normal
bidirection detect information:
    action: shutdown-port
    state : normal
loop detect information:
    action: shutdown-port
    state : normal
```

6. Common Errors

- RLDP is enabled together with private multicast address authentication or TPP.
- Neighbor negotiation is not enabled when unidirectional or bidirectional link detection is configured. RLDP must be enabled on a neighbor device in global or interface configuration mode; otherwise a unidirectional or bidirectional failure is detected.
- If neighbor negotiation prior to RLDP detection is specified when unidirectional or bidirectional link detection is configured, normal detection fails because no neighbor is learned in the case of an existing link failure. In this situation, you are advised to rectify the link failure first.
- You are not advised to specify Shutdown SVI as the failure handling method on a Layer 3 interface.
- You are not advised to specify Block as the failure handling method for a port, on which a loop protection protocol such as STP is enabled.
- Ensure that the VLAN is an allowed VLAN of other interfaces when enabling loop detection for it. Otherwise, VLAN loop detection packets cannot be forwarded, causing VLAN loop detection to fail.

1.4.2 Configuring Unidirectional Link Detection

1. Requirements

As shown in Figure 1-3, device A is connected to device B through an optical fiber. The two lines are the Tx and Rx lines of the optical fiber. Unidirectional link detection is enabled on devices A and B. If a fault occurs on either the Tx end of device A or Rx end of device B or on either the Rx end of device A or Tx end of device B, RLDP

can detect the unidirectional failure and handle it. If the failure is eliminated, the administrator can manually restore the RLDP state on devices A and B and restart detection.

2. Topology

Figure 1-3 Topology for Configuring Unidirectional Link Detection

3. Notes

- Enable global RLDP on Device A and Device B.
- Configure unidirectional link detection of RLDP on ports and define a method for handling unidirectional failures on Device A and Device B.

4. Procedure

Perform the following configuration on device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# rldp enable
DeviceA(config)# interface GigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# rldp port unidirection-detect shutdown-port
```

Perform the following configuration on device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# rldp enable
DeviceB(config)# interface GigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# rldp port unidirection-detect shutdown-port
```

5. Verification

Check the RLDP state information on device A.

```
DeviceA> enable
DeviceA# show rldp
rldp state        : enable
rldp hello interval: 3
rldp max hello    : 2
rldp local bridge  : 00d0.f822.33aa
-----------------------------------
Interface GigabitEthernet 0/1
port state     : normal
neighbor bridge : 00d0.f800.51b1
neighbor port   : GigabitEthernet 0/1
unidirection detect information:
    action: shutdown-port
```

```
    state : normal
```

Check the RLDP state information on device B.

```
DeviceB> enable
DeviceB# show rldp
rldp state        : enable
rldp hello interval: 3
rldp max hello    : 2
rldp local bridge  : 00d0.f800.51b1
----------------------------------
Interface GigabitEthernet 0/1
port state     : normal
neighbor bridge : 00d0.f822.33aa
neighbor port   : GigabitEthernet 0/1
unidirection detect information:
    action: shutdown-port
    state : normal
```

6. Common Errors

- Global RLDP is not enabled at the local end or peer end.
- The unidirectional link detection function is not configured on the interface of the local or peer end.
- The RLDP detection method configured at the local end is inconsistent with that at the peer end.
- RLDP negotiation is not enabled, so a link failure is judged by mistake when unidirectional link detection of RLDP is configured at a single end.

1.4.3 Configuring Bidirectional Link Detection

1. Requirements

As shown in Figure 1-4, device A is connected to device B through an optical fiber. The two lines are the Tx and Rx lines of the optical fiber. Bidirectional link detection is enabled on devices A and B. If a fault occurs on the Tx end of device A and Rx end of device B or on the Rx end of device A and Tx end of device B, RLDP can detect a bidirectional failure and handle it. If the failure is eliminated, the administrator can manually restore the RLDP state on devices A and B and restart detection.

2. Topology

Figure 1-4 Topology for Configuring Bidirectional Link Detection

3. Notes

- Enable global RLDP on Device A and Device B.
- Configure bidirectional link detection of RLDP on ports and define a method for handling bidirectional failures on Device A and Device B.

4. Procedure

Perform the following configuration on device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# rldp enable
DeviceA(config)# interface GigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# rldp port bidirection-detect shutdown-port
```

Perform the following configuration on device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# rldp enable
DeviceB(config)# interface GigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# rldp port bidirection-detect shutdown-port
```

5. Verification

Check the RLDP state information on device A.

```
DeviceA> enable
DeviceA# show rldp
rldp state       : enable
rldp hello interval: 3
rldp max hello    : 2
rldp local bridge  : 00d0.f822.33aa
----------------------------------
Interface GigabitEthernet 0/1
port state     : normal
neighbor bridge : 00d0.f800.51b1
neighbor port   : GigabitEthernet 0/1
bidirection detect information:
    action: shutdown-port
    state : normal
```

Check the RLDP state information on device B.

```
DeviceB> enable
DeviceB# show rldp
rldp state       : enable
rldp hello interval: 3
rldp max hello    : 2
rldp local bridge  : 00d0.f800.51b1
----------------------------------
Interface GigabitEthernet 0/1
port state     : normal
neighbor bridge : 00d0.f822.33aa
neighbor port   : GigabitEthernet 0/1
bidirection detect information:
    action: shutdown-port
```

```
    state : normal
```

6. Common Errors

- Global RLDP is not enabled at the local end or peer end.
- The unidirectional link detection function is not configured on the interface of the local or peer end.
- The RLDP detection method configured at the local end is inconsistent with that at the peer end.
- If bidirectional link detection needs to be configured but RLDP negotiation is not enabled, a link failure will be detected at one end.

1 Configuring DLDP

The Data Link Detection Protocol (DLDP) achieves rapid detection of Ethernet link failures. A typical Ethernet link detection mechanism detects physical link connectivity through auto-negotiation at the physical layer. However, such a mechanism has limitations in L3 data connectivity detection, for example, the physical connection is normal but L3 data communication is abnormal. DLDP provides reliable L3 link detection information. After detecting a faulty link, DLDP disables the logical function of L3 ports to realize fast L3 protocol convergence.

1.1 Introduction

1.1.1 Basic Concepts

1. Detection Mode

Active mode and passive mode are two DLDP detection modes.

- Active mode (default): In this mode, Internet Control Message Protocol (ICMP) detection packets are sent actively.
- Passive mode: In this mode, ICMP detection packets are received passively. Namely, DLDP returns an ICMP reply packet upon receiving an ICMP echo packet, instead of actively sending ICMP echo packets to the peer end. It judges whether an ICMP echo packet is received within a specified period to determine whether the link to the peer port is faulty. This mode not only implements the function of detecting link connectivity for the both devices, but also saves the bandwidth resources and device CPU resources.

DLDP IPv4 and DLDP IPv6 always use the same detection mode.

2. Inter-Network Segment Detection

If DLDP needs to check whether an IP address in a network segment that is not directly connected is reachable, the next-hop IP address of the interface must be configured, so DLDP IPv4 can obtain the next-hop MAC address through ARP packets, and DLDP IPv6 can obtain the next-hop MAC address through ND packets and correctly encapsulate and send ICMP packets. In this situation, however, you need to avoid receiving an ICMP reply packet from another link; otherwise, DLDP misjudges that the port does not receive an ICMP reply.

3. Detection Time

When a network device does not receive a reply packet from the peer end within the period of the detection interval multiplied by the number of retransmission times, the device determines that an L link failure occurs and actively shuts down the logical function of its L3 port (despite the physical link reachable). Once the L3 link connectivity recovers, the device restores the logical function of the L3 port.

- Detection interval: Indicates the interval at which DLDP detection packets (ICMP echo) are transmitted.
- Retransmission times: Indicates the maximum number of times that DLDP detection packets can be retransmitted after a DLDP detection failure occurs.

4. Recovery Times

A detected link may be unstable, for example, the link can be pinged through only intermittently. The results of single DLDP detection are that the link is up/ down multiple times, which further destabilizes the ring network.

The term recovery times indicates the number of times that DLDP needs to receive reply packets consecutively before a link switches from the down state to up state. The default number of recovery times is 3, that is, a link can be pinged successfully three times before it is set to up. The recovery times configuration reduces link detection sensitivity but increases stability. Related parameters can be adjusted according to the network condition.

1.1.2 DLDP Detection

When detecting that an L3 link is abnormal, DLDP actively shuts down the Layer 3 interfaces. After the DLDP function is enabled, DLDP IPv4 obtains the MAC address and egress interface of the detected device or the next-hop device for reaching the detected device from ARP packets, and DLDP IPv6 does it from ND packets and performs pathway detection through periodic IPv4 ICMP Echo packets. If DLDP does not receive an IPv4 ICMP reply packet from the detected device within a specified period, DLDP determines that the link is abnormal and sets the L3 port to down. You can configure the next-hop IP address, MAC address of the detected device, transmission interval, number of retransmission times, and number of recovery times based on the actual environment to enable the DLDP detection function.

1.1.3 MAC Address Binding

In a complex network environment, DLDP may obtain an invalid MAC address if abnormal ARP packets are transmitted (due to ARP spoofing) in the detected link. As a result, DLDP fails to conduct detection normally. To address this problem, you can bind the to-be-detected IP address (or the next-hop IP address) to the MAC address of the device to avoid a DLDP failure caused by ARP spoofing. After binding, DLDP sends ARP packets and ICMP packets with a fixed destination IP address and a fixed destination MAC address during detection. If the source IP address and MAC address in a received packet do not match the bound IP address and MAC address, DLDP does not process the packet.

1.2 Configuring DLDP Detection

1.2.1 Overview

DLDP detects L3 link connectivity. When an L3 link is abnormal, DLDP shuts down the related Layer 3 interfaces.

1.2.2 Restrictions and Guidelines

- To configure the DLDP function, configure the next-hop IP address, MAC address, transmission interval, retransmission times, and recovery times based on the actual environment. You are not advised to set the number of retransmission times and the number of recovery times to 1. You are advised to use the default value for the transmission interval. The number of DLDP sessions and the configured CPU protect policy (CPP) bandwidth must be considered when you adjust the value. Otherwise, the device performance consumption increases and misjudgment and flapping can be caused easily. In the case of more than 10 sessions, the recommended interval is not smaller than 100 ticks.
- DLDP can detect multiple IP addresses configured on an L3 port. DLDP sets the port to down when none of

the IP addresses returns an ICMP reply. If one of the IP addresses resumes communication, DLDP sets the port to up.

- DLDP uses the first IP address of the L3 port as the source IP address of detection packets.

1.2.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the VLAN interface configuration mode.

  interface vlan *interface-numbe*

(4) Enable DLDP detection.

dldp { *ipv4-address* [*next-hop-ipv4-address*] | *ipv6-address* [*next-hop-ipv6-address*] } [**mac-address** *mac-address*] [**interval** *tick-interval*] [**resume** *resume-number*] [**retry** *retry-number*]

By default, the number of retransmission times of DLDP detection is **4**, the number of recovery times is **3**, and the detection interval is **1** second.

(5) (Optional) Configure a DLDP detection mode.

dldp passive

The default DLDP detection mode is active mode.

This configuration takes effect on both DLDP IPv4 and DLDP IPv6.

(6) Exit the global configuration mode.

exit

(7) (Optional) Configure a global detection interval for DLDP detection.

dldp interval *tick-interval*

The default global detection interval of DLDP detection is **1** second.

This configuration takes effect immediately for the detection interval of all DLDP detections (DLDP IPv4 and DLDP IPv6).

(8) (Optional) Configure the number of global retransmission times for DLDP detection.

dldp retry *retry-number*

The default number of global retransmission times of DLDP detection is **4**.

This configuration takes effect immediately for the number of retries of all DLDP detections (DLDP IPv4 and DLDP IPv6).

(9) (Optional) Configure the number of link recovery times for all DLDP detection operations.

dldp resume *resume-number*

The default number of link recovery times of all DLDP detection operations is **3**.

This configuration takes effect immediately for the number of link recovery times of all DLDP detections (DLDP IPv4 and DLDP IPv6).

1.3 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

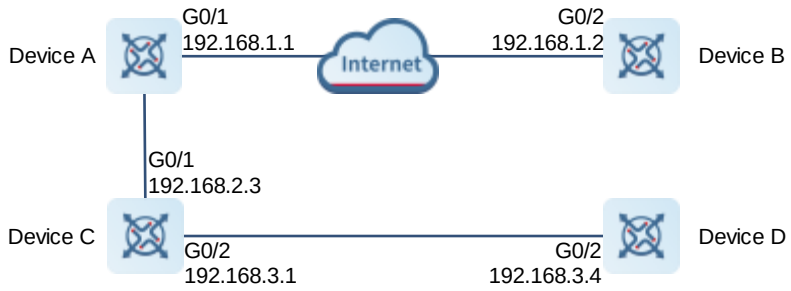
Caution

Running the **clear** command during operation of the device may lose vital information and interrupt services.

Table 1-1 DLDP Monitoring

Command	Purpose
clear dldp [**interface** *interface-type interface-number* [*ipv4-address* | *ipv6-address*]]	Clears the statistics on link up/down counts of a DLDP monitoring point.
show dldp [**ipv6**] [**interface** *interface-type interface-number*]	Displays the configuration of a DLDP monitoring point.
show dldp [**pv6**] [**interface** *interface-type interface-number*] [**statistic**]	Displays the statistics of a DLDP monitoring point.

1.4 Configuration Examples



1.4.1 Configuring DLDP IPv4 Detection

1. Requirements

DLDP detection needs to be enabled on an L3 network to control the Layer 3 interfaces of devices A and B.

2. Topology

Figure 1-1 DLDP Topology

3. Notes

- Enable DLDP detection on the Layer 3 interfaces (GigabitEthernet 0/1 and GigabitEthernet 0/2) on device A to detect the L3 network connectivity from device A to device B and from device A to device D.
- To control the Layer 3 interfaces (GigabitEthernet 0/2) of device B, enable DLDP detection and configure passive mode on the port.

4. Procedure

Perform the following configuration on device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no switchport
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# dldp 192.168.1.2
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# no switchport
DeviceA(config-if-GigabitEthernet 0/2)# ip address 192.168.2.1 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/2)# dldp 192.168.3.4 192.168.2.3
```

Perform the following configuration on device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# interface gigabitethernet 0/2
DeviceB(config-if-GigabitEthernet 0/2)# no switchport
DeviceB(config-if-GigabitEthernet 0/2)# ip address 192.168.1.2 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/2)# dldp 192.168.1.1
DeviceB(config-if-GigabitEthernet 0/2)# dldp passive
```

5. Verification

Run the **show dldp** command to check the DLDP state information on devices A and B and check whether DLDP detection is enabled and works normally.

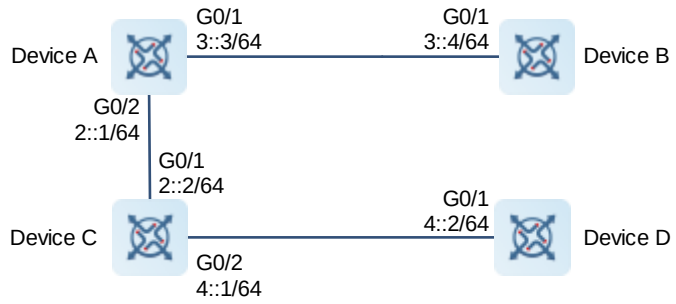
```
DeviceA# show dldp
```

```
Interface  Type        Ip       Next-hop    Interval  Retry  Resume  State
---------  -------  -----------  -----------  --------  -----  ------  ------
Gi0/1      Active   192.168.1.2  0.0.0.0       100       4      3       Up
Gi0/1      Active   192.168.3.4  192.168.2.3   100       4      3       Up
```

```
DeviceB# show dldp
Interface  Type        Ip       Next-hop    Interval  Retry  Resume  State
---------  -------  -----------  -----------  --------  -----  ------  ------
Gi0/2      Passive  192.168.1.1   0.0.0.0       100       4      3       Up
```

6. Common Errors

- An unreachable IPv4 unicast route is misjudged as a DLDP detection failure.
- DLDP detection fails because the peer device does not support ARP/ICMP replies.
- No next-hop IPv4 address is configured for inter-network segment DLDP detection.



1.4.2 Configuring DLDP IPv6 Detection

1. Requirements

DLDP detection needs to be enabled on an L3 network to control the Layer 3 interfaces of devices A and B.

2. Topology

Figure 1-2 DLDP IPv6 topology

3. Notes

- Enable DLDP detection on the Layer 3 interfaces (GigabitEthernet 0/1 and GigabitEthernet 0/2) on device A to detect the L3 network connectivity from device A to device B and from device A to device D.
- To control the Layer 3 interfaces (GigabitEthernet 0/1) of device B, enable DLDP detection and configure passive mode on the port.

4. Procedure

Perform the following configuration on device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# dldp 3::4
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# dldp 4::2 2::2
```

Perform the following configuration on device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# dldp 3::3
DeviceB(config-if-GigabitEthernet 0/1)# dldp passive
```

5. Verification

Run the **show dldp** command to check the DLDP state information on devices A and B and check whether DLDP detection is enabled and works normally.

```
DeviceA# show dldp
Interface  Type        Ipv6       Next-hop    Interval  Retry  Resume  State
---------  -------  -----------  -----------  --------  -----  ------  ------
Gi0/1      Active   3::4         ::     100      4     3      Up
Gi0/1      Active   4::2       2::2     100      4     3      Up
```

```
DeviceB# show dldp
Interface  Type        Ip       Next-hop    Interval  Retry  Resume  State
---------  -------  -----------  -----------  --------  -----  ------  ------
Gi0/1      Passive  3::3       ::       100      4     3      Up
```

6. Common Errors

- An unreachable IPv6 unicast route is misjudged as a DLDP detection failure.
- DLDP detection fails because the peer device does not support ARP/ICMPv6 replies.
- No next-hop IPv6 address is configured for inter-network segment DLDP detection.

1.6.1 Connecting to an IP Network in Dual-Homing Mode 16

1 Configuring M-LAG

Caution

This function is released under control. To avoid performance deterioration and data loss, contact technical support and deploy this function under the guidance of technical support.

1.1 Introduction

The multi-chassis link aggregation group (M-LAG) technology enables two devices supporting link aggregation to form a dual-active system, which is equivalent to one device. The equivalent device and the downlink device are interconnected through an aggregate interface. Deploying M-LAG improves the link reliability to the device level to meet the requirements of high availability scenarios.

1.1.1 Basic Concepts

Figure 1-1 M-LAG Topology

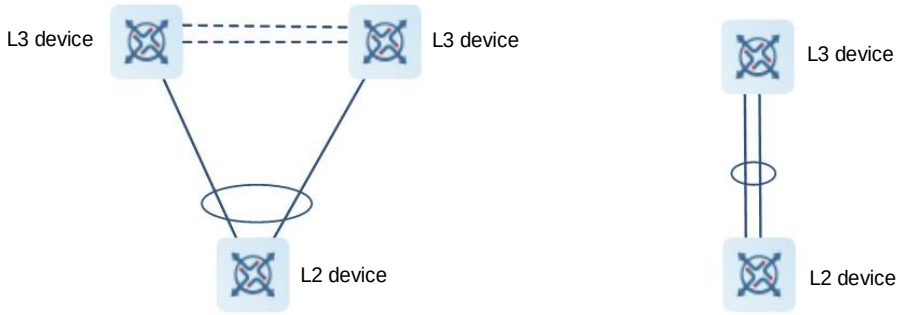

Figure 1-1 shows the M-LAG topology. Another similar technology is virtual switching unit (VSU), which also virtualizes multiple devices into one. M-LAG features the following advantages compared with the VSU topology.

- Stacking is discarded and only Layer 2 virtualization is required. The two devices are still independent of each other. M-LAG reduces deployment difficulties and eliminates shortcomings brought by device stacking (for example, the software failure of the master device may make both devices unavailable).
- Devices can be upgraded independently without affecting the normal operation of the other device.

1. Domain ID

A domain ID is the unique identifier of an M-LAG system and distinguishes different M-LAG systems. Only two devices that share the same domain ID can compose an M-LAG system. At present, only one domain can be configured for one device, and only two devices can be configured in one domain.

2. VAP

On the two devices of M-LAG, a pair of link aggregations connected to the same access device form a virtual aggregate interface group (also known as VAP), which allows an access device to connect in dual-homing

mode. Different access devices connect to different VAPs. Only Layer 2 link aggregations are supported in a VAP.

When the Link Aggregation Control Protocol (LACP) is enabled on the two link aggregations of a VAP, the same LACP system ID and system priority are used in LACP negotiation. For the uplink devices of an access device, the M-LAG dual devices are logicallyone device.

Note

Only Layer 2 link aggregations are supported in a VAP.

3. Peer Link

The link between two devices of M-LAG is called a peer-link, which is used to synchronize data and transmit some traffic. The directly connected ports at both ends of a peer-link are called peer-linkpeer-link interfaces, which must be configured as Layer 2 link aggregations. To improve the reliability of the peer-link, you are advised to deploy multiple physical links for the peer-link. For chassis devices, deploy multiple physical ports on different cards to reduce the impact of a card failure.

To enhance the reliability of data transmission between M-LAG devices, use Transmission Control Protocol (TCP) for synchronous data transmission. You need to configure a switch virtual interface (SVI) on the peer-link and configure Layer 3 reachability between the master and slave devices of M-LAG to achieve data synchronization between the devices.

4. Device Role

During normal operation, the two M-LAG devices negotiate to decide the master and slave roles. Normally, both the master and slave devices participate in forwarding and there is no difference between them. When a fault occurs, the behaviors of the master and slave devices are different. For example, if the peer-link gets faulty and the VAP of the two devices fails, service ports on the slave device need to be shut down and traffic needs to be forcibly switched to the master device, to prevent abnormal forwarding of the access device.

5. VAP Member Port

An aggregate interface joining a VAP is called a VAP member port, which is used to connect to an aggregate interface of an access device. You are advised to use LACP to enhance reliability.

6. Dual-Active Detection Link

A dual-active detection link is a Layer 3 path, which is used to detect the dual-active state of M-LAG devices in case of a peer-link failure. To ensure real-time detection, the dual-active detection link does not participate in any forwarding. You are advised to configure a separate Layer 3 reachable link as a dual-active detection link (for example, configure the directly connected link between the management ports of two devices as a dual-active detection link).

7. Heartbeat Hold Time

When the peer-link fails, both devices start the heartbeat hold timer, and waits for the packet of the keepalive mechanism on the dual-active detection link to be ready. After the timer expires, the devices start the dual-active detection to prevent error detection due to a packet delay.

8. Domain Negotiation Timeout Time

The VAPs on the two M-LAG devices use the same LACP system ID and system priority. When the devices are just started, VAP member ports start LACP negotiation only after M-LAG negotiation succeeds and the LACP system ID and system priority are obtained. However, if the peer device is powered off, the negotiation fails all the time, causing the local VAP member port to fail. Therefore, you need to set negotiation timeout time. After the timeout time expires, the local device is deemed to work in the standalone state, and the LACP system ID and system priority of the local device are directly used to perform LACP negotiation.

9. Fast Convergence Mode

Fast convergence mode refers to unidirectional isolation without blocking unicast packets. When a VAP member port recovers from a failure, the MAC entry egress of the uplink port switches from the peer-linkpeer-link interface to the VAP member port. However, when there are many MAC entries, some traffic sent to the access device continues to use the peer-linkpeer-link interface during the switching. Due to the anti-loop mechanism of the M-LAG system, the peer device enables unidirectional isolation (the peer-linkpeer-link interface does not forward packets to the downlink port), resulting in traffic interruption. To implement fast convergence, you can configure not to block unicast packets during unidirectional isolation, but this may cause the downlink access device to receive duplicate packets. For example, device 1 and device 2 form an M-LAG system according to M-LAG configuration. The request packet of a downlink device is forwarded by device 1. At this moment, device 1 learns the MAC entry of the downlink device, but has not synchronized it to device 2. If the reply packet is forwarded by device 2, device 2 floods the packet in the VAP member port and peer-linkpeer-link interface. After receiving the packet from the peer-linkpeer-link interface, device 1 searches for the MAC address of the downlink device in the MAC address table, and also forwards the packet through the VAP member port. Now, the downlink device receives two duplicate reply packets.

Enabling the fast convergence mode accelerates the convergence for failure recovery, but there may be instantaneous duplicate packets. If you do not want duplicate packets in some scenarios, disable the fast convergence mode.

1.1.2 M-LAG System Negotiation

The basis of M-LAG application is that two devices pair with each other to form a system and provide the inter-device aggregation capability. The process is as follows:

1. System Pairing

After the domain ID, peer-link, and peer-link-based Layer 3 channel are configured for the two M-LAG devices, the devices synchronize the domain ID with each other through the Layer 3 channel. After receiving a synchronization message, a device checks whether the domain ID is consistent with its local domain ID. If yes, the two devices pair with each other successfully.

2. Master/Slave Negotiation

After successful pairing, the two devices synchronize the system MAC address and M-LAG priority with each other, and compare their M-LAG priorities and system MAC addresses to elect the master and slave roles. The devices first compare their priorities. The device with a higher priority is elected as the master device, and the device with a lower priority becomes the slave device. If their priorities are the same, they compare their MAC addresses. The device with a smaller MAC address is elected as the master device, and the device with a larger MAC address becomes the slave device.

The LACP system ID and LACP system priority of the master device are selected as the LACP system ID and system priority of the M-LAG VAP. The LACP system ID and system priority are used when Layer 2 link aggregations in a VAP perform LACP negotiation.

Caution

When both the master and slave devices operate properly, packet forwarding is the same on them. However, packet forwarding is different on them in failure scenarios. For example, when the peer-link is faulty, the VAP between the two devices fails. To avoid abnormal forwarding of traffic from the access device, the service ports on the slave device are shut down to switch traffic to the master device.

3. Forwarding Entry Synchronization

After successful M-LAG negotiation, the two devices synchronize forwarding entries mutually such as MAC entries and ARP entries, to ensure that the forwarding function of the dual-active system is consistent.

4. Dual-Active Detection

After M-LAG runs properly, heartbeat packets are sent periodically between the two devices to detect availability of the dual-active link. When a dual-active link failure is detected, if the peer-link works properly, a prompt is displayed, reminding you to check the dual-active link.

When the peer-link is faulty, the devices send dual-active detection packets to each other.

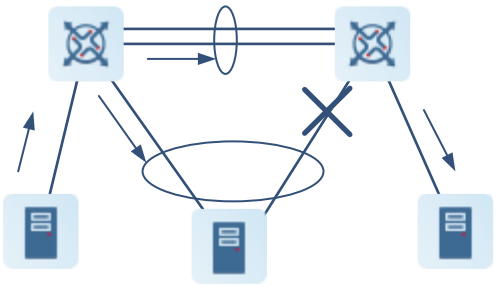
- If a device receives a detection response packet, dual master devices exist, and the service ports (the ports other than MGMT ports, peer-linkpeer-link interfaces, and stacked ports) on the slave device are forced to enter the errdisable down state. To exempt a port from the errdisable down state, you can configure it as an excluded port, for example, the port used for dual-active detection.
- If no detection response packet is received, the peer device is faulty. If the local device is the slave device, it becomes the master device. If the local device is the master device, it does not take any actions.
- When the peer-link recovers from the failure, the ports in the errdisable down state on the slave device recover immediately. However, because there may be a lot of protocols, it takes a certain period of time to complete convergence. During this period of time, the VAP member port is set to the up state in advance, which leads to a traffic forwarding failure and traffic interruption. Therefore, you can configure a delay for the port recovery so that the VAP member port recovers after the delay time expires.

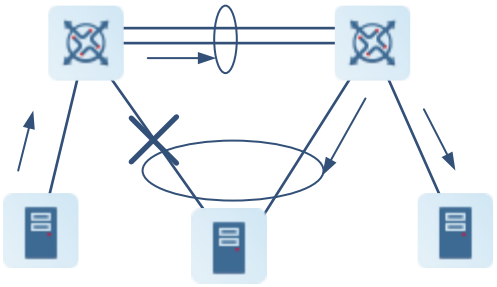
1.1.3 Anti-Loop Mechanism

When an access device connects to a network through M-LAG in dual-homing mode, the two aggregate interfaces of the VAP are distributed on two independent devices, and independent forwarding by the two aggregate interfaces may result in a loop or receiving of two copies of packets. M-LAG anti-loop rules are as follows:

- When the peer VAP member port works properly, traffic from the peer-link is not forwarded to the local VAP member port, as shown in Figure 1-2.
- When the peer VAP member port fails, traffic from the peer-link needs to be forwarded to the local VAP member port, as shown in Figure 1-3.

Figure 1-2 Peer Link Loop Prevention





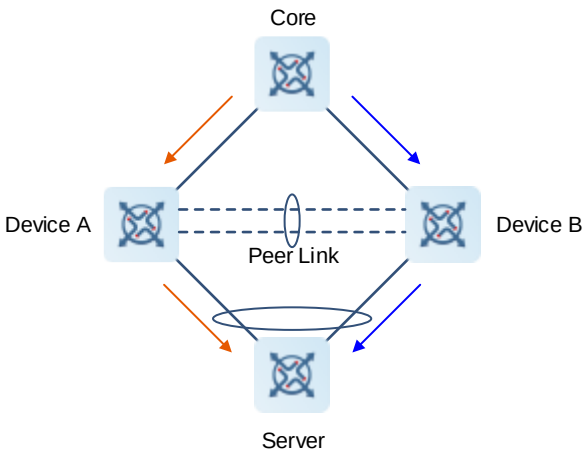


Figure 1-3 Peer Link Loop Removal

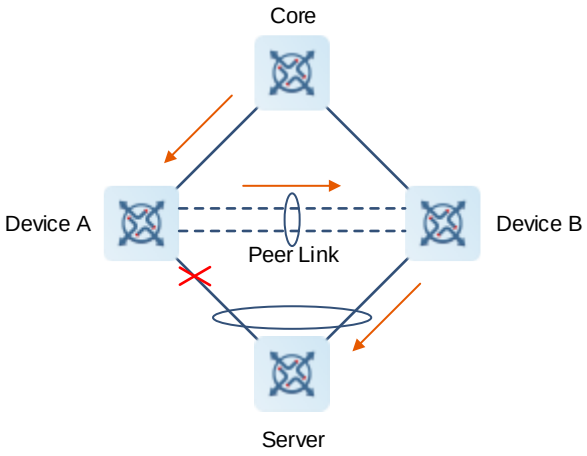
1.1.4 Local Port Preferential Forwarding

In a network, a peer-link is regarded as a backup link. Service traffic is preferentially forwarded by local VAP member ports instead of peer-links.

Figure 1-4 Forwarding Path of Service Traffic on a Normal Network



Through the following mechanism, M-LAG ensures that the device forwards service traffic by local VAP member ports preferentially on a normal network.

- The interfaces of a peer-link keeps learning MAC addresses to ensure that the egress MAC addresses learned by the local ports are downlink ports.
- If a MAC table entry is synchronized from the M-LAG peer side, the device replaces the egress port of the

MAC table entry with a local downlink port.

- Once the local VAP member ports of the device fail, service traffic will be forwarded through a peer-link.

Figure 1-5 Forwarding Path of Service Traffic When the VAP Member Ports of Device A Fail

1.1.5 Configuration Consistency Check

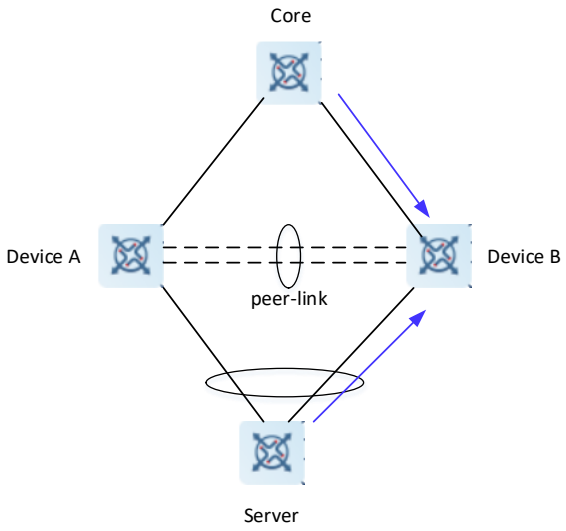
In the M-LAG scenario, some service configurations need to be consistent on the two devices composing the M-LAG system, to ensure normal operation of the M-LAG system functions. Configuration information sharing of the M-LAG system realizes automatic configuration consistency check for the two devices in the M-LAG system. The configuration change at one end automatically triggers the configuration consistency check. When the configurations of the M-LAG master and slave devices are inconsistent, an alarm is prompted. If the key configurations on the master and slave devices of the M-LAG system are inconsistent, the service ports on the slave device are set to the errdisable down state; when the configuration consistency is restored, M-LAG recovers the ports in the errdisable down state on the slave device. According to the impact caused by configuration inconsistency, the configurations that need to be kept consistent are classified into two categories: key configuration (Type-1) and general configuration (Type-2).

- Key configuration: If the configurations are inconsistent between the devices at both ends of the M-LAG system, it causes the problems of a loop and a normal state with long-term packet loss.
- General configuration: If the configurations are inconsistent between the devices at both ends of the M-LAG system, the M-LAG system may operate abnormally. Compared with the key configuration, the problem of general configuration is easier to be found, and its impact on the networking environment is relatively minor.

Table 1-1 Configuration Consistency Check Table

Command Mode	Consistency Check Configuration Item	Type
Global configuration mode	Whether the Spanning Tree Protocol (STP) function is enabled	Type-1
	Configuration of the STP working mode	
	Whether the bridge protocol data unit (BPDU) protection function is enabled	

Command Mode	Consistency Check Configuration Item	Type
	Mappings between the Multiple Spanning Tree Protocol (MSTP) instances and virtual local area networks (VLANs)	
	SVI	Type-2
VAP member port	Whether the root protection function of an STP port is enabled	Type-1
	LACP mode configuration	
	STP priority	Type-2
	VLAN, to which a port is added	



Based on the handling method of inconsistency found in key configuration check, M-LAG consistency check can be performed in strict mode or loose mode.

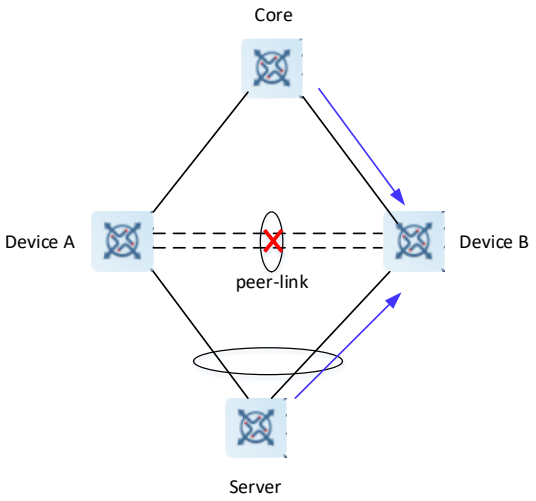
- In strict mode, if the key configurations are inconsistent, the service ports on the M-LAG slave device are set to the errdisable state.
- When the general configurations are inconsistent, only an alarm is prompted regardless of the check mode.

1.1.6 Service Continuity Upon Device Upgrade

During an M-LAG device upgrade, traffic is redirected to the other M-LAG member device to ensure service continuity during the upgrade and restart.

Figure 1-6 Forwarding Path of Service Traffic When Device A Is Upgraded

M-LAG adjusts traffic to Device B through the following mechanisms:



- Adjust the metric of the route to switch the downlink traffic to Device B.
- Configure **lacp force-vap-down [enhance]** in global configuration mode to switch uplink traffic to Device B.

1.1.7 Intelligent Switching Upon Faults

When the peer-link fails, traffic is pre-switched from the M-LAG salve device to the master device, and then the violation port of the standby device is delayed. When the peer-link recovers, the M-LAG standby device restores the uplink and downlink ports to the up state first and then switches traffic back to the M-LAG active device. This ensures that services are not interrupted in case of a peer-link failure or during the failback process.

The intelligent switching function can ensure service continuity during peer-link failures and restoration, except for new services. In addition, the access device must be able to process received packets even after the member interface is removed from the aggregate interface.

Figure 1-7 Forwarding Path for Service Traffic Pre-switching When the Peer-Link Fails

M-LAG implements service continuity in case of a peer-link failure and restoration through the following mechanisms:

- The **fast-convergence enhance** command is used to enable or disable intelligent switching upon M-LAG faults.
- On the device where intelligent switching upon M-LAG faults is enabled, when the peer link is faulty and dual-active devices are detected, the slave device is associated with the dynamic routing protocol to increase the metric and enhanced pre-switching function of LACP to switch traffic to the M-LAG master device. After the delay specified by *down-interval,* all service interfaces except the peer-link interface, management interface, VSL interface, and excluded interface are set to the Error-Down state.
- After the fault of the peer-link is rectified, the interface in Error-Down state recovers after a delay. After the interfaces goes Up and the delay is reached, the device interworks with the dynamic routing protocol and LACP to restore the route metric and negotiates the VAP status to switch traffic back to the slave device. When the device is started, the processing logic is the same as that of peer-link fault rectification.
- Only the OSPF protocol is supported, and the access device needs to connect to the M-LAG in LACP mode.

1.2 Restrictions and Guidelines

- The peer-link between the two devices must be an aggregate link. You are advised to use LACP aggregation

and configure the peer-link as a trunk port in Layer 2 mode. The trunk port must permit packets from all service VLANs of the M-LAG master and slave devices by using the **switchport trunk allowed vlan all** command by default. Do not configure other services on the port.

- You are advised to configure multiple physical links for the peer-link. For chassis devices, deploy physical links on different cards to avoid the impact of a card failure on the network.
- The dual-active detection link needs to be independent of the peer-link to avoid a dual-active detection failure in case of a peer-link failure.
- The M-LAG devices only synchronize the dynamic MAC/ARP entries, but not the static MAC/ARP configuration. The same static MAC/ARP entries need to be configured on the M-LAG devices.
- Only Layer 2 aggregate interfaces can be configured as peer-linkpeer-link interfaces or VAP member ports.

1.3 Configuration Task Summary

M-LAG configuration includes the following tasks:

(1) Configuring the M-LAG Function

a Configuring a VAP Domain and Local and Peer IP Addresses

b Configuring Peer-Link Interfaces

c (Optional) Configuring M-LAG Attributes

d Configuring VAP Member Ports

e (Optional) Configuring Exceptional Interfaces

f (Optional)Configuring Intelligent Switching Upon Faults

1.4 Configuring the M-LAG Function

1.4.1 Overview

You can configure device link aggregation to enable an access device to connect to an M-LAG system in dual-homing mode. The traffic from an M-LAG device to the access device is first forwarded through the local VAP member port. When the local VAP member port fails, the traffic is forwarded to the M-LAG peer device. The dual-homing access meets requirements for balanced forwarding of traffic. When a single device or a single link fails, the device traffic is not affected and can be forwarded continuously.

1.4.2 Restrictions and Guidelines

- On M-LAG device, the two ports connected to the dual-homed access device need to join the same VAP.
- You are advised to use consistent configuration for the member ports of the same VAP on the two M-LAG devices to ensure normal traffic forwarding.
- The data synchronization channel needs to be established on the peer-link.
- Due to the restriction of the M-LAG master and slave role election rules, the M-LAG master and slave roles are not changed under the following cases:
  - When the role of one device in the M-LAG system has been selected and the role of the other device is not selected, the priority change will not lead to role election.
  - When one device in the M-LAG system is in the dual-active errdisable state, the priority change will not

lead to role election.

- Devices in an M-LAG system can be restarted only after you power down the system or run the **reload** command. Using other methods to restart the device may cause the shutdown time of the keepalive port to be later than that of the peer-link and the keepalive packet transmission interval out of the heartbeat hold time, and, consequently, the M-LAG slave device is wrongly set to the errdisable state by the dual-active detection mechanism. In this case, you are advised to configure a longer heartbeat hold time.

Table 1-2 Table of Special Constraints with Other Services

Feature	Description
Stacking	Devices can be used to build a stack first, and then the stack system can be used as an independent unit to build an M-LAG system.
GVRP	The M-LAG and GARP VLAN Registration Protocol (GVRP) functions are mutually exclusive. They cannot be configured at the same time.
ERPS	The M-LAG and Ethernet Ring Protection Switching (ERPS) functions are mutually exclusive. They cannot be configured at the same time.
RLDP	The M-LAG and Rapid Link Detection Protocol (RLDP) functions are mutually exclusive. They cannot be configured at the same time.
Web authentication	The M-LAG and Web authentication functions are mutually exclusive. They cannot be configured at the same time.
dot1x	The M-LAG and dot1x functions are mutually exclusive. They cannot be configured at the same time.
Dynamic ARP detection	The M-LAG and dynamic ARP detection functions are mutually exclusive. They cannot be configured at the same time.
DHCP	The two devices composing an M-LAG system do not support Dynamic Host Configuration Protocol (DHCP) snooping DHCP relay needs to be configured on both devices composing an M-LAG system. The DHCP server needs to be configured on both devices composing an M-LAG system and the addresses in the address pools of the two devices cannot be overlapped.
IP unicast routing	The M-LAG devices and connected devices cannot establish routing neighbor relationships through VAP member ports.
Multicast	M-LAG does not support IPv4 multicast or IPv6 multicast services.
Storm control	You are not advised to configure multicast packet storm control on physical member ports of a peer-link. Otherwise, M-LAG synchronization packets are suppressed, resulting in data packet forwarding exceptions in the M-LAG system.

1.4.3 Configuration Tasks

M-LAG configuration includes the following tasks:

(1) Configuring a VAP Domain and Local and Peer IP Addresses

(2) Configuring Peer-Link Interfaces

(3) (Optional) Configuring M-LAG Attributes

(4) Configuring VAP Member Ports

(5) (Optional) Configuring Exceptional Interfaces

(6) (Optional) Configuring Intelligent Switching Upon Faults

1.4.4 Configuring a VAP Domain and Local and Peer IP Addresses

1. Overview

To ensure normal negotiation between two devices that form an M-LAG system, you need to configure a VAP domain for the devices and specify the local and peer IP addresses for entry synchronization and dual-active detection channels.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the dual-active link unreachability logging.

logging vap keepalive-det

(4) Configure a VAP domain and enter the VAP domain configuration mode.

vap domain *domain-id*

No VAP domain ID is configured by default.

The same VAP domain ID needs to be configured for the two devices used for dual-homing access.

(5) Configure the local and peer IP addresses for the Layer 3 channel used for entry synchronization.

data-sync { **local** *local-ipv4-address* **peer** *peer-ipv4-address* | **local** *local-ipv6-address* **peer** *peer-ipv6-address* }

No local and peer IP addresses are configured for a Layer 3 channel used for entry synchronization by default.

(6) Configure the local and peer IP addresses for the Layer 3 channel used for dual-active detection.

peer-keepalive { **local** *local-ipv4-address* **peer** *peer-ipv4-address* | **local** *local-ipv6-address* **peer** *peer-ipv6-address* } [**mgmt** *interface-number*]

The Layer 3 channel used for dual-active detection is disabled by default.

1.4.5 Configuring Peer-Link Interfaces

1. Overview

The peer-link is used to synchronize data and transmit some traffic. The directly connected ports at both ends of a peer-link are called peer-linkpeer-link interfaces, which must be configured as a Layer 2 aggregate

interface. To improve the reliability of the peer-link, you are advised to deploy multiple physical links for the peer-link.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the Layer 2 aggregate interface configuration mode.

interface aggregateport *interface-number*

(4) Specify a Layer 2 aggregate interface to configure peer-linkpeer-link interfaces.

peer-link

When a port is configured as a peer-linkpeer-link interface, other services cannot be configured on the port, for example, it cannot be configured as a protected port. Moreover, MAC address learning is disabled on the port, that is, M-LAG devices communicate with each other through flooding. You are advised to configure a peer-linkpeer-link interface to work in the trunk mode.

No peer-linkpeer-link interface is configured bydefault.

1.4.6 Configuring M-LAG Attributes

1. Overview

The values of the M-LAG attributes can be adjusted based on networking and service requirements.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a VAP domain and enter the VAP domain configuration mode.

vap domain *domain-id*

No VAP domain ID is configured by default.

(4) The following tasks are optional. Select them according to actual condition.

- Configure the domain negotiation timeout time.

  domain-match delay *interval*

  The default delay time is **120** seconds.

- Configure the fast convergence mode.

  fast-convergence

  The default fast convergence mode depends on the product version.

- Configure a priority.

  priority *priority*

The default priority is **4**.

- Configure an interface recovery delay.

  recover up-delay *interval* [**none-vap** *none-vap-interval*]

  The default recovery delay time of VAP ports and other ports is both **120** seconds.

- Configure the heartbeat hold time.

  peer-keepalive hold-time *interval*

  The default heartbeat hold time for dual-active detection is **3** seconds.

- Configure dual-active automatic recovery.

  dual-active auto recovery

  The dual-active automatic recovery function is disabled by default.

- Configure consistency check.

  vap consistency-check [**disable** | **loose** | **strict**]

  Consistency check is not configured by default.

- Configure a delay for forcible recovery of a port in the errdisable state after device startup.

  start-up force-recover-up delay *interval*

  The default forcible recovery time of a port in the errdisable state after device startup is **300** seconds.

1.4.7 Configuring VAP Member Ports

1. Overview

You can add aggregate interfaces connecting access devices to a VAP. You are advised to use LACP to enhance reliability.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the Layer 2 link aggregation configuration mode.

interface aggregateport *interface-number*

(4) Add an aggregate interface to the VAP.

vap *vap-id*

1.4.8 Configuring Exceptional Interfaces

1. Overview

If M-LAG detects two active devices, it will configure the service interfaces (except for management interfaces, peer-linkpeer-link interfaces, and stack interfaces) on the standby device as error down interfaces. To prevent an interface from being configured as an error down interface, you can configure this interface as an exceptional interface.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregation interface configuration mode.

  interface aggregateport *interface-number*

(4) (Optional) Configure an excluded port.

vap error-down except

No excluded port is configured by default.

1.4.9 Configuring Intelligent Switching Upon Faults

1. Overview

On the device where intelligent switching upon M-LAG faults is enabled, when the peer link is faulty and dual-active devices are detected, the slave device is associated with the dynamic routing protocol to increase the metric and enhanced pre-switching function of LACP to switch traffic to the M-LAG master device. After the delay specified by *down-interval,* all service interfaces except the peer-link interface, management interface, VSL interface, and excluded interface are set to the Error-Down state. After the fault of the peer-link is rectified, the interface in Error-Down state recovers after a delay. After the interfaces goes Up and the delay specified by *recover-interval* is reached, the device interworks with the dynamic routing protocol and LACP to restore the route metric and negotiates the VAP status to switch traffic back to the slave device. When the device is started, the processing logic is the same as that of peer-link fault rectification.

2. Configuration Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a VAP domain and enter the VAP domain configuration mode.

vap domain *domain-id*

No VAP domain ID is configured by default.

(4) Enable intelligent switching upon M-LAG faults.

fast-convergence enhance [**down-delay** *down-interval* [**recover-delay** *recover-interval*] | **recover-delay** *recover-interval*]

Intelligent switching upon M-LAG faults is disabled by default.

1.5 Monitoring

Run the **show** command to check the configuration.

Run the **debug** command to output debugging information.

Caution

Debugging occupies system resources, so disable it immediately if not required.

Run the **clear** command to clear information.

Caution

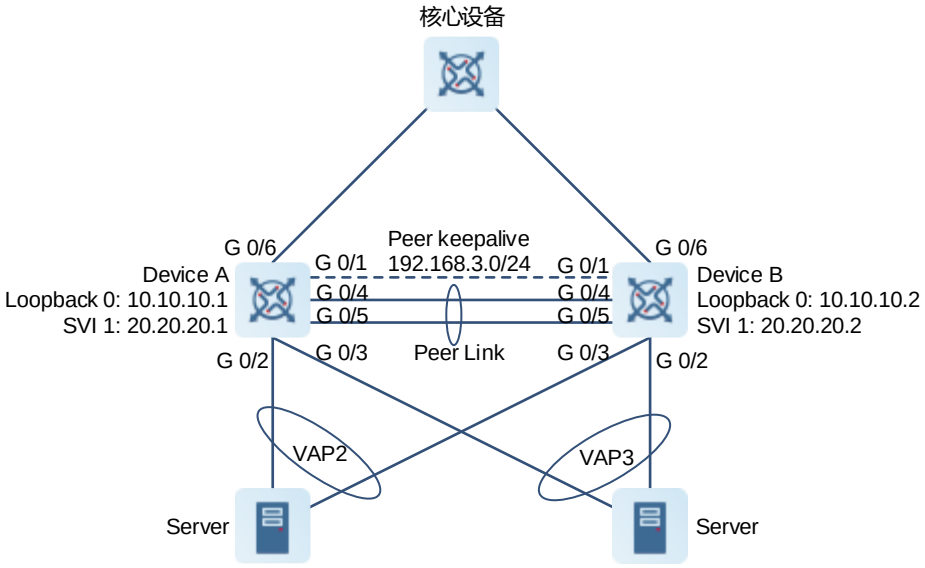
During device operation, running the clear command may cause service interruption due to key information loss.

Table 1-3 M-LAG Monitoring

Command	Purpose
show mlag cons-check	Displays consistency check information of M-LAG configurations.
show mlag consult data	Displays the M-LAG negotiation information.
show mlag global data	Displays the global M-LAG information.
show mlag interface { *ifx* | *interface-type interface-number* | **brief** | **verbose** }	Displays the M-LAG interface list information.
show mlag lacp data	Displays the M-LAG LACP information.
show mlag memory	Displays the M-LAG memory usage.
show mlag mom *database information*	Displays the M-LAG MOM database.
show mlag peer-keepalive	Displays the M-LAG dual-active detection information.
show mlag vap-group data	Displays the M-LAG VAP group information.
show vap error-down except	Displays the configuration of the excluded port exempt from the errdisable state.
show vap consistency-check vap id [**all**]	Displays the configuration consistency check result of a specified VAP.

Command	Purpose
show vap consistency-check global [**all**]	Displaythe global configuration consistencycheck results of a VAP domain.
debug mlag event	Debugs M-LAG events.
debug mlag dad	Debugs M-LAG dual-active detection events.
debug mlag dad-pkt	Debugs M-LAG keepalive packets.
debug mlag mom	Debugs the M-LAG database.
debug mlag cli	Debugs the M-LAG CLI configuration.
debug mlag role	Debugs the M-LAG role negotiation.
debug mlag role-pkt	Debugs M-LAG role negotiation packets.
debug mlag error	Debugs M-LAG error events.
debug mlag keypnt	Debugs M-LAG key events.
debug mlag vap	Debugs the M-LAG group management.
debug mlag log-file	Debugs the function of writing M-LAG logs into files.
debug mlag [**cons-check** | **cons-mom**]	Debugs M-LAG configuration consistencycheck.
debug mlag snmp	Debugs M-LAG trap.
clear vap error-down	Clears the ports from the errdisable state caused by M-LAG.
clear vap data-sync	Clears data records of the data synchronization channel.
clear vap keepalive	Clears data records of the heartbeat channel.

1.6 Configuration Examples



1.6.1 Connecting to an IP Network in Dual-Homing Mode

1. Requirements

A device needs to be configured to connect to an IP network in dual-homing mode.

2. Topology

Figure 1-8 Topology for Connecting to an IP Network in Dual-Homing Mode

3. Notes

- Configure interface IP addresses for all the devices.
- Configure a dynamic routing protocol (such as OSPF) on devices A and B and the core device.

4. Procedure

Configure a VAP domain on device A.

```
Device A> enable
Device A# configure terminal
Device A(config)# vap domain 1
Device A(config-vap-domain)# exit
```

Configure a data backup channel and a dual-active detection channel. (A common physical port needs to be configured as an excluded port when used in a dual-active detection channel.)

```
Device A(config)# interface loopback 0
Device A(config-if-Loopback 0)# ip address 10.10.10.1/32
Device A(config-if-Loopback 0)# exit
Device A(config)# vap domain 1
Device A(config-vap-domain)# data-sync local 20.20.20.1 peer 20.20.20.2
Device A(config-vap-domain)# peer-keepalive local 192.168.3.1 peer 192.168.3.2
Device A(config-vap-domain)# exit
Device A(config)# int vlan 1
Device A(config-if-VLAN 1)# ip address 20.20.20.1/24
Device A(config-if-VLAN 1)# exit
Device A(config)# ip route 10.10.10.2 255.255.255.255 20.20.20.2
Device A(config)# interface gigabitethernet 0/1
Device A(config-if-GigabitEthernet 0/1)# no switchport
```

```
Device A(config-if-GigabitEthernet 0/1)# ip address 192.168.3.1/24
Device A(config-if-GigabitEthernet 0/1)# vap error-down except
```

Configure peer-link aggregate interface 1. Add member port GigabitEthernet 0/4 and member port GigabitEthernet 0/5.

```
Device A(config)# interface aggregateport 1
Device A(config-if-AggregatePort 1)# switchport mode trunk
Device A(config-if-AggregatePort 1)# peer-link
Device A(config-if-AggregatePort 1)# exit
Device A(config)# interface gigabitethernet 0/4
Device A(config-if-GigabitEthernet 0/4)# port-group 1 mode active
Device A(config-if-GigabitEthernet 0/4)# exit
Device A(config)# interface gigabitethernet 0/5
Device A(config-if-GigabitEthernet 0/5)# port-group 1 mode active
```

Configure VAP 2. Add the downlink port GigabitEthernet 0/2 to aggregate interface 2 and aggregate interface 2 to VAP 2.

```
Device A(config)# interface gigabitethernet 0/2
Device A(config-if-GigabitEthernet 0/2)# port-group 2 mode active
Device A(config-if-GigabitEthernet 0/2)# exit
Device A(config)# interface aggregateport 2
Device A(config-if-AggregatePort 2)# switchport access vlan 2
Device A(config-if-AggregatePort 2)# vap 2
```

Configure VAP 3. Add the downlink port GigabitEthernet 0/3 to aggregate interface 3 and aggregate interface 3 to VAP 3.

```
Device A(config)# interface gigabitethernet 0/3
Device A(config-if-GigabitEthernet 0/3)# port-group 3 mode active
Device A(config-if-GigabitEthernet 0/3)# exit
Device A(config)# interface aggregateport 3
Device A(config-if-AggregatePort 3)# switchport access vlan 3
Device A(config-if-AggregatePort 3)# vap 3
```

Configure a VRRP dual-active gateway.

```
Device A(config)# vlan 2
Device A(config-vlan)# exit
Device A(config)# interface vlan 2
Device A(config-if-VLAN 2)# ip address 30.30.2.1/24
Device A(config-if-VLAN 2)# vrrp 1 ip 30.30.2.1
Device A(config-if-VLAN 2)# vrrp mode dual-active
Device A(config-if-VLAN 2)# exit
Device A(config)# vlan 3
Device A(config-vlan)# exit
Device A(config)# interface vlan 3
Device A(config-if-VLAN 2)# ip address 30.30.3.1/24
Device A(config-if-VLAN 2)# vrrp 1 ip 30.30.3.1
Device A(config-if-VLAN 2)# vrrp mode dual-active
```

Configure a monitor link, with the uplink port GigabitEthernet 0/6 and downlink ports GigabitEthernet 0/2 and GigabitEthernet 0/3.

```
Device A(config)# link state track 1 up-delay 60
Device A(config)# interface gigabitethernet 0/6
Device A(config-if-GigabitEthernet 0/6)# link state group 1 upstream
Device A(config-if-GigabitEthernet 0/6)# exit
Device A(config)# interface gigabitethernet 0/2
Device A(config-if-GigabitEthernet 0/2)# link state group 1 downstream
Device A(config-if-GigabitEthernet 0/2)# exit
Device A(config)# interface gigabitethernet 0/3
Device A(config-if-GigabitEthernet 0/3)# link state group 1 downstream
```

Perform the following configuration on device B.

```
Device B> enable
Device B# configure terminal
```

Configure a VAP domain and enter the VAP domain configuration mode.

```
Device B(config)# vap domain 1
Device B(config-vap-domain)# exit
```

Configure a data backup channel and a dual-active detection channel. (A common physical port needs to be configured as an excluded port when used in a dual-active detection channel.)

```
Device B(config)# interface loopback 0
Device B(config-if-Loopback 0)# ip address 10.10.10.2/32
Device B(config-if-Loopback 0)# exit
Device B(config)# vap domain 1
Device B(config-vap-domain)# data-sync local 20.20.20.2 peer 20.20.20.1
Device B(config-vap-domain)# peer-keepalive local 192.168.3.2 peer 192.168.3.1
Device B(config-vap-domain)# exit
Device B(config)# int vlan 1
Device B(config-if-VLAN 1)# ip address 20.20.20.2/24
Device B(config-if-VLAN 1)# exit
Device B(config)# ip route 10.10.10.1 255.255.255.255 20.20.20.1
Device B(config)# interface gigabitethernet 0/1
Device B(config-if-GigabitEthernet 0/1)# no switchport
Device B(config-if-GigabitEthernet 0/1)# ip address 192.168.3.2/24
Device B(config-if-GigabitEthernet 0/1)# vap error-down except
```

Configure peer-link aggregate interface 1. Add member ports GigabitEthernet0/4 and GigabitEthernet 0/5.

```
Device B(config)# interface aggregateport 1
Device B(config-if-AggregatePort 1)# switchport mode trunk
Device B(config-if-AggregatePort 1)# peer-link
Device B(config-if-AggregatePort 1)# exit
Device B(config)# interface gigabitethernet 0/4
Device B(config-if-GigabitEthernet 0/4)# port-group 1 mode active
Device B(config-if-GigabitEthernet 0/4)# exit
Device B(config)# interface gigabitethernet 0/5
Device B(config-if-GigabitEthernet 0/5)# port-group 1 mode active
```

Configure VAP 2. Add the downlink port GigabitEthernet 0/2 to aggregate interface 2 and aggregate interface 2 to VAP 2.

```
Device B(config)# interface gigabitethernet 0/2
Device B(config-if-GigabitEthernet 0/2)# port-group 2 mode active
Device B(config-if-GigabitEthernet 0/2)# exit
Device B(config)# interface aggregateport 2
Device B(config-if-AggregatePort 2)# switchport access vlan 2
Device B(config-if-AggregatePort 2)# vap 2
```

Configure VAP 3. Add the downlink port GigabitEthernet 0/3 to aggregate interface 3 and aggregate interface 3 to VAP 3.

```
Device B(config)# interface gigabitethernet 0/3
Device B(config-if-GigabitEthernet 0/3)# port-group 3 mode active
Device B(config-if-GigabitEthernet 0/3)# exit
Device B(config)# interface aggregateport 3
Device B(config-if-AggregatePort 3)# switchport access vlan 3
Device B(config-if-AggregatePort 3)# vap 3
```

Configure a VRRP dual-active gateway.

```
Device B(config)# vlan 2
Device B(config-vlan)# exit
Device B(config)# interface vlan 2
Device B(config-if-VLAN 2)# ip address 30.30.2.2/24
Device B(config-if-VLAN 2)# vrrp 1 ip 30.30.2.1
Device B(config-if-VLAN 2)# vrrp mode dual-active
Device B(config-if-VLAN 2)# exit
Device B(config)# vlan 3
Device B(config-vlan)# exit
Device B(config)# interface vlan 3
Device B(config-if-VLAN 2)# ip address 30.30.3.2/24
Device B(config-if-VLAN 2)# vrrp 1 ip 30.30.3.1
Device B(config-if-VLAN 2)# vrrp mode dual-active
```

Configure a monitor link, with the uplink port GigabitEthernet 0/6 and downlink ports GigabitEthernet 0/2 and GigabitEthernet 0/3.

```
Device B(config)# link state track 1 up-delay 60
Device B(config)# interface gigabitethernet 0/6
Device B(config-if-GigabitEthernet 0/6)# link state group 1 upstream
Device B(config-if-GigabitEthernet 0/6)# exit
Device B(config)# interface gigabitethernet 0/2
Device B(config-if-GigabitEthernet 0/2)# link state group 1 downstream
Device B(config-if-GigabitEthernet 0/2)# exit
Device B(config)# interface gigabitethernet 0/3
Device B(config-if-GigabitEthernet 0/3)# link state group 1 downstream
```

5. Verification

Check whether the VAP member port of device A and its state are correct.

```
Device A# show vap summary
M-LAG domain         : 1
M-LAG role           : Master
Local address        : 20.20.20.1
Peer address         : 20.20.20.2
Negotiation status    : ok

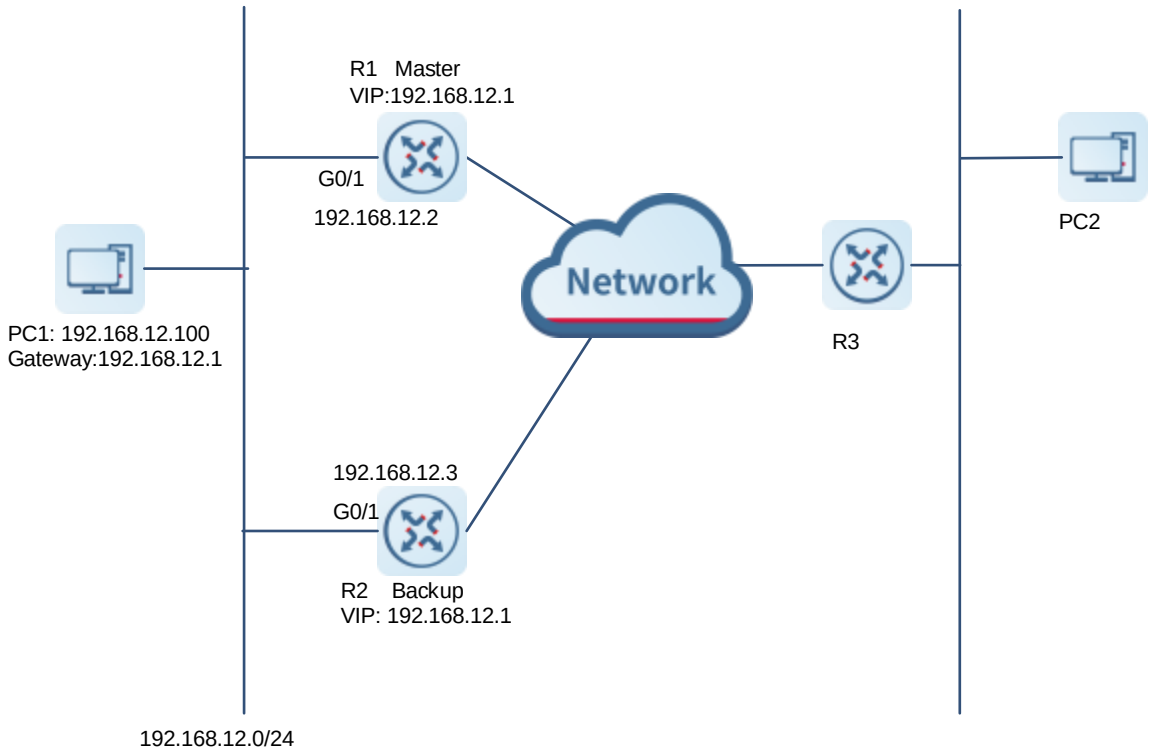
1 Configuring VRRP



1.1 Introduction

Virtual Router Redundancy Protocol (VRRP) is a fault-tolerant routing protocol, which is mainly used for router redundancy on the egress of a local area network (LAN). VRRP adopts the active/standby mode. When a device used for routing and forwarding on a LAN fails, the backup device automatically takes over the forwarding tasks, which helps achieve hot backup and fault tolerance of IP routing. In addition, VRRP ensures communication continuity and reliability for the hosts on the LAN.

1.1.1 Basic Concepts

As shown in Figure 1-1, router 1 and router 2 form a VRRP group, and the gateway IP address configured for PC 1 is the virtual IP address of the VRRP group.

Figure 1-1 Diagram of Configuring VRRP

1. VRRP Router

A VRRP router refers to a device running VRRP. The device can be a single device or a logical device virtualized from multiple devices.

2. Virtual Router

A virtual router, also called a VRRP group, is usually regarded as the default gateway of hosts on a shared LAN. A VRRP group contains a virtual router identifier (VRID) and a set of virtual IP addresses.

3. Virtual IP Address

A virtual IP address is the IP address of a virtual router. A virtual router can be configured with one or multiple virtual IP addresses.

4. Virtual MAC Address

A virtual MAC address of VRRP complies with the Request for Comments (RFC) protocol standard. The virtual MAC address of an IPv4 VRRP group is "00-00-5E-00-01-{VRID}", the virtual MAC address of an IPv6 VRRP group is "00-00-5E-00-02-{VRID}", with the first five bytes fixed and the last byte of a VRRP group ID. A VRRP group responds to an ARP request by using its virtual MAC address instead of the real MAC address of an interface.

5. IP Address Owner

If the virtual IPv4/IPv6 address of a VRRP group is consistent with the IPv4/IPv6 address of the Ethernet port on which the VRRP group is configured, that is, the VRRP group has the real IP address of the Ethernet port, the VRRP group is collectively called an IP address owner. In such a case, the priority of the VRRP group is 255. If the Ethernet port is available, the VRRP group enters the master state automatically. The IP address owner receives and processes the packets whose destination IP address is the IP address of the virtual router.

6. Master Router

In a VRRP group, only the master router responds to Address Resolution Protocol (ARP) requests and forwards IP packets. If a device is the IP address owner, it becomes the master router.

7. Backup Router

In a VRRP group, a backup router only monitors the state of the master router but does not respond to ARP requests or forward IP packets. When the master router fails, the backup router takes the chance to become the master router via election.

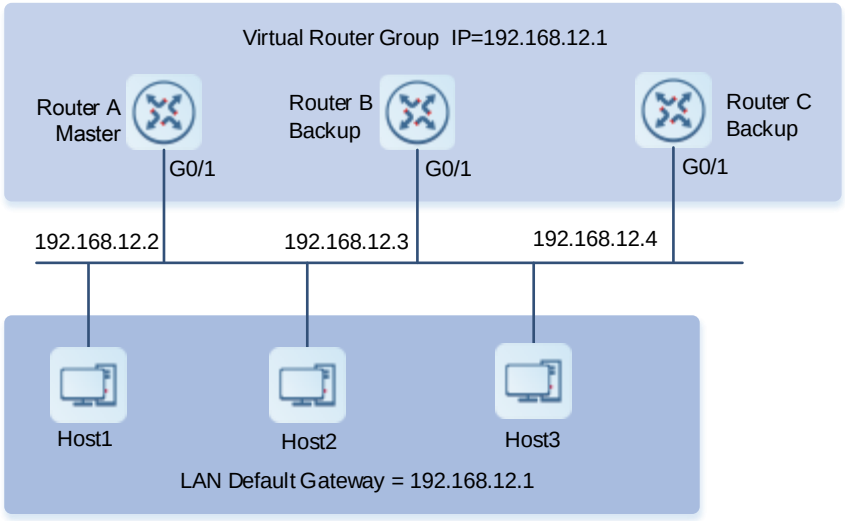
8. VRID

A virtual router identifier (VRID) is the unique identifier of a virtual router and distinguishes different VRRP back groups. Only a group of routers with the same VRID can form a VRRP group.

9. Priority

The priority of each device in a VRRP group determines the role that each device plays. The configurable priority range is from 1 to 254, and the priority of the VRRP router with the virtual router IP address must be 255. When the priority is 0, the current master node no longer joins the VRRP group, and the backup router is triggered to become the master node rapidly without waiting for the current master node to time out.

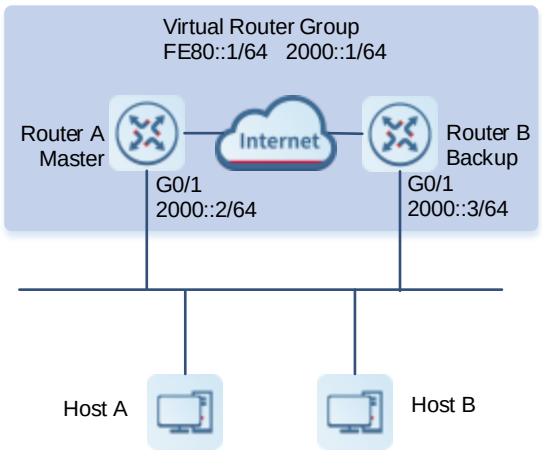
10. Preemption Mode



If a VRRP group runs in preemption mode, a backup router with a higher priority replaces the master router with a lower priority to become the master router of the VRRP group. If the VRRP group runs in the non-preemption mode, as long as the master router runs properly, the backup router does not become the master router even if it is configured with a higher priority later. In some cases, even if the non-preemption mode is configured, a router that is just started in a VRRP group will preempt the position of the VRRP master router. The reason is that, when a device is started or the port just becomes active, the VRRP group on the port fails to receive the

VRRP packet sent by the master device of the same backup group in time. In this case, the above problem can be avoided by delaying the start of the VRRP group.

1.1.2 VRRP Application

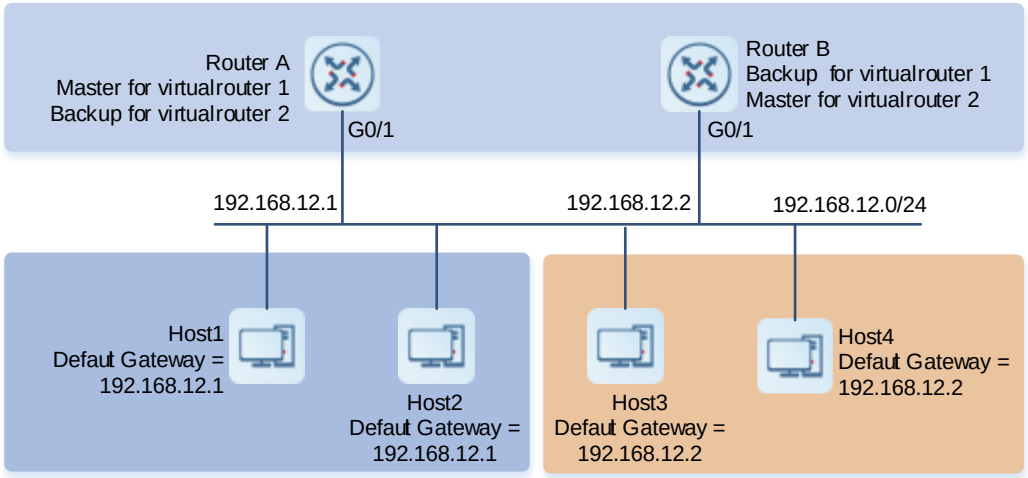


1. Master/Backup Redundancy

Figure 1-2 IPv4-based VRRP Master/Backup Redundancy

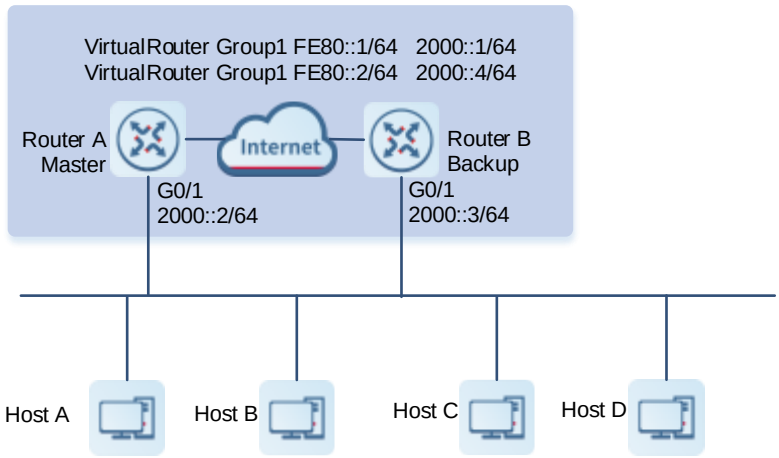
As shown in Figure 1-2, routers A, B, and C are all connected to the LAN through Ethernet ports, and VRRP is configured on the Ethernet ports connected to the LAN. The routers are in the same VRRP group, and the virtual IP address of the VRRP group is 192.168.12.1. Router A is elected as the master router of the VRRP group, and routers B and C are used as backup routers. Hosts 1, 2 and 3 use the IP address of the virtual router 192.168.12.1 as the gateway address. Packets from a host on the LAN to other networks are forwarded by the master router (router A). If router A fails, a master router is reelected between router B and router C to forward packets, to achieve simple routing redundancy.

Figure 1-3 IPv6-based VRRP Master/Backup Redundancy



As shown in Figure 1-3, both routers A and B are connected to the LAN through Ethernet ports, and IPv6 VRRP is configured on the Ethernet ports connected to the LAN. The routers are in the same IPv6 VRRP group, and the virtual IPv6 addresses of the IPv6 VRRP group are FE80::1/64 and 2000::1/64. Router A is elected as the master router of VRRP, and router B functions as a backup router. The hosts on the LAN take the IPv6 link local address FE80::1/64 of the virtual router as the gateway address. Packets from the hosts on the LAN to other networks are forwarded by the master router. If router A fails, router B forwards packets on behalf of router A, achieving simple routing redundancy.

- Before implementation: If the uplink or downlink port of router A fails, the data flow is interrupted, that is, a single point of failure occurs.
- After implementation: If router A fails, VRRP implements switching within seconds to ensure that services are not interrupted, this effectively avoids the problem of network interruption after a single link fails. In addition, you do not need to modify the configuration such as the dynamic routing protocol and routing discovery protocol. You do not need to modify the default gateway configuration for the host node of local link.



2. Load Balancing

Figure 1-4 IPv4-based VRRP Load Balancing

As shown in Figure 1-4, two virtual routers are configured. For virtual router 1, router A uses the IP address 192.168.12.1 of the Ethernet port GigabitEthernet 0/0 as the IP address of the virtual router, so router A becomes the master router and router B becomes the backup router. For virtual router 2, router B takes the IP address 192.168.12.2 of Ethernet port GigabitEthernet 0/0 as the IP address of the virtual router, so router B becomes the master router and router A becomes the backup router. In the LAN, hosts 1 and 2 take the IP address 192.168.12.1 of virtual router 1 as the default gateway address, while hosts 3 and 4 take the IP address 192.168.12.2 of virtual router 2 as the default gateway address. In this application of VRRP, routing redundancy is achieved between routers A and B, and the LAN traffic is shared between them to achieve load balancing.

Figure 1-5 IPv6-based VRRP Load Balancing

As shown in Figure 1-5, two virtual routers are configured. For virtual router 1, router A uses the IP address fe80::1/64 of the Ethernet port GigabitEthernet 0/1 as the IP address of the virtual router, so router A becomes the master router and router B becomes the backup router. For virtual router 2, router B takes the IP address fe80::2/64 of Ethernet port GigabitEthernet 0/1 as the IP address of the virtual router, so router B becomes the master router and router A becomes the backup router. On the LAN, hosts A and B use the IP address FE80::1 of virtual router 1 as the default gateway address (manually configured static IPv6 gateway), and hosts C and D use the IP address FE80::2 of virtual router 2 as the default gateway address (manually static configured IPv6 gateway). In this way, routing redundancy is achieved between routers A and B, and the LAN traffic is shared between them to achieve load balancing.

The devices involved are L3 devices or routers. L2 devices are not applicable.

- Before implementation: All traffic goes through the master router, causing a certain burden to the master router. Before the master router fails, the backup router has been always idle, leading to a resource waste.
- After implementation: Each device is not a single master router or backup router, but acts as different roles in different groups. Therefore, the connected devices can be assigned to different groups and forward traffic to different gateways to achieve traffic load balancing. Moreover, no device is kept idle all the time, and resources are fully utilized.

1.1.3 Packet Structure

VRRP has two versions available: VRRPv2 and VRRPv3. VRRPv2 is only applicable to IPv4 networks, and VRRPv3 is applicable to both IPv4 and IPv6 networks. A VRRP packet is used to send the priority and state of the master device to all backup devices in the same backup group in multicast mode (with the destination address 224.0.0.18). The packet is encapsulated in an IP packet. The source address is the primary IP address (not the virtual IP address) of the packet sending port, the time to live (TTL) is 255, and the protocol ID is 112. Figure 1-6 and Figure 1-7 show the structures of VRRPv2 and VRRPv3 packets respectively.

Figure 1-6 Structure of VRRPv2 Packets

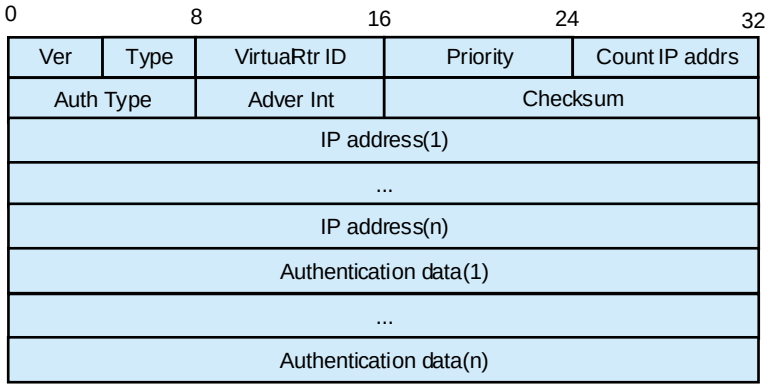


Figure 1-7 Structure of VRRPv3 Packets

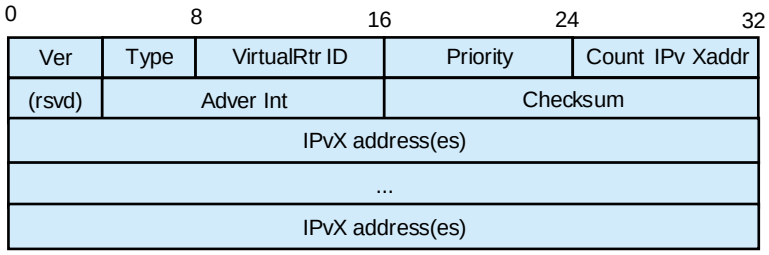

Table 1-1 Fields of VRRP Packets and Description

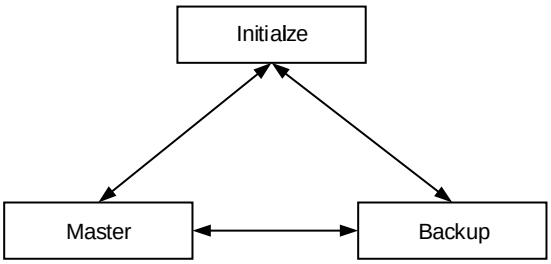
Packet Field	Description	
	VRRPv2	**VRRPv3**
Ver	Protocol version number. The value is 2.	Protocol version number. The value is 3.
Type	VRRP packet type. The value is 1, indicating that only the advertisement packets of VRRP are supported.	VRRP packet type. The value is 1, indicating that only the advertisement packets of VRRP are supported.
Virtual Rtr ID (VRID)	The Virtual Rtr ID field identifies the virtual router this packet is reporting status for.. The value range is from 1 to 255.	The Virtual Rtr ID field identifies the virtual router this packet is reporting status for. The value range is from 1 to 255.



Packet Field	Description	
	VRRPv2	**VRRPv3**
Priority	Priority of the router in the backup group. The value range is from 0 to 255, and the default value is **100**. A larger value indicates a higher priority. When the priority is 0, the current master node no longer joins the VRRP group and the backup router is triggered to become the master node, instead of waiting for the current master node to time out. The priority 255 is reserved for the IP address owner, and the configurable range is from 1 to 254 for other routers.	Priority of the router in the backup group. The value range is from 0 to 255, and the default value is 100. A larger value indicates a higher priority. When the priority is 0, the current master node no longer joins the VRRP group and the backup router is triggered to become the master node, instead of waiting for the current master node to time out. The priority 255 is reserved for the IP address owner, and the configurable range is from 1 to 254 for other routers.
Count IP Addrs/Count IPvX Addr	Number of virtual IPv4 addresses in the backup group.	Number of virtual IPv4 or virtual IPv6 addresses in the backup group.
Auth Type	Authentication type. Three authentication types are defined: ● **0**: Indicates no authentication. ● **1**: Indicates simple password (plaintext) authentication. ● **2**: Indicates MD5 authentication.	-
Adver Int	Interval of sending advertisement packets, in seconds. The default value is 1 second.	Interval of sending advertisement packets, in centiseconds. The default value is 100 centiseconds, namely, 1 second.
Checksum	16-bit checksum, used to check data corruption in the VRRP packet.	16-bit checksum, used to check data corruption in the VRRP packet.
IP Address/IPvX Address(es)	Virtual IPv4 addresses in the backup group. The number of addresses contained is defined in the **Count IP Addrs** field.	Virtual IPv4 addresses or virtual IPv6 addresses in the VRRP group. The number of addresses contained is defined in the **Count IPvX Addrs** field.
Authentication data	Authentication key of the VRRP packet. At present, the authentication key is only used for simple password authentication. For the other authentication methods, the value 0 is filled in this field.	-

Packet Field	Description	
	VRRPv2	VRRPv3
rsvd	-	Reserved field for the VRRP packet. The field must be set to **0**.

1.1.4 VRRP State

There are three VRRP states: initialize, backup, and master. Figure 1-8 shows the state transition process.

Figure 1-8 VRRP State Transition Diagram

1. Initialize

Initialize is the initial state of VRRP. The system enters this state after startup. It only responds to startup, that is, it does not process VRRP packets.

- When the system is started, if the priority of the local VRRP group is 255 (namely, the IP address owner), then:
  - VRRP packets are sent immediately.
  - If the local VRRP group is an IPv4 virtual router, gratuitous ARP packets are sent to all the IPv4 addresses of the virtual router. If the local VRRP group is an IPv6 virtual router, gratuitous NA packets are sent to all the IPv6 addresses of the virtual router, the routing flag bit is 1, the request flag bit is 0, the coverage flag bit is 1, the target address is the IPv6 address of the virtual router (not destination address), and the link layer address in the target link layer option is the MAC address of the virtual router.
  - The advertisement information timer is configured to send VRRP advertisements regularly, that is, **Adver_Timer** is set to **Advertisement_Interval**.
  - The local VRRP group switches to the master state.
- When the system is started, if the priority of the local VRRP group is not 255, then:
  - **Master_Adver_Interval** is set to **Advertisement_Interval**.
  - **Master_Down_Timer** is set to **Master_Down_Interval**.
  - The local VRRP group switches to the backup state.

2. Backup

A backup virtual router is used to monitor the validity and state of the master virtual router.

- An IPv4 backup virtual router does not respond to the ARP request for the IP address of the virtual router, and an IPv6 backup virtual router does not respond to the neighbor solicitation (NS) packet for the IPv6 address of the virtual router.
- The backup virtual router discards packets whose destination MAC addresses are the MAC address of the VRRP group and packets whose destination IP addresses are the IP address of the VRRP group.
- The backup virtual router does not send protocol packets. It must receive the VRRP multicast packets sent by the master router to know the state of the master router.
- When a shutdown event is received, the backup virtual router deletes the host timeout timer and switches to the initialize state.
- If a timeout event of the host timeout timer is received, the backup virtual router sends VRRP advertisement information immediately. If the backup virtual router is an IPv4 virtual router, it broadcasts ARP packets to all the IPv4 addresses of the virtual router. If the backup virtual router is an IPv6 virtual router, it computes and joins the solicited-node multicast address for the IPv6 address associated with the virtual router, and sends non-request (gratuitous) NA packets to all the IPv6 addresses of the virtual router. The routing flag bit is 1, the request flag bit is 0, the coverage flag bit is 1, the target address is the IPv6 address of the virtual router (not destination address), and the link layer address in the target link layer option is the MAC address of the virtual router. **Adver_Timer** is set to **Advertisement_Interval**, and the virtual router switches to the master state.
- If a VRRP packet is received and the priority is 0, the host timeout timer **Master_Down_Timer** is reset to **Skew_Time**; if the priority of the received VRRP packet is greater than 0, and preemption is not allowed or the priority of the packet is greater than or equal to the priority of the local virtual router, **Adver Interval** is set to the **Master_Adver_Interval** field value in the packet and **Master_Down_Interval** is set to **Master_Down_Timer**, otherwise the packet is discarded.

3. Master

As the forwarding role in a VRRP group, the virtual router in the master state forwards virtual gateway packets.

- It sends VRRP multicast packets regularly, and forwards relevant packets passing through the virtual IP address and packets whose destination MAC address is the VRRP virtual MAC address.
- If the virtual router is an IPv4 virtual router, the VRRP virtual MAC address must be used to respond to the ARP requests whose destination IP addresses are the virtual IP address of the virtual router. If the virtual router is an IPv6 virtual router, it must respond to the NS packets whose destination IP addresses are the virtual IPv6 address of the virtual router and must be a member of the solicited-node multicast address for the IPv6 address associated with the virtual router.
- If **Accept_Mode** or **IPvX Owner** is configured, that is, the virtual router is the IPv4/IPv6 address owner, the packets whose destination IP addresses are the virtual IP address of the virtual router must be received, otherwise the packets are discarded.
- When the network port where the VRRP virtual router is located receives a shutdown event, the virtual router deletes the regular advertisement timer, removes the value of **Adver_Timer**, immediately sends a VRRP advertisement packet with priority 0, and switches to the initialize state.
- If the timer for sending VRRP packets times out or a VRRP packet with priority 0 is received, the VRRP advertisement message is sent immediately, the timer for sending VRRP packets is reset, and **Adver_Timer** is assigned to **Advertisement_Interval**.
- If the priority of the received VRRP packet is greater than or equal to that of the corresponding VRRP virtual

router at the local end and the source IP address of the received packet is greater than the primary IP address at the local end, the host timeout timer is reset, the regular advertisement timer is configured, and the virtual router switches to the backup state.

- If none of the above requirements is met, the packets are discarded.

1.1.5 VRRP Election

VRRP provides a simple mechanism for electing the master router, which provides the actual routing and forwarding service. The master router is elected in the following order:

(1) VRRP judges whether the VRRP device is an IP address owner. If so, VRRP switches to the master state.

(2) VRRP judges the VRRP priority in the same VRRP group. The device with a larger priority is in the master state.

(3) VRRP judges the primary IP address of the network port. The device with a larger primary IP address changes to the master state.

(4) The backup device determines whether to switch the state by monitoring the VRRP packet regularly sent by the master device. It switches the state in the following two cases:

  - If the received advertisement state of the master device is normal, the priority of the master device's advertisement is lower than that of the backup device, and the preemption mode has been configured, the backup device switches to the master state.
  - If no state advertisement is received from the master device within the timeout period and the preemption mode is configured, the backup device switches to the master state.

1.1.6 VRRP Timer

The main VRRP timers include the VRRP advertisement sending interval timer and the VRRP preemption delay timer.

- VRRP advertisement sending interval timer

  You can adjust the time interval for the master router to send VRRP advertisement packets by configuring the VRRP advertisement sending interval timer. If the backup router still fails to receive a VRRP advertisement packet after waiting for at least three intervals, it regards itself as the master router, and sends a VRRP advertisement packet to reelect the master router.

- VRRP preemption delay timer

  To avoid frequent master/backup switching between the members of the backup group and allow the backup router to have enough time to collect necessary information (such as the routing information), the backup router does not immediately preempt the position of the master router after receiving the advertisement packet with a priority lower than the local priority, but waits for a period of time (preemption delay) before sending a VRRP advertisement packet to take the place of the original master router.

1.1.7 VRRP Tracking

By correlating with the tracking function, VRRP monitors port state changes and the IP host accessibility and automatically adjusts the priority of the backup group to trigger role competition in the backup group, which causes state switching in the backup group and achieves fault monitoring and automatic switching. In this way, the network traffic is not interrupted. Two detection methods are available:

- Port state: VRRP detects the port state by receiving port state change messages. When a port is no longer

in the up state, the priority of the current master router is automatically reduced to enable other backup routers to have the opportunity to become the master router. This avoids the failure of the entire virtual router due to the disconnection of a certain line.

- Host accessibility: Internet Control Message Protocol (ICMP) detection packets are sent regularly, and the time interval for sending detection packets, timeout time for waiting for responses, and continuous timeout count are configured to judge accessibility of the destination addresses.

Caution

- A monitored port must be a routable L3 logical port (for example, a routed port, an SVI, or a loopback port). If a VRRP group is an IPv6 group, the IPv6 function needs to be enabled on the port first.
- The decrease in the priority value must be greater than the priority difference between the master and backup devices; otherwise the priority of the master device may be the same as that of the backup device after priority adjustment, and the master/backup state cannot be switched.

1.1.8 Protocols and Standards

- RFC 2338: Virtual Router Redundancy Protocol
- RFC 3768: Virtual Router Redundancy Protocol (VRRP)
- RFC 5798: Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6

1.2 Restrictions and Guidelines

- The IPv6 VRRP and IPv4 VRRP groups share the VRRP group ID. One VRRP group ID is applicable to an IPv4 VRRP group and an IPv6 VRRP group configured on the same port.
- When the IPv4 VRRP and IPv6 VRRP groups of the same port use the same VRRP group ID, two VRRP group IDs are used.
- When the VRRP status changes and a rate limit log is generated, to ensure that the rate limit log of status change is not lost, the system delays rate limit log output within the configured rate limit interval (50s by default).

1.3 Configuration Task Summary

VRRP configuration includes the following tasks:

(1) Configuring IPv4 VRRP

(2) Configuring IPv6 VRRP

(3) Configuring IPv4 VRRP Tracking

(4) Configuring IPv6 VRRP Tracking

(5) (Optional) Configuring VRRP Attributes

All the following configuration tasks are optional and may be selected as needed.

- Configuring VRRP Basic Attributes
- Configuring a Method of Sending IPv4 VRRP Packets on a Super VLAN Port
- Configuring the Dual-Active Mode for an IPV4 VRRP Group
- Configuring the IPv4 VRRP Packet Version

1.4 Configuring IPv4 VRRP

1.4.1 Overview

IPv4 VRRP creates a backup group on a specified LAN segment after the backup group ID and virtual IPv4 address are configured, and then the VRRP single backup function is enabled on the corresponding port. You can configure multiple VRRP groups on the same Ethernet port to achieve load balancing and offer more stable and reliable network services through mutual backup.

To prevent illegal users from building packets to attack the backup group, you can add authentication words in VRRP packets to verify received VRRP packets. VRRP provides the following authentication modes:

- **md5**: The sending router uses the authentication word and MD5 algorithm for digest operation of VRRP packets and stores the result in the Authentication Header. The receiving router performs the same operation based on the authentication word and MD5 algorithm and compares the result with that in the Authentication Header. If they are the same, the received VRRP packet is legal; otherwise, the received packet is illegal.
- **simple**: The sending router adds the authentication word to the VRRP packet. The receiving router compares the authentication word in the received packet with the local authentication word. If they are the same, the received VRRP packet is legal; otherwise, the received packet is illegal.

1.4.2 Restrictions and Guidelines

- To achieve VRRP, the routers in a VRRP group must be configured with the same virtual IPv4 address.
- To achieve mutual backup between multiple IPv4 VRRP groups, configure multiple same IPv4 VRRP groups with different priorities on ports so that they act as the master and backup groups mutually.
- When enabling MD5 authentication for a batch of VRRP groups, run the **vrrp timers advertise** command to increase the interval. Otherwise, the session may be unstable.
- The two authentication modes are subject to the **service password-encryption** command. If the **service password-encryption** command is globally configured:
  - If the **vrrp** *group-id* **authentication simple 0** *key* command is configured, this command is displayed as ciphertext of **vrrp** *group-id* **authentication simple 7** *key*, that is, the simple plaintext is converted into simple ciphertext for storage.
  - If the **vrrp** *group-id* **authentication md5 0** *key* command is configured, this command is displayed as ciphertext of **vrrp** *group-id* **authentication md5 7** *key*.
- The **vrrp** *group-id* **authentication** *key* command is always displayed as simple plaintext. That is, regardless of whether the service password-encryption command is configured, the **vrrp** *group-id* **authentication** *key* command is always displayed as simple plaintext in the echo of the **show running-config** command.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Enable IPv4 VRRP.

vrrp *group-id* **ip** *ipv4-address* [**secondary**]

IPv4 VRRP is disabled on a port by default.

(5) Configure a priority for the IPv4 VRRP group.

vrrp *group-id* **priority** *priority*

The default priority of an IPv4 VRRP group is **100**.

(6) (Optional) Configure a VRRP packet standard for the IPv4 VRRP group.

vrrp *group-id* **version** { **2** | **3** }

IPv4 VRRP adopts the VRRPv2 standard by default.

(7) (Optional) Configure an authentication string for the IPv4 VRRP group.

vrrp *group-id* **authentication** [{ **md5** | **simple** } { **0** | **7** }] key

The authentication mode and word for IPv4 VRRP packets are not configured by default.

(8) (Optional) Configure a name for the IPv4 VRRP group.

vrrp *group-id* **description** *group-name*

No VRRP group name is configured by default.

(9) (Optional) Configure a VRRP advertisement interval for the IPv4 VRRP master router.

vrrp *group-id* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* }

The default VRRP advertisement interval of the VRRP master router is **1** second.

(10) (Optional) Enable the IPv4 VRRP timer learning function.

vrrp *group-id* **timers learn**

The advertisement interval timer learning function is disabled for an IPv4 VRRP group by default.

(11) (Optional) Configure the preemption mode for the IPv4 VRRP group.

vrrp *group-id* **preempt** [**delay** *delay-seconds*]

IPv4 VRRP runs in the preemption mode without preemption delay by default.

(12) (Optional) Configure a startup delay for the VRRP group on the port.

vrrp delay { **minimum** *min-seconds* | **reload** *reload-seconds* }

No VRRP group startup delay is configured by default.

1.5 Configuring IPv6 VRRP

1.5.1 Overview

IPv6 VRRP creates a backup group on a specified LAN segment after the backup group ID and virtual IPv6 address are configured, and then the VRRP single backup function is enabled on the corresponding port. You can configure multiple VRRP groups on the same Ethernet port to achieve load balancing and offer more stable and reliable network services through mutual backup.

1.5.2 Restrictions and Guidelines

- The first configured virtual address for IPv6 VRRP must be a link-local address, which can be deleted only after other virtual addresses are deleted.
- The IPv6 function must be enabled on a port before IPv6 VRRP is configured.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Enable the IPv6 function on the port.

ipv6 enable

(5) Enable IPv6 VRRP.

vrrp *group-id* **ipv6** *ipv6-address*

IPv6 VRRP is disabled on a port by default.

(6) Enable the function of receiving packets whose destination addresses are the IPv6 address of the virtual router.

vrrp ipv6 accept_mode

By default, an IPv6 VRRP group in the master state is not permitted to receive packets whose destination addresses are the IPv6 address of a virtual router, except the IPv6 VRRP group in owner state or the received NA/NS packets.

(7) Configure a priority for the IPv6 VRRP group.

vrrp ipv6 *group-id* **priority** *priority*

The default priority of an IPv6 VRRP group is **100**.

(8) (Optional) Configure a name for the IPv6 VRRP group.

vrrp ipv6 *group-id* **description** *group-name*

No VRRP group name is configured by default.

(9) (Optional) Configure a VRRP advertisement interval for the IPv6 VRRP master router.

vrrp ipv6 *group-id* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* }

The default VRRP advertisement interval of the VRRP master router is **1** second.

(10) (Optional) Enable the IPv6 VRRP timer learning function.

vrrp ipv6 *group-id* **timers learn**

The advertisement interval timer learning function is disabled for an IPv6 VRRP group by default.

(11) (Optional) Configure the preemption mode for the IPv6 VRRP group.

vrrp ipv6 *group-id* **preempt** [**delay** *delay-seconds*]

IPv6 VRRP runs in the preemption mode without preemption delay by default.

1.6 Configuring IPv4 VRRP Tracking

1.6.1 Overview

IPv4 VRRP tracking monitors the changes in port state and the IPv4 host accessibility. You can configure the optional packet detection parameter and bidirectional forwarding detection (BFD) correlation. The priority of a backup group can be adjusted dynamically to implement automatic switching and recovery of the backup group in case of a failure monitored.

1.6.2 Restrictions and Guidelines

- A monitored port must be a routable L3 logical port (for example, a routed port, an SVI, a loopback port).
- The support for BFD depends on the product version.
- If a VRRP group uses the actual IP address of an Ethernet port (in the owner state), the group priority is 255, and the monitored IP address or port can be configured, but the priority of the VRRP group is not changed.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Configure a port to be monitored by an IPv4 VRRP group.

vrrp *group-id* **track** { *interface-type interface-number* | **bfd** *interface-type interface-number ipv4-address* } [*priority*]

No port to be monitored by an IPv4 VRRP group is configured by default. If a port to be monitored by an IPv4 VRRP group is configured and the priority parameter is not specified, the priority change value is 10.

(5) Configure an IP address to be monitored by the IPv4 VRRP group.

vrrp *group-id* **track** *ipv4-address* [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*]

No IP address to be monitored by an IPv4 VRRP group is configured by default. If an IP address to be monitored by an IPv6 VRRP group is configured, the time interval for sending detection packets is 3 seconds, and the timeout time for waiting for a response to a sent detection packet is 1 second, and the consecutive timeout count for judging that a tracked IP address is unreachable is 3.

(6) Configure BFD correlation with the IPv4 VRRP group.

vrrp *group-id* **bfd** *ipv4-address*

BFD correlation with an IPv4 VRRP group is not configured on a port by default.

(7) Return to the global configuration mode.

exit

(8) Configure global IPv4 VRRP BFD.

vrrp bfd *interface-type interface-number ipv4-address*

By default, no global BFD mode is configured for IPv4 VRRP to detect whether the master device is active.

1.7 Configuring IPv6 VRRP Tracking

1.7.1 Overview

IPv6 VRRP tracking monitors the changes in port state and the IPv6 host accessibility. You can configure the optional packet detection parameter to dynamically adjust the priority of a backup group and implement automatic switching and recovery of the backup group in case of a failure monitored.

1.7.2 Restrictions and Guidelines

- A monitored port must be a routable L3 logical port (for example, a routed port, an SVI, a loopback port).
- The IPv6 function needs to be first enabled on a port.
- If a tracked host IP address is a link-local address, specify a network port.
- If a VRRP group (in the owner state) uses the actual IP address of an Ethernet port, the group priority is 255, and the monitored IP address or port can be configured, but the priority of the VRRP group is not changed.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Enable the IPv6 function on the port.

ipv6 enable

(5) Configure a port to be monitored by an IPv6 VRRP group.

vrrp ipv6 *group-id* **track** { *interface-type interface-number* | **bfd** *interface-type interface-number peer-ipv6-address* } [*priority*]

No port to be monitored by an IPv6 VRRP group is configured by default. If a port to be monitored by an IPv6 VRRP group is configured and the priority parameter is not specified, the priority change value is 10.

(6) Configure an IPv6 address to be monitored by the IPv6 VRRP group.

vrrp ipv6 *group-id* **track** { *ipv6-global-address* | *ipv6-linklocal-address interface-type interface-number* } [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*Priority*]

No IP address to be monitored by an IPv6 VRRP group is configured by default. If an IP address to be monitored by an IPv6 VRRP group is configured, the time interval for sending detection packets is 3 seconds, the timeout time for waiting for a response to a sent detection packet is 1 second, and the consecutive timeout count for judging that a tracked IP address is unreachable is 3.

(7) Configure the linkage between IPv6 VRRP groups and BFD.

vrrp ipv6 *group-id* **bfd** *ipv6-address*

Linkage between IPv6 VRRP groups and BFD is not configured on the interface by default.

(8) Exit the global configuration mode.

exit

(9) Configure global IPv6 VRRP BFD.

vrrp ipv6 bfd *interface-type interface-number ipv6-address*

Global BFD is not configured to check whether the Master is in active state for IPv6 VRRP by default.

1.8 Configuring VRRP Attributes

1.8.1 Overview

If a VRRP group has been set up, you can configure enhancement to increase the usability of the VRRP group.

1.8.2 Configuration Tasks

The VRRP attribute configuration includes the following tasks:

All the following configuration tasks are optional and maybe selected as needed.

- Configuring VRRP Basic Attributes
- Configuring a Method of Sending IPv4 VRRP Packets on a Super VLAN Port
- Configuring the Dual-Active Mode for an IPV4 VRRP Group
- Configuring the IPv4 VRRP Packet Version

1.8.3 Configuring VRRP Basic Attributes

1. Overview

If a VRRP group has been set up, you can configure basic attributes according to the actual situation.

2. Prerequisites

A VRRP group has been set up.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure VRRP to add the IP packet header and authentication header to the authentication field when using the MD5 algorithm. This step can be performed only for VRRPv2.

vrrp authentication md5 with-ip-auth-header

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI interface configuration mode.

  interface vlan *interface-number*

(5) Configure VRRP basic attributes as needed.

- Configure a priority for the IPv4 VRRP group.

  vrrp *group-id* **priority** *priority*

  The default priority of an IPv4 VRRP group is **100**.

- Configure a VRRP advertisement interval for the IPv4 VRRP master router.

  vrrp *group-id* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* }

  The default VRRP advertisement interval of the VRRP master router is **1** second.

- Configure the preemption mode for the IPv4 VRRP group.

  vrrp *group-id* **preempt** [**delay** *delay-seconds*]

  IPv4 VRRP runs in the preemption mode without preemption delay by default.

- Enable the IPv4 VRRP timer learning function.

  vrrp *group-id* **timers learn**

  The advertisement interval timer learning function is disabled for an IPv4 VRRP group by default.

- Configure a name for the IPv4 VRRP group.

  vrrp *group-id* **description** *group-name*

  No VRRP group name is configured by default.

- Configure a startup delay for the VRRP group on a port.

  vrrp delay { **minimum** *min-seconds* | **reload** *reload-seconds* }*

  No VRRP group startup delay is configured by default.

1.8.4 Configuring a Method of Sending IPv4 VRRP Packets on a Super VLAN Port

1. Overview

The IPv4 VRRP protocol packets can be sent by the following three methods in a super-VLAN. You can configure the method of sending advertisement packets.

- Sending IPv4 VRRP packets only to the first up sub VLAN in a super-VLAN.
- Sending IPv4 VRRP packets to a specified sub VLAN in a super-VLAN.
- Sending IPv4 VRRP packets to all the sub VLANs in a super-VLAN.

2. Restrictions and Guidelines

- The configuration is effective only on super-VLAN interfaces.
- If VRRP and VRRP plus are both enabled on a super-VLAN interface, VRRP packets are sent to all the up

sub-VLAN interfaces of the super-VLAN interface.

3. Prerequisites

VRRP has been enabled on a super-VLAN interface.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the VLAN configuration mode.

vlan *vlan-id*

(4) Configure the super-VLAN mode.

supervlan

The super-VLAN mode is not configured by default.

(5) Configure a sub-VLAN range.

subvlan *vlan-range*

No sub-VLAN range is configured by default.

(6) Enter the SVI configuration mode.

interface vlan *vlan-id*

(7) Configure a method of sending IPv4 VRRP packets on a super-VLAN port.

vrrp detection-vlan { **first-subvlan** | *subvlan-id* }

The IPv4 VRRP packets on a super-VLAN port are sent to the first up sub VLAN only by default.

1.8.5 Configuring the Dual-Active Mode for an IPV4 VRRP Group

1. Overview

A VRRP group works in master/backup mode by default. To set both ends of a VRRP group in the master state and avoid sending keepalive packets, configure the dual-active mode for the VRRP group.

2. Restrictions and Guidelines

- The dual-active mode can be configured only on an SVI.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the SVI configuration mode.

interface vlan *vlan-id*

(4) Configure a VRRP group to work in dual-active state and configure the VRRP group not to send keepalive packets.

vrrp mode dual-active

A VRRP group works in master/backup mode by default.

1.8.6 Configuring the IPv4 VRRP Packet Version

1. Overview

The devices belonging to the same VRRP group should send packets according to the unified packet protocol: VRRPv2 or VRRPv3. By default, VRRPv2 is used for sending packets. VRRPv3 routers can recognize VRRPv2 packets, but VRRPv2 routers cannot recognize VRRPv3 packets. Configuring this function enables VRRPv3 routers to send VRRPv2 packets so as to communicate with VRRPv2 routers.

2. Restrictions and Guidelines

- The configuration is applicable to IPv4 VRRP only.
- If simple authentication has been configured for a VRRP group and the VRRP group is configured to send VRRPv2 packets, the authentication information is carried. If a VRRP group is configured to send VRRPv3 packets, the authentication information is not carried.
- The configuration only applies to the sending mode of VRRP packets and does not affect the receiving mode. For example, a VRRPv3 router can identify both VRRPv2 and VRRPv3 packets.

3. Prerequisites

IPv4 VRRP has been configured.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Configure the VRRP packet standard for an IPv4 VRRP group.

vrrp *group-id* **version** { **2** | **3** }

IPv4 VRRP adopts the VRRPv2 standard by default.

1.9 Monitoring

Run the **show** command to check the configuration.

You can run the **debug** command to output debugging information.

Caution

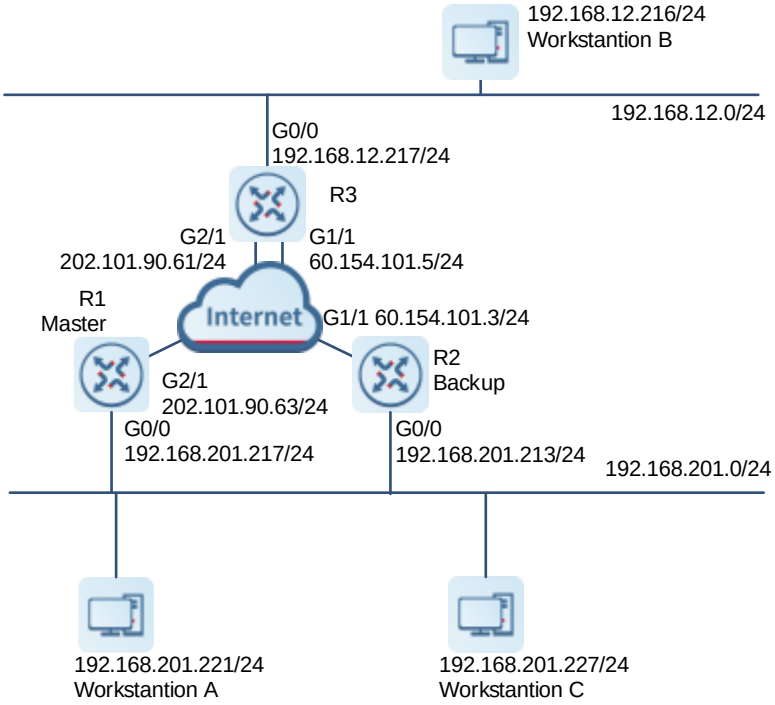
Debugging occupies system resources, so disable it immediately if not required.

Table 1-2 VRRP Monitoring

Command	Purpose
show [**ipv6**] **vrrp** [**brief** | *group-id*]	Displays the brief or detailed information of IPv4/IPv6 VRRP.
show [**ipv6**] **vrrp interface** *interface-type interface-number* [**brief**]	Displays the information of an IPv4/IPv6 VRRP group on a specified port.
show vrrp [**brief** | *group-id*]	Displays the brief or detailed information of IPv4 VRRP.
show vrrp interface *interface-type interface-number* [**brief**]	Displays the information of an IPv4 VRRP group on a specified port.
show [**ipv6**] **vrrp bfd-neighbor**	Displays the association between the VRRP and BFD.
show vrrp client [[**pid** *pid*] **brief** | **reset**]	Displays information about clients connected to the VRRP server.
show vrrp jemalloc-statistic	Displays detailed Jemalloc information about the VRRP software.
show vrrp log { **dbg** | **error** | **init** }	Displays the VRRP log files.
show vrrp memory	Displays the memory information of a VRRP process.
show vrrp mom	Displays the exchange information between the VRRP and the MOM.
show vrrp packet statistics [*interface-type interface-number* | **total**]	Displays the statistics of VRRP packets.
show vrrp server-statistic [**reset**]	Displays the statistics of the VRRP server.
show [**ipv6**] **vrrp work-state** [**interface** *interface-type interface-number* [*group-id*]]	Displays the current detailed status of the VRRP group.

Command	Purpose
debug [**ipv6**] **vrrp**	Debugs VRRP errors, events, packets, and state.
debug [**ipv6**] **vrrp errors**	Debugs VRRP errors.
debug [**ipv6**] **vrrp events**	Debugs VRRP events.
debug vrrp packets [**acl** *acl-id* **|** [**icmp** | **protocol**] **interface** *interface-type interface-number* [*group-id*]] **debug ipv6 vrrp packets** [**acl** *acl-name* | [**icmp** | **protocol**] **interface** *interface-type interface-number* [*group-id*]]	Debugs VRRP packets.
debug [**ipv6**] **vrrp state**	Debugs VRRP state.
debug vrrp packets [**acl** *acl-id* **|** [**icmp** | **protocol**] **interface** *interface-type interface-number* [*group-id*]]	Debugs VRRP packets.
debug vrrp state	Debugs VRRP state.

1.10 Configuration Examples



1.10.1 Configuring IPv4 VRRP

1. Requirements

An IPv4 VRRP group and a to-be-monitored port need to be configured.

2. Topology

Figure 1-9 Topology for Configuring a VRRP Group and a To-Be-Monitored Port

3. Notes

- Configure the work station cluster (192.168.201.0/24) to use the backup group composed of routers R1 and R2 and set the gateway address to the virtual router IP address configured for the backup group (192.168.201.1) so that the work station cluster accesses the remote work station cluster (192.168.12.0 /24) through the virtual router 192.168.201.1.
- On router R1, configure GigabitEthernet 2/1 as a VRRP monitored port.
- No VRRP but an ordinary routing function is configured on router 3.

4. Procedure

Configure R1.

(1) Configure an interface address.

```
R1> enable
R1# configure terminal
R1(config)# interface gigabitEthernet 0/1
R1(config-if-GigabitEthernet 0/1)# no switchport
R1(config-if-GigabitEthernet 0/1)# ip address 192.168.201.217 255.255.255.0
R1(config-if-GigabitEthernet 0/1)# exit
R1(config)# interface gigabitEthernet 0/2
R1(config-if-GigabitEthernet 0/2)# no switchport
R1(config-if-GigabitEthernet 0/2)# ip address 202.101.90.63 255.255.255.0
R1(config-if-GigabitEthernet 0/2)# exit
```

(2) Configure OSPF routes to ensure Layer 3 reachability between devices.

```
R1(config)# router ospf
R1(config-router)# network 202.101.90.0 0.0.0.255 area 10
R1(config-router)# network 192.168.201.0 0.0.0.255 area 10
R1(config-router)# exit
```

(3) Configure VRRP on GigabitEthernet 0/1.

Set the VRRP priority to 120.

```
R1(config)# interface gigabitEthernet 0/1
R1(config-if-GigabitEthernet 0/1)# vrrp 1 priority 120
```

Set the interval for a VRRP group to send VRRP advertisements to 3 seconds.

```
R1(config-if-GigabitEthernet 0/1)# vrrp 1 timers advertise 3
```

Set the ID of a VRRP group to 1 and virtual address to 192.168.201.1.

```
R1(config-if-GigabitEthernet 0/1)# vrrp 1 ip 192.168.201.1
```

Configure GigabitEthernet 0/2 as a monitored port of a VRRP group and configure the VRRP priority to change to 30 when the link state of the monitored port changes.

```
R1(config-if-GigabitEthernet 0/1)# vrrp 1 track GigabitEthernet 0/2 30
R1(config-if-GigabitEthernet 0/1)# exit
```

Configure R2.

(1) Configure an interface address.

```
R2> enable
R2# configure terminal
R2(config)# interface GigabitEthernet 0/1
R2(config-if-GigabitEthernet 0/1)# no switchport
R2(config-if-GigabitEthernet 0/1)# ip address 192.168.201.213 255.255.255.0
R2(config-if-GigabitEthernet 0/1)# exit
R2(config)# interface GigabitEthernet 0/2
R2(config-if-GigabitEthernet 0/2)# no switchport
R2(config-if-GigabitEthernet 0/2)# ip address 60.154.101.3 255.255.255.0
R2(config-if-GigabitEthernet 0/2)# exit
```

(2) Configure OSPF routes to ensure Layer 3 reachability between devices.

```
R2(config)# router ospf
R2(config-router)# network 60.154.101.0 0.0.0.255 area 10
R2(config-router)# network 192.168.201.0 0.0.0.255 area 10
```

(3) Set the ID of a VRRP group to 1 and virtual address to 192.168.201.1.

Set the ID of a VRRP group to 1 and virtual address to 192.168.201.1.

```
R2(config-if-GigabitEthernet 0/1)# vrrp 1 ip 192.168.201.1
```

Set the interval for a VRRP group to send VRRP advertisements to 3 seconds.

```
R2(config-if-GigabitEthernet 0/1)# vrrp 1 timers advertise 3
```

Configure R3.

(1) Configure an interface address.

```
R3> enable
R3# configure terminal
R3(config)# interface GigabitEthernet 0/1
R3(config-if-GigabitEthernet 0/1)# no switchport
R3(config-if-GigabitEthernet 0/1)# ip address 192.168.12.217 255.255.255.0
R3(config-if-GigabitEthernet 0/1)# exit
R3(config)# interface GigabitEthernet 0/2
R3(config-if-GigabitEthernet 0/2)# no switchport
R3(config-if-GigabitEthernet 0/2)# ip address 60.154.101.5 255.255.255.0
R3(config-if-GigabitEthernet 0/2)# exit
R3(config)# interface GigabitEthernet 0/3
R3(config-if-GigabitEthernet 0/3)# no switchport
R3(config-if-GigabitEthernet 0/3)# ip address 202.101.90.61 255.255.255.0
R3(config-if-GigabitEthernet 0/3)# exit
```

(2) Configure OSPF routes to ensure Layer 3 reachability between devices.

```
R3(config)# router ospf
R3(config-router)# network 202.101.90.0 0.0.0.255 area 10
R3(config-router)# network 192.168.12.0 0.0.0.255 area 10
R3(config-router)# network 60.154.101.0 0.0.0.255 area 10
```

5. Verification

(1) Run the **show vrrp** command to verify the configuration.

Configure R1 as the master router.

```
R1# show vrrp
GigabitEthernet 0/1 - Group 1
  State is Master
  Virtual IP address is 192.168.201.1 configured
  Virtual MAC address is 0000.5e00.0101
  Advertisement interval is 3 sec
  Preemption is enabled
    min delay is 0 sec
  Priority is 120
  Master Router is 192.168.201.217 (local), priority is 120
  Master Down interval is 10.59 sec
  Tracking state of 1 interface, 1 up:
up   GigabitEthernet 0/2 priority decrement=30
```

Configure R2 as the backup router.

```
R2#show vrrp
GigabitEthernet 0/1 - Group 1
  State is Backup
  Virtual IP address is 192.168.201.1 configured
  Virtual MAC address is 0000.5e00.0101
  Advertisement interval is 3 sec
```

```
  Preemption is enabled
    min delay is 0 sec
  Priority is 100
  Master Router is 192.168.201.217 , priority is 120
  Master Advertisement interval is 3 sec
  Master Down interval is 10.82 sec
```

(2) When GigabitEthernet 0/2 of R1 used to connect to the WAN is unavailable, the priority of R1 in the VRRP group is decreased by30 to 90. In this case, R2 becomes the master router.

```
R1# show vrrp
GigabitEthernet 0/1 - Group 1
  State is Backup
  Virtual IP address is 192.168.201.1 configured
  Virtual MAC address is 0000.5e00.0101
  Advertisement interval is 3 sec
  Preemption is enabled
    min delay is 0 sec
  Priority is 100
  Master Router is 192.168.201.217 , priority is 100
  Master Advertisement interval is 3 sec
  Master Down interval is 10.82 sec
```

(3) When GigabitEthernet 0/2 of R1 connected to the WAN changes to Up, the priority of R1 in the VRRP group is increased by30 to 120, and R1 becomes the master router again.

```
R1# show vrrp
GigabitEthernet 0/1 - Group 1
  State is Master
  Virtual IP address is 192.168.201.1 configured
  Virtual MAC address is 0000.5e00.0101
  Advertisement interval is 3 sec
  Preemption is enabled
    min delay is 0 sec
  Priority is 120
  Master Router is 192.168.201.217 (local), priority is 120
  Master Down interval is 10.59 sec
  Tracking state of 1 interface, 1 up:
up   GigabitEthernet 0/2 priority decrement=30
```

6. Configuration Files

- Device R1 configuration file

```
hostname R1
!
interface GigabitEthernet 0/0
 no switchport
 ip address 192.168.201.217 255.255.255.0
 vrrp 1 priority 120
 vrrp 1 timers advertise 3
```

```
 vrrp 1 ip 192.168.201.1
 vrrp 1 track GigabitEthernet 2/1 30
!
interface GigabitEthernet 2/1
 no switchport
 ip address 202.101.90.63 255.255.255.0
!
router ospf
 network 202.101.90.0 0.0.0.255 area 10
 network 192.168.201.0 0.0.0.255 area 10
!
end
```

- Device R2 configuration file

```
hostname R2
!
interface GigabitEthernet 0/0
 no switchport
 ip address 192.168.201.213 255.255.255.0
 vrrp 1 timers advertise 3
 vrrp 1 ip 192.168.201.1
!
interface GigabitEthernet 1/1
 no switchport
 ip address 60.154.101.3 255.255.255.0
!
router ospf
 network 60.154.101.0 0.0.0.255 area 10
 network 192.168.201.0 0.0.0.255 area 10
!
end
```

- Device R3 configuration file

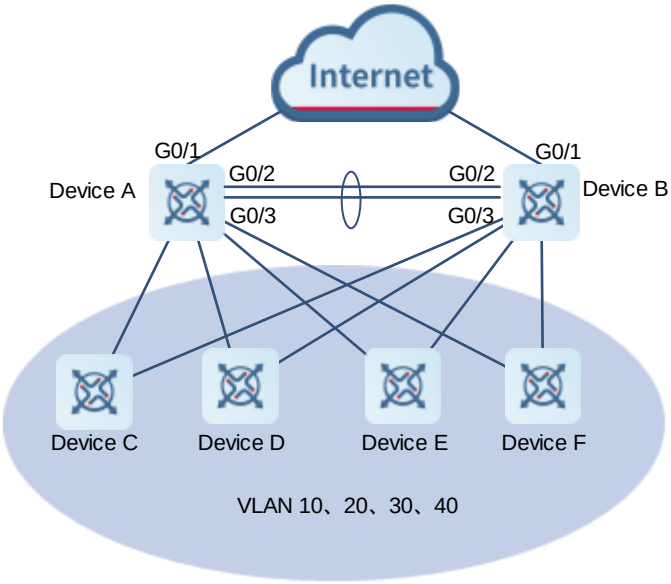
```
hostname R3
!
interface GigabitEthernet 0/0
 no switchport
 ip address 192.168.12.217 255.255.255.0
!
interface GigabitEthernet 1/1
 no switchport
 ip address 60.154.101.5 255.255.255.0
!
interface GigabitEthernet 2/1
 no switchport
 ip address 202.101.90.61 255.255.255.0
!
```

```
router ospf
 network 202.101.90.0 0.0.0.255 area 10
 network 192.168.12.0 0.0.0.255 area 10
 network 60.154.101.0 0.0.0.255 area 10
!

end
```

7. Common Errors

- Different virtual IP addresses of VRRP are configured on the routers in the same VRRP group, resulting in multiple master routers in the group.
- Different VRRP advertisement transmission intervals are configured on the routers in the same VRRP group and the timer learning function is not configured. As a result, multiple master routers arise in the group.
- Different VRRP packet versions are configured on the routers in the same VRRP group, resulting in multiple master routers in the group.
- For VRRPv2, the Ethernet ports of the routers in the same VRRP group all use the plaintext password authentication mode but use different authentication strings. As a result, multiple master routers arise in the group.



1.10.2 Configuring VRRP + MSTP

1. Requirements

As shown in Figure 1-10, VRRP and Multiple Spanning Tree Protocol (MSTP) can be configured to build a dual link backup network by using access devices and aggregation devices.

2. Topology

Figure 1-10 Topology for Configuring VRRP + MSTP

3. Notes

- Enable MSTP on devices (devices A, B, C, D, E, and F in this example). Configure VLAN-instance mappings (map VLANs 10 and 20 to instance 1, VLANs 30 and 40 to instance 2, and the rest VLANs to instance 0), and configure gateway devices (devices A and B in this example) as the root bridges of corresponding instances.
- Add the SVIs of all VLANs to corresponding VRRP groups, and set gateways to the master and backup routers of corresponding backup groups. Table 1-3 lists the configuration details in the example.

Table 1-3 Parameters for VRRP + MSTP Topology Configuration

Gateway	VLAN ID	SVI	Backup Group	Virtual IP Address	State
Device A	10	192.168.10.2	VRRP 10	192.168.10.1	Master
Device B		192.168.10.3			Backup
Device A	20	192.168.20.2	VRRP 20	192.168.20.1	Master
Device B		192.168.20.3			Backup
Device A	30	192.168.30.2	VRRP 30	192.168.30.1	Backup
Device B		192.168.30.3			Master
Device A	40	192.168.40.2	VRRP 40	192.168.40.1	Backup
Device B		192.168.40.3			Master

- Configure the uplink ports (port GigabitEthernet 0/1 of devices A and B in the example) of master routers in backup groups as the monitored ports of the master routers.
  - Create VLANs. Create VLANs 10, 20, 30, and 40 on devices A and B.
  - Configure MST regions. Map VLANs 10 and 20 to instance 1, VLANs 20 and 30 to instance 2, and the rest VLANs to instance 0 on devices A and B.
  - Configure device A as the root bridge of MST 0 and MST 1, and device B as the root bridge of MST 2.
  - Enable MSTP.
  - Configure SVIs for all the VLANs, add the SVIs to corresponding backup groups, and configure virtual IP addresses for the backup groups. Table 1-3 provides the corresponding configuration parameters.
  - Configure master routers and backup routers for all the groups.
  - Configure the uplink ports of master routers in VRRP groups as monitored ports of the VRRP groups.
  - Configure the interconnected ports of the core routers as a Layer 2 link aggregation.

4. Procedure

(1) Perform the following configuration on Device A:

Create VLANs 10, 20, 30, and 40.

```
DeviceA> enable
DeviceA# configure terminal
```

```
DeviceA(config)# vlan range 10,20,30,40
DeviceA(config-vlan-range)# exit
```

Map VLANs 10 and 20 to instance 1, VLANs 30 and 40 to instance 2, and the rest VLANs to instance 0.

```
DeviceA(config)# spanning-tree mst configuration
DeviceA(config-mst)# instance 1 vlan 10,20
DeviceA(config-mst)# instance 2 vlan 30,40
DeviceA(config-mst)# exit
```

On switch A, set the priority of MST 0 and MST 1 to **4096**, and the priority of MST 2 to **8192**.

```
DeviceA(config)# spanning-tree mst 0 priority 4096
DeviceA(config)# spanning-tree mst 1 priority 4096
DeviceA(config)# spanning-tree mst 2 priority 8192
```

Enable MSTP.

```
DeviceA(config)# spanning-tree
```

Configure SVIs for all the VLANs, add the SVIs to corresponding backup groups, and configure virtual IP addresses for the backup groups.

```
DeviceA(config)# interface vlan 10
DeviceA(config-if-VLAN 10)# ip address 192.168.10.2 255.255.255.0
DeviceA(config-if-VLAN 10)# vrrp 10 ip 192.168.10.1
DeviceA(config-if-VLAN 10)# exit
DeviceA(config)# interface vlan 20
DeviceA(config-if-VLAN 20)# ip address 192.168.20.2 255.255.255.0
DeviceA(config-if-VLAN 20)# vrrp 20 ip 192.168.20.1
DeviceA(config-if-VLAN 20)# exit
DeviceA(config)# interface vlan 30
DeviceA(config-if-VLAN 30)# ip address 192.168.30.2 255.255.255.0
DeviceA(config-if-VLAN 30)# vrrp 30 ip 192.168.30.1
DeviceA(config-if-VLAN 30)# exit
DeviceA(config)# interface vlan 40
DeviceA(config-if-VLAN 40)# ip address 192.168.40.2 255.255.255.0
DeviceA(config-if-VLAN 40)# vrrp 40 ip 192.168.40.1
DeviceA(config-if-VLAN 40)# exit
```

Increase the priority of backup groups 10 and 20 on switch A to **120**.

```
DeviceA(config)# interface vlan 10
DeviceA(config-if-VLAN 10)# vrrp 10 priority 120
DeviceA(config-if-VLAN 10)# exit
DeviceA(config)# interface vlan 20
DeviceA(config-if-VLAN 20)# vrrp 20 priority 120
DeviceA(config-if-VLAN 20)# exit
```

Configure the port GigabitEthernet 0/1 of switch A as a route port, and set the IP address to10.10.1.1/24.

```
DeviceA(config)# interface gigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no switchport
DeviceA(config-if-GigabitEthernet 0/1)# ip address 10.10.1.1 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Configure the port GigabitEthernet 0/1 of switch A as the monitored port of backup groups 10 and 20, and set *Priority decrement* to 30.

```
DeviceA(config)# interface vlan 10
DeviceA(config-if-VLAN 10)# vrrp 10 track gigabitEthernet 0/1 30
DeviceA(config-if-VLAN 10)# exit
DeviceA(config)# interface vlan 20
DeviceA(config-if-VLAN 20)# vrrp 20 track gigabitEthernet 0/1 30
DeviceA(config-if-VLAN 20)# exit
```

Configure the ports GigabitEthernet 0/2 and GigabitEthernet 0/3 to belong to a Layer 2 link aggregation, and configure the link aggregation as a trunk port.

```
DeviceA(config)# interface range gigabitEthernet 0/2-3
DeviceA(config-if-range)# port-group 1
DeviceA(config)# interface aggregateport 1
DeviceA(config-if-AggregatePort 1)# switchport mode trunk
```

(2) Perform the following configuration on device B:

Create VLANs 10, 20, 30, and 40.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# vlan range 10,20,30,40
DeviceB(config-vlan-range)# exit
```

Map VLANs 10 and 20 to instance 1, VLANs 30 and 40 to instance 2, and the rest VLANs to instance 0.

```
DeviceB(config)# spanning-tree mst configuration
DeviceB(config-mst)# instance 1 vlan 10,20
DeviceB(config-mst)# instance 2 vlan 30,40
DeviceB(config-mst)# exit
```

On switch B, set the priority of MST 2 to **4096**, and the priority of MST 0 and MST 1 to **8192**.

```
DeviceB(config)# spanning-tree mst 2 priority 4096
DeviceB(config)# spanning-tree mst 0 priority 8192
DeviceB(config)# spanning-tree mst 1 priority 8192
```

Enable MSTP.

```
DeviceB(config)# spanning-tree
```

Configure SVIs for all the VLANs, add the SVIs to corresponding backup groups, and configure virtual IP addresses for the backup groups.

```
DeviceB(config)# interface vlan 10
DeviceB(config-if-VLAN 10)# ip address 192.168.10.3 255.255.255.0
DeviceB(config-if-VLAN 10)# vrrp 10 ip 192.168.10.1
DeviceB(config-if-VLAN 10)# exit
DeviceB(config)# interface vlan 20
DeviceB(config-if-VLAN 20)# ip address 192.168.20.3 255.255.255.0
DeviceB(config-if-VLAN 20)# vrrp 20 ip 192.168.20.1
DeviceB(config-if-VLAN 20)# exit
DeviceB(config)# interface vlan 30
```

```
DeviceB(config-if-VLAN 30)# ip address 192.168.30.3 255.255.255.0
DeviceB(config-if-VLAN 30)# vrrp 30 ip 192.168.30.1
DeviceB(config-if-VLAN 30)# exit
DeviceB(config)# interface vlan 40
DeviceB(config-if-VLAN 40)# ip address 192.168.40.3 255.255.255.0
DeviceB(config-if-VLAN 40)# vrrp 40 ip 192.168.40.1
DeviceB(config-if-VLAN 40)# exit
```

Increase the priority of VRRP 30 and VRRP 40 on Device B to **120**.

```
DeviceB(config)# interface vlan 30
DeviceB(config-if-VLAN 30)# vrrp 30 priority 120
DeviceB(config-if-VLAN 30)# exit
DeviceB(config)# interface vlan 40
DeviceB(config-if-VLAN 40)# vrrp 40 priority 120
DeviceB(config-if-VLAN 40)# exit
```

Configure the port GigabitEthernet 0/1 of Device B as a route port, and set the IP address to 10.10.2.1/24.

```
DeviceB(config)#interface gigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# no switchport
DeviceB(config-if-GigabitEthernet 0/1)# ip address 10.10.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Configure the port GigabitEthernet 0/1 of Device B as the monitored port of backup groups 30 and 40, and set *Priority decrement* to 30.

```
DeviceB(config)# interface vlan 30
DeviceB(config-if-VLAN 30)# vrrp 30 track gigabitEthernet 0/1 30
DeviceB(config-if-VLAN 30)# exit
DeviceB(config)# interface vlan 40
DeviceB(config-if-VLAN 40)# vrrp 40 track gigabitEthernet 0/1 30
DeviceB(config-if-VLAN 40)# exit
```

Configure the ports GigabitEthernet 0/2 and GigabitEthernet 0/3 to belong to a Layer 2 link aggregation, and configure the link aggregation as a trunk port.

```
DeviceB(config)# interface range gigabitEthernet 0/2-3
DeviceB(config-if-range)# port-group 1
DeviceB(config)# interface aggregateport 1
DeviceB(config-if-AggregatePort 1)# switchport mode trunk
```

5. Verification

(1) Run the **show vrrp brief** commands to check whether the configuration is correct.

- Check the VRRP state of device A.

```
DeviceA# show vrrp brief
Interface  Grp  Pri  timer  Own  Pre  State   Master addr   Group addr
VLAN 10    10   120  3      -    P    Master  192.168.10.2  192.168.10.1
VLAN 20    20   120  3      -    P    Master  192.168.20.2  192.168.20.1
VLAN 30    30   100  3      -    P    Backup  192.168.30.3  192.168.30.1
VLAN 40    40   100  3      -    P    Backup  192.168.40.3  192.168.40.1
```

- Check the VRRP state of device B.

```
DeviceB# show vrrp brief
Interface  Grp  Pri  timer  Own  Pre  State   Master addr   Group addr
VLAN 10    10   100  3      -    P    Backup  192.168.10.2  192.168.10.1
VLAN 20    20   100  3      -    P    Backup  192.168.20.2  192.168.20.1
VLAN 30    30   120  3      -    P    Master  192.168.30.3  192.168.30.1
VLAN 40    40   120  3      -    P    Master  192.168.40.3  192.168.40.1
```

(2) Disconnect the uplink of switch A and run the **show vrrp brief** commands to check the VRRP state of the device.

```
DeviceA# show vrrp brief
Interface  Grp  Pri  timer  Own  Pre  State   Master addr   Group addr
VLAN 10    10   90   3      -    P    Backup  192.168.10.3  192.168.10.1
VLAN 20    20   90   3      -    P    Backup  192.168.20.3  192.168.20.1
VLAN 30    30   100  3      -    P    Backup  192.168.30.3  192.168.30.1
VLAN 40    40   100  3      -    P    Backup  192.168.40.3  192.168.40.1
```

(3) Disconnect the uplink of device B and run the **show vrrp brief** commands to check the VRRP state of the device.

```
DeviceB# show vrrp brief
Interface  Grp  Pri  timer  Own  Pre  State   Master addr   Group addr
VLAN 10    10   100  3      -    P    Master  192.168.10.3  192.168.10.1
VLAN 20    20   100  3      -    P    Master  192.168.20.3  192.168.20.1
VLAN 30    30   120  3      -    P    Master  192.168.30.3  192.168.30.1
VLAN 40    40   120  3      -    P    Master  192.168.40.3  192.168.40.1
```

7. Common Errors

- Different VRRP authentication modes are configured on the Ethernet ports of routers in the same VRRP

group, resulting in multiple master routers in the group.

- For VRRPv2, the Ethernet ports of the routers in the same VRRP group all use the plaintext password authentication mode but use different authentication strings. As a result, multiple master routers arise in the group.
- Different VRRP advertisement transmission intervals are configured on the routers in the same VRRP group and the timer learning function is not configured. As a result, multiple master routers arise in the group.
- Different virtual IP addresses of VRRP are configured on the routers in the same VRRP group, resulting in multiple master routers in the group.

1 Configuring VRRP Plus

1.1 Introduction

Virtual Router Redundancy Protocol Plus (VRRP Plus) is an extension of VRRP. It uses VRRP to implement gateway backup and load balancing in an IEEE 802.3 local area network (LAN). A backup router with VRRP enabled cannot forward packets. To use VRRP to implement load balancing, you need to manually configure multiple VRRP groups and set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This increases the workload of the network administrator. VRRP Plus is designed to address this issue. VRRP Plus automatically implements load balancing. It automatically distributes traffic of different hosts to members of a VRRP Plus group, and you do not need to configure multiple VRRP groups or set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This reduces the workload of the network administrator. You can enable a load balancing policy within a VRRP group without configuring multiple VRRP groups or different default gateways for hosts.

1.1.1 Basic Concepts

1. BVG

The balancing virtual gateway (BVG) allocates virtual MAC addresses to members of a VRRP Plus group. It responds to the gateway Address Resolution Protocol/Neighbor Discovery (ARP/ND) requests in the LAN, and forwards packets of hosts in the LAN.

2. BVF

The balancing virtual forwarder (BVF) forwards packets of hosts in the LAN. If a virtual MAC address is allocated to a BVF, the BVF participates in packet forwarding; otherwise, the BVF does not participate in packet forwarding.

3. Correlation with VRRP

VRRP Plus relies on VRRP, and runs in the following way:

- A master device in VRRP corresponds to a BVG in VRRP Plus.
- A backup device in VRRP corresponds to a BVF in VRRP Plus. Gateway addresses of hosts in a LAN are set to the virtual IPv4/IPv6 address of VRRP.

4. MAC Address Allocation

A BVG allocates virtual MAC addresses to BVFs. For an IPv4 VRRP Plus group, the BVG directly uses the virtual MAC address of VRRP to ensure compatibility between IPv4 VRRP Plus and IPv4 VRRP. That is, the virtual MAC address used by the BVG is 00-00-5E-00-01-{VRID} (VRID is the VRRP group number). The virtual MAC address used by a BVF is 00-1A-A9-16-{MemberID}-{VRID} (MemberID is the member ID of the BVF in the VRRP Plus group). Currently, a VRRP Plus group can have up to four members. The BVG uses the member ID 01, and the other BVFs use the member IDs 02 to 04.

For an IPv6 VRRP Plus group, the BVG directly uses the virtual MAC address of IPv6 VRRP to ensure compatibility between IPv6 VRRP Plus and IPv6 VRRP. That is, the virtual MAC address used by the BVG is

00-00-5E-00-02-{VRID} (VRID is the IPv6 VRRP group number). The virtual MAC address used by a BVF is 14-14-4B-72-{76 + MemberID }-{VRID}. The value range of MemberID is from 01 to 03.

5. Load Balancing Policies

The BVG responds to the gateway ARP/NS requests sent from hosts in a LAN. According to a specific load balancing policy, the BVG responds to hosts by using different virtual MAC addresses. The following load balancing policies are available:

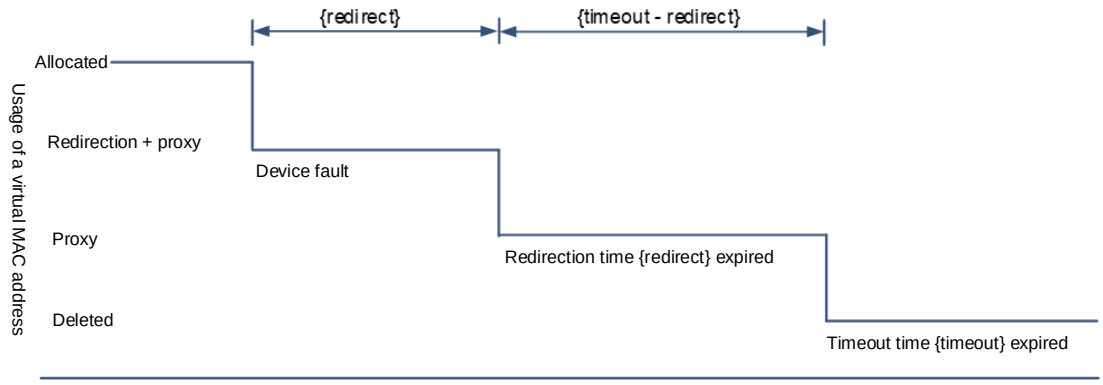
- Host-dependent policy: A specific virtual MAC address is used to respond to the requests sent by a specific host.
- Round-robin policy: Virtual MAC addresses in a backup group are used in a cyclic manner to respond to the gateway ARP/NS requests sent by hosts.
- Weighted policy: The ARP/NA requests are responded based on the forwarding capability of a device.

Policy switching is described below:

- If the load balancing mode is changed, load balancing is always implemented in the new load balancing mode. For example, if the round-robin load balancing mode is previously used, and later the weighted mode is used, load balancing is implemented in weighted mode. Load balancing cannot be implemented for hosts that have learned the VRRP virtual gateway addresses before the configuration of VRRP Plus. Therefore, if VRRP Plus is configured after a VRRP group switches to the master state, real load balancing cannot be implemented before aging of the ARP/ND entries learned by hosts. Load balancing is implemented only after the gateway ARP/ND entries learned by the hosts age and the hosts request new gateway addresses.
- Weight configuration means configuring different weights for different devices. In this way, more traffic is distributed to the device with a greater weight and less traffic is distributed to the device with a smaller weight, thereby fully utilizing the forwarding performance of different devices (if the total weight of virtual routers in a VRRP Plus group is 0, the ARP/NS requests are not responded). When the weight of a BVF in a backup group is smaller than the lower threshold, the BVF automatically exits the forwarding role. When the weight recovers and is greater than the upper threshold, the BVF automatically applies to the forwarding role. The forwarding role can be recovered when one or more remaining virtual MAC addresses or proxy virtual MAC addresses exist.
- The function of periodically sending of gratuitous ARP packets on an interface also affects the load balancing function of VRRP Plus. When VRRP Plus is enabled, the function of sending gratuitous ARP/NA packets of VRRP virtual IP addresses will be disabled. When a virtual IP address overlaps with an actual IP address, gratuitous ARP/NA packets of this address are no longer sent.
- When an address conflict occurs between a host and the local device, the ARP/NA module will broadcast gratuitous ARP/NA packets of this address. If a conflict occurs on the VRRP Plus virtual address, sending gratuitous ARP/NA packets results in re-learning of the host's gateway MAC address, which negatively affects the load balancing function of VRRP Plus. Therefore, the load balancing function of VRRP Plus is currently not supported in this scenario.

6. Proxy Virtual MAC Address

When a device with a virtual MAC address assigned becomes faulty in a backup group, traffic of hosts that use this virtual MAC address as the gateway MAC address will be interrupted. The BVG in the VRRP Plus backup group can quickly detect the fault, and automatically allocate the virtual MAC address of the faulty BVF to another device in the backup group. The new device acts as the proxy of the faulty device to forward packets of



the virtual MAC address. In addition, this proxy device takes over traffic of original hosts to prevent traffic interruption. The virtual MAC address allocated to a device in a backup group can be called a master virtual MAC address, and the virtual MAC address used by this device on behalf of another device is called a proxy virtual MAC address.

7. Redirection Interval and Timeout

VRRP Plus provides the virtual MAC address proxy function so that another device can take the place of a faulty device with a virtual MAC address assigned to forward packets. If a BVF recovers from the fault, its forwarding role should be restored and the BVF continues to forward packets of the virtual MAC address allocated to this BVF. If the faulty BVF does not recover all the time, the backup group stops redirecting traffic to this virtual MAC address. That is, when gateway ARP requests are received again, this virtual MAC address is no longer used to give responses. After a sufficient long period of time, it is believed that hosts that use the virtual MAC address as the gateway MAC address already update the ARP/ND table entry of the gateway address, and the traffic is already taken over by other devices. Now, this virtual MAC address can be deleted, and packets sent to this virtual MAC address should be discarded.

VRRP Plus allows configuring the redirection interval and timeout for a backup group. When a device is faulty, the backup group allocates the virtual MAC address of the faulty device to another device. Within the redirection interval, the backup group continues to use this virtual MAC address to respond to the ARP/NS requests. When the redirection time expires, the backup group no longer uses this virtual MAC address to respond to the requests. When the timeout time elapses, the backup group deletes this virtual MAC address and stops using it for proxy forwarding. Figure 1-1 shows the changes in the role of a virtual MAC address within the redirection interval and timeout time.

Figure 1-1 Diagram of Changes in the Role of an Allocated Virtual MAC Address

8. Correlation with Track

VRRP Plus supports correlation with bidirectional forwarding detection (BFD) and can adjust the weight based on the link status. Each device in a backup group can associate its weight with the link status. When a link is abnormal or unreachable, the device automatically decreases its weight. When the weight is too low, the device automatically exits the forwarding role. If a backup group is currently using the weighted load balancing policy, traffic can be distributed based on the new weight. When the associated link recovers, the device automatically restores its original weight and the forwarding role. If the backup group is currently using the weighted load balancing policy, traffic is distributed based on the restored weight.

9. Forwarding Preemption

VRRP Plus supports the function of preempting the forwarding role. In VRRP Plus, at most four devices can participate in load balancing. That is, a VRRP Plus backup group generates at most four virtual MAC addresses. If more than four devices are added to a VRRP Plus group, only four devices participate in packet forwarding. The remaining devices only listen to the statuses of other devices and do not participate in packet forwarding. Only when a device participating in packet forwarding is faulty, another device that originally does not participate in packet forwarding takes the place of the faulty device to forward packets. Assume that a VRRP Plus backup group already has four devices and all these devices participate in packet forwarding; a fifth device is added to the VRRP Plus group, and the forwarding capability of this device is strong or a device taking the forwarding role encounters a link failure and consequently the degradation of forwarding performance. In this case, if the preemption mode is enabled, the fifth device preempts the forwarding role from a device with a smaller weight (that is, with weaker forwarding capability). A greater weight is configured for a device with stronger forwarding capability. When the weight of a device in listening state is greater than that of a forwarding device, the device in listening state automatically preempts the forwarding role from the forwarding device. That is, the device with stronger forwarding capability forwards packets, whereas the device with lower forwarding capability is in listening state. This minimizes the waste of resources.

The BVG in a backup group is responsible for allocating virtual MAC addresses. Therefore, the BVG role cannot be preempted, and only the forwarding role of a BVF can be seized. If the BVG is faulty, VRRP re-elects a new master device, which assumes the BVG role.

1.1.2 Packet Structure

Figure 1-2 shows the structure of VRRP Plus packets.

Figure 1-2 Structure of VRRP Plus Packets

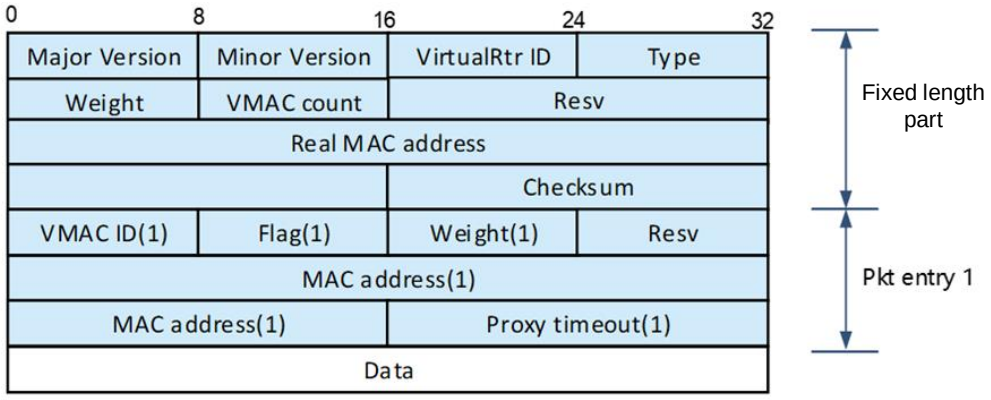


Table 1-1 Field Description of VRRP Plus Packets

Packet Field	Description
Major Version	Major version number. The current version is 1.
Minor Version	Minor version number. The current version is 0.
VirtualRtr ID	Virtual router ID, that is, the ID of a VRRP Plus backup group.

Packet Field	Description
Type	Type of VRRP Plus packets. Values and corresponding types are as follows: ● **0**: Indicates a tricky packet. ● **1**: Indicates a virtual MAC request packet. ● **2**: Indicates a keepalive packet of a BVF. ● **3**: Indicates the virtual MAC address release packet sent by the BVF to the BVG. ● **4**: Indicates the virtual MAC address allocation packet sent by the BVG to a BVF.
Weight	Weight of the device.
VMAC count	Number of virtual MAC addresses filled in the packet.
Resv	Reserved field in the fixed length part.
Real MAC address	Real MAC address of the interface on the local device.
Checksum	Packet checksum (including the fixed length part and filling part).
VMAC ID	Filled virtual MAC ID.
Flag	Flag information of the virtual MAC address.
Weight	Weight of the device to which the virtual MAC address is allocated.
Resv	Reserved field in the filling part.
MAC address	Real MAC address of the interface on the device to which the virtual MAC address is allocated.
Proxy timeout	Remaining time before timeout of the virtual MAC address filling in the case of a proxy virtual MAC address.

1.2 Configuration Task Summary

VRRP Plus configuration includes the following tasks:

(1) Configuring VRRP Plus

1.3 Configuring VRRP Plus

1.3.1 Overview

This section describes how to enable the VRRP Plus function and adjust the VRRP Plus weight based on the track object, to implement automatic balancing among multiple backup groups.

1.3.2 Restrictions and Guidelines

To enable the VRRP Plus function, you must configure a VRRP virtual IP address for the corresponding backup group.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

(4) Enable IPv4 VRRP.

vrrp *group-id* **ip** *ipv4-address* [**secondary**]

IPv4 VRRP is disabled on a port by default.

(5) Configure a priority for the IPv4 VRRP backup group.

vrrp *group-id* **priority** *Priority*

The default priority of an IPv4 VRRP backup group is **100**.

(6) Enable the VRRP Plus function on the interface.

vrrp [**ipv6**] *group-id* **balance**

The VRRP Plus function is disabled by default.

(7) Configure a VRRP Plus load balancing policy.

vrrp [**ipv6**] *group-id* **load-balancing** { **host-dependent** | **round-robin** | **weighted** }

By default, VRRP Plus uses the host-dependent load balancing policy, that is, host-dependent.

(8) Configure the redirection interval and timeout time for proxy virtual MAC addresses of the VRRP Plus backup group.

vrrp [**ipv6**] *group-id* **timers redirect** *redirect-interval redirect-timeout*

The default redirection interval of proxy virtual MAC addresses of a VRRP Plus backup group is **300** seconds and the default redirection timeout time is **14400** seconds.

(9) Configure the weight and upper and lower thresholds for the VRRP Plus backup group.

vrrp [**ipv6**] *group-id* **weighting** *weight-limit* [**lower** *min-weight-value*] [**upper** *max-weight-value*]

The default weight, default upper threshold, and default lower threshold of a VRRP Plus backup group are **100**, **1**, and **100** respectively.

(10) Configure the forwarding preemption function for the VRRP Plus backup group.

vrrp [**ipv6**] *group-id* **forwarder preempt**

The forwarding preemption function is enabled for a VRRP Plus backup group by default.

(11) Configure a track object for adjusting the weight for the VRRP Plus backup group.

vrrp [**ipv6**] *group-id* **weighting track** *object-number* [**decrement** *value*]

VRRP Plus tracking is not configured by default.

1.4 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

⚠ Caution

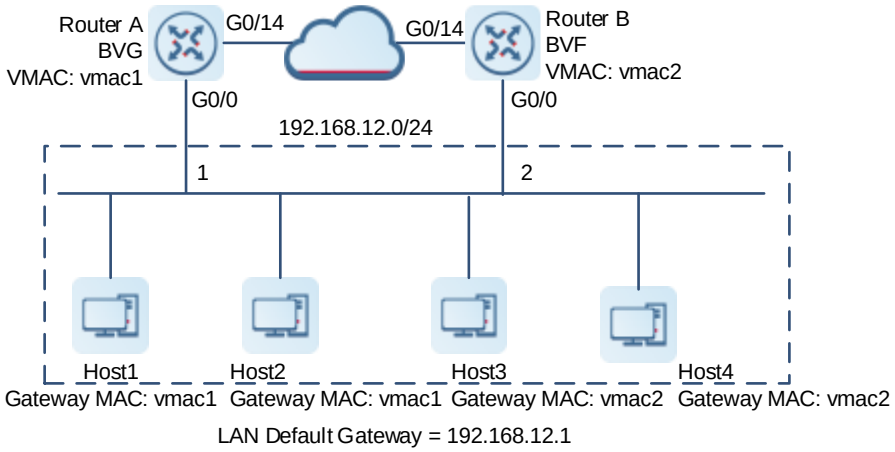
The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-2 VRRP Plus Monitoring

Command	Purpose
show [**ipv6**] **vrrp balance** [*group-id* | [**interface** *interface-type interface-number*] **brief**]	Displays the brief or detailed information about VRRP Plus.
show vrrp balance bfd-neighbor	Displays the association between VRRP Plus and BFD.
show vrrp balance debug-logging	Displays the content of VRRP Plus log files.
show vrrp balance jemalloc-statistic	Displays the Jemalloc information of VRRP Plus.
show vrrp balance memory	Displays the memory information of a VRRP Plus process.
show vrrp balance mom-info	Displays the exchange information between VRRP Plus and MOM.
show vrrp balance server-statistic [**reset**]	Displays the VRRP Plus server statistics.
show [**ipv6**] **vrrp balance work-state** [**interface** *interface-type interface-number* [*group-id*]]	Displays the current detailed status of the VRRP Plus backup group.
debug [**ipv6**] **vrrp balance**	Debugs the VRRP Plus function.
debug [**ipv6**] **vrrp balance error**	Debugs errors.
debug [**ipv6**] **vrrp balance event**	Debugs events of a VRRP Plus group.
debug [**ipv6**] **vrrp balance messages**	Debugs messages of VRRP Plus.
debug [**ipv6**] **vrrp balance packets**	Debugs the VRRP Plus packets.

Command	Purpose
debug [**ipv6**] **vrrp balance state**	Debugs the VRRP Plus group status.
debug [**ipv6**] **vrrp balance timer**	Debugs the timers of a VRRP Plus group.

1.5 Configuration Examples



1.5.1 Configuring IPv4 VRRP Plus

1. Requirements

A load balancing policyneeds to be enabled in an IPv4 VRRP group.

2. Topology

Figure 1-3 Topology for Configuring IPv4 VRRP Plus

3. Notes

- Configure a VRRP group and enable VRRP Plus on both routers Aand B. Configure the local IP addresses so that router A becomes the BVG (master) device and router B becomes a BVF (backup) device.
- Configure the weighted load balancing policy for VRRP Plus. Configure a track object for adjusting the weight, and set the weight decrement value to 100.
- Retain default configurations for the weight, upper and lower thresholds, redirection interval, timeout time, and forwarding preemption function of the backup group.
- Set the default gateway addresses of hosts 1 to 4 in the LAN to the virtual IP address of VRRP, that is, 192.168.12.1.

4. Procedure

Perform the following configuration on router A:

```
RouterA> enable
RouterA# configure
```

```
RouterA(config)# interface GigabitEthernet0/0
RouterA(config-if-GigabitEthernet 0/0)# no switchport
RouterA(config-if-GigabitEthernet 0/0)# ip address 192.168.12.3 255.255.255.0
RouterA(config-if-GigabitEthernet 0/0)# vrrp 1 ip 192.168.12.1
RouterA(config-if-GigabitEthernet 0/0)# vrrp 1 balance
RouterA(config-if-GigabitEthernet 0/0)# vrrp 1 load-balancing weighted
```

Perform the following configuration on router B:

```
RouterB> enable
RouterB# configure
RouterB(config)# interface GigabitEthernet0/0
RouterB(config-if-GigabitEthernet 0/0)# no switchport
RouterB(config-if-GigabitEthernet 0/0)# ip address 192.168.12.2 255.255.255.0
RouterB(config-if-GigabitEthernet 0/0)# vrrp 1 ip 192.168.12.1
RouterB(config-if-GigabitEthernet 0/0)# vrrp 1 balance
RouterB(config-if-GigabitEthernet 0/0)# vrrp 1 load-balancing weighted
```

5. Verification

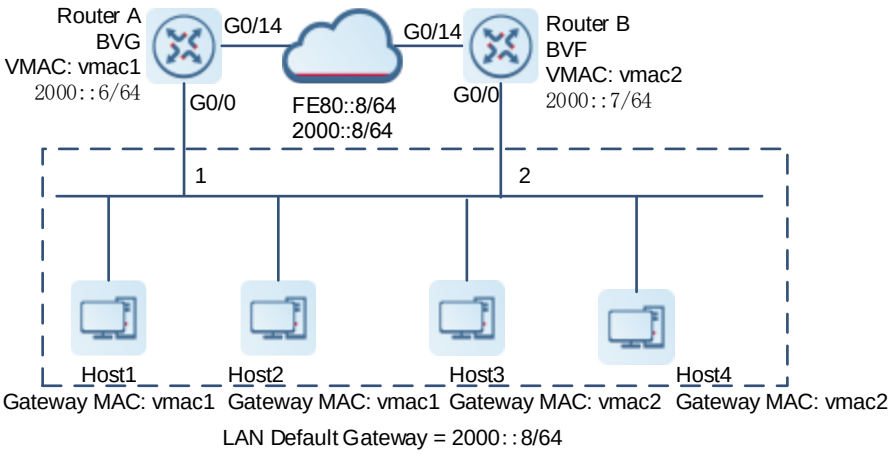
Run the **show vrrp balance** command on Router A to display the configuration of the VRRP Plus backup group. If the backup group has packet forwarding tasks, **local** is displayed in the **Forwarder** field, and the virtual MAC address allocated to this backup group is also displayed.

```
RouterA# show vrrp balance interface GigabitEthernet0/0
State is BVG
  Virtual IP address is 192.168.12.1
  Hello time 1 sec, hold time 3 sec
  Load balancing: weighted
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 100 (configured 100), thresholds: lower 1, upper 100
  There are 2 forwarders
  Forwarder 1 (local)
    MAC address:
      0000.5e00.0101
    Owner ID is 0000.0001.0006
    Preemption disabled (BVG cannot be preempted)
  Forwarder 2
    MAC address:
001a.a916.0201
    Owner ID is 00d0.f822.33a3
Preemption enabled
```

Run the **show vrrp balance** command on Router B to display the configuration of the VRRP Plus backup group. If the backup group has packet forwarding tasks, **local** is displayed in the **Forwarder** field, and the virtual MAC address allocated to this backup group is also displayed.

```
RouterB# show vrrp balance interface GigabitEthernet0/0
  State is BVF
  Virtual IP address is 192.168.12.1
  Hello time 1 sec, hold time 3 sec
```

```
  Load balancing: weighted
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 100 (configured 100), thresholds: lower 1, upper 100
  There are 2 forwarders
  Forwarder 1
    MAC address:
      0000.5e00.0101
    Owner ID is 0000.0001.0006
    Preemption disabled (BVG cannot be preempted)
  Forwarder 2 (local)
    MAC address:
001a.a916.0201
    Owner ID is 00d0.f822.33a3
    Preemption enabled
```



1.5.2 Configuring IPv6 VRRP Plus

1. Requirements

A load balancing policyneeds to be enabled in an IPv6 VRRP group.

2. Topology

Figure 1-4 Topology for Configuring IPv6 VRRP Plus

3. Notes

- Configure an IPv6 VRRP group and enable IPv6 VRRP Plus on both routers Aand B. Configure the priorities so that router A becomes the BVG (master) device and router B becomes a BVF (backup) device.
- Configure the weighted load balancing policyfor the IPv6 VRRP Plus backup group.
- Retain default configurations for the weight, upper and lower thresholds, redirection interval, timeout time, and forwarding preemption function of the backup group.
- Hosts 1 to 4 are hosts in the LAN. Set their IPv6 gateway addresses to 2000::8.

4. Procedure

Perform the following configuration on router A:

```
RouterA> enable
RouterA# configure
RouterA(config)# interface GigabitEthernet0/0
RouterA(config-if-GigabitEthernet 0/0)# no switchport
RouterA(config-if-GigabitEthernet 0/0)# ipv6 address 2000::6/64
RouterA(config-if-GigabitEthernet 0/0)# vrrp 1 ipv6 fe80::8
RouterA(config-if-GigabitEthernet 0/0)# vrrp 1 ipv6 2000::8
RouterA(config-if-GigabitEthernet 0/0)# vrrp ipv6 1 priority 120
RouterA(config-if-GigabitEthernet 0/0)# vrrp ipv6 1 balance
RouterA(config-if-GigabitEthernet 0/0)# vrrp ipv6 1 load-balancing weighted
```

Perform the following configuration on router B:

```
RouterB> enable
RouterB# configure
RouterB(config)# interface GigabitEthernet0/0
RouterB(config-if-GigabitEthernet 0/0)# no switchport
RouterB(config-if-GigabitEthernet 0/0)# ipv6 address 2000::7/64
RouterB(config-if-GigabitEthernet 0/0)# vrrp 1 ipv6 fe80::8
RouterB(config-if-GigabitEthernet 0/0)# vrrp 1 ipv6 2000::8
RouterB(config-if-GigabitEthernet 0/0)# vrrp ipv6 1 balance
RouterB(config-if-GigabitEthernet 0/0)# vrrp ipv6 1 load-balancing weighted
```

5. Verification

Run the **show vrrp balance** command on Router A to display the configuration of the VRRP Plus backup group. If the backup group has packet forwarding tasks, **local** is displayed in the **Forwarder** field, and the virtual MAC address allocated to this backup group is also displayed.

```
RouterA# show ipv6 vrrp balance interface GigabitEthernet0/0
GigabitEthernet 0/0 - Group 1
  State is BVG
  Virtual IPv6 address is as follows:
    FE80::8
    2000::8
  Hello time 1 sec, hold time 3 sec
  Load balancing: weighted
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 100 (configured 100), thresholds: lower 1, upper 100
  There are 2 forwarders
  Forwarder 1 (local)
    MAC address:
      0000.5e00.0201
    Owner ID is 00d0.f8fb.96f3
    Preemption disabled (BVG cannot be preempted)
  Forwarder 2
    MAC address:
```

```
    1414.4b72.7701
  Owner ID is 00d0.f8fb.6c42
  Preemption enabled
```

Run the **show vrrp balance** command on Router B to display the configuration of the VRRP Plus backup group. If the backup group has packet forwarding tasks, **local** is displayed in the **Forwarder** field, and the virtual MAC address allocated to this backup group is also displayed.

```
RouterB# show ipv6 vrrp balance interface GigabitEthernet0/0
GigabitEthernet 0/0 - Group 1
  State is BVF
  Virtual IPv6 address is as follows:
    FE80::8
    2000::8
  Hello time 1 sec, hold time 3 sec
  Load balancing: weighted
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 150 (configured 150), thresholds: lower 1, upper 100
  There are 2 forwarders
  Forwarder 1
    MAC address:
      0000.5e00.0201
    Owner ID is 00d0.f8fb.96f3
    Preemption disabled (BVG cannot be preempted)
  Forwarder 2 (local)
    MAC address:
      1414.4b72.7701
    Owner ID is 00d0.f8fb.6c42
Preemption enabled
```

6. Common Errors

- VRRP Plus does not take effect because no VRRP virtual IP address is configured for a group.

1.8.1 Configuring BFD Support for OSPF 14

1 Configuring BFD

1.1 Introduction

Bidirectional forwarding detection (BFD) provides a light-load and fast method for detecting the connectivity of the forwarding path between two adjacent routers. It quickly detects faults on the bidirectional forwarding path between two routers for upper layer protocols such as routing protocols so that measures can be taken in a timely manner to guarantee services. BFD minimizes the impact of faults on services and improves network availability.

1.1.1 Basic Concepts

1. Packet Format

Detection packets transmitted by BFD are User Datagram Protocol (UDP) packets, which are classified into two types:

- Control packets: The protocol defines a specific format, as shown in Figure 1-1. Currently, there are two versions (v0 and v1) for the format of control packets: v1 is adopted by default for establishing a BFD session; if a device receives packets of v0 from the peer system, the device automatically switches to v0.
- Echo packets: Echo packets are only used by the local system of a BFD session, and the protocol does not define a specific format.

Figure 1-1 BFD Packet Format

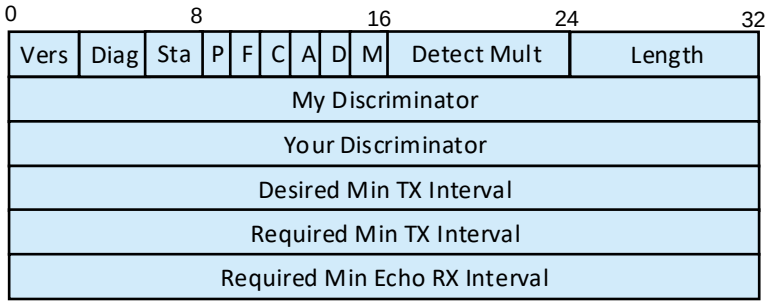

Table 1-1 Description of BFD Packet Fields

Field	Description
Vers	BFD protocol version number, which is 1 currently.

Field	Description
Diag	Causes for the local system to switch from up state to another state last time, including: **0**: Indicates no diagnostic information. **1**: Controls timeout detection. **2**: Indicates that the echo function failed. **3**: Indicates that a neighbor advertises session down. **4**: Indicates forwarding plane reset. **5**: Indicates that the path failed. **6**: Indicates that the connection path failed. **7**: Indicates that the local system enters the AdminDown state.
Sta	BFD local session states, including: **0**: Indicates the AdminDown state. **1**: Indicates the Down state. **2**: Indicates the Init state. **3**: Indicates the Up state.
P	The transmitter sets this flag to **1** in a BFD packet upon parameter changes. The receiver must immediately respond to this packet.
F	This flag must be set to **1** in the response packet for responding to the P flag that is set to **1**.
C	Forwarding/control separation flag. If it is set to **1**, the control plane changes do not affect BFD detection. For example, if the control plane is Open Shortest Path First (OSPF), when OSPF is restarted or experiences graceful restart (GR), BFD can continue to detect the link state.
A	Authentication flag. If it is set to **1**, a session needs to be authenticated.
D	Query request. If it is set to **1**, the transmitter desires the query mode for detecting links.
M	It is used in point-to-multipoint applications in the future. It must be set to **0** currently.
Detect Mult	Detection timeout multiplier. It is used by the detector to calculate the detection timeout time.
Length	Packet length.
My Discriminator	Discriminator of the local end of a BFD session.
Your Discriminator	Discriminator of the remote end of a BFD session
Desired Min Tx Interval	Minimum BFD packet transmission interval supported by the local end.

Field	Description
Required Min RX Interval	Minimum BFD packet receiving interval supported by the local end.
Required Min Echo RX Interval	Minimum echo packet receiving interval supported by the local end. It is set to **0** if the local end does not support the echo function.
Auth Type	Authentication type. It is an optional field and can be set to the following values: Simple Password Keyed MD5 Meticulous Keyed MD5 Keyed SHA1 Meticulous Keyed SHA1
Auth Length	Authentication data length.
Authentication Data	Authentication data area.

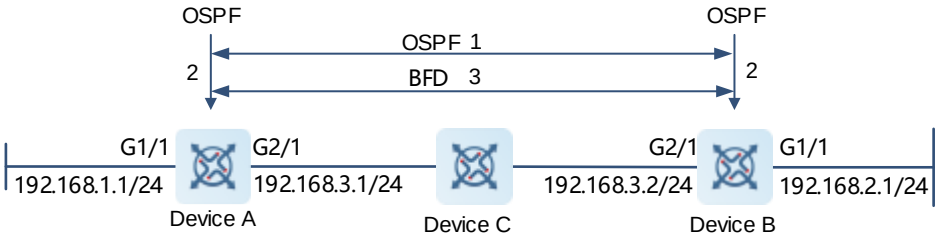
2. Session State

BFD migrates the state machine based on the local session state and the BFD packets received from the peer end. A BFD state machine is established and torn down using a three-way handshake mechanism, to ensure that both ends know the state change. A BFD session can be in any of the following four basic states:

- Down: Indicates that a session is in the down state or is established just now.
- Init: Indicates that the local system has communicated with the peer system and desires to bring the session to the up state.
- Up: Indicates that a session has been established successfully.
- AdminDown: Indicates that a session is in the AdminDown state.

3. Transmission Interval and Detection Time

During the establishment of a BFD session, both ends negotiate about BFD parameters to determine the transmission interval and detection time. After a BFD session is established, both ends dynamically negotiate about BFD parameters (for example, the minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.



1.1.2 Session Establishment

BFD detection starts from the establishment of a BFD session.

1. Session Establishment Process

BFD itself is unable to discover neighbors. It needs an upper-layer protocol to specify the neighbor, with which BFD needs to establish a session. As shown in Figure 1-2, two routers running OSPF and BFD are connected through an an intermediate network device.

Figure 1-2 BFD Session Establishment

The BFD session establishment process is as follows:

- OSPF discovers a neighbor and establishes a connection with the neighbor.
- OSPF instructs BFD to establish a session with the neighbor.
- BFD establishes a session with the neighbor.

2. Session Establishment Mode

The BFD protocol specifies that a BFD session can be established in two modes:

- Active mode: Before the establishment of a session, BFD actively transmits a control packet for establishing a BFD session regardless of whether it receives a control packet for establishing a BFD session from the peer end.
- Passive mode: BFD does not actively transmit a control packet for establishing a BFD session before a session is established but waits till it receives a control packet for establishing a BFD session from the peer end.

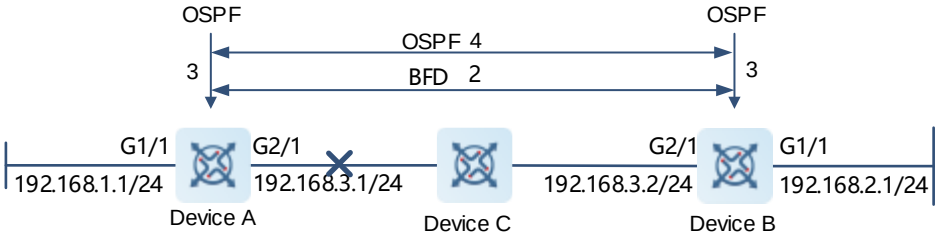
Specification

The passive mode is not supported currently.

3. Negotiation of Session Parameters

Both ends negotiate about BFD session parameters during the establishment of a BFD session, to determine the transmission interval and detection time. Pay attention to the following points:

- BFD session parameters (including the minimum transmission interval, minimum receiving interval, and detection timeout multiplier) must be set for interfaces at both ends. Otherwise, a BFD session cannot be established.
- Interfaces at both ends negotiate about BFD session parameters and detect the session based on the parameters during the establishment of a BFD session.
- After a BFD session is established, both ends dynamically negotiate about BFD parameters (for example, the minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.
- BFD session parameters can be updated only after all the original sessions on a port complete negotiation; otherwise an error is prompted. You can run a related command to query the negotiation status of the original sessions.



1.1.3 Session Detection

Link detection starts after the establishment of a BFD session. BFD periodically transmits BFD control packets. If it fails to receive BFD packets from the peer end within the detection time, it deems that the session is down and instructs the associated application to accelerate the convergence.

1. Detection Process

As shown in Figure 1-3, two routers running OSPF and BFD are connected through an intermediate network device.

Figure 1-3 Topology for BFD Session Detection

The handling process after a BFD session is down is as follows:

- The link between router A and the switch fails.
- The BFD session between routers Aand B detects the failure.
- BFD notifies the local OSPF that the forwarding path to the neighbor is faulty.
- OSPF processes the neighbor down situation. If a backup forwarding path is available, it starts protocol convergence to enable the backup forwarding path.

2. Detection Mode

BFD supports the following detection modes:

- Asynchronous mode

  In asynchronous mode, systems transmit BFD control packets periodically to each other. If a system fails to receive BFD control packets from the peer end within the detection time, it advertises that the session is down.

- Query mode

  In query mode, it is assumed that each system has an independent method for confirming its connection with other systems. After a BFD session is established, the system stops transmitting BFD control packets unless it needs to explicitly verify the connectivity. In such a case, the system transmits a shot-sequence BFD control packet. If the system fails to receive a returned packet within the detection time, it advertises that the session is down. If it receives a response from the peer end, the forwarding path is reachable.

- Echo mode

  In echo mode, the local system periodically transmits BFD echo packets and a remote system receives and loops back the packets through the forwarding path. If the local system fails to receive several consecutive echo packets within the detection time, it advertises that the session is down. The echo function can be used together with the preceding two detection modes. The echo packet detection function does not

require the involvement of the control plane of the remote system. Packets are returned by the forwarding plane of the remote system, which reduces the delay and ensures faster fault detection in comparison with transmission of control packets. Enabling the echo function in asynchronous mode greatly reduces transmission of control packets because the detection is accomplished by the echo function. Enabling the echo function in query mode thoroughly cancels transmission of control packets after a session is established. The echo function must be enabled at both ends of a BFD session. Otherwise, the echo function does not take effect.

The echo mode includes the echo mode and one-armed echo mode. The one-armed echo mode is applicable to the single-hop IP link scenario and generally used in two directly connected devices, where one device supports the BFD function and the other does not. The echo mode requires that the echo mode be configured for both detection parties.

Specification

- The query mode is not supported and cannot be configured at present.
- Only BFD session version 1 supports the BFD echo mode.
- The echo mode is not supported for an IPv6 BFD session with the link-local address as the source or destination address.

1.1.4 BFD Support for Applications

By supporting BFD, the associated applications can utilize the fast fault detection of BFD to improve the protocol convergence performance. In general, the fault detection time can be shortened to less than 1 second. After BFD support for a certain application is enabled, BFD rapidly detects faults occurring on an established BFD session. When a link fault occurs, BFD can rapidly identify the fault and notify the associated application to process the fault, thereby improving its convergence.

1.1.5 BFD Protection

If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets), BFD sessions will flap. You can enable the BFD protection to provide protection. If both BFD and BFD protection are enabled on a device, the device discards the BFD packets received from the previous-hop device, which affects the establishment of a BFD session between the previous-hop device and other devices.

1.1.6 BFD Flapping Advertisement Dampening

A BFD session may frequently switch between the down and up states due to link instability. As a result, an associated application (such as static routing) may frequently switch forwarding paths, causing the frequent switching of the BFD session between the down and up states. This function allows users to set the delay for status change advertisement. After a BFD session is up for a certain period of time, BFD informs an associated application of BFD up. Otherwise, BFD informs it of BFD down.

1.1.7 Protocols and Standards

- draft-ietf-bfd-base-09: Bidirectional Forwarding Detection
- draft-ietf-bfd-generic-05: Generic Application of BFD
- draft-ietf-bfd-mib-06: Bidirectional Forwarding Detection Management Information Base
- draft-ietf-bfd-v4v6-1hop-09: BFD for IPv4 and IPv6 (Single Hop)

- draft-ietf-bfd-multihop-07: BFD for IPv4 and IPv6 (Multihop)

Specification

Currently, draft-ietf-bfd-mib-06 and draft-ietf-bfd-multihop-07 are not supported.

1.2 Restrictions and Guidelines

- You are advised to keep the parameter configuration consistent at both ends of a BFD session. The purpose is to ensure that application protocols associated with BFD take effect simultaneously and prevent occurrence of one-way forwarding path due to different dampening time at both ends.
- Transmission bandwidth differences of different interfaces need to be taken into account during parameter configuration. If the configured minimum Tx interval and minimum Rx interval are very small, BFD may occupy excessive bandwidth and affect data transmission.
- BFD session parameters can be configured only after all the sessions on the current port complete negotiation. Otherwise, a configuration error is prompted. Run the **show bfd neighbors parm-consult** command to display the negotiation status of all the sessions.
- Ensure that BFD support is enabled on neighbors of a BFD session. Otherwise, a BFD session cannot be established. If a dynamic routing protocol or another application instructs BFD to establish a session with a neighbor, the BFD session can also be established.
- For a single-hop session whose source and destination IP addresses belong to the same network segment, if the interface specified by a BFD session is different from the actual BFD packet outbound interface because of IP routing, or if the interface specified during BFD session creation is different from the actual BFD packet inbound interface, a BFD session cannot be established. For a multi-hop session whose source and destination IP addresses belong to different network segments, associated applications do not need to specify an interface and BFD transmits and receives packets based on IP routing. Such BFD sessions can be established provided that returned BFD packets can be received.
- When BFD session traffic is sent and no BFD session parameters are configured on the device (the **show bfd neighbors** command shows that the number of BFD sessions is 0), the CPU protect policy (CPP) entries are not delivered. Therefore, the BFD traffic sent to the local device is not matched with the CPP entries and not sent to the local device. In this case, BFD sessions must be configured for sending the traffic to the local device.
- In the process that the forwarding plane of the peer device returns echo packets transmitted by the local end to the local end, the echo packets may be lost due to congestion of the peer device, causing a session detection failure. In this case, you need to configure a quality of service (QoS) policy to ensure that echo packets are processed preferentially or disable the echo function.
- The echo detection function of BFD does not support multi-hop detection. Ensure that the echo function is disabled when configuring multi-hop detection.
- The echo mode takes effect only after it is enabled at both ends of a BFD session.
- Before enabling the echo mode of BFD, run the **no ip redirects** command on the neighbors of a BFD session to disable the function of sending Internet Control Message Protocol (ICMP) redirection packets, and run the **no ip deny land** command to disable the distributed denial of service (DDoS) function to prevent the land-based attack.

1.3 Configuration Task Summary

BFD configuration includes the following tasks:

(1) Configuring BFD Basic Functions

- Configuring BFD Parameters
- (Optional) Configuring the BFD Echo Mode
- (Optional) Configuring the BFD Slow Timer
- (Optional) Configuring BFD Support for L3 Interfaces

(2) (Optional) Configuring BFD Protection

(3) (Optional) Configuring BFD Flapping Advertisement Dampening

1.4 Configuring BFD Basic Functions

1.4.1 Overview

You can establish BFD sessions and configure BFD support for applications to perform link fault detection.

1.4.2 Configuration Tasks

The basic function configuration of BFD includes the following tasks:

(1) Configuring BFD Parameters

(2) (Optional) Configuring the BFD Echo Mode

(3) (Optional) Configuring the BFD Slow Timer

(4) (Optional) Configuring BFD Support for L3 Interfaces

1.4.3 Configuring BFD Parameters

1. Overview

- Unless otherwise specified, for single-hop sessions, a BFD session should be established between routers at both ends to be detected by BFD and BFD parameters must be configured at the egresses. Multi-hop sessions use global parameters for session establishment by default. If different negotiation parameters need to be configured for different multi-hop sessions, BFD templates need to be associated with the sessions.
- Transmission bandwidth differences of different interfaces need to be taken into account during parameter configuration. If the configured minimum Tx interval and minimum Rx interval are very small, BFD may occupy excessive bandwidth and affect data transmission.

2. Restrictions and Guidelines

- Negotiation parameters can be configured only after all the original sessions on a port complete negotiation.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 2 aggregate interface configuration mode

  interface aggregateport *interface-number*

- Enter the Layer 3 aggregate sub-interface configuration mode

  interface aggregateport *interface-number.subnumber*

- Enter the SVI interface configuration mode

  interface vlan *interface-number*

- Entry lookback interface configuration mode

  interface loopback interface-*number*

(4) Configure BFD parameters.

bfd interval *milliseconds* **min_rx** *milliseconds* **multiplier** *interval-multiplier*

No BFD session parameters are configured by default.

1.4.4 Configuring the BFD Echo Mode

1. Overview

- (Optional) Ports run in asynchronous mode by default. If a BFD session needs to run in echo mode, the echo mode needs to be configured. The echo mode includes the echo mode and one-armed echo mode.
- Complete the configuration on ports of switches or routers.
- A BFD session runs in asynchronous mode as long as either of routers at both ends is configured to run in asynchronous mode. If routers at both ends are configured to run in echo mode by default, a BFD session finally runs in echo mode. This function is disabled by default and can be enabled after the **bfd echo** command is executed.
- Run the **bfd echo one-arm** command to enable the one-armed echo mode.

2. Restrictions and Guidelines

By default, when BFD session parameters are configured, the system automatically enables the echo mode. To disable the BFD echo function, run the **no bfd echo** command in interface configuration mode. The minimum Tx interval and minimum Rx interval of echo packets adopt the **Interval milliseconds** and **min_rx milliseconds** parameters configured for a session.

Before enabling the echo mode of BFD, run the **no ip redirects** command on the neighbors of a BFD session to disable the function of sending ICMP redirection packets, and run the **no ip deny land** command to disable the DDoS function to prevent the land-based attack.

The BFD one-armed echo function and **ip redirect-drop** cannot be configured at the same time, otherwise the function fails.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode

  interface aggregateport *interface-number.subnumber*

- Enter the SVI interface configuration mode

  interface vlan *interface-number*

- Entry lookback interface configuration mode

  interface loopback interface-*number*

(4) Configure the BFD echo mode.

bfd echo [**one-arm**]

The echo mode is disabled for a BFD session bydefault.

1.4.5 Configuring the BFD Slow Timer

1. Overview

You can specify the interval for sending slow control packets in echo mode.

2. Restrictions and Guidelines

- The default slow timer is **3000** milliseconds. The value can be changed as required.
- In BFD echo mode or during session establishment, control packets are sent based on the slow timer. A larger value indicates that the required time for negotiating and establishing a BFD session is longe r and the time required for transmitting slow BFD packets in echo mode is longer.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the BFD slow timer.

bfd slow-timer [*interval*]

The default slow timer time in the echo mode is **2000** milliseconds.

1.4.6 Configuring BFD Support for L3 Interfaces

1. Overview

This function is used to enable BFD support for Layer 3 interfaces so as to rapidly detect connectivity of Layer 3 interfaces.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode

  interface aggregateport *interface-number.subnumber*

- Enter the SVI interface configuration mode

  interface vlan *interface-number*

- Enter lookback interface configuration mode

  interface loopback interface-*number*

(5) Configure BFD support for L3 interfaces.

bfd bind peer-ip *ipv4-address* [**source-ip** *ipv4-address*] **process-pst**

BFD support for interfaces is not configured by default.

1.5 Configuring BFD Protection

1.5.1 Overview

- If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets), BFD sessions flap. In this case, you can configure BFD protection to provide protection.

1.5.2 Restrictions and Guidelines

- The BFD basic functions must be configured.
- If both BFD and BFD protection are enabled on a device, the device discards the BFD packets received from the previous-hop device, which affects the establishment of a BFD session between the previous-hop device and other devices.

1.5.3 Prerequisites

Basic functions of BFD have been configured.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure BFD protection.

bfd cpp

Configure BFD protection on a switch in the network where attacks exist.

The BFD protection is enabled by default.

1.6 Configuring BFD Flapping Advertisement Dampening

1.6.1 Overview

- A BFD session may frequently switch between the down and up states due to link instability. As a result, a relevant application (such as static routing) may frequently switch forwarding paths and the running services are affected.
- Users can set a delay for status change advertisement, after which BFD informs an associated application of BFD up. After a BFD session is up for a certain period of time, BFD informs an associated application of BFD up. Otherwise, BFD informs it of BFD down. This aims to reduce flapping of associated protocols caused by unstable links.

1.6.2 Restrictions and Guidelines

- The BFD basic functions must be configured.
- If a BFD session does not frequently switch between the down and up states, enabling BFD flapping advertisement dampening will delay notifying an associated application of BFD up.
- Enabling BFD flapping advertisement dampening can relieve frequent processing of associated applications (such as route re-calculation) caused by frequent advertisement of BFD status changes. The larger the configured time is, the longer the required BFD stability time is. BFD notifies an application module of BFD up only after the stability time reaches the configured time.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *interface-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode

  interface aggregateport *interface-number*

- Enter the Layer 3 aggregate interface configuration mode

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode

  interface aggregateport *interface-number.subnumber*

- Enter the SVI interface configuration mode

  interface vlan *interface-number*

- Entry lookback interface configuration mode

  interface loopback interface-*number*

(5) Configure flapping dampening parameters.

bfd up-dampening { *milliseconds* }

The BFD flapping advertisement dampening is disabled on ports by default. If a BFD session frequently switches between the down state and up state, you are advised to enable this function.

1.7 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Caution

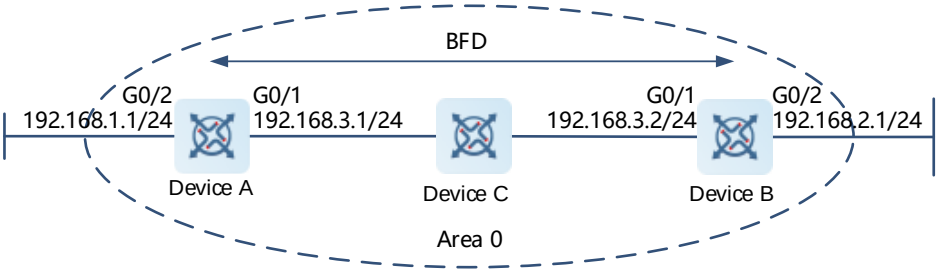
The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-2 BFD Monitoring

Command	Purpose
show bfd neighbors [**vrf** *vrf-name*] [**client** { **ap** | **bgp** | **ospf** | **rip | vrrp | static-route | pbr | vrrp-balance** | **ldp-lsp | static-lsp | backward-lsp-with-ip** | **pst** }] [**ipv4** *ipv4-address* | **ipv6** *ipv6-address*] [**details**] [**parm-consult** [*interface-type interface-number*]]	Displays BFD session information.

Command	Purpose
debug bfd event [**interface** *interface-type interface-number* **| ipv4** *ipv4-address* **| ipv6** *ipv6-address*]	Debugs BFD events.
debug bfd packet [**interface** *interface-type interface-number* **| ipv4** *ipv4-address* **| ipv6** *ipv6-address*]	Debugs BFD packets.

1.8 Configuration Examples



1.8.1 Configuring BFD Support for OSPF

1. Requirements

Three devices are used to build a network, the devices run the OSPF protocol, and BFD support for OSPF is enabled on two devices.

2. Topology

Figure 1-4 Topology for Configuring BFD Support for OSPF

3. Notes

- Configure IP addresses for ports connecting devices Aand B.
- Run the OSPF protocol on devices A and B.
- Configure BFD parameters for the interconnected ports of devices A and B.
- Enable BFD support for OSPF on devices A and B.

4. Procedure

Perform the following configuration on device A.

```
DeviceB# configure terminal
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet0/1)# no switchport
DeviceB(config-if-GigabitEthernet0/1)# ip address 192.168.3.2 255.255.255.0
DeviceB(config-if-GigabitEthernet0/1)# bfd interval 200 min_rx 200 multiplier 5
DeviceB(config-if-GigabitEthernet0/1)# exit
DeviceB(config)# interface gigabitethernet 0/2
DeviceB(config-if-GigabitEthernet0/2)# no switchport
DeviceB(config-if-GigabitEthernet0/2)# ip address 192.168.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet0/2)# exit
```

```
DeviceB(config)# router ospf 123
DeviceB(config-router)# log-adj-changes detail
DeviceB(config-router)# network 192.168.3.0 0.0.0.255 area 0
DeviceB(config-router)# network 192.168.2.0 0.0.0.255 area 0
DeviceB(config-router)# bfd all-interfaces
```

Perform the following configuration on device B.

```
DeviceB# configure terminal
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet0/1)# no switchport
DeviceB(config-if-GigabitEthernet0/1)# ip address 192.168.3.2 255.255.255.0
DeviceB(config-if-GigabitEthernet0/1)# bfd interval 200 min_rx 200 multiplier 5
DeviceB(config-if-GigabitEthernet0/1)# exit
DeviceB(config)# interface gigabitethernet 0/2
DeviceB(config-if-GigabitEthernet0/2)# no switchport
DeviceB(config-if-GigabitEthernet0/2)# ip address 192.168.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet0/2)# exit
DeviceB(config)# router ospf 123
DeviceB(config-router)# log-adj-changes detail
DeviceB(config-router)# network 192.168.3.0 0.0.0.255 area 0
DeviceB(config-router)# network 192.168.2.0 0.0.0.255 area 0
DeviceB(config-router)# bfd all-interfaces
```

5. Verification

Run the **show bfd neighbors details** command to check whether BFD support configuration is correct.

```
DeviceA# show bfd neighbors details
OurAddr       NeighAddr   LD/RD   RH/RS   Holdown(mult)   State   Int
192.168.3.1   192.168.3.2     1/2     Up      532 (3 )            Up      Ge0/1

6. Common Errors

- For a single-hop session, BFD parameters may not be configured for the port on the device at one end of the session.
- If different negotiation parameters need to be configured for different multi-hop sessions, templates need to be associated with the sessions and negotiation parameters need to be configured in the templates.
- For multi-hop BFD sessions, if the sessions use different templates, negotiation parameters in the template used by a session that becomes up first are used for transmitting and receiving packets.
- BFD support for applications is not configured.
- BFD support for applications is enabled only on the device at one end.

1.6.2 Configuring to Track the Results of RNS Instances 5

1.6.3 Reporting the Status of a Track Instance to the Associated Interface 6

1 Configuring Track

1.1 Introduction

The track module supports monitoring and fault transmission. It connects to the detection module to detect the link status and network performance, and connects to the application module to transmit the detection results of link failure and network performance. In this way, the application module can quickly perceive the changes of the network status and respond in time, thereby preventing communication failures or service quality deterioration.

1.1.1 Principles

Each track instance is used to track one type of monitored object. The status of the track instance reflects the status of the tracked object. When the status of the tracked object changes, the status change can be transmitted to the application module that interoperates with the track instance. Currently, the following objects can be tracked:

- RNS test result.
- Interface link status
- Test result of the RNS list
- Track list status
- Reporting the status of a track instance to the associated interface

  Configure a track instance to detect the RNS instance and report the track instance status to the associated interface.

  - When **same** is specified in the command, if the track instance status is Up and the status of the associated interface will be Up; if the track instance status is Down, the status of the associated interface will be Down.
  - When **opposite** is specified in the command, if the track instance status is Up and the status of the associated interface will be Up; if the track instance status is Down, the status of the associated interface will be Down.

1.2 Configuration Task Summary

The track configuration includes the following tasks:

(1) Configuring Track

(2) (Optional) Reporting the Status of a Track Instance to the Associated Interface

1.3 Configuring Track

1.3.1 Overview

The track function can be used to track the RNS test results, the interface link status, the track list status, and the status of the RNS test list. The status change of the track object can be advertised to the corresponding

application module to enable the application module to quickly perceive the network status change and respond in time.

1.3.2 Restrictions and Guidelines

- To configure the track function to track the test result of an RNS instance, you need to configure the related RNS instance.
- To configure the track function to track the link status of an interface, you need to configure the related interface.
- To configure the track function to track the status of a track list, you need to configure the members for the related track list.
- To configure the track function to track the status of an RNS list, you need to configure the members for the related RNS list.
- A longer delay indicates a lengthier waiting period before notifying the modules monitoring that Track instance of the status.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the track object. Select at least one of the following to configure.

- Configure to track the link status of an interface.

  track *object-number* **interface** *interface-type interface-number* **line-protocol**

- Configure to track the RNS test result.

  track *object-number* **rns** *entry-number*

- Configure to track the status of a track list.

  track *object-number* **list boolean** { **and** | **or** }

- Configure to track the status of an RNS list.

  track *object-number* **rns-list** *men-list* { **and** | **or** }

(4) Configure a track member.

object *object-number* [**not**]

No member object is configured by default.

(5) Configure the notification delay of a track object.

delay { **down** *interval* | **up** *interval* } *

By default, the status of the tracked object is immediately notified upon an Up/Down status change.

1.4 Reporting the Status of a Track Instance to the Associated Interface

1.4.1 Overview

Configure the device to report the status of a track instance to the associated interface.

1.4.2 Restrictions and Guidelines

- This command can be used only when the track instance is used to detect the status of an RNS instance.
- The device can report the status of a track instance to multiple interfaces, but cannot report the status of different track instances to the same interface.

1.4.3 Configuration Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a track instance to detect an RNS instance and enter the track configuration mode.

track *object-number* **rns** *number*

No track instance is configured by default.

(4) Configure the device to report the status of a track instance to the associated interface.

trigger interface *interface-type interface-number* **link-state** { **same** | **opposite** }

The device is not configured to report the status of a track instance to the associated interface by default.

Layer 2 Ethernet interfaces, Layer 2 aggregate interfaces, Layer 3 Ethernet interfaces, and Layer 3 aggregate interfaces are supported.

(5) (Optional) Configure the delay for notifying the status change of a track object.

delay { **down** *interval* | **up** *interval* } *

No delay is set for notifying the track object status change from Up to Down or from Down to Up by default.

1.5 Monitoring

Run the **show** command to check the configuration.

Run the **debug** command to output debugging information.

Caution

Debugging occupies system resources, so disable it immediately if not required.

Table 1-1 RNS Monitoring

Command	Purpose
show track [*object-number*]	Displays the statistics of one or more track objects.
show track client	Displays the statistics of a track client.
debug track { **all** | **client** | **proc-event** | **rdnd-event** }	Debugs the track module.

1.6 Configuration Examples

1.6.1 Configuring to Track Link Status of Interfaces

1. Requirements

Configure track object 3. When track object 1 is Up and object 2 is Down, track object 3 is Up.

2. Topology

Figure 1-1 Topology for Configuring to Track the Status of Multiple Interfaces

3. Notes

- Configure track objects 1 and 2.
- Configure track object 3,. Its members include track objects 1 and 2.

4. Procedure

Perform the following configuration on Device A.

```
DeviceA# config
DeviceA(config)# track 1 interface gigabitEthernet 0/0 line-protocol
DeviceA(config-track)# delay up 20 down 40
DeviceA(config-track)# exit
DeviceA(config)# track 2 interface gigabitEthernet 0/1 line-protocol
DeviceA(config-track)# delay down 30
DeviceA(config-track)# exit
DeviceA(config)# track 3 list Boolean and
DeviceA(config-track)# object 1
DeviceA(config-track)# object 2 not
```

5. Verification

```
DeviceA# show track 3
Track 3
  List boolean and
```

```
  Object 1
  Object 2 not
  The state is Down
    1 change,current state last:10 secs
  Delay up 0 secs,down 0 secs
```

6. Configuration Files

```
track 1 Interface GigabitEthernet 0/0 line-protocol
 delay up 20 down 40
!
track 2 Interface GigabitEthernet 0/1 line-protocol
 delay down 30
!
track 3 list boolean and
 object 1
 object 2 not
!
```

1.6.2 Configuring to Track the Results of RNS Instances

1. Requirements

Configure track object 5 for tracking the test results of an RNS list (consisting of RNS instances 1, 2-5, and 8).

2. Notes

- Configure and start an RNS test.
- Configure a track object for tracking the test result of an RNS list.
- Configure the delay for notifying the test result change from Up to Down, and the delay for notifying the test result change from Down to Up.

3. Procedure

Perform the following configuration on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# track 5 rns-list 1,2-5,8 and
DeviceA(config-track)# delay up 20 down 30
```

4. Verification

Make the test result of one of the RNS instances 1, 2-5, and 8 change from successful to unsuccessful. When the test result changes to unsuccessful, immediately check the status of track object 7, and verify that the status is still up. Check the status of the track object 30s later, and verify that the status changes to Down.

```
DeviceA# show track 5
Track 5
  rns-list 1,2-5,8 and
  The state is Down
    2 change, current state last: 10 secs
Delay up 20 secs, down 30 secs
```

5. Configuration Files

```
track 5 rns-list 1,2-5,8 and
 delay up 20 down 30
!
```

1.6.3 Reporting the Status of a Track Instance to the Associated Interface

1. Requirements

Configure track object 1 to detect RNS instance 1, and report its status to GigabitEthernet 1/1/1.

2. Notes

- Configure a track object to detect the interface status.
- Configure an interface association command.

3. Procedure

Perform the following configuration on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# track 1 rns 1
DeviceA(config-track)# trigger interface gigabitEthernet 1/1/1 link-state same
```

4. Verification

Make gigabitEthernet 1/1/0 to go Down and confirm that gigabitEthernet 1/1/1 is Down. When gigabitEthernet 1/1/0 changes from Down to Up, gigabitEthernet 1/1/1 also goes Up.

```
DeviceA# show track
Track 1
  Reliable Network Service 1
  Trigger:
    Interface GigabitEthernet 1/1/1 link-state same
  The state is Up
    3 change,current state last:1327 secs
  Delay up 0 secs,down 0 secs
```

5. Configuration Files

- Device A configuration file

```
track 1 rns 1
 trigger interface GigabitEthernet 1/1/1 link-state same
!
```

1.3.3 Procedure 2

1.4 Monitoring 3

1.5 Configuration Examples 3

1.5.1 Configuring IP Event Dampening 3

1 Configuring IP Event Dampening

1.1 Introduction

When an L3 network interface frequently goes Up or Down due to manual enabling/disabling or other external causes, the routing table on the device flaps repeatedly. If a routing protocol is configured, the protocol may extend the flap to the entire network, causing repeated updates and recalculation of neighboring routes. As a result, this wastes network bandwidth and destabilizes the network. Repeated route updates and recalculation on devices consume many CPU resources, and thus affect the normal running of customer networks.

The function of IP Event Dampening detects abnormal Up/Down flapping and automatically suppresses frequent interface state changes, which prevents a routing protocol from propagating single-point link failures. When an interface is restored to stable, it is automatically released, thus reducing network flaps and CPU resource consumption while improving network stability.

1.1.1 Basic Concepts

1. Penalty

IP Event Dampening uses the penalty method to perceive and control interface changes. Whenever an interface goes Up or Down, the penalty accumulates, but when the interface is stable, the penalty decreases exponentially. In this way, interface behaviors can be sensed and processed intelligently.

2. Suppress threshold

To identify an interface flap event, the function of IP Event Dampening configures a suppress threshold. When the cumulative penalty of an interface exceeds a suppress threshold, the interface is considered to flap and is suppressed.

3. Half-life period

The half-life period is the period for the penalty to decrease to half of the original value when an interface becomes stable. It defines the speed at which the penalty decays exponentially. The shorter the half-life period, the faster the penalty decays, and the faster the interface is detected to be stable, but the flap detection sensitivity is reduced more greatly.

4. Reuse threshold

When an interface does not flap and its penalty decays to a certain degree (below the suppress threshold), the interface is considered to be stable and is released.

5. Maximum suppress time

When an interface keeps flapping and reaches a very large penalty, the interface is not usable for a long time. To avoid this problem, we define the maximum suppress time to ensure that the interface suppression duration is less than the maximum suppress time no matter how long the interface has flapped.

6. Interface flap suppression

- An interface configured with IP Event Dampening is assigned a penalty. The interface gets a penalty of 1000 whenever it goes Down, and the penalty decreases with time. If the interface goes Down again, the penalty

increases. When the cumulative penalty exceeds the suppress threshold, the interface is suppressed. For the affected upper-layer protocol, the suppressed interface is always Down regardless of the interface state. When the penalty decreases to the reuse threshold, the interface is released and restored to its real state.

- If an L3 interface is not configured with IP Event Dampening or is not suppressed, the routing protocol or other protocols concerned about the interface state still work normally. When the interface is configured with IP Event Dampening and is suppressed, the upper-layer protocol considers the interface to be Down. During this process, any state change of the interface does not affect the routing table or the route calculation and advertisement performed by the upper-layer routing protocol until the interface is released.

1.1.2 Protocols and Standards

- RFC 2439: BGP Route Flap Damping

Note

The suppression algorithm core used by IP Event Dampening is the same as that used by Border Gateway Protocol (BGP) Route Flap Dampening stipulated in RFC 2439.

1.2 Restrictions and Guidelines

- The function of IP Event Dampening is supported only on L3 interfaces.

1.3 Configuring IP Event Dampening

1.3.1 Overview

When an interface configured with IP Event Dampening keeps flapping until the predefined threshold is exceeded, the interface is set to Down.

1.3.2 Restrictions and Guidelines

- When an L3 interface on a device is converted into an L2 interface, the IP Event Dampening command configured on the interface is deleted.
- IP Event Dampening can be configured only on the primary interface of a router but takes effect to all subinterfaces related to the primary interface. IP Event Dampening cannot be configured on **virtual templates**.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

interface aggregateport *interface-number*

- Enter the SVI interface configuration mode

interface vlan *interface-number*

(4) Configure the function of IP Event Dampening.

dampening [*half-life-period* [*reuse-threshold suppress-threshold max-suppress* [**restart** [*restart-penalty*]]]]

The function of IP Event Dampening is disabled on an interface by default.

1.4 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

Run the **debug** commands to output debugging information.

Caution

- Running the **clear** command during operation of the device may lose vital information and interrupt services.
- The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
clear counters	Clears interface statistics.
show dampening interface	Displays statistics about interfaces with IP Event Dampening.
show interfaces [*interface-type interface-number*] **dampening**	Displays IP Event Dampening configurations.
debug dampening interface	Debugs IP Event Dampening.

1.5 Configuration Examples

1.5.1 Configuring IP Event Dampening

1. Requirements

Configure IP Event Dampening on L3 interfaces.

2. Topology

Figure 1-1 Configuring IP Event Dampening

3. Notes

- Enable IP Event Dampening on interface GigabitEthernet 0/1 on Routers A and B respectively, and set the half-time period to 30s, the reuse threshold to 1500, the suppress threshold to 10,000, and the maximum suppress time to 120s.

4. Procedure

Configure IP Event Dampening on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# dampening 30 1500 10000 100
```

Configure IP Event Dampening on Device B.

```
DeviceB# configure terminal
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# dampening 30 1500 10000 100
```

5. Verification

Run the **show interfaces dampening** command to display the detailed information about Event Dampening on an interface.

```
DeviceA# show interfaces dampening
GigabitEthernet 0/1
  Flaps Penalty Supp    ReuseTm HalfL   ReuseV  SuppV   MaxSTm  MaxP    Restart
  0     0       FALSE   0       30      1500    1000    100     15119   0
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 no switchport
 dampening 30 1500 10000 100
!
end
```

- Device B configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 no switchport
 dampening 30 1500 10000 100
!
end
```

7. Common Errors

- IP Event Dampening is configured for an interface on a Layer 3 device before the interface is converted to a

Layer 3 interface by running the **no swithport** command.

1.4 Monitoring 2

1 Configuring HAM

1.1 Introduction

High availability module (HAM) is a self-developed system high availability (HA) technology. It monitors exceptional exit of software processes of a device to automatically start the processes or monitors frequent restart of a software process to automatically restart the device, thus quickly and automatically restore services. Used during patch upgrade, this function can prevent device reset due to patch upgrade exceptions.

1.2 HAM Application

HAM is mainly used for:

- Software process HA service: When a software process exits abnormally, HAM automatically starts the software process to restore services.
- Device restart service: When a software process restarts frequently, HAM attempts to automatically restart the device to restore services.

Typically, the HA service of one frequently restarting process is enabled on all devices. You can run command line interface (CLI) commands on the master device to enable/disable this service and synchronize the service status to other non-master devices. During a patch upgrade, a process may restart due to an abnormal process. If the device automatically restarts, traffic may be interrupted. Therefore, you must disable the HA service of one frequently restarting process. After a patch upgrade, you can enable the HA service of one frequently restarting process when confirming that no process restarts frequently.

Caution

If you disable the HA service of one frequently restarting process by running a command, services may not automatically be restored to normal because some processes frequently restart due to no automatic restarting of the device. As a result, failure time prolongs.

1.2.1 Detection Process

HAM monitors kernel advertisements to perceive the status of an abnormal process and automatically restores services based on the following rules:

- If one process exits five times within two minutes, HAM attempts to start the process five minutes later.
- If a process restarts twice within 10 minutes, services cannot be restored. In this case, you must restart the device to restore them.

1.3 Configuring the HA Service of One Frequently Restarting Process

1.3.1 Overview

When one process exits abnormally, you can automatically restore services by configuring the HA service of one process that restarts frequently. You can further determine the exception to check whether the device needs to be restarted to restore services.

1.3.2 Restrictions and Guidelines

If one process frequently restarts, disabling its HA service may lead to a longer failure time. Therefore, you are advised to enable the configuration in scenarios other than patch upgrades.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Disable the HA service of one frequently restarting process.

no ham single-process-ha auto-restart enable

The HA service of one frequently restarting process is enabled by default.

1.4 Monitoring

Run the **show** command to display the configuration.

Command	Purpose
show ham log { **all** | **bad-script** | **error** | **kill** | **multi-instance** | **no-alive** | **reg-alive** | **reg-restart** | **restart** | **running-event** }	Displays the HAM log information.
show ham register { **alive** | **delay-restart** | **fail-chain** | **restart** }	Displays the detailed HAM information of service registration.

1 SYSHA 1

1.1 Introduction 1

1.1.1 Overview 1

1.1.2 Principles 1

1.2 Monitoring 2

1 SYSHA

1.1 Introduction

1.1.1 Overview

On a complex network, the operating system of a device may be exhausted when the device receives and processes a large number of packets, affecting normal service running. SYSHA monitors software resources of devices and provides self-healing upon resource exceptions, preventing long service interruptions.

1.1.2 Principles

1. System Resources

Software resources monitored by SYSHA include the following items.

- CPU usage

  The CPU usage is the ratio of the CPU load to the CPU processing capability, which is expressed in percentage. It indicates the percentage of time that the CPU occupies for processing and computing tasks within a period of time. For example, if the CPU usage is 30%, 30% of the CPU time is used for calculation, and the remaining time is idle.

- File descriptor

  A file descriptor is an index created by the kernel to manage opened files and points to an opened file. The operating system limits the total number of file descriptors that can be used by software. Once the number of file descriptors used by the software exceeds the limit, the software encounters an exception.

- Memory usage

  The memory usage is the ratio of the used memory to the total memory. If the software occupies excessive system memory resources, normal running of other software on the device will be affected.

- Number of threads

  A thread is the smallest unit of an operating system for performing computing and scheduling. It is included in a process and is the operation unit of the process. One process can have multiple threads running concurrently, and each thread runs a different task simultaneously. The operating system allocates a thread ID to each thread, but the total number of thread IDs is limited. Therefore, a process cannot occupy too many thread resources. Otherwise, thread IDs will be exhausted, affecting normal running of other software.

2. Monitoring and Self-healing

SYSHA uses scheduled sampling to monitor the system resource usage of software. At intervals, SYSHA scans and records the system resource usage of software, calculates the average value of multiple rounds, and determines whether the current system resource usage of the process is normal. If SYSHA detects that the software occupies too many device software resources and affects normal operation of services, it will restart the services or the device.

1.2 Monitoring

Run the **show** command to display the configuration.

Table 1-1 SYSHA Monitoring

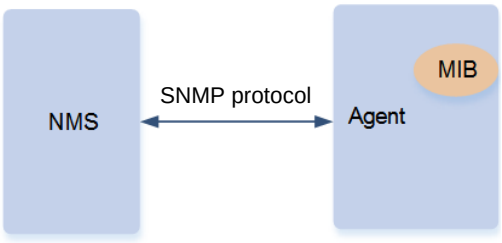
1 Configuring SNMP

1.1 Introduction

1.1.1 Overview

The Simple Network Management Protocol (SNMP) is used for network monitoring and management. Because many vendors support SNMP, SNMP has become a network management standard and applies to the interconnected environment of systems of multiple vendors. By using SNMP, the network administrator can implement information query for network nodes, network configuration, fault locating, and capacity planning.



1.1.2 Principles

1. Basic Concepts

The SNMP management system has the following components:

- Network Management System (NMS)
- SNMP agent
- MIB

Figure 1-1 Relationship Between the NMS and Network Management Agent

- SNMP network manager

  The NMS is the system that uses the SNMP to control and monitor the network, or the server on which the network management software is deployed.

  The NMS sends SNMP commands to the SNMP agent to query or modify one or multiple parameters and receives Trap commands from the SNMP agent to learn about the running status of managed devices.

- SNMP agent

  The SNMP agent ("agent") is software running on the managed devices. It is responsible for receiving, processing, and responding to monitoring and control packets from the NMS. The agent may also actively send messages to the NMS.

- MIB

  The MIB is a virtual network management information base. The managed network devices contain lots of information. To uniquely identify a specific management unit among SNMP packets, the MIB adopts the tree hierarchical structure. Nodes in the tree indicate specific management units. A string of digits are used

to uniquely identify a management unit system among network devices. The MIB is a set of unit identifiers of network devices.

- Operation types

  Six operation types are defined for information exchange between the NMS and the agent based on SNMP:

  - Get-Request: The NMS extracts one or more parameter values from the agent.
  - Get-Next-Request: The NMS extracts the parameter value next to one or more parameters from the agent.
  - Get-Bulk: The NMS extracts a batch of parameter values from the agent.
  - Set-Request: The NMS sets one or more parameter values of the agent.
  - Get-Response: The agent returns one or more parameter values, which are the operations of the agent in response to the three operations performed by the NMS.
  - Trap: The agent actively sends a message to notify the NMS of the situation happening in the agent.

  The first four packets are sent by the NMS to the agent and the last two packets are sent by the agent to the NMS. The first three operations of the NMS and the response operations of the agent are based on UDP port 161. The Trap operation performed by the agent is based on UDP port 162. For details, see Figure 1-2.

Caution

SNMPv1 does not support the Get-Bulk operation.

Figure 1-2 SNMP Packet Interaction

2. Basic SNMP Functions

SNMP interaction is response interaction (for interaction of packets, see Figure 1-2). The NMS actively sends requests to the agent, including Get-request, Get-next-request, Get-bulk, and Set-request. The agent receives the requests, completes operations, and returns a Get-response. Sometimes, the agent actively sends a Trap

message and an Inform message to the NMS. The NMS does not need to respond to the Trap message but needs to return an Inform-response to the agent. Otherwise, the agent re-sends the Inform message.

3. SNMP Versions

- SNMPv1

  SNMPv1 is the first official version of SNMP and is defined in RFC 1157. Based on community names, SNMPv1 has simple structure of management information (SMI) and simple management information base (MIB) and lower security.

- SNMPv2c

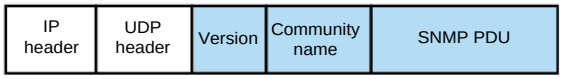
  SNMPv2c is a community-based SNMP management architecture and is defined in RFC 1901. SNMPv2c is compatible with SNMPv1. Compared with SNMPv1, SNMPv2c has two more protocol operations Get-Bulk and Inform and supports more data types and error code information.

- SNMPv3

  SNMPv3 defines security extension capability and provides the following security features by identifying and encrypting data.

  - Ensuring that data is not tampered during transmission.
  - Ensuring that data is transmitted from legal data sources.
  - Encrypting packets and ensuring data confidentiality.

4. Principles of SNMPv1 and SNMPv2c



SNMPv1 and SNMPv2c adopt the community-based security architecture. The administrator who can perform operations on the MIB of the agent is limited by defining the host address and authentication name (community string).

SNMPv1 and SNMPv2c determine whether the administrator has the right to use MIB objects by using the authentication name. To be able to manage devices, the NMS must ensure that its authentication name is the same as an authentication name defined in devices.

In SNMPv2c, the Get-bulk operation enables more detailed error message types to be returned to the NMS. The Get-bulk operation allows all information from a table or lots of data to be obtained at a time, so as to reduce the request-response times. The enhanced error handling capabilities of SNMPv2c include extension of error codes to differentiate error types. In SNMPv1, however, only one error code is provided for the errors. In SNMPv2c, the error codes can be used to differentiate error types. Because management workstations on the network may support SNMPv1 and SNMPv2c at the same time, the SNMP agent must be able to identify SNMPv1 packets and SNMPv2c packets and return packets of the corresponding versions.

SNMPv1 and SNMPv2c packets are composed of version, community name, and SNMP protocol data unit (PDU). Figure 1-3 shows the structure of the packets.

Figure 1-3 Structure of SNMPv1 and SNMPv2c Packets

- The main fields in packets are as follows:

- Version: Indicates an SNMP version. For SNMPv1 packets, the corresponding field value is 0. For SNMPv2c packets, the field value is 1.
- Community name: It is used for authentication between the agent and NMS. The field value is a string that can be customized. The community names include readable and writable community names. During Get-Request and Get-Next-Request operations, a readable community name is used for authentication. During Set operations, a writable community name is used for authentication.
- SNMP PDU: Includes information such as PDU type, request identifier, and variable binding list. SNMPv1 PDUs include GetRequest PDU, GetNextRequest PDU, SetRequest PDU, Response PDU, and Trap PDU. Compared with SNMPv1, SNMPv2c has GetBulkRequest PDU and InformRequest PDU.

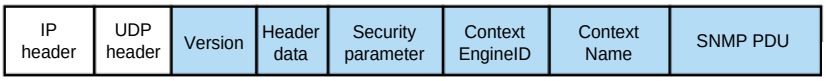
- Security

  An authentication name has the following attributes:

  - Read-only: Provides the read permission of all MIB variables for authorized management workstations.
  - Read-write: Provides the read/write permission of all MIB variables for authorized management workstations.

5. Principles of SNMPv3

SNMPv3 redefines the SNMP architecture and includes functions of SNMPv1 and SNMPv2c into the SNMPv3 system.



The NMS and SNMP agent are SNMP entities. In the SNMPv3 architecture, SNMP entities consist of the SNMP engine and SNMP applications. The SNMP engine is used to send and receive messages, identify and encrypt information, and control access to managed objects. SNMP applications refer to internal applications of SNMP, which work by using the services provided by the SNMP engine.

SNMPv3v determines whether a user has the right to use MIB objects by using the user-based security model (USM). The security level of the NMS user must be the same as that of a specified SNMP user defined in devices so as to manage devices.

SNMPv3 requires the NMS to obtain the SNMP agent engine IDs on devices when the NMS manages devices. SNMPv3 defines the Discover and Report operation mechanisms. When the NMS does not know the agent engine ID, the NMS may first send a Discover message to the agent and the agent returns a Report message carrying an engine ID. Later, management operations between the NMS and the agent must carry the engine ID.

SNMPv3 defines a new packet format, which is shown in Figure 1-4.

Figure 1-4 Structure of SNMPv3 Packets

- The main fields in SNMP packets are as follows:
  - Version: Indicates an SNMP version. For SNMPv3 packets, the field value is 2.
  - Header data: Mainly includes description information such as the maximum message size supported by the message sender and the security model of the message.

- Security parameter: Includes such security information as SNMP engine-related information, username, authentication parameter, and encryption parameter.
- Context EngineID: A unique identifier of SNMP. This field and the PDU type decide the application to which the packets are sent.
- Context name: Decides the MIB view of the managed devices based on the Context EngineID.
- SNMP PDU: Includes information such as PDU type, request identifier, and variable binding list. SNMPv3 PDUs include GetRequest PDU, GetNextRequest PDU, SetRequest PDU, Response PDU, Trap PDU, GetBulkRequest PDU, and InformRequest PDU.

- Security

  SNMPv3 determines the data security mechanism based on the security model and security level. At present, security models include SNMPv1, SNMPv2c, and SNMPv3. SNMPv3 includes SNMPv1 and SNMPv2c into the security model.

Table 1-1 Security Models and Security Levels of SNMPv1 and SNMPv2c

Security Model	Security Level	Authentication	Encryption
SNMPv1	noAuthNoPriv	Authentication name	N/A
SNMPv2c	noAuthNoPriv	Authentication name	N/A

Table 1-2 Security Model and Security Level of SNMPv3

Security Model	Security Level	Authentication	Encryption	Description
SNMPv3	noAuthNoPriv	Username	N/A	Data validity is confirmed through username.
SNMPv3	authNoPriv	MD5 or SHA	N/A	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA is provided.
SNMPv3	authPriv	MD5 or SHA	DES	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA and the data encryption mechanism based on CBC-DES are provided.

- Engine ID

  An engine ID is used to uniquely identify an SNMP engine. Because each SNMP entity includes only one SNMP engine, the SNMP engine uniquely identifies an SNMP entity in a management domain, therefore, the SNMPv3 agent as an entity must has a unique engine ID, that is, SnmpEngineID.

  An engine ID is an octet string that consists of 5 to 32 bytes. RFC 3411 defines the format of an engine ID:

  - The first four bytes indicate the private enterprise ID (allocated by the Internet Assigned Numbers Authority (IANA)) of a vendor, which is expressed in hexadecimal.
  - The fifth byte indicates remaining bytes.

0: Reserved.

1: The later four bytes indicate an IPv4 address.

2: The later 16 bytes indicate an IPv6 address.

3: The later six bytes indicate a MAC address.

4: Text consisting of up to 27 bytes, which is defined by the vendor.

5: Hexadecimal value consisting of up to 27 bytes, which is defined by the vendor.

6-127: Reserved.

128-255: Formats specified by the vendor.

1.1.3 Protocols and Standards

- RFC 1157, Simple Network Management Protocol (SNMP)
- RFC 1901, Introduction to Community-based SNMPv2
- RFC 2578, Structure of Management Information Version 2 (SMIv2)
- RFC 2579, Textual Conventions for SMIv2
- RFC 3411, An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks
- RFC 3412, Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)
- RFC 3413, Simple Network Management Protocol (SNMP) Applications
- RFC 3414, User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)
- RFC 3415, View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)
- RFC 3416, Version 2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)
- RFC 3417, Transport Mappings for the Simple Network Management Protocol (SNMP)
- RFC 3418, Management Information Base (MIB) for the Simple Network Management Protocol (SNMP)
- RFC 3419, Textual Conventions for Transport Addresses

1.2 Configuration Task Summary

SNMP configuration includes the following tasks:

(1) Configuring Basic SNMP Features

(2) (Optional) Configuring the Trap Function

(3) (Optional) Configuring the Agent Shielding Function

(4) (Optional) Configuring SNMP Control Parameters

1.3 Configuring Basic SNMP Features

1.3.1 Overview

After the basic SNMP function is configured, users can access the agent through the NMS.

1.3.2 Restrictions and Guidelines

- When an authentication name is configured, the default access permission is read-only if no access permission is specified.
- When the view-based access control model (VACM) is used, an SNMP user group must be configured. By associating specified users with a group and associating the group with a view, you can ensure that the users in the group have the same access permission. In this way, you can determine whether managed objects associated with an operation are in the allowable range of a view. Only managed objects in the range of a view can be accessed.
- When you configure users in SNMPv3, you can specify the security level, authentication algorithm (MD5 or SHA), authentication password, encryption algorithm (DES at present), and encryption password.
- When SNMPv3 is used to manage network devices, a user must be configured.
- After the SNMP attack prevention and detection function is configured, the corresponding action can be taken after authentication fails consecutively.
- The permanently forbidden source IP addresses can be authenticated for access again only after the administrator manually unlocks the IP addresses. The source IP addresses that are forbidden in a period of time can be authenticated for access again after the period expires or after the administrator manually unlocks the IP addresses.
- By default, password dictionary check is not performed for communities and users. If community names and usernames are too simple and are easily cracked, enable password dictionary check for the communities and users. The function must be used with the **password policy** command in the global configuration mode.
- The SNMP logging function records the Get, Get-Next, and Set operations performed by the NMS on the SNMP Agent. When the Get and Get-Next operations are performed, the agent records the IP address of the NMS user, operation type, and OID of the operation node. When the Set operation is performed, the agent records the IP address of the NMS user, operation type, OID of the operation node, and set value. These logs are sent to the information center of devices. The level of these logs is informational, that is, the logs are used as prompt information of devices. A large number of logs will affect device performance. In normal conditions, you are advised to disable the SNMP logging function.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure an SNMP view.

snmp-server view *view-name oid-tree* { **include** | **exclude** }

An SNMP view needs to be configured when the View-based Access Control Model (VACM) function is used.

The default view allows access to all MIB objects.

(4) (Optional) Configure an SNMP user group.

snmp-server group *group-name* { **v1** | **v2c** | **v3** { **auth** | **noauth** | **priv** } } [**read** *readview*] [**write** *writeview*] [**access** { *acl-name* | *acl-number* | **ipv6** *ipv6-acl-name* [*acl-name* | *acl-number*] }]

No user group is configured by default.

(5) Configure an authentication name and access permission.

snmp-server community [**0** | **7** | **secret** [**0** | **8**]] *community* [**view** *view-name*] [**ro** | **rw**] [**host** *ipv4-address* | **host** *ipv6-address*] [*acl-name* | *acl-number* | **ipv6** *ipv6-acl-name* [*acl-name* | *acl-number*]]

No authentication name is configured and the access permission of all communities is read-only by default.

When SNMPv1 and SNMPv2C are used to manage network devices, an authentication name must be configured on the agent.

(6) Configure an SNMP user.

snmp-server { [**remote-engineid** *engineid*] **user** *username group-name* **v3** { [**encrypted**] [**auth** { **md5 | sha** | **sha2-256** | **sha2-512 | sm3** } *auth-password* [**priv** { **3des | aes128 | des56** | **sm4** } *priv-password*]] | **interactive** [**auth** { **md5** | **sha** | **sha2-256** | **sha2-512 | sm3** } [**priv** { **3des | aes128 | des56** | **sm4** }]] } | **user** *username group-name* { **v1** | **v2c** } } [**access** { *acl-name* | *acl-number* | **ipv6** *ipv6-acl-name* [*acl-name* | *acl-number*] }]

No SNMP user is configured by default.

(7) (Optional) Enable the agent function.

enable service snmp-agent

The SNMP agent function is enabled by default.

(8) (Optional) Enable the SNMP attack prevention and detection function.

snmp-server authentication attempt *attempt-times* **exceed** { **lock** | **lock-time** *lock-time* | **unlock** }

By default, the SNMP attack detection function is enabled, the maximum number of consecutive SNMP authentication failures is 3, and a source IP address can be authenticated again in five minutes after it is prohibited.

(9) (Optional) Configure password dictionary check for communities and users.

snmp-server enable secret-dictionary-check

Password dictionary check is not configured for communities and users by default.

(10) (Optional) Configure the SNMP logging function to record the Get, Get-Next, and Set Operations performed by the NMS on the SNMP Agent.

snmp-server logging { **authentication** { **fail | success** } | **get-operation** | **set-operation** | **trap-info** }

By default, the function of logging the Get and Get-Next Operations performed by the NMS on the SNMP agent is disabled and the function of logging the Set Operation is enabled.

(11) (Optional) Display SNMP help information. All the following configuration tasks are optional. Select the configuration tasks as required.

- Display help information about SNMP.

  snmp-server help

- Display help information about SNMP authentication names and access permissions.

  snmp-server community help

- Display help information about the SNMP user group.

  snmp-server group help

- Display help information about SNMP users.

snmp-server user help

- Display help information about the SNMP view.

  snmp-server view help

1.4 Configuring the Trap Function

1.4.1 Overview

After the Trap function is configured, the agent actively sends Trap messages to the NMS.

1.4.2 Restrictions and Guidelines

- The host address of the NMS must be configured when the agent actively sends Trap messages to the NMS. That is, the **snmp-server host** command is used with the **snmp-server enable traps** command in the global configuration mode.
- Multiple SNMP hosts can be configured to receive Trap messages. A host can combine different types of Trap messages, ports, and VRF forwarding tables. If a host is configured with the same port and VRF in multiple configurations, the last configuration is combined with the previous configurations. To send different Trap messages to the same host, configure different types of Trap messages each time. These configurations are finally combined.
- The system reboot notification function must be enabled on the agent so that the RGOS system sends Trap messages to the NMS to notify system reboot before reloading or rebooting of the device.
- After the Link Trap message sending function is enabled on an interface, the SNMP sends a Link Trap message if the link status on the interface changes. Otherwise, the SNMP does not send the message.
- By default, the IP address of an interface that sends SNMP packets is used as the source address of the SNMP packets. If you want to use a fixed local IP address as the source address to facilitate management, configure the source address for sending Trap messages on the agent.
- The **snmp-server trap-format private** command can be run to include private fields in Trap messages. The supported private field is the alarm generation time. For the specific data types and data ranges of the fields, see the RUIJIE-TRAP-FORMAT-MIB.mib file.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure an NMS host address.

Management interface configuration:

snmp-server host [**oob**] { *ipv4-address* | **ipv6** *ipv6-address* | **domain** *domain-name* } [**informs** | **traps**] [**version** { { **1** | **2c** } [**0** | **7**] *community* | **3** { **auth** | **noauth** | **priv** } *username* }] [**udp-port** *port-number*] [**via mgmt** *interface-number*] [*notification-type*]

Non-management interface configuration:

snmp-server host { *ipv4-address* | **ipv6** *ipv6-address* | **domain** *domain-name* } [**vrf** *vrf-name*] [**informs** | **traps**] [**version** { { **1** | **2c** } [**0** | **7**] *community* | **3** { **auth** | **noauth** | **priv** } *username* }] [**udp-port** *port-number*] [*notification-type*]

No SNMP host address is configured by default.

(4) (Optional) Enable the agent to actively send Trap messages to the NMS.

snmp-server enable traps [**authentication all-protocols** | **bridge** | **entity** | **envom** | **mac-notification** | **mpls** *mpls-trap* | **nfpp** | **normal** | **ospf** | **running-config-change** | **snmp** [**authentication** | **coldstart** | **heartbeat** | **linkdown** | **linkup** | **warmstart**] * | **startup-config-change** | **vrrp** | **web-auth**]

The SNMP agent is forbidden to send Trap messages to the NMS by default.

(5) (Optional) Configure the system reboot trap sending function.

snmp-server system-shutdown

The SNMP system reboot notification function is disabled by default.

(6) (Optional) Configure a source address for Trap messages.

snmp-server trap-source *interface-type interface-number*

The IP address of the interface that sends SNMP packets is used as the source address by default.

(7) (Optional) Include private fields in sent Trap messages.

snmp-server trap-format private

SNMP Trap messages do not include private fields by default.

(8) Configure Inform message sending attempts and timeout time.

snmp-server inform { **retries** *retry-number* | **timeout** *timeout* }

The number of default Inform message sending attempts is **3** and the default Inform message timeout time is **15** seconds.

(9) (Optional) Enable the function of carrying the device SN in the Trap message.

snmp-server trap-format device-serial-number

This function is disabled by default.

(10) (Optional) Enable the function of carrying the SYSMAC in the Trap message.

snmp-server trap-format sysmac

This function is disabled by default.

(11) (Optional) Enable the Link Trap message sending function on an interface.

a Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

interface aggregateport *interface-number*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

b Enable the Link Trap message sending function on an interface.

snmp-server link-status

The Link Trap message sending function is enabled on an interface by default.

1.5 Configuring the Agent Shielding Function

1.5.1 Overview

After the agent shielding function is enabled, the port access frequency and network attack probability are reduced.

1.5.2 Restrictions and Guidelines

The SNMP agent function is disabled by default. When SNMP agent parameters (for example, NMS host address, authentication name, and access permission) are configured, the SNMP agent service is automatically enabled. The **enable service snmp-agent** command must be run so that the SNMP agent service can take effect. If the SNMP agent service is disabled or the **enable service snmp-agent** command is not run, the SNMP agent service does not take effect. The **no snmp-server** command is used to shield all SNMP agent service configurations. In this case, running the **show running-config** command will not display the configurations. The configurations can be restored after the SNMP agent service is enabled again. The **no enable service snmp-agent** command is used to disable the SNMP agent service. In this case, the SNMP agent function is disabled and packets and trap messages are not sent and received, but the SNMP agent configurations are not shielded.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the SNMP agent shielding function.

no snmp-server

The SNMP agent function is enabled by default.

(4) Enable the SNMP agent function of a device.

enable service snmp-agent

The SNMP agent function is disabled by default.

1.6 Configuring SNMP Control Parameters

1.6.1 Overview

After basic parameters such as device contact mode, device location, serial number, and Trap message sending are configured, the NMS can obtain information such as the contact person and physical location of the device by accessing the parameters.

1.6.2 Restrictions and Guidelines

- When too many SNMP request packets cause SUMP tasks to occupy a large CPU space, you can configure SNMP traffic control to limit the number of request packets processed per second in each SNMP task to control the CPU usage.
- SNMP contains three versions: v1, v2C, and v3. If only a specified version is used for MIB interaction management in practice, you can disable unused SNMP versions by running the **no snmp-server enable version** [**v1** | **v2c** | **v3**] command.
- All the parameters are optional. Set them based on requirements.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the contact mode of the system.

snmp-server contact *contact-text*

The contact mode of the system is empty by default.

(4) Configure the system location.

snmp-server location *location-text*

The system location is empty by default.

(5) Configure the system serial number.

snmp-server chassis-id *chassis-id-text*

The default system serial number is 60FF60.

In general, the device serial number is used as the SNMP serial number to facilitate identification of the device.

(6) Configure NE information of a device.

snmp-server net-id *net-id-text*

The NE code information of a device is empty by default.

(7) Configure the maximum packet length of the SNMP agent.

snmp-server packetsize *packetsize*

The maximum packet length of the SNMP agent is 1,472 bytes by default.

(8) Configure the UDP port ID of the SNMP service.

snmp-server udp-port *port-number*

The default UDP port ID of the SNMP service is **161**.

(9) Configure the source port of the device on which the SNMP service is deployed.

snmp-server source-interface *interface-type interface-number*

The source port of a device with a valid IP address is used to receive SNMP packets by default.

(10) Configure the queue length of Trap messages.

snmp-server queue-length *queue-length*

The default queue length of the Trap messages is **100**.

(11) Configure the sending interval of Trap messages.

snmp-server trap-timeout *trap-timeout-time*

The Trap messages are resent with a timeout time of **300** milliseconds by default.

(12) Configure SNMP traffic control.

snmp-server flow-control pps *packet-count*

About 300 SNMP request packets are processed every second by default.

(13) Configure the status of SNMP versions.

snmp-server enable version [**v1** | **v2c** | **v3**]

SNMPv1 and SNMPv2c are disabled and SNMPv3 is enabled by default.

(14) Enable sending the heartbeat Trap message.

snmp-server heartbeat on

This function of sending the heartbeat Trap message is enabled by default.

(15) Configure the interval for sending the heartbeat Trap message.

snmp-server heartbeat period *seconds*

The default interval is 300s.

(16) Configure the local engine ID.

snmp-server local-engineid *engineid*

The local engine ID is automatically generated by default. The default length is 11 bytes. The first bit has a fixed binary value of 1, and the first four bytes are the private number of the enterprise device allocated by IANA, which is a fixed decimal value of 4881, so the fixed hexadecimal value of the first five bytes is 8000131103. The last six bytes are the MAC address.

1.7 Monitoring

Run the **show** command to check the configuration.

Run the **clear** command to clear information.

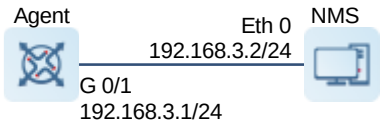
Caution

During device operation, running the **clear** command may cause service interruption due to key information loss.

Table 1-3 Monitoring

Command	Purpose
clear snmp locked-ip [**ipv4** *ipv4-address* | **ipv6** *ipv6-address*]	Clears the list of source IP addresses that are locked after authentication fails consecutively.
clear snmp locked-user	Clears information of users that are locked after SNMP authentication fails consecutively.
clear snmp proc-mib-time-list	Clears the SNMP MIB timer counters.
show snmp [**group** | **host** | **locked-ip** | **locked-user** | **message** | **mib** | **oid** | **process-mib-time** | **trap** | **user** | **version** | **view**]	Displays the SNMP status information.

1.8 Configuration Examples



1.8.1 Configuring Basic SNMPv2c Function

1. Requirements

Network devices are managed and monitored through the SNMP network manager, as shown in Figure 1-5.

2. Topology

Figure 1-5 Topology of Basic SNMPv2c Function

3. Procedure

Enable the SNMP agent function.

```
Device> enable
Device# configure terminal
Device(config)# enable service snmp-agent
```

Configure a read/write community with the name community_name.

```
Device(config)# snmp-server community community_name rw
```

Configure an IP address for the agent: set the address of GigabitEthernet 0/1 to 192.168.3.1/24, so that it can communicate with the NMS.

```
Device(config)# interface gigabitEthernet 0/1
Device(config-if-gigabitEthernet 0/1)# ip address 192.168.3.1 255.255.255.0
Device(config-if-gigabitEthernet 0/1)# exit
```

4. Verification

Run the **ping** command to verify that the agent and NMS are mutually reachable via L3 routes.

```
Device# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **show service** command to check whether the SNMP agent function is enabled.

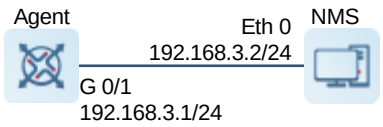
```
Device# show service
snmp-agent    : enabled
ssh-server    : disabled
telnet-server : enabled
```

5. Configuration Files

Agent configuration file

```
interface GigabitEthernet 0/1
 ip address 192.168.3.1 255.255.255.0
!
snmp-server community community_name rw
!
end
```

1.8.2 Configuring Basic SNMPv3 Function



1. Requirements

The network management station is connected to the managed network devices. On the network management station, users access the MIB on the network devices through the SNMP network manager and receive messages actively sent by the network devices to manage and monitor the network devices.

- The management workstation (NMS) manages network devices (agents) based on the authentication and encryption mode of users.
- Network devices can control the operation permission of users to access MIB objects.
- Network devices can actively send authentication and encryption messages to the NMS.

2. Topology

Figure 1-6 Topology of Basic SNMPv3 Function

3. Notes

- Configure an SNMP user group.
- Configure an SNMP user.
- Configure an SNMP host.
- Configure an IP address for the agent.

4. Procedure

Enable the SNMP agent functio

```
Device> enable
Device# configure terminal
Device(config)# enable service snmp-agent
```

Create an SNMP user group with the name **Snmpv3group**, select v3 as the version, and configure an authentication and encryption mode with the security level priv.

```
Device(config)# snmp-server group Snmpv3group v3 priv
```

Note

In actual scenarios, to improve network security, you can configure a MIB view to control the access permissions of MIB objects. The configuration example is as follows:

Create an MIB view with the name view1, which includes the associated MIB object 1.3.6.1.2.1.1. Create an MIB view with the name view2, which includes the associated MIB object 1.3.6.1.2.1.1.4.0.

```
Device(config)# snmp-server view view1 1.3.6.1.2.1.1 include
```

Create an MIB view with the name view2, which includes the associated MIB object 1.3.6.1.2.1.1.4.0.

```
Device(config)# snmp-server view view2 1.3.6.1.2.1.1.4.0 include
```

Create an SNMP user group with the name **Snmpv3group**, select v3 as the version, and configure an authentication and encryption mode with the security level priv. Configure view1 as a readable view and view2 as a writable view.

```
Device(config)# snmp-server group Snmpv3group v3 priv read view1 write view2
```

Configure an SNMP user. Create a user with the name **Snmpv3user** under the group **Snmpv3group**, select v3 as the version, and set the authentication mode to SHA2-256, authentication password to test1@123, encryption mode to AES128, and encryption password to test2@321.

```
Device(config)# snmp-server user Snmpv3user Snmpv3group v3 auth sha2-256 test1@123
priv aes128 test2@321
```

Configure the SNMP host: Set the host address to 192.168.3.2, and the version to v3, configure an authentication and encryption mode with the security level priv, and associate the username **Snmpv3user**.

```
Device(config)# snmp-server host 192.168.3.2 traps version 3 priv Snmpv3user
```

Enable the agent to actively send Trap messages to the NMS.

```
Device(config)# snmp-server enable traps
```

Enable the agent to actively send Trap messages to the NMS.

```
Device(config)# snmp-server enable traps
```

Configure an IP address for the agent: set the address of GigabitEthernet 0/1 to 192.168.3.1/24, so that it can communicate with the NMS.

```
Device(config)# interface gigabitEthernet 0/1
Device(config-if-gigabitEthernet 0/1)# ip address 192.168.3.1 255.255.255.0
Device(config-if-gigabitEthernet 0/1)# exit
```

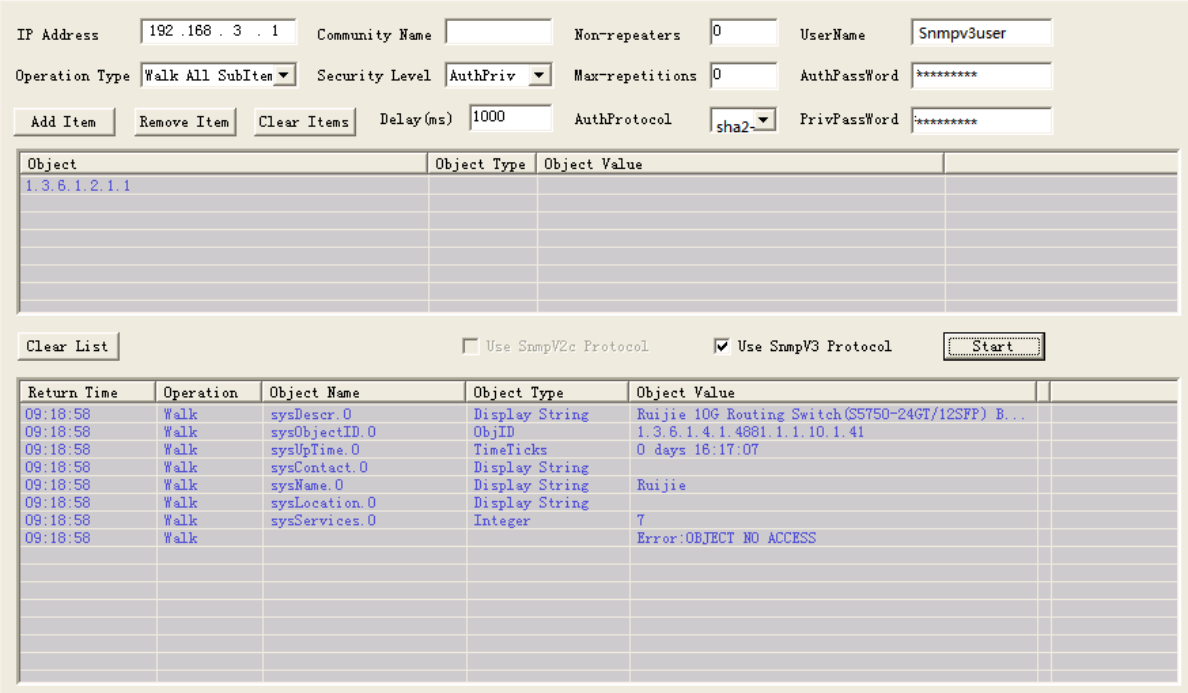
5. Verification

Run the **ping** command to verify that the agent and NMS are mutually reachable via L3 routes.

```
Device# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **show snmp user** command to display the SNMP user.

```
Device# show snmp user
User name: Snmpv3user
Engine ID: 80001311037042d3a3d3ed
storage-type: permanent    active
Security level: auth priv
Auth protocol: SHA2-256
Auth key: db 24 65 26 3b 1e 7d b0 14 10 2c ec be 93 7a 6a a1 c2 33 f5 19 c5 46 0c 29
c8 16 35 a2 1d 04 cf
Priv protocol: AES
Priv key: db 24 65 26 3b 1e 7d b0 14 10 2c ec be 93 7a 6a
Group-name: Snmpv3group
Device# show snmp group
groupname: Snmpv3group
securityModel: v3
securityLevel:authPriv
readview:
writeview:
```



```
notifyview:
```

Run the **show snmp host** command to display the host information configured by the user.

```
Device# show snmp host
Notification host: 192.168.3.2
udp-port: 162
type: trap
user: Snmpv3user
security model: v3 authPriv
```

In the NMS, enter the IP address of the device: 192.168.3.1 and **Snmpv3user** in UserName, select AuthPriv for Security Level, enter **test1@123** in AuthPassWord, select **SHA2-256** for AuthProtocol, and enter **test2@321** in PrivPassWord. Click **Add Item** and select an MIB management unit to be queried, for example, System. Click **Start** to query the MIB of the network devices. The query results are displayed in the lowest pane of the dialog box, as shown in Figure 1-7.

Figure 1-7 MIB-browser Query Example

6. Configuration Files

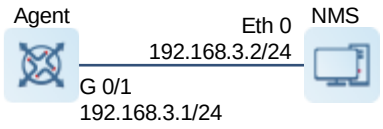
Agent configuration file

```
interface GigabitEthernet 0/1
 ip address 192.168.3.1 255.255.255.0
!
snmp-server user Snmpv3user Snmpv3group v3 encrypted auth sha2-256
DB2465263B1E7DB014102CECBE937A6AA1C233F519C5460C29C81635A21D04CF priv aes128
DB2465263B1E7DB014102CECBE937A6A
```

```
snmp-server group Snmpv3group v3 priv read view1 write view2
snmp-server host 192.168.3.2 traps version 3 priv Snmpv3user
snmp-server enable traps
!
end
```

7. Common Errors

The authentication and encryption modes selected on the network management software are inconsistent with those configured on the device, causing MIB operation failures.



1.8.3 Configuring Basic Trap Function

1. Requirements

The network management station (NMS) manages network devices (agents) based on the community authentication mode, and the network devices can actively send messages to the network management station.

2. Topology

Figure 1-8 Topology of Basic Trap Function

3. Procedure

Set the agent and NMS to be reachable via L3 routes: set the IP address of GigabitEthernet 0/1 on the agent to 192.168.3.1.

```
Device> enable
Device# configure terminal
Device(config)#interface gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0
Device(config-if-GigabitEthernet 0/1)#exit
```

Set the SNMP host address to 192.168.3.2, the message format to Version 2c, and the authentication name to Snmpv3user. Enable the agent to actively send Trap messages to the NMS.

```
Device> enable
Device# configure terminal
Device(config)# snmp-server host 192.168.3.2 traps version 2c Snmpv3user
Device(config)# snmp-server enable traps
```

4. Verification

Run the **ping** command to verify that the agent and NMS are mutually reachable via L3 routes.

```
Device# ping 192.168.3.2
Sending 5, 100-byte ICMP Echoes to 192.168.3.2, timeout is 2 seconds:
  < press Ctrl+C to break >
```

```
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **show snmp** command to display the SNMP status.

```
Device# show snmp
Chassis: 1234567890
0 SNMP packets input
       0 Bad SNMP version errors
       0 Unknown community name
       0 Illegal operation for community name supplied
       0 Encoding errors
       0 Number of requested variables
       0 Number of altered variables
       0 Get-request PDUs
       0 Get-next PDUs
       0 Set-request PDUs
       0 Drop PDUs
       0 UDP parse errors
0 SNMP packets output
       0 Too big errors (Maximum packet size 1472)
       0 No such name errors
       0 Bad values errors
       0 General errors
       0 Response PDUs
       0 Trap PDUs
SNMP global trap: enabled
SNMP logging: enabled
SNMP trap logging: disabled
SNMP authentication success logging: enabled
SNMP authentication fail logging: enabled
SNMP agent: enabled
SNMP v1:  disabled
SNMP v2c: disabled
SNMP v3:  enabled
```

5. Configuration Files

Agent configuration file

```
interface GigabitEthernet 0/1
 ip address 192.168.3.1 255.255.255.0
!
snmp-server host 192.168.3.2 traps version 2c Snmpv3user
snmp-server enable traps
!
end
```

1 Configuring RMON

1.1 Introduction

1.1.1 Overview

The Remote Network Monitoring (RMON) protocol is a network management protocol that is built on the Simple Network Management Protocol (SNMP) architecture. RMON provides statistics and alarm functions for a managing device to remotely monitor and manage devices. he statistics function means that a managed device can trace and calculate different types of traffic information on a network segment that is connected to the port of the device regularly or continuously. For example, the device can trace and calculate the total number of packets or the total number of excessively long packets received on a network segment in a period. The alarm function means that a managed device can monitor specified management information base (MIB) variables and automatically record an event and send Trap messages to the managing device when one of the variables reaches the alarm threshold, for example, the port rate or the ratio of broadcast packets reaches a specified value.

Both RMON and SNMP are used for remote network management. Compared with SNMP, RMON has the following advantages:

- RMON notifies the managing device of alarm variable abnormality in Trap messages by using the SNMP Trap message sending mechanism. Though the Trap function is also defined in SNMP, this function is used to notify the managing device of the function running status of a managed device and physical state change of an interface. SNMP and RMON have different monitored objects, trigger conditions, and report content.
- Compared with SNMP, RMON can monitor remote network devices more effectively and actively, thus providing an efficient means of monitoring subnet running. According to RMON, a managed device can automatically send Trap messages when a value reaches the alarm threshold. This frees the managing device from frequently obtaining and comparing values of MIB variables and thus reduces the communication between the managing device and managed device. As a result, large interconnected networks are being managed simply yet effectively.

1.1.2 Principles

RMON defines different RMOM groups, and the company's devices support the statistics group, history group, alarm group, and event group. The four groups are as follows:

1. Statistics Group

A statistics group is used to monitor and calculate traffic data on an Ethernet interface. The traffic data consists of cumulative values and is calculated from the time of entry creation to the current time. Statistical objects include discarded packets, broadcast packets, CRC errors, over-small or over-large packets, and conflicts. The statistical results are saved in the Ethernet statistical table for the administrator to view at any time.

2. History Group

A history group is used to collect network traffic periodically and records cumulative values of the traffic and bandwidth usage in each period. The data is saved in the history control table for the administrator to process. A history group includes two sub-groups:

- The HistoryControl sub-group is used to configure control information such as sampling interval and sampling data sources.
- The EthernetHistory sub-group provides the administrator with history data of a specific network segment, including traffic, error packets, broadcast packets, usage, and hit times.

3. Alarm Group

The alarm group is used to monitor specified MIB objects. When the value of an MIB object exceeds the set upper limit or lower limit, an alarm is triggered and processed as an event.

4. Event Group

An event group is used to define processing methods of events. When a monitored MIB object reaches the alarm condition, an event is triggered. The event can be processed with one of the following methods:

- None: The event is ignored.
- Log: The event related information is recorded in a log table for the administrator to view at any time.
- Snmp-trap: The Trap message is sent to the network management station to notify the occurrence of the event.
- Log-and-trap: The event-related information is recorded in a log table and the Trap message is sent to the network management station.

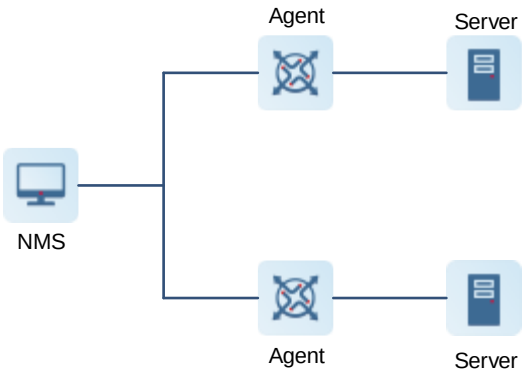
5. Working Process of RMON

RMON allows multiple monitor authorities to collect data with the following two methods: use the special RMON probe to collect data so that the NMS can obtain all MIB information from the RMON probe; embed the RMON agent into a network device so that the device possesses the function of an RMON probe. The NMS uses basic commands of SNMP to exchange data with the network device and collect network management information. Limited by the device resources, this method does not obtain all data of the RMON MIB. Generally, only four groups of information are collected.

Through the RMON agent running on the managed network device, the NMS can obtain information such as traffic, error statistics, and performance statistics on the network segment that is connected to the port of this network device, to remotely manage this network device. Figure 1-1 shows the communication network between the NMS and RMON agent.

- RMON Ethernet statistics function

  Make the statistics of network traffic on the Ethernet interface from the time of entry creation to the current time.



- RMON history statistics function

  Record cumulative statistical values of traffic on the Ethernet interface in each period.

- RMON alarm function

  Monitor changes of alarm variable values periodically. If an alarm variable value exceeds the specified upper or lower limit, corresponding event is triggered, for example, a Trap message is sent or a LogTable entry record is created. Continuous excess of an upper or a lower limit triggers an event only once and the event can be triggered again by excess of the opposite limit.

Figure 1-1 Communication Network Between the NMS and RMON Agent

1.1.3 Protocols and Standards

- STD 0059 / RFC 2819: Remote Network Monitoring Management Information Base
- RFC 4502: Remote Network Monitoring Management Information Base Version 2
- RFC 3919: Remote Network Monitoring (RMON) Protocol Identifiers for IPv6 and Multi Protocol Label Switching (MPLS)
- RFC 3737: IANA Guidelines for the Registry of Remote Monitoring (RMON) MIB Modules
- RFC 3434: Remote Monitoring MIB Extensions for High Capacity Alarms
- RFC 3395: Remote Network Monitoring MIB Protocol Identifier Reference Extensions
- RFC 3287: Remote Monitoring MIB Extensions for Differentiated Services
- RFC 3273: Remote Network Monitoring Management Information Base for High Capacity Networks
- RFC 2896: Remote Network Monitoring MIB Protocol Identifier Macros
- RFC 2895: Remote Network Monitoring MIB Protocol Identifier Reference

1.2 Configuration Task Summary

RMON configuration includes the following tasks:

- Configuring the Ethernet Statistics Function
- Configuring the History Statistics Function
- Configuring the Alarm Function

1.3 Configuring the Ethernet Statistics Function

1.3.1 Overview

With the Ethernet statistics function of RMON, you can learn the cumulative statistical values of traffic generated on the monitored Ethernet interface from the time of entry creation to the current time.

1.3.2 Restrictions and Guidelines

- To calculate and monitor a specified interface, you must configure the Ethernet statistics function on this interface.

- After the statistics entry is created on the specified interface, the statistics group calculates the traffic of this interface. That is, make the statistics of variables defined by the Ethernet statistics table and record the cumulative values of variables that are generated from the creation time of the RMON statistics table to the current time.
- This function cannot be configured in the batch interface configuration mode.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the Layer 2 or Layer 3 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

(4) Configure statistical items of RMON.

rmon collection stats *collection-stats-table-index* [**owner** *owner-name*]

The Ethernet statistics function is not configured on an Ethernet interface by default.

1.4 Configuring the History Statistics Function

1.4.1 Overview

With the history statistics function of RMON, you can learn the cumulative statistical values of traffic generated in each period and the bandwidth utilization on the monitored interface.

1.4.2 Restrictions and Guidelines

- The history group makes the statistics of variables defined by the history statistics function and records cumulative values of variables in each period.
- To collect network statistics on a specified interface, you must configure the history control function on the interface. This function cannot be configured in the batch interface configuration mode.
- It is not allowed to modify parameters of the configured history statistics function.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the Layer 2 or Layer 3 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

(4) Configure the history statistics function of an Ethernet interface.

rmon collection history *collection-history-table-index* [**buckets** *bucket-number*] [**interval** *period-time*] [**owner** *owner-name*]

The history statistics function is not configured on an Ethernet interface by default.

1.5 Configuring the Alarm Function

1.5.1 Overview

The alarm function of RMON monitors whether the values of alarm variables vary within the valid range periodically.

1.5.2 Restrictions and Guidelines

- If alarm variables are MIB variables defined by the RMON statistical group or history group, the RMON statistics function or history statistics function must be configured on the monitored Ethernet interface. Otherwise, the alarm table fails to be created.
- The alarm function is implemented by the alarm table and event table. After an alarm event is triggered, the SNMP agent must be configured so that Trap messages can be sent to the managing device. For more information about SNMP agent configuration, see *Configuring SNMP*.
- Configured event table parameters, including event type, Trap community name, event description, and event creator, can be modified.
- Configured alarm table parameters, including alarm variable, sampling type, table creator, sampling interval, upper/lower limit, and event, can be modified.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an event table.

rmon event *event-table-index* [**description** *description-string* | **log** | **owner** *owner-name* | **trap** *community*]*

No RMON event is configured by default.

(4) Configure the alarm function.

rmon alarm *alarm-table-index alarm-variable sampling-interval* { **absolute** | **delta** } **rising-threshold** *sampling-rising-threshold-value* [*event-number*] **falling-threshold** *falling-threshold-value* [*event-number*] [**owner** *owner-name*]

The RMON alarm function is not configured by default.

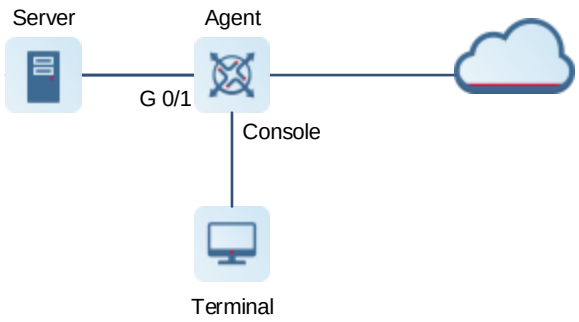
1.6 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
show rmon	Displays all RMON configurations.
show rmon history	Displays the historycontrol table information.
show rmon alarm	Displays the alarm table information.
show rmon event	Displays the event table information.
show rmon sql	Displays RMON database information.
show rmon statistics	Displays Ethernet statistics.
show rmon timer	Displays RMON timer information.

1.7 Configuration Examples



1.7.1 Configuring the Ethernet Statistics Function

1. Requirements

The RMON agent is connected to a server. The network administrator uses the RMON statistics group to calculate the performance of received packets on GigabitEthernet 0/1. Thus, the network administrator can understand the data of packets received on an interface at any time by viewing data, and take timely actions to process network abnormalities.

2. Topology

Figure 1-2 Topology of the RMON Ethernet Statistics Function

3. Procedure

Configure a statistics table instance on GigabitEthernet 0/1 of the device on which the RMON agent is deployed to make the statistics of traffic on this interface.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# rmon collection stats 1 owner admin
```

4. Verification

Run the **show rmon stats** command to display Ethernet statistics information.

```
Device# show rmon stats
ether statistic table:
                index = 1
                interface = GigabitEthernet 0/1
                owner = admin
                status = 1
                dropEvents = 0
                octets = 25696
                pkts = 293
                broadcastPkts = 3
                multiPkts = 0
                crcAlignErrors = 0
                underSizePkts = 0
                overSizePkts = 0
                fragments = 0
                jabbers = 0
                collisions = 0
                packets64Octets = 3815
                packets65To127Octets = 1695
                packets128To255Octets = 365
                packets256To511Octets = 2542
                packets512To1023Octets = 152
                packets1024To1518Octets = 685
```

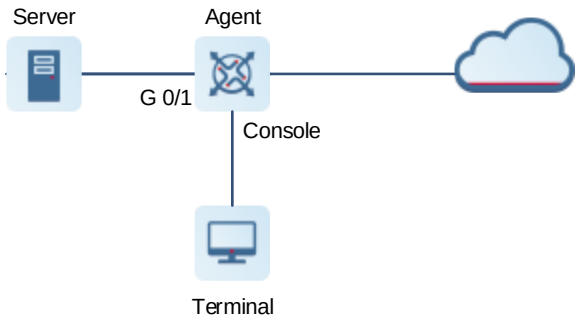
5. Configuration Files

Agent configuration file

```
hostname Device
!
interface GigabitEthernet 0/1
 rmon collection stats 1 owner admin
!
end
```

6. Common Errors

The parameters of configured statistics entries are reconfigured or modified.



1.7.2 Configuring the History Statistics Function

1. Requirements

The RMON agent is connected to a server. The network administrator uses the history group to make the statistics of received packets on GigabitEthernet 0/1 every minute so as to monitor the network and master emergencies.

2. Topology

Figure 1-3 Topology of the History Statistics Function

3. Procedure

Configure a history control table on GigabitEthernet 0/1 of the device on which the RMON agent is deployed to make the statistics of traffic on this interface periodically.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# rmon collection history 1 buckets 5 interval
300 owner admin
```

4. Verification

Run the **show rmon history** command to display history group statistics.

```
Device# show rmon history
rmon history control table:
                index = 1
                interface = GigabitEthernet 0/1
                bucketsRequested = 5
                bucketsGranted = 5
                interval = 60
                owner = admin
                stats = 1

rmon history table:
                index = 1
                sampleIndex = 786
                intervalStart = 6d:18h:37m:38s
                dropEvents = 0
                octets = 2040
                pkts = 13
                broadcastPkts = 0
                multiPkts = 0
                crcAlignErrors = 0
```

```
underSizePkts = 0
overSizePkts = 0
fragments = 0
jabbers = 0
collisions = 0
utilization = 0

index = 1
sampleIndex = 787
intervalStart = 6d:18h:38m:38s
dropEvents = 0
octets = 1791
pkts = 16
broadcastPkts = 1
multiPkts = 0
crcAlignErrors = 0
underSizePkts = 0
overSizePkts = 0
fragments = 0
jabbers = 0
collisions = 0
utilization = 0

index = 1
sampleIndex = 788
intervalStart = 6d:18h:39m:38s
dropEvents = 0
octets = 432
pkts = 6
broadcastPkts = 0
multiPkts = 0
crcAlignErrors = 0
underSizePkts = 0
overSizePkts = 0
fragments = 0
jabbers = 0
collisions = 0
utilization = 0

index = 1
sampleIndex = 789
intervalStart = 6d:18h:40m:38s
dropEvents = 0
octets = 432
pkts = 6
broadcastPkts = 0
```

```
                multiPkts = 0
                crcAlignErrors = 0
                underSizePkts = 0
                overSizePkts = 0
                fragments = 0
                jabbers = 0
                collisions = 0
                utilization = 0

                index = 1
                sampleIndex = 790
                intervalStart = 6d:18h:41m:38s
                dropEvents = 0
                octets = 86734
                pkts = 934
                broadcastPkts = 32
                multiPkts = 23
                crcAlignErrors = 0
                underSizePkts = 0
                overSizePkts = 0
                fragments = 0
                jabbers = 0
                collisions = 0
                utilization = 0
```

5. Configuration Files

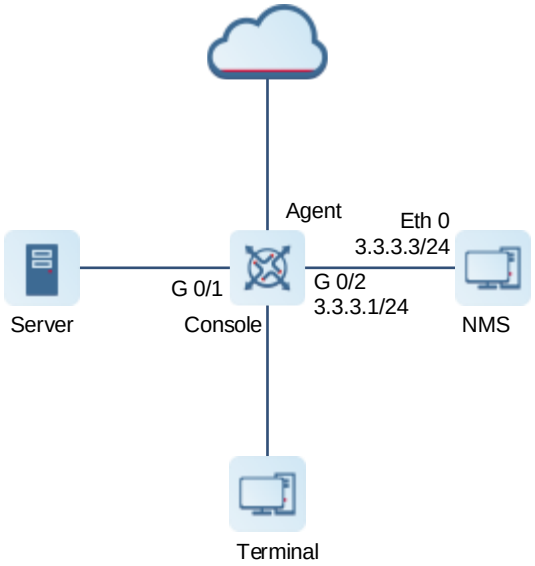
Agent configuration file

```
hostname Device
!
interface GigabitEthernet 0/1
rmon collection history 1 owner admin buckets 5 interval 300

!
end
```

6. Common Errors

The parameters of configured historycontrol entries are reconfigured or modified.



1.7.3 Configuring the Alarm Function

1. Requirements

The RMON agent is configured on a terminal device and connected to the NMS device for communication. The port GigabitEthernet 0/1 is connected to the server and must be monitored the number of received packets with unknown protocols. The sampling interval is 60 seconds. When the absolute collection value is smaller than 10, only a log record is generated. When the absolute sampling value is greater than 100, a log record is generated and a notification is sent to the NMS in a Trap message.

2. Topology

Figure 1-4 Topology of the Alarm Function

3. Notes

- Run SNMPv1 on the NMS, configure a community name public1, set the attribute to RW, and set the Trap message receiving address to 3.3.3.3.
- Monitor the number of packets with unknown protocols, received on GigabitEthernet0/1, and check whether the OID value is 1.3.6.1.2.1.2.2.1.15.3, sampling method is relative sampling, and sampling interval is 60 seconds. Check whether event 1 or event 2 is triggered when the relative sampling value is greater than 100 or smaller than 10. For event 1, a Trap message is sent and a log record is generated. For event 2, a log record is generated.

4. Procedure

Set the IP address of GigabitEthernet0/2 on the agent to 3.3.3.1.

```
Device> enabel
Device# configure terminal
Device(config)# interface gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# ip address 3.3.3.1 255.255.255.0
Device(config-if-GigabitEthernet 0/1)# exit
```

Configure an event group to process alarms.

```
Device(config)# snmp-server community public1 rw
Device(config)# snmp-server host 3.3.3.3 trap public1
Device(config)# rmon event 1 description rising-threshold-event log trap public1 owner
admin
Device(config)# rmon event 2 description falling-threshold-event log owner admin
```

Configure the alarm function.

```
Device(config)# rmon alarm 1 1.3.6.1.2.1.2.2.1.15.3 60 delta rising-threshold 100 1 falling-threshold 10 2
owner admin
```

5. Verification

Run the **ping** command to verify that the agent and NMS are mutually reachable via L3 routes.

```
Device# ping 3.3.3.3
Sending 5, 100-byte ICMP Echoes to 3.3.3.3, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/3 ms.
```

Run the **show rmon event** command to display the event table information.

```
Device# show rmon event
rmon event table:
                index = 1
                description = rising-threshold-event
                type = 4
                community = public
                lastTimeSent = 0d:0h:0m:0s
                owner = admin
                status = 1

                index = 2
                description = falling-threshold-event
                type = 2
                community =
                lastTimeSent = 6d:19h:21m:48s
                owner = admin
                status = 1

rmon log table:
                eventIndex = 2
                index = 1
                logTime = 6d:19h:21m:48s
                logDescription = falling-threshold-event
```

Run the **show rmon alarm** command to display the alarm table information.

```
Device# show rmon alarm
rmon alarm table:
         index: 1,
         interval: 60,
         oid = 1.3.6.1.2.1.2.2.1.15.3
         sampleType: 2,
         alarmValue: 0,
         startupAlarm: 3,
         risingThreshold: 100,
         fallingThreshold: 10,
```

```
risingEventIndex: 1,
fallingEventIndex: 2,
owner: admin,
stauts: 1
```

6. Configuration Files

Agent configuration file

```
hostname Device
!
interface GigabitEthernet 0/1
 ip address 3.3.3.1 255.255.255.0
!
rmon alarm 1 1.3.6.1.2.1.2.2.1.15.3 60 delta rising-threshold 100 1 falling-threshold
10 2 owner admin
rmon event 1 description rising-threshold-event log trap public1 owner admin
rmon event 2 description falling-threshold-event log owner admin
!
snmp-server host 3.3.3.3 traps public1
snmp-server community public1 rw
!
end
```

7. Common Errors

- The entered object OID is improper. For example, the variable corresponding to this OID does not exist or the OID type is not an integer or unsigned integer.
- The upper limit is smaller than or equal to the lower limit.

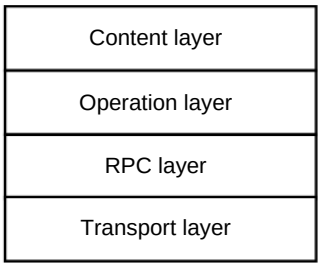
1.7.2 Configuring NETCONF Authentication 16

1 Configuring NETCONF

1.1 Introduction



1.1.1 Overview

As network scale, complexity, and heterogeneity increase, it becomes more and more difficult for the traditional IP network management protocol Simple Network Management Protocol (SNMP) to manage the complicated network. In particular, SNMP cannot meet the requirements for configuration management and application system development of a large network. To overcome the shortcomings of SNMP, the Internet Engineering Task Force (IETF) formulates an extensible markup language (XML) based network management protocol – Network Configuration Protocol (NETCONF). NETCONF provides a programmable method to configure and manage network devices. This protocol configures parameters and obtains parameter values and statistics in XML packets and supports scalability, making network device configuration and management easy and efficient.

1.1.2 Structure of NETCONF

NETCONF supports the client/server (C/S) communication mode, in which a device runs the server of the protocol and a client runs the client program of the protocol. NETCONF packets, including all configuration data and protocol messages, follow the XML format. With a hierarchical similarity to the ISO/OSI system, NETCONF consists of four layers from down to up: transport layer, remote procedure call (RPC) layer, operation layer, and content layer, as shown in Figure 1-1.

Figure 1-1 Structure of NETCONF

1. Transport Layer

The transport layer provides secure transmission channels for NETCONF and supports security protocols such as Secure Shell (SSH), Simple Object Access Protocol (SOAP), and Blocks Extensible Exchange Protocol (BEEP). Now, SSH is preferred.

2. RPC Layer

The RPC layer provides a simple transmission-irrelevant mechanism. The client uses the <rpc> element to encapsulate the NETCONF request message, and the server uses the <rpc-reply> element to encapsulate the NETCONF reply message. RPC defines three message types:

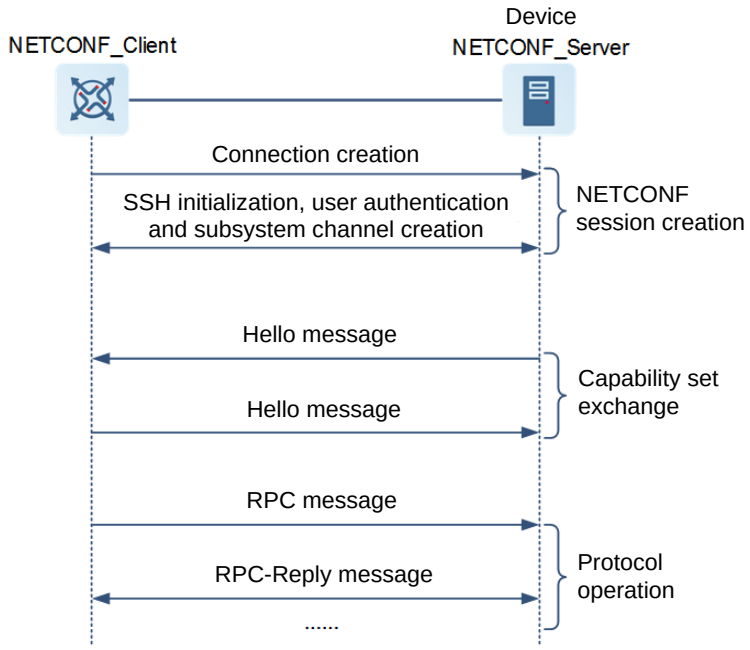
- Hello: The hello messages are used to complete capability set exchange when a session is created between the NETCONF client and server.

- RPC and RPC-Reply: RPC are request messages sent by the NETCONF client to the NETCONF server, and RPC-Reply are reply messages returned by the NETCONF server to the NETCONF client. The reply messages are returned only when the NETCONF server receives RPC request messages; the reply messages and the received RPC request messages must contain the same message ID.
- Notification: The notifications are sent by means of subscription.

3. Operation Layer

Based on the basic primitive operation sets applied in RPC, 9 types of basic operation methods are defined:

- Data acquisition: Get and Get-Config
- Configuration: Edit-Config, Copy-Config, and Delete-Config
- Protection for critical resource (for example, configuration file) concurrency: Lock and Unlock
- Session ending: Close-Session and Kill-Session



4. Content Layer

The content layer is a set of managed data objects. The content layer is the only layer that is not standardized and does not have a unified data model in NETCONF.

Note

The products use YANG for data modeling and XML for data transmission.

Figure 1-2 NETCONF Session Message Interaction

1.1.3 NETCONF Session Interaction Procedure

Figure 1-2 shows the NETCONF session interaction procedure, which falls into three parts.

1. Session Creation

(1) The transport layer of NETCONF relies on SSH. After the NETCONF server on a device starts the NETCONF process, a monitoring port is created.

(2) The NETCONF server monitors port 830 and creates an SSH channel. The SSH channel is created after a series of transport algorithm negotiations (including key agreement, compression algorithm, hash algorithm, encryption algorithm, and signature algorithm) and client authentication.

(3) After a session is created on the transport layer, the NETCONF client can exchange with the NETCONF server through this session.

Note

According to NETCONF, the default SSH TCP port ID is 830, which is customized based on the particular situation.

2. Capability Set Exchange

After the session is created, the NETCONF server and client send hello messages mutually to provide respective realized capability sets and ignore capabilities that are not understandable or realizable. The basic capability (urn:ietf:params:netconf:base:1.1) must be supported by the NETCONF server and client. To be compatible with earlier versions of NETCONF, the NETCONF server and client must support the basic capability (urn:ietf:params:netconf:base:1.0) of the earlier versions of NETCONF The NETCONF server and client finally obtain the intersected capabilities to perform subsequent data operation and management.

Caution

- In addition to the exchange capabilities defined in NETCONF RFC, developers can design other capabilities based on the specifications and formats described in NETCONF RFC.
- Capability exchange messages sent by the NETCONF client to the NETCONF server do not contain the session ID node (<session-id>).

3. Protocol Operation

- Get: Obtains device status or configuration data.
- Get-config: Obtains configuration data based on the filtering node.

Note

The Get-config operation can obtain configuration data subsets through different subtree filtering rules but cannot obtain device status.

- Edit-config: Configures a device based on the model definitions and operation attributes.

  In the edit-config packet, there are five operation attributes which are given in the description of the operation attribute of the XML packet. These five attributes are as follows:

  - Merge: Merges the configuration data that includes this attribute in the Edit-config packets to the specified configuration file or database. If this configuration data does not exist, create this configuration data.
  - Replace: Replaces the configuration data node in the specified configuration file or database with the

configuration data that includes this attribute in the Edit-config packets. If this configuration data does not exist, create this configuration data based on the delivered content.

- Create: Creates configuration data that includes this attribute in the Edit-config packets in the specified configuration file or database.
- Delete: Deletes configuration data that includes this attribute in the Edit-config packets from the specified configuration file or database.
- Remove: Removes configuration data that includes this attribute in the Edit-config packets from the specified configuration file or database.

Specification

Currently, Ruijie devices do not support the Replace operation. If this operation is delivered, it is processed as a Merge operation.

Note

- If the Edit-config packet does not include the error-option node, the default value of the error-option node is stop-on-error. Once a configuration error occurs on a node, the remaining configuration in the Edit-config packet stops immediately and an RPC-error is returned.
- If the Edit-config packet does not include the test-option node, the default value of the test-option node is **test-then-set**.
- If the Edit-config packet does not include the default-operation node, the default value of the default-operation node is **merge**.

- Copy-config: Copies the configuration file.
- Delete-config: Deletes the configuration file. It is not allowed to delete the running file.

Specification

Now, only the startup configuration can be synchronized to the running configuration file.

Lock: Locks the configuration file. The configuration file can be accessed or modified through the current client, but cannot be accessed or modified by other clients or non-NETCONF clients (for example, SNMP or CLI).

Note

According to RFC 6241, the Lock operation is used to lock the configuration database (configuration files) and prevent multiple sources (for example, CLI, SNMP, and NETCONF sessions) from concurrently revising the configuration files. This avoids introducing other irrelevant configuration revisions. The device removes some functions of the operation, and can only prevent concurrent modifications (running configuration) from multiple NETCONF.

- Unlock: Unlocks the configuration database (configuration file, which indicates the running configuration file in a device). This operation is opposite to the Lock operation.
- Close-session: Closes the current session, including resource and lock release and disconnection.

Note

Before the Close-session operation closes the current session, ensure that proceeding business has been completed and no new business request is received.

- Kill-session: Forcibly closes the current session, including resource and lock release and disconnection.

Caution

- Before using the Kill-session operation to forcibly close the current session, ensure that proceeding business has been stopped and unfinished business is rolled back to original state.
- The Kill-session operation cannot close the current session.

1.1.4 Authentication Mechanism

The NETCONF authentication mechanism is used to manage the NETCONF operations of specific clients and the access to NETCONF resources, allowing the clients to perform operations and access data nodes stipulated by NETCONF.

1. Access Permissions Supported by the NETCONF Authentication Mechanism

The NETCONF authentication function is not configured by default. Therefore, authorized clients have all NETCONF permissions. Access permissions supported by the NETCONF authentication mechanism are as follows:

- Create: Permits or denies new data nodes to be added.
- Read: Permits or denies data nodes to be read.
- Update: Permits or denies data nodes to be updated.
- Delete: Permits or denies data nodes to be deleted.
- Execute: Permits or denies all protocol operations.

2. Content Supported by the NETCONF Authentication Mechanism

The NETCONF authentication function supports RPC method authentication and data node authentication.

- RPC method authentication

  RPC method authentication of NETCONF is used to control permissions of the operation methods stipulated by NETCONF. Table 1-1 lists the RPC methods and default permissions.

Table 1-1 RPC Methods and Default Permissions

RPC Method	Function	Default Permission (R: read; W: write; X: execute)
get	Obtains data.	X→R
get-config	Obtains configuration.	X→R
edit-config	Edits configuration.	X→W

RPC Method	Function	Default Permission (R: read; W: write; X: execute)
copy-config	Replaces the target configuration with the source configuration.	X
delete-config	Deletes configuration.	X
validate	Performs syntax check.	X
commit	Validates the candidate configuration and runs the configuration.	X
cancel-commit	Cancels the confirmed-commit operation.	X
discard-changes	Discards candidate configuration that has not taken effect.	X
lock/unlock	Locks or unlocks configuration.	X
close-session	Closes the current session.	X
kill-session	Closes other sessions.	X
get-schema	Obtains the YANG file.	X

Note

- All RPC methods require the execution permission by default. The Get, Get-config, and Edit-config methods require the check of read/write permission for the data node.
- The Close-session method is permitted by default and cannot be denied.
- The Delete-config and Kill-session methods are denied by default, and can be configured as Permitted. Other RPC methods are permitted by default.
- The Lock and Unlock methods must be paired. If the Lock permission is configured, the Unlock permission is available as well.

- Data node authentication

  Data node authentication of NETCONF is used to control permissions of NETCONF data nodes. It can control the permissions of all modules, single module, and specific data nodes.

  - If only the slash (/) is configured, the authentication of NETCONF can control the permissions of the data nodes of all modules.
  - If a module name is configured, for example, /rg-snmp:snmp, the authentication of NETCONF can control the permissions of the data nodes of the single module.
  - In other configuration conditions, permission control is applied to the data nodes of specific modules.

1.1.5 Protocols and Standards

- RFC 4741: NETCONF Configuration Protocol

- RFC 4742: Using the NETCONF Configuration Protocol over Secure Shell (SSH)
- RFC 4743: Using NETCONF over the Simple Object Access Protocol (SOAP)
- RFC 4744: Using the NETCONF Protocol over the Blocks Extensible Exchange Protocol (BEEP)
- RFC 5277: NETCONF Event Notifications
- RFC 5381: Experience of Implementing NETCONF over SOAP
- RFC 5539: NETCONF Over Transport Layer Security (TLS)
- RFC 5717: Partial Lock RPC for NETCONF
- RFC 6022: NETCONF Monitoring Schema
- RFC 6241: Network Configuration Protocol
- RFC 6242: Using the Network Configuration Protocol over Secure Shell
- RFC 6243: With-defaults capability for NETCONF
- RFC 6470: NETCONF Notification Events
- RFC 6536: NETCONF Access Control Model (NACM)

Note

RFC 4741 and RFC 4742 have been replaced by RFC 6241 and RFC 6242 respectively.

1.2 Configuration Task Summary

NETCONF configuration includes the following tasks:

(1) Configuring Communication Between the NETCONF Server and Client

(2) (Optional) Configuring NETCONF Authentication

(3) (Optional) Configuring the Active NETCONF Connection

1.3 Configuring Communication Between the NETCONF Server and Client

1.3.1 Overview

After the NETCONF function is enabled on the NETCONF server, the NETCONF server can communicate with the NETCONF client to manage network devices.

1.3.2 Restrictions and Guidelines

- The **netconf yang multi-revision** command must be configured before the capability packet (Hello packet) of the NETCONF server is advertised.
- The **no netconf yang multi-revision** command must be configured before the capability packet (Hello packet) of the NETCONF server is advertised and one YANG module can advertise only its current latest version in the capability notification packet.
- In strict check mode, some XML packets that can be delivered in lightweight check mode may be intercepted.

- After the **netconf session-timeout** *time* command is configured, if a user does not enter any command during the configured timeout interval, the system terminates the current connection.

1.3.3 Prerequisites

The NETCONF protocol is based on the SSH protocol. Before the NETCONF protocol is enabled, the SSH protocol must be configured. For the configuration procedure, see *Configuring SSH*.

1.3.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the attribute parameters of the NETCONF server. The configuration tasks below are optional. Select tasks as required.

- (Optional) Enable the NETCONF service.

  netconf enable

  The NETCONF function is enabled by default.

- Configure the NETCONF capability to send submodules of a YANG file.

  netconf enable-submodule

  The NETCONF capability to send submodules of the YANG file is enabled by default.

- (Optional) Configure the maximum number of session connections supported by NETCONF.

  netconf max-sessions *max-sessions-numbers*

  The maximum number of session connections supported by NETCONF is **5** by default.

- (Optional) Configure the timeout time of the Edit-config operation in a NETCONF session.

  netconf timeout *timeout*

  The default timeout time of the Edit-config operation in a NETCONF session is **120** seconds.

- (Optional) Enable the YANG module multi-version notification function.

  netconf yang multi-revision

  The YANG module multi-version notification function of NETCONF is enabled by default.

- (Optional) Configure the NETCONF capabilities.

  netconf capability{ **candidate** | **rollback** | **validate** }

  The NETCONF-related capabilities are not configured by default.

- (Optional) Configure the NETCONF check mode.

  netconf calibration-mode { **lightweight** | **strict** }

  The default NETCONF check mode is lightweight check.

- (Optional) Enable the NETCONF logging function.

  netconf log { **capability** | **edit** | **get** | **session** }

  The NETCONF logging function is disabled by default.

- (Optional) Configure the port ID of the NETCONF server.

  netconf port *port-number*

  The default port ID of the NETCONF server is 830.

- Configure the NETCONF session timeout interval.

  netconf session-timeout *time*

  The NETCONF session does not time out by default.

1.4 Configuring NETCONF Authentication

1.4.1 Overview

The NETCONF authentication mechanism is configured to manage the NETCONF operations of specific clients and the access to NETCONF resources, allowing the clients to perform operations and access data nodes stipulated by NETCONF.

1.4.2 Restrictions and Guidelines

- A user group cannot be named with the asterisk (*), because the symbol indicates all user groups.
- For a single rule list, the rules are successively matched based on the rule configured by users. When an operation matches a permit rule, the operation is permitted. When an operation matches a deny rule or does not match a rule, the operation is denied in the current rule list.
- For multiple rule lists, the rules in the lists are matched based on the rule configuration sequence. When an operation matches a permit rule in a rule list, the operation is permitted. When an operation matches a deny rule, the operation is denied. When an operation does not match any rule in the list, the operation matches the rules of the next list.
- RPC operation methods include Get, Get-Config, Edit-Config, Copy-Config, Delete-Config, Validate, Commit, Cancel-Commit, Discard-Changes, Lock, Kill-Session, and Get-Schema.
- If no rule type is configured, permission control is applied to both RPC operation methods and data node rules.
- Rule control for enabling RPC operation methods can be configured. If the Execute permission is included in the access operation permissions configured under the rules, the rules are matched during RPC operation method check. Otherwise, such rule matching does not occur.
- Rule control for enabling data nodes can be configured. If at least one of the Create, Read, Update and Delete permissions is included in the access operation permissions configured under the rules, the rules are matched during data node check. Otherwise, such rule matching does not occur.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the authentication configuration mode.

netconf acm

(4) Configure a user group and enter the authentication user group configuration mode.

user-group-name *name*

No user group is configured by default.

(5) Associate users with the user group.

user-name *name*

No user is associated with a user group by default.

(6) Quit the authentication configuration mode.

exit

(7) Configure a rule list and enter the authentication rule list configuration mode.

rule-list *name*

No rule list is configured by default.

(8) Associate the user group with the rule list.

user-group { ***** | *name* }

No user group is associated with a rule list by default.

(9) Configure rules and enter the rule mode of the authentication rule list.

rule *name* **action** { **permit** | **deny** }

No rule is configured by default.

(10) Configure rule types.

rule-type { **rpc-name** { *name* | ***** } | **path** *path* }

No rule type is configured by default.

(11) Configure access permissions of the rules.

access-operation { * | { create | delete | exec | read | update } * }

No access permission of a rule is configured by default.

1.5 Configuring the Active NETCONF Connection

1.5.1 Overview

If the NMS does not support automatic device discovery, the NMS cannot manage the device in a timely manner. In this scenario, you can configure the active NETCONF connection function to enable the device to send a NETCONF connection request to the NMS and establish a NETCONF connection with the NMS after the device goes online, so that a network administrator can manage the device in a timely manner through the NMS.

1.5.2 Restrictions and Guidelines

- NETCONF must be enabled before the active NETCONF connection is enabled. When NETCONF is unavailable, the active connection function does not take effect.
- If the source IP address or source interface is configured for the active NETCONF connection but the IP address is not configured on the device, the IP address of the interface that initiates the active connection is still used as the source IP address.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure attribute parameters of the NETCONF server. Perform the following configuration as needed.

- Configure active and standby NETCONF connections.

  netconf callhome [**standby**] { [**oob**] { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } [**via mgmt** *interface-number*] | { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } [**vrf** *vrf-name*] } [**port** *port*]

  Active and standby NETCONF connections are not configured by default.

- Configure the reconnection interval and count for the active NETCONF connection.

  netconf ch-reconnect { **interval** *seconds* **| time** *time* } *

  The reconnection interval is 5 seconds and the reconnection count is 3 by default.

- Configure the source interface for the NETCONF connection.

  netconf source interface *interface-type interface-number*

  No source interface is configured for the NETCONF connection by default.

- Configure the source address for the NETCONF active connection.

  netconf source { **ip** *ip-address* | **ipv6** *ipv6-address* }

  No source address is configured for a NETCONF connection by default.

1.6 Monitoring

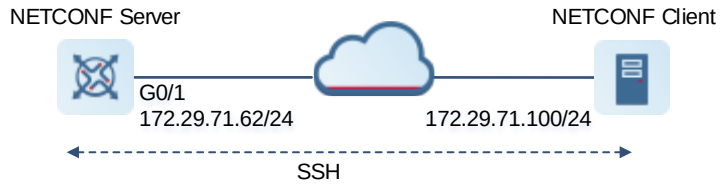
Run the **show** command to check the configuration.

Table 1-2 Monitoring

Command	Purpose
show netconf authorization user-name *name* { **rule-list** [**detail**] | **user-group** }	Displays a rule list that users are associated with, list details, and user group information.
show netconf callhome	Displays information about active and standby NETCONF connections.
show netconf candidate-tree	Displays the configuration received by the NETCONF candidate database.
show netconf capability	Displays information about NETCONF capabilities.
show netconf lock	Displays lock information about the NETCONF running and candidate databases.
show netconf session	Displays all session information of NETCONF.

Command	Purpose
show netconf statistics	Displays global statistics of NETCONF.
show netconf yang file	Displays all YANG files supported currently.
show netconf yang node-path	Displays all node paths supported currently.
show netconf yang schema-node-path [*module*]	Displays the YANG path corresponding to the YANG model.
show netconf yang tree	Displays all YANG model trees supported currently.

1.7 Configuration Examples



1.7.1 Configuring NETCONF

1. Requirements

NETCONF can be used as a network management tool to meet the high security and scalability requirements for network device management. NETCONF is based on SSH. As a security protocol of the application layer, SSH ensures security of NETCONF. As shown in Figure 1-3, the NETCONF network management software is used to manage and monitor network devices.

2. Topology

Figure 1-3 NETCONF Topology

3. Notes

- Configure an IP address for the gigabitEthernet 0/1 of the NETCONF server to ensure that the NETCONF server and client are mutually reachable via L3 routes.
- Enable the SSH function on the NETCONF server.
- Configure NETCONF related parameters on the NETCONF server to meet requirements of actual scenarios.
- Connect the NETCONF server to the NETCONF client through SSH to manage and monitor network devices.

4. Procedure

Configure an IP address for the gigabitEthernet 0/1 of the NETCONF server.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1))# ip address 172.29.71.62 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1))# exit
```

Enable the SSH function and generate a local key. For more information about the rule of selecting a key type, see the Usage Guidelines in the **crypto key generate** command in *SSH Commands*.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# enable service ssh-server
Hostname(config)# crypto key generate rsa
% You already have RSA keys.
% Do you really want to replace them? [yes/no]:y
Choose the size of the rsa key modulus in the range of 512 to 2048
and the size of the dsa key modulus in the range of 360 to 2048 for your
Signature Keys. Choosing a key modulus greater than 512 may take
a few minutes.
Choose the size of the ecc key modulus from (256, 384, 521)

How many bits in the modulus [1024]:2048
% Generating 2048 bit RSA1 keys ...[ok]
% Generating 2048 bit RSA keys ...[ok]
Hostname(config)#
```

Create an SSH user with the username **netconf** and set the password to net_1234.

```
Hostname(config)# username netconf privilege 15 password net_1234
```

Caution

To ensure security, you are advised to regularly modify the username and password.

Configure local user authentication of a VTY line.

```
Hostname(config)# line vty 0 35
Hostname(config-line)# login local
```

Enable the NETCONF service on the NETCONF server.

```
Hostname(config)# netconf enable
```

Set the maximum number of session connections supported by the NETCONF server to 6.

```
Hostname(config)# netconf max-sessions 6
```

Set the timeout time of the Edit-config operation in a NETCONF session to 100 seconds on the NETCONF server.

```
Hostname(config)# netconf timeout 100
```

Enable the YANG module multi-version notification function on the NETCONF server.

```
Hostname(config)# netconf yang multi-revision
```

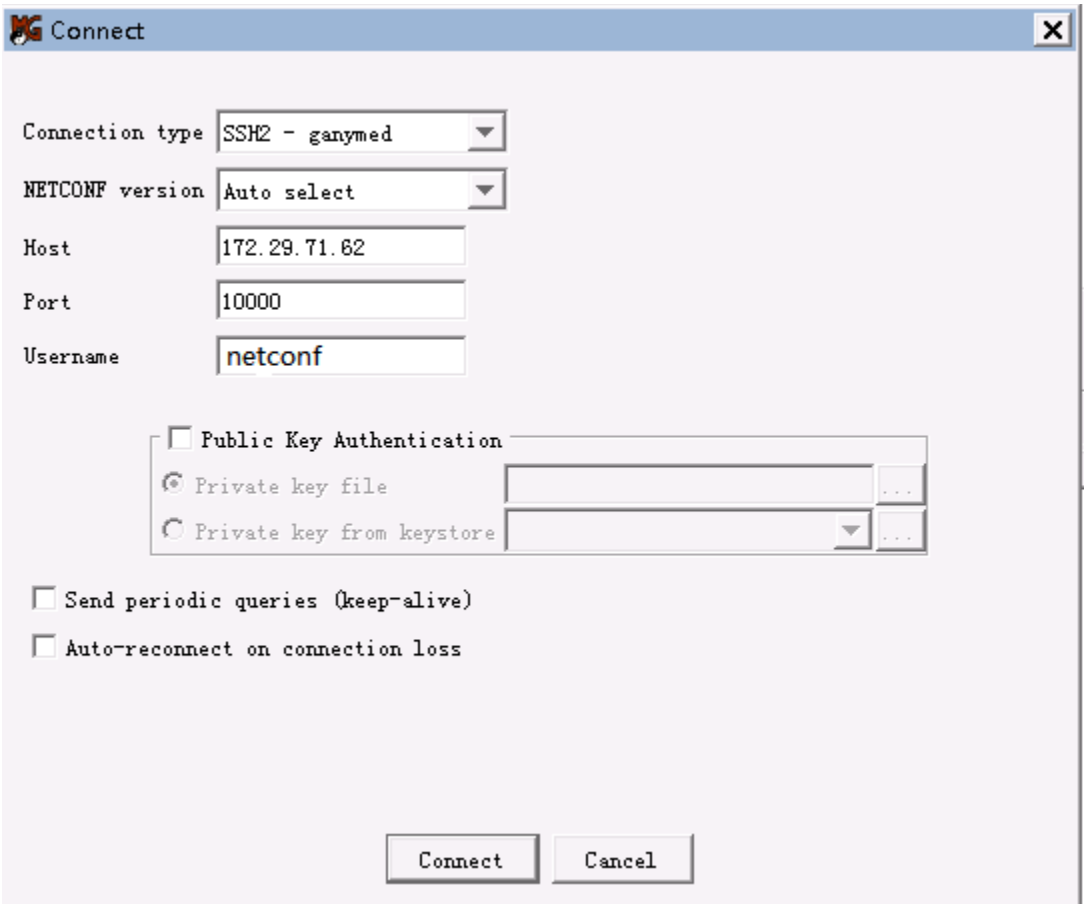
Enable the candidate capability on the NETCONF server.

```
Hostname(config)# netconf capability candidate
```

Configure the check mode as lightweight check on the NETCONF server.

```
Hostname(config)# netconf calibration lightweight
```

Enable the syslog function related to the NETCONF sessions on the NETCONF server.



```
Hostname(config)# netconf log session
```

Set the port ID of the NETCONF service to 5000 on the NETCONF server.

```
Hostname(config)# netconf port 5000
```

Log in to the NETCONF server through the SSH protocol by using the NETCONF client software and manage and monitor network devices, as shown in Figure 1-4.

Figure 1-4 Device Login Example Through the NETCONF Client Software

5. Verification

Run the **ping** command to check whether the NETCONF server and client are mutually reachable via L3 routes.

```
Hostname# ping 172.29.71.100
Sending 5, 100-byte ICMP Echoes to 172.29.71.100, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/3 ms.
Hostname#
```

Run the **show service** command to check whether the SSH service is enabled.

```
Hostname# show service
snmp-agent    : enabled
ssh-server    : enabled
telnet-server : enabled
```

Run the **show netconf session** command to check whether the NETCONF server is connected to the NETCONF client software through the SSH protocol.

```
Hostname# show netconf session
************************session information************************
                      Session count: 1

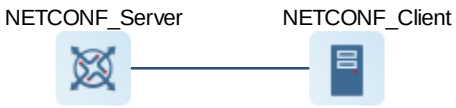
6. Configuration Files

NETCONF_Server configuration file

```
hostname Hostname
!
username netconf privilege 15 password 7 $10$393$wpgQ1hbo7hc=$
!
netconf log session
netconf capability candidate
netconf port 5000
netconf max-sessions 6
netconf timeout 100
!
enable service ssh-server
```

```
!
interface GigabitEthernet 0/1
 ip address 172.29.71.62 255.255.255.0
!
line vty 0 35
 login local
!
end
```



1.7.2 Configuring NETCONF Authentication

1. Requirements

The user **user1** has the permission to get all modules, and the user **user2** has the permission to create SNMP modules.

2. Topology

Figure 1-5 Topology of NETCONF Authentication

3. Notes

Configure the Get permission for all modules for **user1**.

Configure the Create permission for SNMP modules for **user2**.

4. Procedure

(1) Configure the Get permission for all modules for **user1**.

Configure a user **user1**.

```
Device> enable
Device# configure terminal
Device(config)# username user1 password test_12345
```

Enter the authentication configuration mode.

```
Device(config)# netconf acm
```

Configure a user group **guser1**.

```
Device(config-nacm)# user-group-name guser1
```

Associate **user1** with **guser1**.

```
Device(config-nacm-user-group)# user-name user1
Device(config-nacm-user-group)# exit
```

Configure a rule list rule-list1.

```
Device(config-nacm)# rule-list rule-list1
```

Associate **guser1** with rule-list1.

```
Device(config-nacm-rule-list)# user-group guser1
```

Configure a permit rule rule1.

```
Device(config-nacm-rule-list)# rule rule1 action permit
```

Configure the RPC method as Get.

```
Device(config-nacm-rule-list-rule)# rule-type rpc-name get
Device(config-nacm-rule-list-rule)# end
```

(2) Configure the Create permission for SNMP modules for **user2**.

Configure a user **user2**.

```
Device# configure terminal
Device(config)# username user2 password test_12345
```

Enter the authentication configuration mode.

```
Device(config)# netconf acm
```

Configure a user group **guser2**.

```
Device(config-nacm)# user-group-name guser2
```

Associate a user group **user2** with a user **guser2**.

```
Device(config-nacm-user-group)# user-name user2
```

Configure a rule list rule-list2.

```
Device(config-nacm-user-group)# exit
```

Associate a user group **guser2** with a rule list rule-list2.

```
Device(config-nacm)# rule-list rule-list2
Device(config-nacm-rule-list)# user-group guser2
```

Configure a permit rule rule2.

```
Device(config-nacm-rule-list)# rule rule2 action permit
```

Configure a data node type and configure the data node as an SNMP module name.

```
Device(config-nacm-rule-list-rule)# rule-type path /rg-snmp:snmp
```

Configure the access permission as Create.

```
Device(config-nacm-rule-list-rule)# access-operation create
```

5. Verification

Run the **show netconf authorization user-name user1 user-group** command to display user group information of a user **user1**.

```
Device # show netconf authorization user-name user1 user-group
UserGroup: guser1
```

Run the **show netconf authorization user-name user2 user-group** command to display user group information of a user **user2**.

```
Device # show netconf authorization user-name user2 user-group
UserGroup: guser2
```

Run the **show netconf authorization user-name user1 rule-list detail** command to display details of the rule list associated with a user **user1**.

```
Device# show netconf authorization user-name user1 rule-list detail
RuleList: rule-list1
  ------------------------------------------------------------------
  Rule           Action   AccessOperation   Type     Entity
  ------------------------------------------------------------------
  rule1          permit   RCUDX           RPC      get
  [R:Read C:Create U:Update D:Delete X:Exec]
```

Run the **show netconf authorization user-name user2 rule-list detail** command to display details of the rule list associated with a user **user2**.

```
Device# show netconf authorization user-name user2 rule-list detail
RuleList: rule-list2
  ------------------------------------------------------------------
  Rule           Action   AccessOperation   Type     Entity
  ------------------------------------------------------------------
  rule2          permit   -C---           PATH     /rg-snmp:snmp
  [R:Read C:Create U:Update D:Delete X:Exec]
```

6. Configuration Files

Device configuration file

```
hostname Device
!
username user1 password 7 $10$391$/9kemZ1jG1+E0A==$
username user2 password 7 $10$0cb$3opZPP7Q4HmK9g==$
!
netconf acm
 user-group-name guser1
  user-name user1
 user-group-name guser2
  user-name user2
 rule-list rule-list1
  user-group guser1
  rule rule1 action permit
   rule-type rpc-name get
 rule-list rule-list2
  user-group guser2
  rule rule2 action permit
   access-operation create
   rule-type path /rg-snmp:snmp
!
end
```

1.14.1 Configuring Basic Functions of gRPC 16

1 Configuring gRPC

1.1 Introduction

1.1.1 Overview

The Google Remote Procedure Calls (gRPC) is a high-performance open source software framework developed by Google using the Hyper Text Transfer Protocol 2 (HTTP2) as a data transmission protocol. gRPC provides a network configuration and management method that supports multiple programming languages. On the gRPC framework, secondary development can be performed.

1.1.2 Principles

1. Basic Concepts

- **Channel**

  A channel connects a device and the server.

2. Enabling the gRPC Function

After gRPC is enabled on the device, the device can function as a gRPC Server to receive authentication requests and obtain messages and as a gRPC Client to report gRPC data.

gRPC communication is implemented over the HTTP2 protocol. After a gRPC client initiates a request and a server returns a response, a data interaction is completed. Only the client can initiate a request, and the end of the interaction is indicated by the receipt of a response from the server. See Figure 1-1.

Figure 1-1 gRPC Communication Flow

(1) After gRPC is configured on the device, the gRPC Client and gRPC Server services are enabled.

(2) The gRPC Server of the device receives an obtainment event message from the server, and returns a response to the obtainment event to the server.

(3) The gRPC Client of the device reports gRPC data to the gRPC Server of the server based on the subscribed event type and waits for a response.

3. Supporting Login and Logout Functions

- Supporting Login Initiated by the Server

  a After gRPC is configured on the device, the gRPC Server services are enabled.

  b The device receives a login request initiated by the server, authenticates the server locally, and returns a login result to the server.

  c The gRPC Server of the device receives only the obtainment events initiated by the server that has been logged in.

  For the procedure, see Figure 1-2.

Figure 1-2 gRPC Login Flow

- Supporting Logout Initiated by the Server

  a After gRPC is configured on the device, the gRPC Server services are enabled.

  b The device receives a logout request initiated by the server, deletes the local matched login information, and returns a logout result to the server.

  c The gRPC Server of the device does not receive the obtainment events initiated by the server that has been logged out.

  For the procedure, see Figure 1-3.

Figure 1-3 gRPC Logout Flow

4. Supporting Some Event Types

gRPC supports realtime events, periodic events, and obtainment events.

- Realtime events: This type of events are triggered when a specified threshold is met, irrespective of time. In this case, the device collects information once and reports it to the server.

- Periodic events: This type of events are reported regularly. When the time is up, the device collects information once and reports it to the server.
- Obtainment events: This type of events are initiated by the server to query data. After the device receives a query request, the device collects information and reports it to the server.

5. Specifying a Source Interface to Send Data

gRPC is configured on the device and a channel is created. Before sending some packets to the server, the device creates a socket and attempts to send ping packets to check whether the path is reachable. If so, the device sends the gRPC packets. By default, the created socket is bound randomly to the source address of a device port to send ping packets. If the server receives only packets from the specified source address, the default behavior of gRPC does not make the path reachable. As a result, gRPC packets cannot be uploaded. If a specified source address is bound when a socket is created, the reachable path can ensure that gRPC packets are correctly uploaded.

6. Supporting Server Subscription and Events

- The device can pre-create a server to be subscribed to and an event of concern based on a configured command or NETCONF or other channels.
- The device can configure a standby server based on a configured command or NETCONF or other channels. When the active server becomes faulty, it automatically sends data to the standby server.
- The device can delete the subscription server and event based on a configured command or NETCONF or other channels.

7. Pre-configuring Server Login User Information

- The device can use configuration commands to pre-store authenticated server login information, simulate a client login request to the server, complete authentication, and save the user login information.
- The device can use configuration commands to remove authenticated server login information, simulate a client logout request, and delete the saved user login information.

8. Supporting Data Subscription of the YANG Model

- The device can deliver configuration defined by openconfig-telemetry.yang to collect YANG model data of the device based on a configured command or NETCONF or other channels.
- The device can delete the configuration defined by openconfig-telemetry.yang based on a configured command or NETCONF or other channels.

9. Supporting Third-party Defined RPC Methods

- Running a configured command, the device can enable RPC methods that support the gnmi.proto definition. Data can be collected with the RPC methods such as Get, Set, and Subscribe.
- Running a configured command, the device can disable RPC methods that do not support the gnmi.proto definition.
- Running a configured command, the device can enable RPC methods that support the t_agent.proto and t_health_check.proto definition of openR. openR related functions can be performed with these RPC methods.
- Running a configured command, the device can disable RPC methods that are not defined by openR.

10. Supporting Dial-out RPC Methods

- The device can select an RPC method corresponding to dial-out based on a configured command.
  - The device supports gRPC Network Management Interface (gNMI) based open source RPC methods of Sonic.
  - The device supports gNMI based private RPC methods.
  - The device supports private RPC methods.
- The device can restore the default RPC method based on a configured command. The gNMI based open source RPC methods of Sonic are used by default.

1.2 Configuration Task Summary

gRPC configuration includes the following tasks:

(1) Configuring Basic Functions of gRPC

(2) Configuring the gRPC Response Timeout Time

(3) Configuring Event Types Supported by gRPC

(4) Configuring gRPC to Support Pre-configuration Functions

- Configuring gRPC to Pre-configure a Subscription Server and Event
- Configuring gRPC to Support User Login Information of the Functional Server

(5) Configuring a YANG Model Path

(6) Configuring the gRPC Subscription Function

- (Optional) Configuring gRPC to Specifying a Source Interface to Send Data
- Configuring the Active and Standby Destination Servers of gRPC
- Configuring gRPC Subscription

(7) (Optional) Configuring gRPC to Support the Login and Logout Function

(8) Configuring a Third-party Defined RPC Method

(9) Configuring a Dial-out RPC Method

(10) (Optional) Configuring gRPC Server

1.3 Configuring Basic Functions of gRPC

1.3.1 Overview

The gRPC function is enabled, and the gRPC Client and gRPC Server are created. The gRPC Client uploads data to the server, and the gRPC Server parses authentication messages sent from the server and obtains the message content.

1.3.2 Restrictions and Guidelines

- The connection between the device and server must be normal.
- The port number of the local gRPC Server is 50051.
- A gRPC instance is created by running a **gRPC** command, the gRPC function is enabled, and the gRPC

configuration mode is enabled.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the gRPC function.

grpc

The gRPC function is disabled bydefault.

1.4 Configuring the gRPC Response Timeout Time

1.4.1 Overview

The data response timeout time is configured for the gRPC Server.

1.4.2 Restrictions and Guidelines

- After the data response timeout time is configured for the gRPC process and the collector delivers a Get or Set operation, a timeout message is returned if the server does not obtain corresponding data within the timeout time.
- The value of the timeout time should be configured based on the actual scenario. If the configured timeout time is too short, part of the required data may not be returned in the timeout period during a Get operation.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure the gRPC data response timeout time.

reply-timeout *time*

The default data authentication timeout time on the gRPC Server is **10** seconds.

1.5 Configuring Event Types Supported by gRPC

1.5.1 Overview

- The device is configured with all realtime events of concern which are subscribed to.
- The device is configured with all periodic events of concern which are subscribed to.
- The timer time of the periodic events is modified.

1.5.2 Restrictions and Guidelines

- The event which the server subscribes to cannot effect unless a specified event which is subscribed to is configured on the device.
- If the device subscribes to a realtime event, a realtime packet is generated and sent to the subscribing server when the threshold of the realtime events is triggered. If the threshold of the realtime events is triggered frequently, many same packets are generated within a short time and sent to the subscribing server. As a result, the cost of the server and the device is added. To prevent such threshold from being triggered frequently, Run the **subscr-realtime-interval** command to suppress realtime events to generate new packets within a period.
- When any periodic events of concern which are subscribed to is configured and the NETCONF manager sends periodic events which are subscribed to, the corresponding periodic timer starts and gRPC data is sent to the subscribing server.
  - If the NETCONF manager does not subscribe to any periodic time, the timer period is determined by the **subscr-sample-interval** command.
  - If the NETCONF manager subscribes to both the periodic events and period time, the period time is subject to the subscription time of the NETCONF manager.
- After any events of concern which are subscribed to are configured by the gRPC process, the gRPC process waits for the NETCONF manager to send the subscription events:
  - If the received subscription message matches the local subscription event, the event triggering gRPC reporting server function is enabled.
  - When the NETCONF manager sends an unsubscription event and the received unsubscription message matches the local subscription event, the event triggering gRPC reporting server function is disabled.
- If no events of concerns which are subscribed to are configured by the gRPC process, the gRPC process ignores the subscription events and unsubscription events sent by the NETCONF manager.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure an event of concern which is subscribed to on the device.

subscr [**realtime** | **sample**] **enable**

No events of concern which are subscribed to are configured by default.

(5) (Optional) Configure the timer time of the periodic events.

subscr-sample-interval *subscr-sample-interval-second* [**millisecond** *subscr-sample-interval-millisecond*]

The default periodic event timer time is **10** seconds.

(6) (Optional) Configure the realtime event suppression time.

subscr-realtime-interval { **all** *subscr-realtime-time* | **realtime** *json-event subscr-realtime-time* }

The realtime event suppression function is not enabled by default.

1.6 Configuring gRPC to Support Pre-configuration Functions

1.6.1 Configuration Tasks

gRPC configuration includes the following tasks:

- Configuring gRPC to Pre-configure a Subscription Server and Event
- Configuring gRPC to Support User Login Information of the Functional Server

1.6.2 Configuring gRPC to Pre-configure a Subscription Server and Event

1. Overview

- After a server and event which are subscribed to is pre-configured, gRPC packets of corresponding events can be reported to the server.
- After a subscribing standby server is pre-configured, its services can be switched over to the standby server and packets are automatically sent to the standby server when the active server becomes faulty.

2. Restrictions and Guidelines

- The address and port number of the subscribing server must be legitimate.
- The events and parameters which are subscribed to must be correct and valid.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure gRPC to support a subscribing server.

user-server *ipv4-address port-number*

No subscribing server is pre-configured by default.

(5) Configure gRPC to support a subscription event.

type *json-event* **value** *value-interval* [**value-extend** *value-extend-interval*]

The event subscription function for a specified server is not enabled by default.

(6) (Optional) Configure gRPC to support the heartbeat detection function.

heartbeat inform [**interval** *interval*] [**keepalive-times** *keepalive-times*]

The heartbeat sending function is not enabled by default.

(7) (Optional) Configure gRPC to pre-configure a standby server for the subscribing server.

standby-server *ipv4-address port-number*

No standby server is pre-configured for the subscribing server by default.

Before configuring a standby server, enable the heartbeat detection function. When an active server becomes faulty, data can be automatically sent to the standby server.

(8) (Optional) Exit the gRPC subscription server configuration mode.

exit-user-server

1.6.3 Configuring gRPC to Support User Login Information of the Functional Server

1. Overview

After user login information is pre-configured for the server, the specified server can obtain correct information after initiating an obtainment event request.

2. Restrictions and Guidelines

- Running a configured command, the device can pre-create user login information of the server that passes authentication, simulate the server to initiate a login request, pass the authentication, and save the user login information.
- Running a configured command, the device can delete user login information of the server that passes authentication, simulate the server to initiate a logout request, and delete the user login information.
- The address of the server must be legitimate.
- The sequence number of the login user must be unique.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure gRPC to pre-configure user login information of the server.

user-client *user-id username ipv4-address*

No user login information is pre-configured for the server by default.

1.7 Configuring a YANG Model Path

1.7.1 Overview

After the YANG model path and data source are collected, data can be sent to the corresponding server based on the path in the subscription association relationship.

1.7.2 Restrictions and Guidelines

- The YANG model path must be legitimate and corresponding data is available on the path.
- In the YANG model path group, a specific YANG model path is configured. For the detailed compilation

method of the path, see the displayed information of the **show grpc yang tree** and **show grpcnode-path** commands in **gRPC Command Reference**.

- After a gRPC YANG model path group is configured, the system switches to the gRPC YANG model path group configuration mode.
- Multiple YANG model paths can be configured for this group in this mode.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure a YANG model path group, and enter the gRPC YANG model path group configuration mode.

sensor-group *sensor-group-id*

No YANG model path group is configured by default.

(5) Configure a gRPC YANG model path and its group.

sensor-path *sensor-path*

No YANG model path is configured by default.

1.8 Configuring the gRPC Subscription Function

1.8.1 Overview

After a subscription association relationship is configured, data of the associated YANG model path group is collected and sent to the destination server of the associated destination group.

1.8.2 Restrictions and Guidelines

A YANG model path group must be configured in advance.

1.8.3 Configuration Tasks

gRPC subscription configuration includes the following tasks:

(1) (Optional) Configuring gRPC to Specifying a Source Interface to Send Data

(2) Configuring the Active and Standby Destination Servers of gRPC

(3) Configuring gRPC Subscription

1.8.4 Configuring gRPC to Specifying a Source Interface to Send Data

1. Overview

gRPC is configured to send packets based on the IP address of a specified interface.

2. Restrictions and Guidelines

- The bound interface must be up and be configured with an IP address.
- If a server receives only packets from a specified source address, this command can be used to configure the specified source interface.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) (Optional) Configure a source interface of realtime data and periodic data.

subscr-source-interface *interface-type interface-number*

The source interface of realtime data and periodic data is a random value by default.

1.8.5 Configuring the Active and Standby Destination Servers of gRPC

1. Overview

Configure addresses of the active and standby destination servers so that the destination server subscribes to a YANG model path based on the subscription association.

2. Restrictions and Guidelines

- The address and port number of the server must be valid.
- After a gRPC destination group is configured, the system switches to the gRPC destination group configuration mode.
- Multiple destination addresses can be configured for this group in this mode.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure a gRPC destination group, and enter the gRPC destination group configuration mode.

destination-group *destination-group-id*

No destination group is configured for the subscription association relationship by default.

(5) Configure destination addresses of the active and standby destination servers.

- Configure an IPv4 destination address.

ip *ipv4-address* **port** *port-number* [**vrf** *vrf-name*] [**standby** { *ipv4-address standby-port-number* [**vrf** *vrf-name*] }&<1-3>]

No IPv4 address or interface is configured for the destination server by default.

- Configure an IPv6 destination address.

  ipv6 *ipv6-address* **port** *port-number* [**vrf** *vrf-name*] [**standby** { *ipv6-address standby-port-number* [**vrf** *vrf-name*] }&<1-3>]

  No IPv6 address or interface is configured for the destination server by default.

(6) Configure a protocol for the destination server.

protocol grpc { **tls** | **no-tls** }

The default protocol is the gRPC protocol that supports plain text transmission.

(7) Configure the keepalive count and interval for the active and standby destination servers.

keepalive { **interval** *interval* | **time** *time* } *

By default, the keepalive interval of the **active and standby** destination servers is 10 seconds, and the keepalive count is 3.

1.8.6 Configuring gRPC Subscription

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure a subscription association relationship group, and enter the gRPC subscription association relationship configuration mode.

subscription *subscriptionid*

No subscription association relationship is configured between the YANG model path group and destination group by default.

(5) Configure the associated YANG model path group and its period interval.

sensor-group *sensor-group-id* [**sample-interval** *sample-interval*]

(6) Configure a destination group of the subscription association relationship.

destination-group *destination-group-id*

No destination group is configured for the subscription association relationship by default.

(7) (Optional) Configure a data encoding format.

encoding { **json** | **json-ietf** }

gRPC uses the JavaScript Object Notation (JSON) encoding format by default.

1.9 Configuring gRPC to Support the Login and Logout Function

1.9.1 Overview

The authentication mode of the gRPC login and logout function is configured as authentication-exemption, AAA local authentication, or AAA server authentication (timeout time and retry times are configurable).

1.9.2 Restrictions and Guidelines

- If the authentication mode is configured as AAA server authentication, the new-model must be enabled.
- The authentication-exemption mode is not recommended.
- You are not advised to modify the timeout time and retry times. During server login in the AAA server authentication mode, if the retry times exceed a limit or the timeout time is too long, AAA may be locked for 15 minutes. The lock time can be canceled by running the AAA command **clear aaa local user lockout all**.
- Upon receiving a login request from the server, the device selects one of the three modes based on the configured authentication mode. After the server passes the authentication, the user login information, namely, IP address and username of the server, is recorded. The device returns responses to the obtainment event requests of the server that passes the authentication.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure an authentication mode of the gRPC login and logout function.

authen login { **local** | **authentication** *mlist* }

The local authentication mode, namely, **authen login local** is used by default.

(5) (Optional) Configure the AAA server authentication attribute of the gRPC login and logout function.

authen aaa-config { **retry** *retry-times* | **timeout** *timeout-time* }

The retry times and timeout time of AAA server authentication are 1 and 4 seconds, respectively, by default.

This authentication mode can be configured only after AAA configuration (aaa new-model) is completed.

1.10 Configuring a Third-party Defined RPC Method

1.10.1 Overview

After a third-party defined RPC method is configured, the RPC method can be used to collect device information and data or perform RPC-related operation.

1.10.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure a third-party defined RPC method.

rpc { **gnmi** | **openr** } **enable**

No RPC defined by gNMI or openR is configured by default.

1.11 Configuring a Dial-out RPC Method

1.11.1 Overview

An RPC method is configured for dial-out so that the RPC method can be selected to receive and send messages.

1.11.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Configure a dial-out RPC method.

dial-out rpc { **sonic** | **custom** }

The RPC method defined by the open source of Sonic is used by default.

1.12 Configuring gRPC Server

1.12.1 Overview

When you need to use gRPC as the server, you can configure the gRPC server functions.

1.12.2 Restrictions and Guidelines

- If you only need to use the dial-out mode after the gRPC function is enabled, you do not need to enable the gRPC server function. You can disable the gRPC server function by using command.
- Modifying the private port number of the server can reduce the probability of scanning attacks.
- After you bind the source interface, gRPC clients can only access the gRPC server through the IP address of the interface, improving the access security.
  - If there are multiple IPv6 addresses on the source interface, the gRPC server supports only the first IPv6 address, and does not support IPv6 link-local addresses or IPv4-mapped IPv6 addresses.
- The SSL/TLS certificate can implement TLS encryption.

- Before loading the SSL/TLS certificate, you need to copy the certificate to the Flash memory partition of the device.

- The CA certificate can be used to perform authentication for clients.
  - Before loading the CA certificate, you need to copy the certificate to the Flash memory partition of the device.
- When you need to filter the illegal connections of the client, you can configure the ACL filter rules of the gRPC server.
- With IP blocking configured, when the number of authentication failures from a gRPC client reaches the threshold for IP blocking, the IP blocking mechanism is triggered, that is, the gRPC client with this source IP address is not allowed to log in, thereby preventing malicious attacks. After the blocking interval expires, the gRPC client with the IP address is allowed to log in again. This function is enabled by default and can be manually disabled.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the gRPC configuration mode.

grpc

(4) Enable the gRPC server function.

server enable

By default, the gRPC server is disabled. If you enable the gRPC function, the gRPC server is also enabled.

(5) (Optional) Configure the gRPC server port number.

server port *port-number*

By default, the listening port number of the gRPC server is 50051.

(6) (Optional) Configure the source interface bound to the gRPC server.

server source-interface *interface-type interface-number*

By default, the source interface bound to the gRPC server is not configured.

(7) (Optional) Load the SSL/TLS certificate of the gRPC server.

server certificate load { **pem** *pem-cert-filename* **private-key** *private-key-filename* | **pfx** *cert-filename* } [**password** *password*]

By default, no SSL/TLS certificate is loaded.

(8) (Optional) Load the trusted CA certificate for gRPC server.

server trusted-ca load *cert-filename*

By default, no CA certificate is loaded.

(9) (Optional) Configure the ACL filter rule for gRPC server.

server access-class { **ipv4** { *acl-name* | *acl-number* } | **ipv6** *acl-name* }

By default, no ACL filter rule is configured.

(10) Configuring IP Blocking for the gRPC Server

a Enable IP blocking for the gRPC server.

ip-block disable

IP blocking is enabled for the gRPC server by default.

b (Optional) Configure the maximum number of authentication failures and the interval for counting the number of authentication failures for IP blocking.

ip-block failed-times *times* **period** *period-time*

By default, the maximum number of authentication failures is 6, and the number of authentication failures is counted at an interval of 5 minutes.

c (Optional) Configure the IP blocking interval for the gRPC server.

ip-block reactive *reactive-interval*

The default IP blocking interval for the gRPC server is 5 minutes. After the IP blocking interval expires, the gRPC client with the IP address is allowed to log in again.

1.13 Monitoring

Run the **show** command to check the configuration.

Run the **clear** command to clear information.

Caution

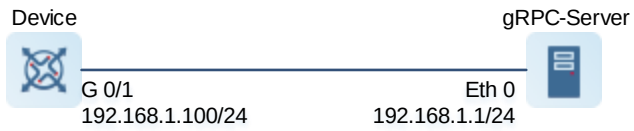
During device operation, running the **clear** command may cause service interruption due to key information loss.

Table 1-1 gRPC Monitoring

Command	Purpose
clear grpc channel [*ipv4-address port-number*] [**counter**]	Clears statistics about the server which gRPC subscribes to.
clear grpc subscr [**sample**] [**counter**]	Clears data about periodic events and real-time events of gRPC.
show grpc channel [**counter**]	Displays server address, port number, subscription events, and different statistics.
show grpc client	Displays gRPC server login information.
show grpc status	Displays gRPC running status information.
show grpc subscr [**realtime** | **sample**]	Displays status and statistics of events which are subscribed to.
show grpc openconfig subscription	Displays information about static subscription association relationship (openconfig-telemetry.proto definition) of the device.

Command	Purpose
show grpc gnmi subscription	Displays information about subscription association relationship generated with the RPC method defined by gnmi.proto.
show grpc openr support-rpc	Displays openR RPC methods supported by the device.
show grpc yang tree	Displays the YANG model tree that is loaded by gRPC.
show grpc yang node-path	Displays paths corresponding to YANG nodes.

1.14 Configuration Examples



1.14.1 Configuring Basic Functions of gRPC

1. Requirements

A tested device is connected to a server and reports gRPC data.

2. Topology

Figure 1-4 Example of gRPC

3. Notes

- Ensure that the device and the PC are mutually reachable via the L3 route.
- Enable the gRPC function on the device.
- On the device, configure data in which the server must be reported.

4. Procedure

(1) Configure that the device and the PC are mutually reachable via the L3 route.

```
Device> enable
Device#configure terminal
Device(config)#interface gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# ip address 192.168.1.100 255.255.255.0
Device(config-if-GigabitEthernet 0/1)# exit
```

(2) Configure the gRPC function.

Enable the gRPC function.

```
Device(config)# grpc
```

Configure gRPC to bind a specified interface to send packets.

```
Device(config-grpc)# subscr-source-interface GigabitEthernet 0/1
```

(3) Configure data in which the server must be reported.

Configure the aaa new-model and the appropriate mlist test.

```
Device(config-grpc)# authen login authentication test
```

Configure realtime events of concern which are subscribed to.

```
Device(config-grpc)# subscr realtime enable
```

Configure the gRPC data response timeout time.

```
Device(config-grpc)# reply-timeout 30
```

Enable the heartbeat mechanism, configure a heartbeat period and an interval, and specify a channel and subscription type.

```
Device(config-grpc)# heartbeat inform interval 1 keepalive-times 1
Device(config-grpc)# user-server 192.168.1.1 12345
Device(config-grpc-us)# type 0x10000000 value 10
Device(config-grpc-us)# exit
```

Configure user login information of the specified server.

```
Device(config-grpc)# user-client 12345 test-user 192.168.1.100
```

Configure a YANG model path.

```
Device(config-grpc)# sensor-group 1
Device(config-grpc-us)# sensor-path
/rg-bridge:bridge/vlan/entry[id='1']/swport-list
Device(config-grpc-us)# exit
```

Configure a destination group.

```
Device(config-grpc)# destination-group 1
```

Configure an IPv4 address and port number of the destination group.

```
Device(config-grpc-destination)# ip 192.168.0.1 port 12345
```

Enable the destination group to use the gRPC protocol that supports TLS encryption.

```
Device(config-grpc-destination)# protocol grpc tls
Device(config-grpc-destination)# exit
```

Configure the subscription association relationship group, associated YANG model group and period interval, associated destination group, and data encoding format json-ietf.

```
Device(config-grpc)# subscription 1
Device(config-grpc-subscription)# sensor-group 1 sample-interval 1000
Device(config-grpc-subscription)# destination-group 1
Device(config-grpc-subscription)# encoding json-ietf
Device(config-grpc-subscription)# exit
```

Configure an RPC method defined by gnmi.proto.

```
Device(config-grpc)# rpc gnmi enable
```

Configure an RPC method defined by openR.

```
Device(config-grpc)# rpc openr enable
```

Configure a private RPC method to receive and send messages.

```
Device(config-grpc)# dial-out rpc gnmi-ext
```

5. Verification

Run the **ping** command to check whether the device and the PC are reachable via the L3 route.

```
Device# ping oob 192.168.1.1
Sending 5, 100-byte ICMP Echoes to 192.168.1.1, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/3/5 ms.
```

Run the **show grpc status** command to check whether the gRPC function is enabled.

```
Device# show grpc status
GRPC:
  Uptime: 00h:28m:21s
```

Run the **show grpc client** command to display the user login information of the gRPC server.

```
Device# show grpc client
Client information all:
  1    : test-user@192.168.1.100, ID 12345
```

Run the **show grpc channel counter** command to display the statistics about the subscription server.

```
Device# show grpc channel counter
Server subscr all:
  server ip 192.168.1.1 port 50051
    state TRANSIENT_FAILURE
    heartbeat state FAILURE
  json list count: 0
  json send count: 1
  json drop count: 0
  call list count: 0
  call send count: 1
  call drop count: 0
```

Run the **show grpc channel counter** command to display the address, port number, and subscribing events of the subscription server.

```
Device# show grpc channel
Server subscr all:
  server ip 192.168.1.1 port 50051
    state TRANSIENT_FAILURE
    heartbeat state FAILURE
  subscr event:
    none
```

Run the **show grpc openconfig subscription** command to display the subscription relationship implemented according to openconfig-telemetry.yang.

```
Device# show grpc openconfig subscription
```

```
all subscriptions:
  subscription 1:
    sensor group 1:
      sample interval:1000
      sample timer count:858
      sensor path: /rg-bridge:bridge/vlan/entry[id='1']/swport-list
        state: NORMAL
        recv count: 858
    destination group 1:
      destination: 192.168.1.100:12345
        state: TRANSIENT_FAILURE
        task list count: 0
        task drop count: 0
        send request count: 0
        send update count: 0
        recv response count: 0
      destination: [1::1]:12345
        state: TRANSIENT_FAILURE
        task list count: 0
        task drop count: 0
        send request count: 0
        send update count: 0
        recv response count: 0
```

6. Configuration Files

- Device configuration file

```
hostname Device
!
grpc
 dial-out rpc gnmi-ext
 rpc gnmi enable
 rpc openr enable
 subscr realtime enable
 reply-timeout 30
 subscr-source-interface gigabitEthernet 0/1
 user-client 12345 test-user 192.168.1.100
 heartbeat inform interval 1 keepalive-times 100
 sensor-group 1
  sensor-path /rg-bridge:bridge/vlan/entry[id='1']/swport-list
  exit-sensor-group
 destination-group 1
  protocol grpc tls
  ip 192.168.1.100 port 12345
  exit-destination-group
 subscription 1
  sensor-group 1 sample-interval 1000
```

```
  destination-group 1
  encoding json-ietf
  exit-grpc-subscription
 user-server 192.168.1.1 50051
  exit-user-server
!
end
```

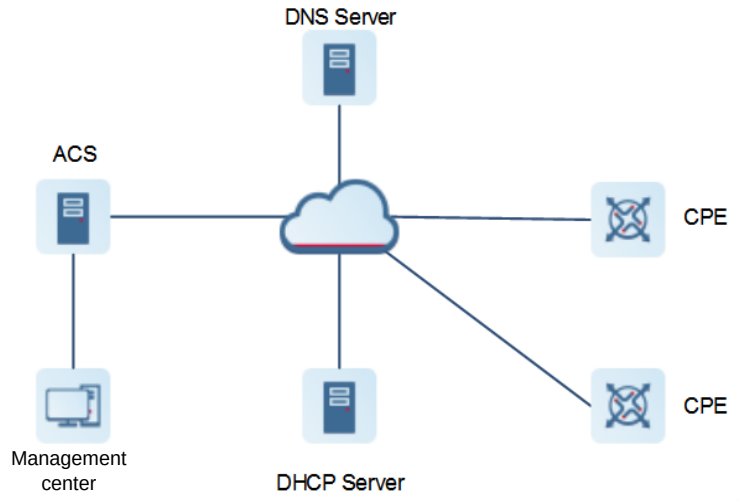
1.5.1 Configuring Basic CWMP Functions 10

1 Configuring CWMP

1.1 Introduction

1.1.1 Overview

The CPE WAN Management Protocol (CWMP), also known as TR-069 protocol, is a management protocol initiated and developed by Digital Subscriber's Line (DSL) forum and numbered TR-069. CWMP provides a general framework of unified device management, related message specifications, management methods, and data models. It solves difficulties in unified management and maintenance of dispersed customer premises equipment (CPEs), improves troubleshooting efficiency, and saves O&M costs.



1.1.2 Principles

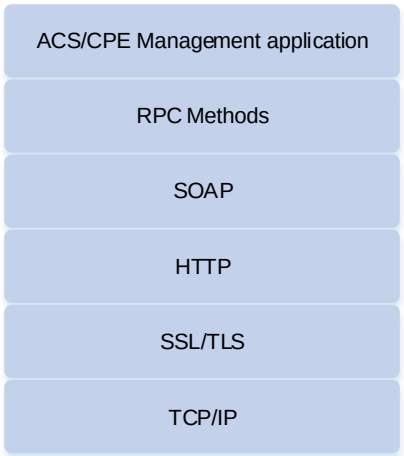
1. Basic Concepts

Figure 1-1 shows the network structure of CWMP, mainly including:

- ACS: The auto-configuration server (ACS) is the managing device in a network.
- CPE: The customer premises equipment (CPE) is the managed device in a network.
- DHCP server: The Dynamic Host Configuration Protocol (DHCP) server obtains the Uniform Resource Locator (URL) of the ACS dynamically.
- DNS server: The dynamic network server (DNS) parses domain names of the ACS or CPE.

Figure 1-1 Network Structure of CWMP

2. Network Structure of CWMP



As shown in Figure 1-2, CWMP work is composed of six layers:

- ACS/CPE management application: This layer is not a part of CWMP. It is the development performed by functional modules of the CPE/ACS to support CWMP. As with the Simple Network Management Protocol

(SNMP), CWMP does not cover the management information base (MIB) management of functional modules.

- RPC methods: This layer provides and implements various RPC methods for interactions between the ACS and the CPE. The ACS manages and monitors the CPE with mostly the following RPC methods:
- Get series methods: The Get methods enable the ACS to remotely obtain RPC methods, as well as names, values and attributes of the data model parameters supported on the CPE.
- Set series methods: The Set methods enable the ACS to remotely set the values and attributes of the data model parameters supported on the CPE.
- Inform method: The Inform method enables the CPE to inform the ACS of their device identifiers, parameter information, and events. This is the first method used when sessions are established between the ACS and the CPE.
- Download method: The Download method enables the ACS to remotely control and manage file download of the CPE, including main program upgrade, configuration file upgrade, and Web package upgrade.
- Upload method: The Upload method enables the ACS to remotely control and manage file upload of the CPE, including configuration file and log file upload.
- Reboot method: The Reboot method enables the ACS to remotely control reboot of the CPE.
- SOAP: The Simple Object Access Protocol (SOAP) layer uses an XML-based syntax to encode and decode CWMP messages. Thus, CWMP messages must comply with the XML-based syntax of SOAP.
- HTTP: The Hypertext Transfer Protocol (HTTP) layer transmits all CWMP messages. Both the ACS and the CPE can behave in the role of HTTP clients and servers. The server is used to monitor reverse connections from the peer.
- SSL/TLS: The secure sockets layer (SSL) or transport layer security (TLS) layer guarantees CWMP security, including data integrity, confidentiality, and authentication.
- TCP/IP: This layer is the Transmission Control Protocol/Internet Protocol (TCP/IP) stack.

Figure 1-2 CWMP Structure

3. Working Process of CWMP

Figure 1-3 shows the working process of CMWP.

(1) Create a TCP connection.

(1) Create a security mechanism during SSL initialization.

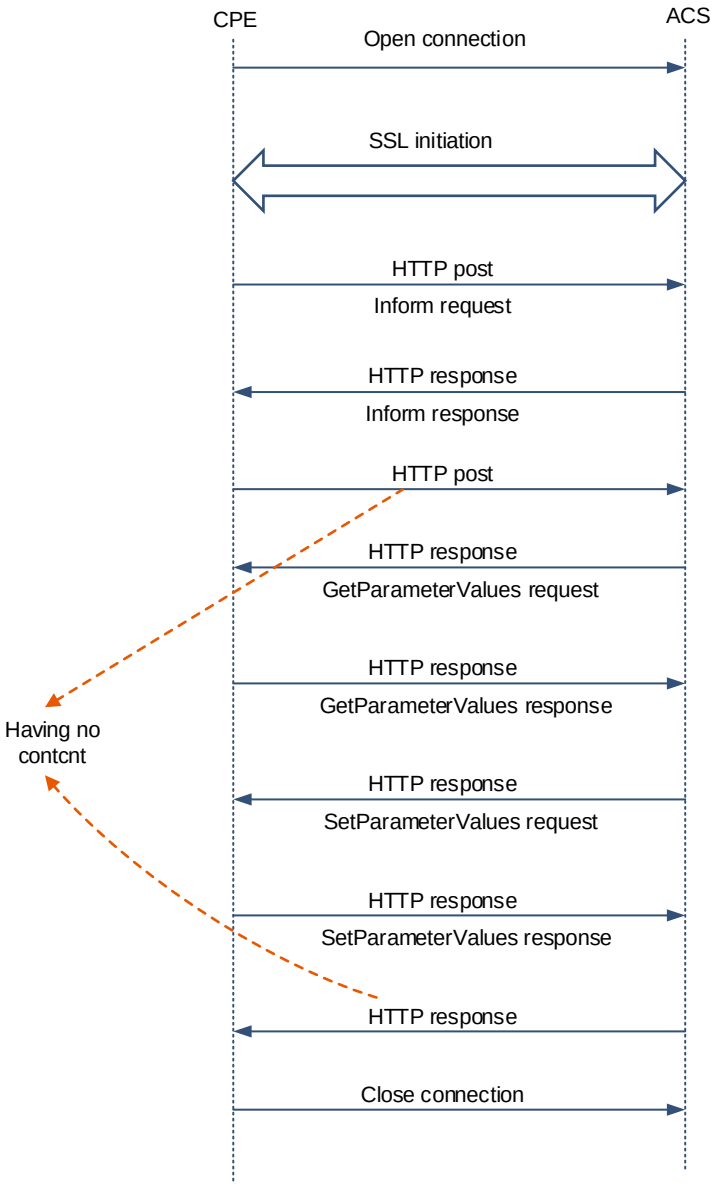
(2) After the CPE sends an Inform packet, start establishing a CWMP connection. Use the Eventcode field to describe the cause of sending this Inform packet in the Inform packet.

(3) If the CPE passes the ACS authentication, the ACS returns an Inform response packet to establish the connection.

(4) If the CPE has no more request, a null packet is sent to meet the rule of HTTP request/response packet interaction. CWMP is based on HTTP, and CWMP packets as data parts of HTTP packets are encapsulated in HTTP packets.

(5) The ACS queries the value of the ACS URL set on the CPE.

(6) The CPE returns the obtained ACS URL to the ACS.



(7) When the ACS discovers that the ACS URL is not the local URL value, the ACS initiates a Set request, requesting the CPE to set its ACL URL to the URL value of the standby ACS.

(8) After the ACL URL is set, the CPE sends a response packet.

(9) The ACS sends a null packet to notify the CPE, there are any other requests.

(10) The CPE closes the session.

Figure 1-3 Work Flowchart of CWMP

- Session management

  CWMP sessions are the basis for CWMP. All CWMP interactions between the ACS and the CPE rely on the sessions. The interaction effectiveness of the sessions is ensured by the transmission, management, and maintenance for effective management and monitoring. An ACS-CPE session is a TCP connection, which starts from the Inform negotiation to TCP disconnection. Sessions are classified into those initiated by the CPE and those requested by the ACS according to the session initiator.

  - The CPE initiates a connection

    The CPE can initiate a connection with the ACS based on the configured ACS address at any time. In the following scenarios, the CPE must establish a connection with the ACS.

    When the CPE is powered on, reset or initialized, the CPE establishes a connection with the ACS for the first time.

    When the ACS URL changes,

an Inform packet must be sent if a parameter is changed.

When the CPE receives a valid connection request from the ACS,

and the CPE is configured to periodically send Inform packets, it sends connection requests both automatically and periodically.

When the CPE is configured to send Inform packets periodically, the CPE automatically send connection requests at the designated time point.

- The ACS initiates a connection

  The ACS can, at any time, require the CPE to initiate a connection request to the ACS by using the connection request notification mechanism to set up the connection with the CPE.

Note

- The CPE must support the connection request notification mechanism. If the ACS is required to actively initiate a connection request, the ACS must support the connection request notification mechanism.
- Communication at least once between the ACS and the CPE is the prerequisite for ACS to initiate a connection. If the ACS desires to actively initiate communication, the ACS stores the management IP address of the CPE in the communication. If the management IP address of the CPE changes, the CPE must send an Inform packet to notify the ACS of the new management IP address to timely update the information of the ACS.

4. Basic Functions of CWMP

CWMP provides mainly the following functions:

- Auto configuration

  After the CPE starts operation, the management center can deliver configuration to the CPE through the ACS server to change the CPE configuration and status and thus manage the CPE. The configuration file is delivered with two methods:

  - Update the configuration file. The configuration file of the CPE is replaced with a specified configuration file so that the new configuration file is run on the CPE after reset.
  - Update running configuration. Specific configuration is directly delivered to the CPE and saved to the running configuration of the CPE. The configuration takes effect immediately upon delivery. The configuration must be saved. Otherwise, the delivered configuration will be lost after CPE reset.

- Status and performance monitoring

  The CPE notifies the ACS of the current status and configuration change of the device through the periodic Inform mechanism. The ACS monitors the CPE based on these notifications of the real-time change.

- Fault diagnosis

  According to the diagnostic information provided by the CPE, the ACS resolves connection problems and other service problems and executes predefined diagnostic actions.

- Main program upgrade

  Main program upgrade means updating main program of the CPE so as to upgrade software version of the CPE. When the ACS detects any latest version of the main program, the ACS delivers the Download method to the CPE. The CPE downloads the main program from the file server specified in the Download method. After the main program is downloaded and the CPE checks the validity of the main program, the

CPE restart to upgrade the main program. After restart, the CPE notifies the ACS of the completion of main program upgrade.

- Data backup

  The ACS controls the CPE to upload configuration files to the ACS or file server with the Upload method.

Note

The file server can be ACS or separately deployed.

- Backup and restoration

  CPE backup and restoration means that when any remote CPE breaks away from the management center due to an abnormal operation on the ACS, the CPE must be restored to the previous status, so that the ACS can correctly manage and operate the remote device of the CPE once again.

  Generally, the CPE breakaway is caused by the delivered incorrect main program or configuration. The CPE must be configured to restore the main program or configuration if any abnormality arises. When the CPE receives any main program upgrade or configuration delivery request, the CPE backs up the current configuration and main program version. After the upgrade or update is completed, the CPE determines whether it is broken away from the ACS. If yes, the CPE restores itself to the previous manageable status.

1.1.3 Protocols and Standards

- TR069: CPE WAN Management Protocol

1.2 Configuration Task Summary

CWMP configuration includes the following tasks:

(1) Establishing a Basic CWMP Connection

(2) (Optional) Configuring CWMP Attributes

1.3 Configuring CWMP

1.3.1 Establishing a Basic CWMP Connection

1. Overview

A session connection is established between the ACS and the CPE.

2. Restrictions and Guidelines

- Only one ACS username can be configured. If the ACS name is configured repeatedly, the latest username configured takes effect.
- The ACS user password can be in plaintext or cyphertext form. Only one ACS user password can be configured. If the ACS password is configured repeatedly, the latest password configured takes effect.
- Only one ACS URL can be configured. If the ACS URL is configured repeatedly, the latest URL configured takes effect. The ACS URL must be in HTTP or HTTPS format.
- When a CPE password is configured for authentication in the connection with the ACS, the encryption type does not need to be entered. If an encrypted password is copied and pasted, the encryption type must be

entered. A valid password should meet the following format requirements:

- Contain 1 to 26 characters including uppercase letters, lowercase letters, and digits.
- Leading spaces will be ignored, while the trailing and middle spaces are valid.

- Only one CPE URL can be configured for the connection between the CPE and the ACS. If the CPE URL is configured repeatedly, the latest URL configured takes effect. The CPE URL must be in HTTP format instead of domain name format. By default, a CPE URL is automatically selected based on the ACS URL. The CPE URL format must meet the following requirements:
  - The CPE URL must be in HTTP format.
  - Contain 256 characters at most.
- Only one CPE username can be configured. If the CPE username is configured repeatedly, the latest user configured takes effect.
- If the ACS URL is not manually configured but a dynamic ACS URL is obtained through DHCP, this dynamic ACS URL is used to initiate a connection to the ACS. Before configuration, ensure that UDP port 7547 on the CPE is unused. This port is used for Simple Traversal of UDP over NATs (STUN) port listening. The ACS URL must meet the following format requirements:
  - The ACS URL must be in HTTP or HTTPS format.
  - Contain 256 characters at most.
- The **cpe source** command and the **cpe url** command are not compatible with each other. When the two commands are not configured, the CPE automatically selects URL based on the ACS URL.
  - The interface name of the CPE must be the full name of the interface and can be automatically filled when a CLI command is entered.
  - If no port ID is configured, the default port ID 7547 is used.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the CWMP function.

cwmp

The CWMP function is enabled by default.

(4) Configure an ACS username for CWMP connection.

acs username *username*

No ACS username is configured for CWMP connection by default.

(5) Configure an ACS password for CWMP connection

acs password { **0** *encryption-password* | **7** *encrypted-password* | *password* }

No ACS password is configured for CWMP connection by default.

(6) (Optional) Configure a CPE username for CWMP connection.

cpe username *username*

No CPE username is configured for CWMP connection by default.

(7) Configure a CPE password for CWMP connection.

cpe password { **0** *encryption-password* | **7** *encrypted-password* | *password* }

No CPE password is configured for CWMP connection by default.

(8) Configure an ACS URL for CWMP connection.

acs url *url*

No ACS URL is configured for CWMP connection by default.

(9) Configure a CPE URL for CWMP connection.

cpe url *url*

No CPE URL is configured for CWMP connection by default.

(10) Configure the CPE URL based on the IP address of the specified interface.

cpe source interface *interface-type interface-number* [**port** *port-number*]

No CPE URL is configured based on the IP address of the specified interface by default.

1.3.2 Configuring CWMP Attributes

1. Overview

You can configure common functions for CPE, for example, backup and restoration of main program and configuration file, acceptance or not of main program and configuration file delivered by the ACS, management or not of configuration/log files uploaded to the ACS.

2. Restrictions and Guidelines

- Any CPE can be configured with the periodic Inform function.
  - If no Inform start time is configured, the Inform enabling time is used as the Inform start time, and Inform is performed once every default Inform interval. For example, no Inform period or start time is configured, but the Inform function is enabled at 12:00 a.m. Then, periodic Inform will start at 12:00 a.m. next day and be performed once every default Inform interval.
  - If the Inform start time is configured, periodic Inform starts at the specified start time. For example, if the Inform interval is set to 60 seconds and the start time is 12:00 a.m. next day, periodic Inform will start at 12:00 a.m. next day and be performed once every 60 seconds.
- If you do not expect CPE to receive any main program and configuration file from the ACS, you can disable the management Inform function of receiving the main program and configuration file delivered by the ACS. Disabling the function of receiving the main program and configuration file delivered by the ACS does not act on configuration script files. The configuration scripts can still be executed even if this function is disabled.
- If you do not expect CPE to upload configuration file and log file to the ACS, you can disable the management function of uploading any configuration file and log file to the ACS.
- The **no disable stun port-adaptive** command can be configured on the CPE to enable the STUN port auto-adaption function so that the CPE automatically adapts to ports 3478 and 3479 of the STUN server. The **no disable stun probe-agingtime** command can be configured on the CPE to enable the NAT age time probe function. The CPE automatically binds with UDP port 7548, detects NAT age time and adjusts STUN port keep-alive time through this UDP port.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the CWMP configuration mode.

cwmp

(4) (Optional) Configure CWMP attributes. Configure at least one of the following tasks.

- Enable the periodic Inform function on the CPE.

  cpe inform [**interval** *interval*] [**starttime** *hh:mm:ss MM/DD/YY*]

  The periodic Inform function of the CPE is disabled by default. The default Inform period is 600 seconds.

- Enable the management Inform function of receiving any main program and configuration file delivered by the ACS.

  no disable download

  The management function of receiving any main program and configuration file delivered by the ACS is enabled by default.

- Enable the management function of uploading any main program and configuration/log file to the ACS from the CPE.

  no disable upload

  The management function of uploading any main program and configuration/log file upload function to the ACS is enabled by default.

- Enable the STUN port auto-adaption and NAT age time probe function.

  no disable stun { **port-adaptive** | **probe-agingtime** }

  The STUN port auto-adaption and NAT age time probe function is disabled by default.

- Configure the maximum keep-alive time of STUN packets.

  stun max-period *interval*

  The maximum keep-alive time of STUN packets is **60** seconds by default.

- Configure the minimum keep-alive time of STUN packets.

  stun min-period *interval*

  The minimum keep-alive time of STUN packets is **20** seconds by default.

- Configure a port of the STUN server.

  stun port *port-number*

  The default port ID of the STUN server is **3478**.

- Configure a STUN server address.
  stun address { *stun-domain-address* | *stun-ipv4-address* }

  No STUN server address is configured by default.

- Enable the backup and restoration function of the CPE main program or configuration file.

cpe back-up [**delay-time** *time*]

The backup and restoration function of the main program or configuration file is disabled by default.

- Configure the CPE timeout time in the case of no ACS response.

  timer cpe-timeout *tiemout*

  The default CPE timeout time is 30 seconds in the case of no ACS response.

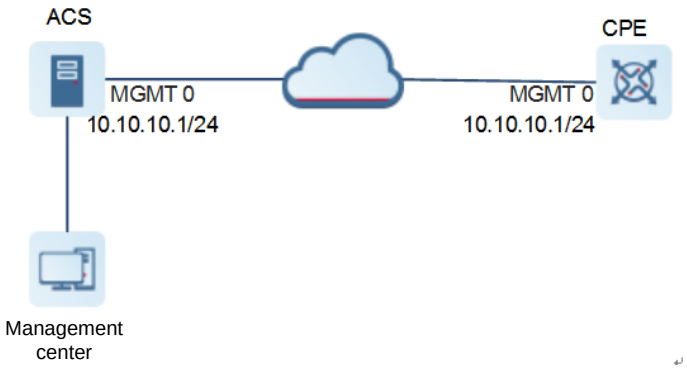
1.4 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
show cwmp configuration	Displays the current configuration of CWMP.
show cwmp status	Displays the current running status of CWMP.

1.5 Configuration Examples



1.5.1 Configuring Basic CWMP Functions

1. Requirements

Many network devices are configured in the corporate network, as shown in Figure 1-4. The network administrator manages and monitors these devices through CWMP to improve O&M efficiency.

2. Topology

Figure 1-4 Topology of Basic CWMP Functions

3. Notes

- Configure that the CPE and ACS are mutually reachable via routes.
- Enable the CWMP function on the CPE.

4. Procedure

Configure an IP address for the network management interface of the CPE.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.10.10.10 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# exit
```

Configure a URL connection between the ACS and CPE.

```
Hostname# configure terminal
Hostname(config)# cwmp
Hostname(config-cwmp)# acs url http://10.10.10.10:7547/acs
Hostname(config-cwmp)# cpe url http://10.10.10.1:7547/
```

Set the periodic Inform interval of the CPE to 60 seconds.

```
Hostname(config-cwmp)#cpe inform interval 60
```

Set the backup and restoration delay to 30 seconds.

```
Hostname(config-cwmp)# cpe back-up delay-time 30
```

Set the CPE timeout time to 100 seconds in the case of no ACS response.

```
Hostname(config-cwmp)# timer cpe-timeout 100
```

Disable the management function of any main program and configuration file delivered and downloaded by the ACS.

```
Hostname(config-cwmp)# disable download
```

Disable the management function of uploading any main program, configuration file and log file to the ACS.

```
Hostname(config-cwmp)# disable upload
```

Enable the CWMP function and enter the CWMP configuration mode.

```
Hostname(config-cwmp)# no disable stun port-adaptive
```

Enable the STUN port auto-adaption and NAT age time probe function.

```
Hostname(config-cwmp)# no disable stun probe-agingtime
```

Configure the username and password of the ACS.

```
Hostname(config-cwmp)# acs username USERB
Hostname(config-cwmp)# acs password Abc123456
```

Configure the username and password of the CPE.

```
Hostname(config-cwmp)# cpe username USERB
Hostname(config-cwmp)# cpe password Abc123456
```

5. Verification

Run the **ping** command to check whether the CPE and ACS are mutually reachable via L3 routes.

```
Hostname# ping oob 10.10.10.1
Sending 5, 100-byte ICMP Echoes to 10.10.10.1, timeout is 2 seconds:
  < press Ctrl+C to break >
```

```
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/3 ms.
Hostname#
```

Run the **show cwmp configuration** command to display the CWMP configuration result on the CPE.

```
Hostname# show cwmp configuration
CWMP status                  : enable
ACS URL                     : http://10.10.10.10:7547/acs
ACS username                 : USERB
ACS password                 : $10$07b$/Qy2cVjc5r8n$
CPE source interface name      :
CPE URL                     : http://10.10.10.1:7547/
CPE username                 : USERB
CPE password                 : $10$07b$/Qy2cVjc5r8n$
CPE inform status             : enable
CPE inform interval           : 60s
CPE inform start-time         : 0:0:0 0 0 0
CPE wait timeout             : 100s
CPE download status           : disable
CPE upload status             : disable
CPE back up status            : enable
CPE back up delay time         : 30s
CPE STUN port-adaptive         : enable
CPE STUN probe nat agingtime    : enable
CPE STUN address             :
CPE STUN port                : 3478
CPE STUN max-period           : 60s
CPE STUN min-period           : 20s
```

6. Configuration Files

Device A configuration file

```
hostname Hostname
!
cwmp
 acs url http://10.10.10.10:7547/acs
 acs username USERB
 acs password 7 $10$07b$/Qy2cVjc5r8n$
 cpe source interface GigabitEthernet 0/1
 cpe username USERB
 cpe password 7 $10$07b$/Qy2cVjc5r8n$
 timer cpe-timeout 100
 disable upload
 cpe back-up delay-time 30
 no disable stun port-adaptive
 no disable stun probe-agingtime
!
```

```
interface GigabitEthernet 0/1
 ip address 10.10.10.10 255.255.255.0
```

7. Common Errors

- The entered password is cyphertext and the password length exceeds 254 or the password is not an even number.
- The entered password is plaintext and longer than 126 characters.
- The entered password is plaintext and contains illegal characters.
- The ACS URL is null.
- The CPE URL is null.

1 Configuring SEM

1.1 Introduction

1.1.1 Overview

The smart embedded manager (SEM) is a network management tool. The tool can be separately deployed through commands, independent from external network management tools, which makes the tool easy to deploy.

Traditional external network management tools must be connected to devices over a network to manage the devices. If a network fails, affecting network connection, the external network management tools lose effect. SEM can directly manage devices under any circumstance and troubleshoot different types of network or device faults or capture key information.

SEM detects configuration events in real time. When an event occurs, SEM takes preset actions. The entire procedure is highly customizable. SEM provides fault detection and processing and automatic management functions, which improves the availability of the device and network.

SEM supports a variety of events, including key events of a device such as key syslog, trap and time point, or input operations such as Command Line Interface (CLI) commands and Simple Network Management Protocol (SNMP) operations, or threshold excess such as interface statistics, SNMP object values, and system resource statistics. SEM supports many actions, including user command running, log sending, and active device reset.

1.1.2 Basic Concepts

- Event

  An event indicates an event that a user cares about. It is configured by users and attached to a policy. One or multiple events can be configured. Each type of events are detected by a specific detector. When conditions are met, corresponding event is triggered by the event detector.

- Action

  An action indicates a measure taken after an event occurs. It is configured by users and attached to a policy. One or multiple actions can be configured. Each type of actions correspond to a type of action configurations. When an event occurs, the policy corresponding to this event runs configured actions in order. For example, to restart a device after an event occurs, run the **action** *example* **reload** command.

- Policy

  A policy organizes relationships between events and between events and actions. A policy must be submitted after it is configured. When an event corresponding to this policy meets a preset rule, this policy is triggered and runs actions in order.

- Event detector

  An event detector is embedded in specific business and monitors the business based on user configuration. When the business complies with the user configuration, corresponding event is triggered. The event detector sends an event notification to the smart management server.

- Smart management server

A smart management server receives the event notification from the event detector and determines whether to trigger a policy based on the event. After the policy is triggered, the smart management server runs the policy in policy management.

- Policy manager

  A policy manager manages SEM policies and runs actions in the policies that are triggered by the smart management server.

- SEM environmental variable

  It indicates a variable that is used by an action of a policy during SEM running. There are three types of SEM environmental variables:

  - Global variable
  - Local system variable
  - Local user variable

  The words and signs located between the United States Dollar sign ($) and the first non-letter, non-digit, and non-underline character are used as the name of a variable to be replaced. Global variables can be used in all policies. Local system variables and local user variables are local variables and can be used in specific policies only. The local system variables are read-only. The local user variables are defined by the actions in the policies during policy running. Therefore, the local system variables start with the underline (_) to avoid confusion with the local user variables.

- Specific application event of SEM

  SEM supports specific application events in the SEM system. These events are used to trigger a policy during running of another policy. Subsets and types are used to distinguish specific application events. Specific application events of SEM are detected by the specific application event detector based on subsets and types, and are released by their actions in the running policy. When an action in the running policy releases a specific application event of a subset and type, the detected event of the subset and type is triggered.

- SEM naming counter

  SEM supports a naming counter in the SEM system. Change in the SEM naming counter is detected by the counting event detector of SEM. The value of the SEM naming counter is operated by the counter action in the running policy. The SEM naming counter can be used for policy trigger counting and numerical statistics.

1.1.3 Principle

Figure 1-1 SEM Structure

As shown in Figure 1-1, SEM provides different types of event detectors. These events detectors are embedded in different business to monitor the business in real time. The detectors try to match event triggering conditions in user configurations with business running events. If a match is hit, the event detector notifies the smart management server of the event.

On the basis of the event configuration in the policy, the smart management server determines whether to trigger a policy to run. If the event triggering conditions are met, the smart management server runs the policy in the policy manager.

The policy in the policy manager runs preset actions in order based on user configuration.

1. Event Detectors Supported by SEM

SEM supports a variety of event detectors. These event detectors are embedded in different business. They detect the running business, and decide whether any event occurs. SEM supports the following detector types:

- Counting event detector

  The counting event detector detects the naming counter in SEM. When the naming counter exceeds the specified threshold, a counter event is triggered. After the counter event is triggered, the counting event detector stops working temporarily, and resumes until the counter reaches the threshold. The value of the naming counter is changed by the action of the running counter and can thus be accumulated by other policies. When the counter reaches a threshold, a counter event is triggered, which triggers the policy to run. During the running of this policy, the value of the counter is reset to realize circulation.

- Interface counting event detector

  The interface counting event detector detects interface statistics of a device. By periodic collection and statistics, the detector determines whether the statistics of an interface exceeds a threshold. If yes, an interface counting event is triggered. After the interface counting event is triggered, the interface counting event detector stops working temporarily and resumes until the interface counter reaches the recovery threshold or the suspension time exceeds the recovery cycle.

- Syslog event detector

  The syslog event detector detects log information of a device and uses regular expressions to match the log information. If the log information is matched using the regular expressions, a syslog event is triggered.

- Timer event detector

  The timer event detector detects time-related events. There are two types of timer events as follows:

  - Countdown timer event: The timer time is the number of seconds before which a policy takes effect. When the effective time reaches the number of such seconds, the timer event is triggered.
  - Watchdog timer event: The timer time is the number of seconds set before which a policy takes effect. When the effective time reaches the number of such seconds, the timer event is triggered.

- Track event detector

  The track event detector detects tracks. Track refers to status change of a reliable network service (RNS). The track event detector detects change in the status of a tracked entity. When the status of a tracked entity changes, the track event is triggered.

2. Policy Actions Supported by SEM

SEM supports different actions. An action runs after a policy is triggered by an event. The actions include information collection and device/network troubleshooting. SEM supports the following actions:

- Run CLI commands: Run commands set by users.
- Send syslog: Send specified log messages.
- Operate naming counter: Operate the naming counter in SEM.
- Reset device: Reset devices.
- Wait during policy running: Wait for some time during policy running.
- Configure environmental variables: Configure local policy variables.

3. Environmental Variables Supported by SEM

SEM can use environmental variables in policies. SEM supports the following environmental variables:

- Global variable

  The values of global variables can be read-only in a policy.

- Local variable

  Local variables generated during policy running are divided into local system variables and local user variables. The local system variables are created by detectors and used to describe events. Therefore, they are read-only. Local user variables are created by actions in policies, and can be modified during policy running.

  The priority of local variables in a policy are higher than that of global variables. Reading an inexistent local variable or global variable or modifying a read-only local variable may generate an error. Configuring an inexistent local variable will cause the local variable to automatically generate.

4. Management of the SEM Smart Management Server

The SEM smart management server provides management interfaces to allow users to view SEM running information and perform management. Users can view different types of SEM information, including:

- Supported detector types

- Versions of the smart management server and event detectors
- User configuration and submitted policies
- Policies being run
- Policies to be run
- Event history
- Currently defined counter
- Currently defined SEM global variables

1.2 Configuration Task Summary

SEM configuration includes the following tasks:

(1) Configuring SEM Policies

(2) Configuring SEM Variables

(3) (Optional) Configuring Parameters of SEM Policies

1.3 Enabling the SEM Function

1.3.1 Overview

SEM is separately deployed in a device independent from external network management tools. SEM allows customers to customize different types of events and policies so that customers can freely obtain or monitor their desired event information and actions taken for the events.

1.3.2 Restrictions and Guidelines

- The syslog function must be enabled by using the **logging** command before syslog actions are configured.
- The device must be equipped with a normal standby engine before actions are switched to the standby engine.
- Run the **action reload** command with caution. It may cause repeated restart of the system or repeated active/standby switchover.

1.3.3 Configuring SEM Policies

1. Overview

By configuring SEM policies, users can monitor events based on actual needs.

2. Restrictions and Guidelines

- When multiple events are configured for a policy, the events are automatically arranged in the alphabetical order of tags. You are advised to use the naming method based on a sequencing rule, for example, 01_cli, 02_timer, and 03_counter.
- The relationship between events refers to the relationship of the current event with the combination of all other events. Only when the first event is triggered, SEM checks whether to trigger a policy. If users try to configure juxtaposition for other events except the first event, the default juxtaposition is an AND relation. In this case, the juxtaposition of the first event is ignored.

- In either of the following scenarios, the **rollback** command can be used to roll back the policy configuration.
  - A new configured policy has not been submitted.
  - A configured policy has been submitted and registered, but changes to the policy have not been submitted.
- If no action is configured for a submitted policy, the policy can be registered. However, no action is taken when the policy is triggered.
- Generally, multiple actions are configured for a policy. When the policy is triggered, the actions are run in the alphabetical order of the *label* parameter.
- To save the I/O of CLI commands, run the **policy record** command. The **smart manager policy record clean**command does not save the command I/O as well.
- If the policy is being edited but is submitted, run the **list-config** command to display the configuration not submitted in the currently edited policy. The **commit** command is not included in the displayed content. If the policy is submitted, the configuration of the submitted policy is displayed. The **commit** command is included in the displayed content.
- The submittable policies are divided into new policies and edited and registered policies. When a registered but unedited policy is not submitted, a notification will be displayed. If users want to quit the changes to the policy configuration before submitting the changes, run the **rollback** command to roll back the policy configuration.
- During submission, the validity of the policy configuration is checked. If the checking fails, the policy configuration fails to be submitted. In this case, the policy is not registered and remains in the editing status. For example, if no event is configured for the policy, the policy submission checking fails.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an SEM policy and enter the SEM configuration mode.

smart manager applet *applet-name*

No policy is configured by default.

(4) Configure events. Configure at least one of the following tasks.

- Configure a counter monitoring event.

  event tag *event-name* [**correlate** { **andnot** | **and** | **or** }] **counter entry-op** *operator* **entry-val** *entry-value* **exit-op** *operator* **exit-val** *exit-value* **name** *counter-name*

  No counter monitoring event is configured by default.

  You can adjust the input sequence of the **entry-op** *operator*, **entry-val** *entry-value*, **exit-op** *operator*, **exit-val** *exit-value*, and **name** *counter-name* parameters.

- Configure an interface monitoring event.

  event tag *event-name* [**correlate** { **andnot** | **and** | **or** }] **interface name** *interface-type interface-number* **parameter** { **link_up** | **link_down** }

No interface monitoring event is configured by default.

You can adjust the input sequence of the **name** *interface-type interface-number* and **parameter** { **link_down** | **link_up** } parameters.

- Configure a log monitoring event.

  event tag *event-name* [**correlate** { **andnot** | **and** | **or** }] **syslog occurs** *num-occurrences* **pattern** *regular-expression* [**period** *period-value* | **priority** *priority-level* | **skip** { **no** | **yes** }] *

  No log monitoring event is configured by default.

  You can adjust the input sequence of the **occurs** *num-occurrences*, **pattern** *regular-expression*, **period** *period-value*, **priority** *priority-level*, and **skip** { **no** | **yes** } parameters.

- Configure a timer monitoring event.

  event tag *event-name* [**correlate** { **andnot | and | or** }] **timer** { **countdown time** *countdown-timer* | **watchdog time** *watchdog-timer* }

  No timer monitoring event is configured by default.

- Configure a track monitoring event.

  event tag *event-name* [**correlate** { **andnot | and | or** }] **track** [*track-id* | **state** { **down | up** }] *

  No track monitoring event is configured by default.

A complete policy is composed of events and actions. If no event is configured for the policy, an error occurs during policy submission, resulting in submission failure.

You can adjust the input sequence of **tag** *event-name* and **correlate** { **and** | **andnot** | **or** }.

(5) Configure actions. Configure one of the following tasks.

- Run CLI commands of a device.

  action *action-label* **cli command** *cli-string*

- Operate SEM counters.

  action *action-label* **counter name** *counter-name* **op** { **dec | inc | nop | set** } **value** *counter-value*

  You can adjust the input sequence of the **name** *counter-name*, **op** { **dec | inc | nop | set** }, and **value** *counter-value* parameters.

- Terminate a policy script and set the exiting status.

  action *action-label* **exit** [*result*]

- Restart the device.

  action *action-label* **reload**

- Set local variables.

  action *action-label* **set** *variable-name variable-value*

- Carry out logging.

  action *action-label* **syslog** [**priority** *priority-level*] **msg** *syslog-message* [**facility** *mnemonics*]

  You can adjust the input sequence of the **facility** *mnemonics*, **msg** *syslog-messag*, and **priority** *priority-level* parameters.

- Pause a policy script.

  action *action-label* **wait** *wait-time*

No action is configured by default.

(6) Enable the function of recording CLI action output.

policy record [**per-instance** *record-size-per-policy* | **per-policy** *record-size-per-policy*]*

The recording function is not enabled for CLI command action output by default.

(7) (Optional) Configure description.

description *string*

No description is configured for an SEM policy by default.

(8) (Optional) Display current policy configuration.

list-config

(9) (Optional) Roll back configuration.

rollback

(10) Submit configuration.

commit

1.3.4 Configuring SEM Variables

1. Overview

By configuring environmental variables of SEM, users can customize names and values of SEM environmental variables and cite the environmental variables during application of monitoring policies.

2. Restrictions and Guidelines

Local system variables are read-only and cannot be modified. If you try modifying local system variables, an error occurs and the policy stops running. The priority of local variables is higher than that of global variables. If a local variable is named the same as a global variable, the referenced variable is changed to a local variable when a variable is referenced using this name.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the SEM configuration mode.

smart manager applet *applet-name*

(4) Configure local variables of SEM.

action *label* **set** *variable-name variable-value*

No local variable of SEM is configured by default.

(5) Configure a policy action to apply the SEM variable.

action *label* **syslog** [**facility** *mnemonics*] **msg** *msg-text* [**priority** *priority-level*]

For details about how to configure policy actions, see .1.3.3 Procedure.

1.3.5 Configuring Parameters of SEM Policies

1. Restrictions and Guidelines

Modification to policy description takes effect immediately without submission.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Clear CLI records generated during SEM policy running.

smart manager policy record clean { **all** | **policy** *registed-policy-name* }

CLI records generated during SEM policy running are not cleared by default.

(3) Enter the global configuration mode.

configure terminal

(4) Configure upper limits of SEM parameters. Configure at least one of the following tasks.

- Configure the upper limits of SEM detector parameters.

  smart manager detector { **counter** | **interface** | **timer** } **event-number** *detector-number*

  By default, the maximum number of events for the counting detector, the maximum number of events for the interface detector, and the maximum number of events for the timer detector are **256**, respectively.

- Configure the maximum number of SEM global variables.

  smart manager global-variant number *global-variant-number*

  By default, the maximum number of global variables is **512**.

- Configure the upper limits of SEM policy parameters.

  smart manager policy { **action-number** *policy-number* | **config-number** *policy-number* | **event-number** *policy-number* | **register-number** *policy-number* | **trigger-delay-number** *policy-number* }

  By default, the maximum number of actions in a policy is **64**; the maximum numbers of policy detectors and registered policies are **128**, respectively; and the maximum numbers of configured policies and policy delayed triggers are **256**, respectively.

- Configure the upper limits of SEM configuration instance parameters.

  smart manager record { **size-of-instance** *record-number* | **size-of-policy** *record-number* }

  By default, the maximum number of policy instances is **50** and the maximum size of a policy file is **1024** KB.

- Configure the upper limits of SEM scheduler parameters.

  smart manager schdulr { **pending-number** *schdulr-number* | **running-number** *schdulr-number* }

  By default, the maximum number of wait policies of the scheduler and the maximum number of policies run by the scheduler are **128**, respectively.

(5) Configure the application delaytime of an SEM policy.

smart manager policy bootup-delay *delaytime*

The application delaytime of an SEM policy is **60** seconds.

(6) Enter the SEM configuration mode.

smart manager applet *applet-name*

(7) Configure the trigger attributes of a policy.

trigger { **correlate-period** *correlate-period-value* | **correlate-start** *period-start-value* | **delay** *delay-value* | **maxrun** *maxruntime-number* | **occurs-period** *occurs-period-value* | **occurs-value** *occurs-value* }*

No trigger attribute is configured for a policy by default.

1.4 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Table 1-1 SEM Monitoring

Command	Purpose
show smart manager detector [**all** | **counter** | **interface** | **syslog** | **timer** | **track**] [**statistics**]	Displays SEM detector information.
show smart manager environment [**all** | *variable-name*]	Displays global variables.
show smart manager history events	Displays SEM history information.
show smart manager policy all	Displays all policies and policy submission information.
show smart manager policy registered [**class** *class-options* | **event-type** *event-name* | **policy** *policy-name*] * [**statistics**]	Displays information of registered policies.
show smart manager scheduler thread [**detailed**]	Displays the running status of a SEM scheduler by thread pool.
show smart manager version	Display SEM versions.

1.5 Configuration Examples

1.5.1 Configuring an Interface Monitoring Event

1. Requirements

Device A is directly connected to Device B through GigabitEthernet 0/1. Due to the problem of the line or Device B, Device A often receives many consecutive error frames, which affects communication. After GigabitEthernet 0/1 of Device A is shut down and restarted, the problem is solved.

2. Topology

Figure 1-2 Topology of an Interface Monitoring Event

3. Notes

(1) Create a policy.

(2) Configure an interface monitoring event.

(3) Configure CLI command actions.

(4) Submit the policy configuration.

4. Procedure

(1) Create a policy with the name policy_interface on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# smart manager applet policy_interface
```

(2) Configure an event with the name event_1 in the policy_interface policy and set the type to interface. The specific parameter configuration is as follows:

Configure the interface counting type as link_down and set the interface status to down.

Configure the interface name as GigabitEthernet 0/1 to specify the interface to be detected.

```
DeviceA(sem-applet)# event tag event_1 interface name gigabitethernet 0/1 parameter
link_down
```

(3) Configure actions of the policy_interface policy.

Configure action_1 to run the **enable** command to enter the privileged EXEC mode.

```
DeviceA(sem-applet)#action action_1 cli command "enable"
```

Configure action_2 to run the **configure terminal** command to enter the global configuration mode.

```
DeviceA(sem-applet)#action action_2 cli command "configure terminal"
```

Configure action_3 to run the **interface gigabitethernet 0/1** command to enter the interface configuration mode.

```
DeviceA(sem-applet)#action action_3 cli command "interface gigabitethernet 0/1"
```

Configure action_4 to run the **no shutdown** command to set the interface status to up.

```
DeviceA(sem-applet)#action action_4 cli command "no shutdown"
```

(4) Submit the policy.

```
DeviceA(sem-applet)# commit
```

(5) Exit the policy editing status.

```
DeviceA(sem-applet)# exit
```

5. Verification

Run the **show smart manager policy registered** command to display a registered SEM policy.

```
DeviceA# show smart manager policy registered
 No.  Name                                                    Type    Event Type
   1  policy_interface                                          applet  interface
  event_1: interface: parameter link_down name gigabitethernet 0/1
  action action_1 cli command "enable"
  action action_2 cli command "configure terminal"
  action action_3 cli command "interface gigabitethernet 0/1"
  action action_4 cli command "no shutdown"
```

Set gigabitethernet 0/1 to the down status to verify whether the policy takes effect.

```
DeviceA# configure terminal
DeviceA(config)# interfce gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)#shutdown
*Mar 19 18:06:19: %SEM-6-PLCY_TRG: Policy policy_1 id 2 is triggered by event 2, and
the policy instance id is 1.
```

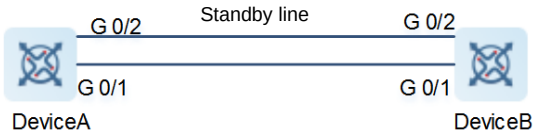
Run the **show smart manager history events detailed** command to display SEM event history.

```
DeviceA# show smart manager history events detailed
No.     Job id   Event Type      Time                   Policy name
1       2       interface       2021-03-22 17:19:38      policy_interface
       Class: default, Policy Type: applet
```

6. Configuration Files

Device configuration file

```
hostname DeviceA
!
smart manager applet policy_interface
 event tag event_1 interface name gigabitethernet 0/1 parameter link_down
 action action_1 cli command "enable"
 action action_2 cli command "configure terminal"
 action action_3 cli command "interface gigabitethernet 0/1"
 action action_4 cli command "no shutdown"
!
end
```



1.5.2 Configuring a Counter Monitoring Event

1. Requirements

Device A is directly connected to Device B through GigabitEthernet 0/1. A low-bandwidth standby line is created between Device A and Device B through GigabitEthernet 0/2. Due to the problem of the line or Device B, Device A often receives many consecutive error frames on GigabitEthernet 0/1, which affects communication. After GigabitEthernet 0/1 of Device A is shut down and restarted, the problem is solved. If the counter monitoring event is triggered more than 50 times, GigabitEthernet 0/1 is shut down permanently and the standby line is used.

2. Topology

Figure 1-3 Topology of a Counter Monitoring Event

3. Notes

(1) Configure an interface monitoring event, including interface counting event, CLI actions, and counter actions.

(2) Configure a counter monitoring event for detecting interface monitoring events.

4. Procedure

(1) Create a policy with the name policy_interface on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# smart manager applet policy_interface
```

(2) Configure an event with the name event_1 in the policy_interface policy and set the type to interface. The specific parameter configuration is as follows:

Configure the interface counting type as link_down and set the interface status to down.

Configure the interface name as GigabitEthernet 0/1 to specify the interface to be detected.

```
DeviceA(sem-applet)# event tag event_1 interface name gigabitethernet 0/1 parameter
link_down
```

(3) Configure actions of the policy_interface policy.

Configure action_1 to run the **enable** command to enter the privileged EXEC mode.

```
DeviceA(sem-applet)#action action_1 cli command "enable"
```

Configure action_2 to run the **configure terminal** command to enter the global configuration mode.

```
DeviceA(sem-applet)#action action_2 cli command "configure terminal"
```

Configure action_3 to run the **interface gigabitethernet 0/1** command to enter the interface configuration mode.

```
DeviceA(sem-applet)#action action_3 cli command "interface gigabitethernet 0/1"
```

Configure action_4 to run the **no shutdown** command to set the interface status to up.

```
DeviceA(sem-applet)#action action_4 cli command "no shutdown"
```

Configure action_5, and increase the value of the naming counter for the SEM policy name of policy_interface by 1.

```
DeviceA(sem-applet)# action action_5 counter name policy_interface op inc value
1
```

(4) Submit the policy.

```
DeviceA(sem-applet)# commit
```

(5) Exit the policy editing status.

```
DeviceA(sem-applet)# exit
```

(6) Create a policy with the name policy_counter.

```
DeviceA(config)# smart manager applet policy_counter
```

(7) Configure an event with the name event_counter in the policy_counter policy and set the event type to SEM counter. The specific parameter configuration is as follows:

Set the counter name to policy_interface, which is the policy name in step (1) .

Set the counter trigger parameter **entry-op ge entry-val** to **6**, indicating that the event is triggered when the value of the SEM counter is equal to or greater than 6.

Set the counter restoration parameter **exit-op gt exit-val** to **5**, indicating that event monitoring is restored immediately when the value of the SEM counter is greater than 5.

```
DeviceA(sem-applet)# event tag event_counter counter name policy_interface
entry-op ge entry-val 6 exit-op gt exit-val 5
```

(8) Configure actions of the policy_counter policy.

Configure action_counter_1 to set the value of the counter policy_interface to 0.

```
DeviceA(sem-applet)# action action_counter_1 counter name policy_interface op set
value 0
```

Configure action_counter_2 to run the **enable** command to enter the privileged EXEC mode.

```
DeviceA(sem-applet)# action action_counter_2 cli command "enable"
```

Configure action_counter_3 to run the **configure terminal** command to enter the global configuration mode.

```
DeviceA(sem-applet)# action action_counter_3 cli command "configure terminal"
```

Configure action_counter_4 to run the **interface gigabitethernet 0/1** command to enter the interface configuration mode.

```
DeviceA(sem-applet)# action action_counter_4 cli command "interface
gigabitethernet 0/1"
```

Configure action_counter_5 to run the **shutdown** command to set the interface status to down permanently.

```
Device A(sem-applet)# action action_counter_5 cli command "shutdown"
```

(9) Submit the policy.

```
Device A(sem-applet)# commit
```

(10) Exit the policy editing status.

```
Device A(sem-applet)# exit
```

5. Verification

Run the **show smart manager policy registered** command to display a registered SEM policy.

```
Device A# show smart manager policy registered
No.  Name                                                Type    Event Type
  1  policy_interface                                      applet  interface
```

```
 event_1: interface: parameter link_down name gigabitethernet 0/1
 action action_1 cli command "enable"
 action action_2 cli command "configure terminal"
 action action_3 cli command "interface gigabitethernet 0/1"
 action action_4 cli command "no shutdown"
  policy record per-instance 50 per-policy 1000

  2  policy_counter                                          applet  counter
 event_counter: counter: name policy_interface entry-op ge entry-val 6 exit-op gt
exit-val 5
 action 1 counter name policy_interface op set value 0
 action action_counter_1 cli command "enable"
 action action_counter_2 cli command "configure terminal"
 action action_counter_3 cli command "interface gigabitethernet 0/1"
 action action_counter_4 cli command "shutdown"
 action action_counter_5 cli command "end"
```

Set gigabitethernet 0/1 to the down status five times. Run the **show smart manager detector** command to displaythe monitoring event information.

```
Device A# show smart manager detector counter statistics
detector counter events number: 1
   event id: 3, event name: event_counter
     counter name: policy_interface
     counter value: 5
     status: enable
     trigger times: 0
     trigger policy times: 0
```

Set gigabitethernet 0/1 to down status again to trigger the policy_counter policy, and run the **show smart manager detector** command to displaythe monitoring event information.

```
Device A# show smart manager detector counter statistics
detector counter events number: 1
   event id: 3, event name: event_counter
     counter name: policy_interface
     counter value: 1
     status: enable
     trigger times: 1
     trigger policy times: 1
```

Run the **show smart manager history events detailed** command to displaySEM event history.

```
Device A# show smart manager history events detailed
No.     Job id   Event Type      Time                  Policy name
1       65      interface       2021-03-24 11:27:30      policy_interface
       Class: default, Policy Type: applet
2       54      counter         2021-03-24 11:27:29      policy_counter
       Class: default, Policy Type: applet
3       64      interface       2021-03-24 11:27:29      policy_interface
       Class: default, Policy Type: applet
```

```
4       63      interface       2021-03-24 11:24:43      policy_interface
        Class: default, Policy Type: applet
5       62      interface       2021-03-24 11:24:41      policy_interface
        Class: default, Policy Type: applet
6       61      interface       2021-03-24 11:24:29      policy_interface
        Class: default, Policy Type: applet
7       60      interface       2021-03-24 11:24:25      policy_interface
        Class: default, Policy Type: applet
8       59      interface       2021-03-24 11:24:07      policy_interface
        Class: default, Policy Type: applet
```

6. Configuration Files

Device A configuration file

```
hostname Device A
!
smart manager applet policy_interface
 event tag event_1 interface name gigabitethernet 0/1 parameter link_down
 action action_1 cli command "enable"
 action action_2 cli command "configure terminal"
 action action_3 cli command "interface gigabitethernet 0/1"
 action action_4 cli command "no shutdown"
 action action_5 counter name policy_interface op inc value 1
!
smart manager applet policy_counter
 event tag event_counter counter name policy_interface entry-op ge entry-val 6 exit-op
gt exit-val 5
 action 1 counter name policy_interface op set value 0
 action action_counter_1 cli command "enable"
 action action_counter_2 cli command "configure terminal"
 action action_counter_3 cli command "interface gigabitethernet 0/1"
 action action_counter_4 cli command "shutdown"
 action action_counter_5 cli command "end"
 commit
!
end
```

1.5.3 Configuring a Timer Monitoring Event

1. Requirements

Device Ais connected to a Trivial File Transfer Protocol (TFTP) server. Device A archives log files to the TFTP server 24 hours later and deletes the original log files.

2. Topology

Figure 1-4 Topology of a Timer Monitoring Event

3. Notes

(1) Configure that Device A and the TFTP server are mutually reachable via routes.

(2) Create a policy.

(3) Configure a timer monitoring event.

(4) Configure actions.

(5) Submit the policy configuration.

4. Procedure

(1) Configure that Device A and the TFTP server are mutually reachable via routes.

```
Device A> enable
Device A# configure terminal
Device A(config)# interface gigabitEthernet 0/1
Device A(config-if-GigabitEthernet 0/1) ip address 172.16.0.1 255.255.255.0
Device A(config-if-GigabitEthernet 0/1) exit
```

(2) Create a policy with the name policy_timer on Device A.

```
Device A# configure terminal
Device A(config)# smart manager applet policy_timer
```

(3) Configure an event with the name event_timer in the policy_timer policy, set the type to one-shot timer, and specify the timer time to 86400s.

```
Device A(sem-applet)#  event tag event_timer timer countdown time 86400
```

(4) Configure actions of the policy_timer policy.

Configure action_timer1 to run the **enable** command to enter the privileged EXEC mode.

```
Device A(sem-applet)# action action_timer1 cli command "enable"
```

Configure action_timer2 to run the **copy** command to archive the log file named syslog_rfc5424_flag.txt to the server with the IP address 172.16.0.2 through TFTP.

```
Device A(sem-applet)# action action_timer2 cli command "copy
flash:syslog_rfc5424_flag.txt tftp://172.16.0.2/syslog_rfc5424_flag.txt"
```

(5) Submit the policy.

```
Device A(sem-applet)# commit
```

(6) Exit the policy editing status.

```
Device A(sem-applet)# exit
```

5. Verification

Run the **ping** command to verify that Device A and the TFTP server are mutually reachable via routes.

```
Device A# ping 172.16.0.2
Sending 5, 100-byte ICMP Echoes to 172.16.0.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/3 ms.
```

Run the **show smart manager policy registered** command to display a registered SEM policy.

```
Device A# show smart manager policy registered
 No.  Name                                                    Type    Event Type
   2  policy_timer                                            applet  timer
  event_timer: timer: countdown time 86400
  action aciton_timer1 cli command "enble"
  action action_timer2 cli command "copy flash:syslog_rfc5424_flag.txt
tftp://172.26.1.33/syslog_rfc5424_flag.txt"
```

Run the **show smart manager history events detailed** command to display SEM event history.

```
Device A# show smart manager history events detailed
No.     Job id   Event Type      Time                  Policy name
1       1       timer          2021-03-22 0:0:10      policy_timer
        Class: default, Policy Type: applet
```

6. Configuration Files

Device A configuration file

```
hostname Device A
!
smart manager applet policy_2
!
smart manager applet policy_timer
 event tag event_timer: timer: countdown time 86400
 action aciton_timer1 cli command "enble"
 action action_timer2 cli command "copy flash:syslog_rfc5424_flag.txt
tftp://172.26.1.33/syslog_rfc5424_flag.txt"
 commit
!
end
```

1.5.4 Configuring a Syslog Monitoring Event

1. Requirements

Though the interface status is down, Device A sends logs. When the logs are detected, the interface status must be restored to up.

2. Topology

Figure 1-5 Topology of a Syslog Monitoring Event

3. Notes

(1) Create a policy.

(2) Configure a syslog monitoring event.

(3) Configure actions.

(4) Configure policytrigger parameters.

(5) Submitthe policy configuration.

4. Procedure

(1) Create a policy with the name policy_syslog on Device A.

```
Device> enable
Device A# configure terminal
Device A(config)# smart manager applet policy_syslog
```

(2) Configure an event with the name event_syslog1 in the policy_syslog policy, set the type to syslog, and put logs with the content "LINEPROTO-5-UPDOWN" within the detection scope.

```
Device A(sem-applet)# event tag event_1 syslog pattern "LINEPROTO-5-UPDOWN"
priority critical
```

(3) Configure an event with the name event_syslog2 in the policy_syslog policy, set the type to syslog, and put logs with the content "GigabitEthernet 0/1" within the detection scope.

```
Device A(sem-applet)# event tag event_syslog2 syslog pattern "GigabitEthernet 0/1"
```

(4) Configure an event with the name event_syslog3 in the policy_syslog policy, set the type to syslog, and put logs with the content "changed state to down" within the detection scope. The conditional relationship between event_syslog3 and event_syslog1/event_syslog2 is an AND relation.

```
Device A(sem-applet)# event correlate and tag event_syslog3 syslog pattern "changed
state to down"
```

(5) Configure actions of the policy_syslog policy.

Configure action_syslog_1 to run the **enable** command to enter the privileged EXEC mode.

```
Device A(sem-applet)# action action_syslog_1 cli command "enable"
```

Configure action_syslog_2 to run the **configure terminal** command to enter the global configuration mode.

```
Device A(sem-applet)# action action_syslog_2 cli command "configure terminal"
```

Configure action_syslog_3 to run the **interface gigabitethernet 0/1** command to enter the interface configuration mode.

```
Device A(sem-applet)# action action_syslog_3 cli command "interface
gigabitethernet 0/1"
```

Configure action_syslog_4 to wait for five seconds.

```
Device A(sem-applet)# action action_syslog_4 wait 5
```

Configure action_syslog_5 to run the **no shutdown** command to set the interface status to up.

```
Device A(sem-applet)# action action_syslog_5 cli command "no shutdown"
```

Configure action_syslog_6 to run the **end** command to exit the privileged EXEC mode.

```
Device A(sem-applet)# action action_syslog_6 cli command "end"
```

Configure action_syslog_7 to run the **show interfaces status | include UP** command to display the interface status.

```
Device A(sem-applet)# action action_syslog_7 cli command "show interfaces status
| include UP"
```

(6) Submit the policy.

```
Device A(sem-applet)# commit
```

(7) Exit the policy editing status.

```
Device A(sem-applet)# exit
```

5. Verification

Run the **show smart manager policy registered** command to display a registered SEM policy.

```
Device A# show smart manager policy registered
 No.  Name                                                Type    Event Type
  1  policy_syslog                                        applet  syslog
  event_syslog1: syslog: pattern "LINEPROTO-5-UPDOWN"
  event_syslog2: syslog: pattern "gigabitethernet 0/1"
  event_syslog3: syslog: pattern "changed state to down"
  action action_syslog_1 cli command "enable"
  action action_syslog_2 cli command "configure terminal"
  action action_syslog_3 cli command "interface gigabitethernet 0/1"
  action action_syslog_4 wait 5
  action action_syslog_5 cli command "no shutdown"
  action action_syslog_6 cli command "end"
  action action_syslog_7 cli command "show interfaces status | include UP"
```

Set gigabitethernet 0/1 to the down status to verify whether the policy takes effect.

```
Device A# configure terminal
Device A(config)# interfce gigabitethernet 0/1
Device A(config-if-GigabitEthernet 0/1)#shutdown
*Mar 23 11:02:03: %LINK-5-CHANGED: Interface gigabitethernet 0/1, changed state to
administratively down.
*Mar 23 11:02:03: %LINEPROTO-5-UPDOWN: Line protocol on Interface gigabitethernet 0/1,
changed state to down.
*Mar 23 11:02:03: %SEM-6-PLCY_TRG: Policy policy_syslog id 7 is triggered by event
10, and the policy instance id is 12.
```

```
*Mar 23 11:02:11: %LINK-3-UPDOWN: Interface gigabitethernet 0/1, changed state to up.
*Mar 23 11:02:11: %LINEPROTO-5-UPDOWN: Line protocol on Interface gigabitethernet 0/1,
changed state to up.
```

Run the **show smart manager history events detailed** command to display SEM event history.

```
Device A# show smart manager history events detailed
No.     Job id   Event Type      Time                  Policy name
1       10      syslog         2021-03-23 11:02:03      policy_syslog
       Class: default, Policy Type: applet
```

6. Configuration Files

```
hostname Device A
!
smart manager applet policy_syslog
 event tag event_syslog1 syslog pattern "LINEPROTO-5-UPDOWN"

end
```

1.5.5 Configuring a Track Monitoring Event

1. Requirements

To facilitate management, a log is printed when the status of a specified or random tracked entity of Device A changes.

2. Topology

Figure 1-6 Topology of a Track Monitoring Event

3. Notes

(1) Create a policy.

(2) Configure a track monitoring event.

(3) Configure actions.

(4) Submit the policy configuration.

4. Procedure

(1) Create a policy with the name policy_track on Device A.

```
Device A> enable
Device A# configure terminal
Device A(config)# smart manager applet policy_track
```

(2) Configure an event with the name event_track in the policy_track policy, set the type to track, and detect all tracked objects in the down status.

```
Device A(sem-applet)# event tag event_track track state down
```

(3) Configure actions of the policy_track policy.

Configure action_track1 to print "track obj down".

```
Device A(sem-applet)# action action_tarck1 syslog msg "track obj down."
```

Configure action_track2 to run the **enable** command to enter the privileged EXEC mode.

```
Device A(sem-applet)# action action_track2 cli command "enable"
```

Configure action_track3 to run the **configure terminal** command to enter the global configuration mode.

```
Device A(sem-applet)# action action_track3 cli command "configure terminal"
```

Configure action_track4 to run the **interface gigabitethernet 0/1** command to enter the interface configuration mode.

```
Device A(sem-applet)# action action_track4 cli command "interface gigabitethernet
0/1"
```

Configure action_track5 to run the **no shutdown** command to set the interface status to up.

```
Device A(sem-applet)# action action_track5 cli command "no shutdown"
```

(4) Submit the policy.

```
Device A(sem-applet)# commit
```

(5) Exit the policy editing status.

```
Device A(sem-applet)# exit
```

(6) Configure a track monitoring event.

```
Device A(config)# track 1 Interface gigabitethernet 0/1 line-protocol
Device A(config-track)# delay down 10
```

5. Verification

Run the **show smart manager policy registered** command to display a registered SEM policy.

```
Device A# show smart manager policy registered
No.  Name                                                Type    Event Type
  1  policy_track                                         applet  track
  event_track: track: all state down
  action action_track1 syslog msg "track obj down"
  action action_track2 cli command "enable"
  action action_track3 cli command "configure terminal"
  action action_track4 cli command "interface gigabitethernet 0/1"
```

```
  action action_track5 cli command "no shutdown"
```

Set gigabitethernet 0/1 to the down status to verify whether the policy takes effect.

```
Device A# configure terminal
Device A(config)# interface gigabitEthernet 0/1
Device A(config-if-GigabitEthernet 0/1)# shutdown
Device A(config-if-GigabitEthernet 0/1)# end
*Mar 22 17:21:59: %SEM-6-PLCY_TRG: Policy track id 4 is triggered by event 4, and the
policy instance id is 8.
*Mar 22 17:21:59: %SEM-6-COMM: track: track obj down
*Mar 22 17:22:01: %LINK-3-UPDOWN: Interface gigabitethernet 0/1, changed state to up.
*Mar 22 17:22:01: %LINEPROTO-5-UPDOWN: Line protocol on Interface gigabitethernet 0/1,
changed state to up.
```

Run the **show smart manager history events detailed** command to display SEM event history.

```
Device A# show smart manager history events detailed
No.     Job id   Event Type      Time                  Policy name
1       4       track          2021-03-22 17:21:59      track
        Class: default, Policy Type: applet
```

6. Configuration Files

Device A configuration file

```
hostname Device A
!
smart manager applet policy_track
 event tag event_track track state down
action action_track1 syslog msg "track obj down"
 action action_track2 cli command "enable"
 action action_track3 cli command "configure terminal"
 action action_track4 cli command "interface gigabitethernet 0/1"
 action action_track5 cli command "no shutdown"
commit
!
track 1 Interface gigabitethernet 0/1 line-protocol
 delay down 10
!
end
```

1.8.3 Configuring Basic Functions of ERPSAN 18

1 Configuring SPAN

1.1 Introduction

1.1.1 Overview

With the development of network technologies, the demand for high network availability is increasing. When exceptions occur in a network, the network node or device port needs to be analyzed for data traffic so that the network can return to normal fast. Meanwhile, the device traffic forwarding should not be affected.

The mirroring function copies messages from a specified port to another port connected to a network monitoring device. The device analyzes data traffic of a suspicious network node or device port, without affecting the traffic forwarding of the monitored device. Mirroring is mainly applied to network monitoring and troubleshooting to monitor network information for security and troubleshoot network failures.

1.1.2 Basic Concepts

1. Source Port

A source port is also called a monitored port. The data traffic of a source port is copied to a destination port for network analysis or troubleshooting.

2. Destination Port

A destination port is also called a monitoring port. A destination port is connected to a device to forward packets received from a source port to a monitoring device.

3. Session

A session is a logical concept, which consists of a source port and a destination port.

4. SPAN

Switch port analyzer (SPAN) is also called local port mirroring or local mirroring. In local port mirroring, the source port and the destination port in a mirroring session are in the same device.

5. RSPAN

Remote switch port analyzer (RSPAN) is an extension of SPAN. In RSPAN, the source port and the destination port in a mirroring session are in different devices.

6. ERSPAN

Encapsulated remote switch port analyzer (ERSPAN) is an extension of RSPAN. ERSPAN allows monitoring multiple switches across switched or routing networks.

7. RSPAN VLAN

An RSPAN VLAN is a special VLAN that only transmits mirrored packets to a destination device.

8. Output Port

An output port on a source device sends mirrored packets to a port on an intermediate device or a destination device.

9. Source Device

A source device is a role in RSPAN and has a source port. A source device copies the packets from a source port and outputs them through an output port on the source device to an intermediate device or destination device.

10. Destination Device

A destination device is a role in RSPAN and has a destination port. A destination device forwards the mirrored packets received from an intermediate or source device to a monitoring device through a destination port.

11. Intermediate Device

An intermediate device is a role in RSPAN and resides between a source device and a destination device. An intermediate device forwards mirrored packets to another intermediate device or a destination device. If a source device is directly connected to a destination device, there is no intermediate device.

12. SPAN Data Streams

SPAN data streams refer to mirrored packets. A SPAN session contains data streams in three directions:

- Input data streams

  All packets received by a source port are copied to a destination port. Users can monitor input packets of one or more source ports in a SPAN session.

- Output data streams

  All packets transmitted by a source port are copied to a destination port. Users can monitor output packets of one or more source ports in a SPAN session.

- Bidirectional data streams

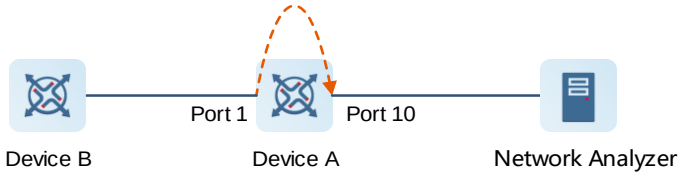
  Bidirectional data streams include input data streams and output data streams. In a SPAN session, users can monitor data streams of one or more source ports in the input and output directions.

1.1.3 Principles

1. SPAN Principles

As shown in Figure 1-1, all packets on port 1 are copied to port 10 through configuring SPAN on Device A. The network analyzer connected to port 10 receives all packets that pass through port 1 even if the network analyzer is not directly connected to port 1. Therefore the network analyzer can monitor the data streams that pass through port 1. The specific process is as follows:

(1) The device identifies and marks the incoming and outgoing packets of the source port 1.



(2) The device searches for the SPAN session to which port 1 belongs.

(3) The device searches for the destination port 10 corresponding to the SPAN session.

(4) The device copies both incoming and outgoing packets of port 1 and sends them to port 10.

(5) Port 10 sends the copied packets to the network analyzer.

Figure 1-1 SPAN Principles

2. RSPAN Working Process

As shown in Figure 1-2, an RSPAN VLAN is created for the source device, intermediate device, and destination device. All ports involved in an RSPAN session must be added to the RSPAN VLAN. Mirrored packets are broadcast in the RSPAN VLAN so that they are forwarded from the source device to the destination device. Then the destination device forwards the mirrored packets to the network analyzer. The following is the specific working process.

(1) Add all ports involved in an RSPAN session of a source device, intermediate device, and destination device to an RSPAN VLAN.

(2) The source device adds the VLAN ID of the RSPAN VLAN to the mirrored packets of the source port. Then the device copies the encapsulated packets to the output port.

Note

As shown in Figure 1-3, for 1:N port mirroring, enable the loopback function on the output port of the source device to make it a loopback port. Add the loopback port (port 1) and the interface of the intermediate device (port 2) to the RSPAN VLAN. The source port adds the VLAN ID of the RSPAN VLAN to the mirrored packets and copies the packets to the loopback port. The loopback port belongs to the RSPAN VLAN and this VLAN is forbidden to learn any MAC address. Therefore the reflected packets are broadcast in the RSPAN VLAN so that all ports in this VLAN can receive the mirrored packets to achieve 1:N port mirroring .

(3) The output port sends the mirrored packets to a port on an intermediate device or a destination device.

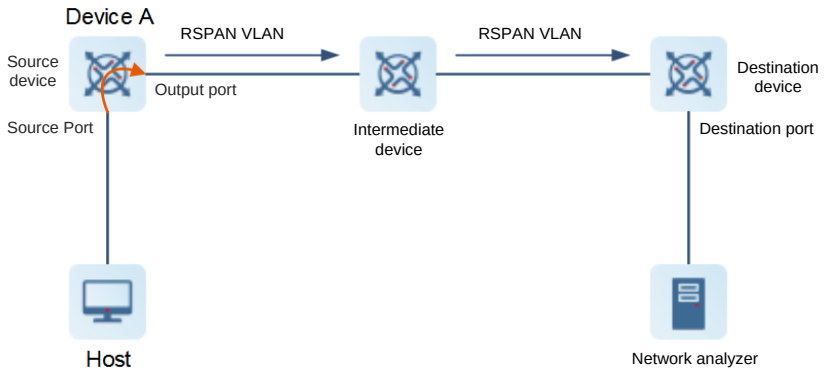
(4) The intermediate device broadcasts mirrored packets in the RSPAN VLAN to transparently transmit the packets to another intermediate device or a destination device.

Note

If a source device is directly connected to a destination device, there is no intermediate device.

(5) After receiving the packets, the destination device determines whether they are mirrored packets through the VLAN ID. If the VLAN ID carried by the packets is the same as the RSPAN VLAN ID, the device regards the packet as a mirrored packet and forwards the packet to the network analyzer through the destination port.

Figure 1-2 Principles of RSPAN



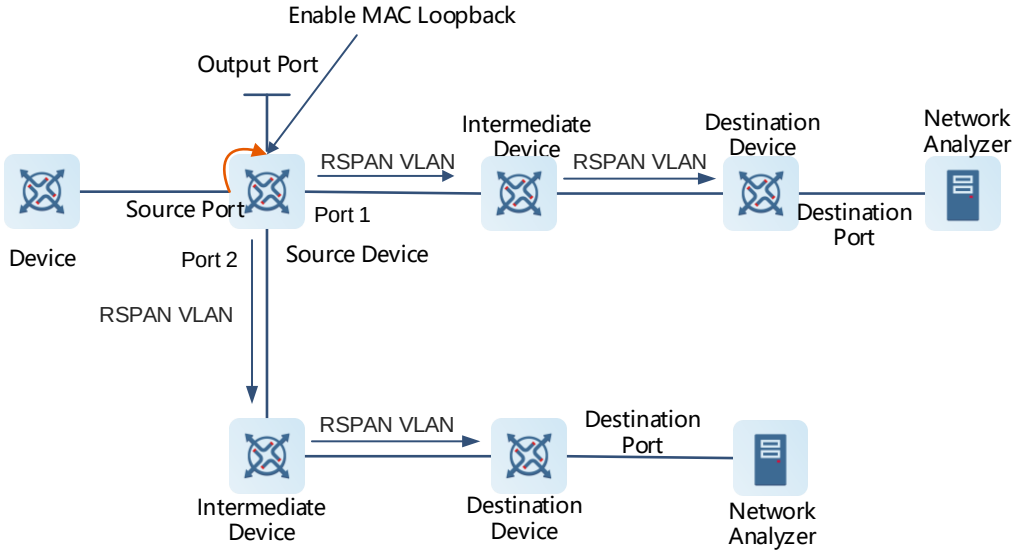


Figure 1-3 Principles of 1:N Port Mirroring Based on RSPAN

3. ERSPAN Working Process

In RSPAN, mirrored packets can be transmitted only at Layer 2 and cannot transmitted across routing networks. However, ERSPAN can encapsulate mirrored packets into IP packets through a generic routing encapsulation (GRE) tunnel and forward the mirrored packets to the destination port of the RSPAN device, thus transmitting mirrored packets across routing networks.

Figure 1-4 shows the specific working process of ERSPAN.

(1) The source device copies and encapsulates the incoming packets of the source port.

- Encapsulate the source and destination IP addresses of the GRE packet.
- Set the TTL and DSCP of the GRE packet.

Note

Figure 1-5 shows the header format of a packet encapsulated in ERSPAN.

(2) The source port forwards the mirrored packets to the destination device through the GRE tunnel.

(3) The destination device decapsulates GRE packets to remove the header encapsulated by ERSPAN, and forwards the packets to the destination port.

(4) The destination port forwards the mirrored packets to the network analyzer.

Caution

The IP packets after GRE encapsulation must be normally routed to the destination device in the network. Therefore, the destination IP address is generally the next-hop IP address of the route. That is, the output port of the source device is the next-hop egress of the L3 path where the destination IP address to be encapsulated is located. The output port must be reachable, and can be an SVI, Layer 3 link aggregation, or Layer 3 Ethernet interface.

Figure 1-4 ERSPAN Principles

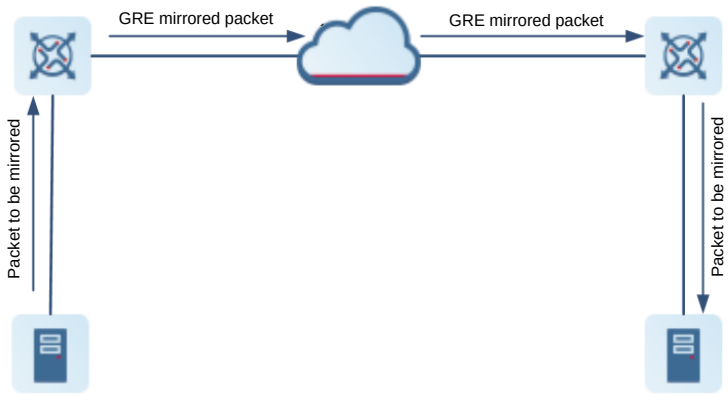

Figure 1-5 Format of an Encapsulated Packet in ERSPAN

MAC_HEADER(14/18B)	IP_HEADER(20B)	GRE_HEADER(48B)	L2_Mirrored_Packet(untagged)

4. Stream Mirroring Principles

Stream mirroring is to associate the source port with an ACL on the basis of SPAN, and filter packets based on the ACL rules, so as to mirror only specified packets. Only the packets matching the permit ACE in the ACL on the source port can be mirrored to the destination port. A source port can be associated with only one ACL.

1.2 Restrictions and Guidelines

- A source port has the following features:
  - The source port and the output port cannot be the same one.
  - The source port can be a Layer 2 Ethernet interface, Layer 3 Ethernet interface, Layer 2 link aggregation or Layer 3 link aggregation.
  - Data streams on multiple source ports on the source device can be mirrored to a specified output port.
  - When the source port is a Layer 3 link aggregation or Ethernet interface, the port monitors both Layer 2

and Layer 3 packets.

- Upon bidirectional monitoring of multiple ports, a packet is received from one port and output from another port, and monitoring is effective as long as one packet is monitored among these ports.
- When a port is STP enabled and in the block state, the incoming and outgoing packets of the port can also be monitored.
- The source port and the destination port can belong to the same VLAN or different VLANs.

  If a source port is added to a link aggregation, the source port exits the SPAN session. The source port acts as only a member port of the link aggregation.

- A destination port has the following features:
  - A destination port cannot be used as a source port simultaneously.
  - The destination port can be an Ethernet interface, link aggregation or an output group.
  - The SPAN destination port is used for the Spanning Tree Protocol (STP) calculation.
- A source port cannot be added to an output group.
- A configured session ID cannot be used as the ID of another SPAN session.
- By default, the switch function is disabled on the SPAN destination port, and the destination port only receives mirrored packets and does not forward data. If the destination port needs to forward data, the switch function must be enabled; otherwise, packets passing through this port will be discarded.
- Due to other reasons (such as port security), incoming packets of a source port may be discarded, but it does not affect the SPAN function, and these packets are still mirrored to the destination port. Due to other reasons, packets sent from other ports to a source port may be discarded, and these packets are not sent to the destination port.
- If the format of a packet output from the source port is changed, for example, the source MAC, destination MAC, VLAN ID, and TTL of the packet change, the format of the packet mirrored to the destination port will change as well.
- Configure ACLs on the source port to mirror specified packets.
- The device does not support secondary mirroring for the destination port. For example, if the source port of mirroring session 2 is configured as the destination port of mirroring session 1, session 2 cannot mirror mirroring packets of the source port.
- If the source and destination ports of mirroring are both configured as LACP aggregate ports, the LACP protocol oscillates repeatedly on the destination port and its peer port.

1.3 Configuration Task Summary

SPAN configuration includes the following tasks:

- Configuring SPAN
- Configuring RSPAN
- Configuring ERSPAN
  - a Configuring Basic Functions of ERSPAN
  - b (Optional) Configuring ERSPAN Attributes

1.4 Configuring SPAN

1.4.1 Overview

SPAN copies packets of the designated port or designated VLAN to the port connected to the data monitoring device, so that you can use the data monitoring device to analyze these copied packets for network monitoring and troubleshooting.

1.4.2 Restrictions and Guidelines

- When configuring the SPAN source port, you can specify the following items as the data source simultaneously: some VLANs, an interface, and specified streams on the specified port.
- When configuring the SPAN source port, if you specify a VLAN as the data source, you cannot specify an interface or streams on the specified port as the data source.
- When configuring the SPAN source port, if you specify some VLANs as the data source, you must also specify the source port.
- If you change the VLAN configuration on the source port or destination port, the configuration takes effect immediately.
- If you disable the source or destination port, the SPAN function does not take effect.
- If you configure a VLAN or a VLAN list as the SPAN source, ensure that the destination port has sufficient bandwidth for receiving mirrored data of the entire VLAN (or VLAN list).

If you add or delete a VLAN source port to or from an effective SPAN session, you need to re-apply the entire SPAN session. Therefore, a few existing mirrored packets may be lost.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a SPAN source port. Configure at least one of the following tasks.

- Specify an interface as the data source of SPAN.

  monitor session *session-number* **source interface** *interface-type interface-number* [**both** | **rx** [**acl** *acl-name* | **acl** *acl-number*] | **tx**]

- (Optional) Configure some VLANs as the data source of SPAN.

  monitor session *session-number* **filter vlan** *vlan-id-list* **rx**

  This command must be configured together with the **monitor session source interface** command. When this command and the **monitor session source interface acl** command are both configured, only the configuration of the **monitor session source interface acl** command takes effect.

- Specify one or more VLANs as the data source of SPAN.

  monitor session *session-number* **source vlan** *vlan-id-list* **rx**

  This function is mutually exclusive with the preceding two configurations.

By default, no source port is configured for a SPAN session.

(4) Configure a destination port for the local SPAN session.

monitor session *session-number* **destination interface** *interface-type interface-number* [**switch**]

By default, no SPAN destination port is configured.

1.5 Configuring RSPAN

1.5.1 Overview

A device enabled with RSPAN can monitor packets across networks for network monitoring and troubleshooting.

1.5.2 Restrictions and Guidelines

- All ports involved in RSPAN must be added to a remote VLAN.
- An RSPAN VLAN must be configured on each device and their VLAN IDs must be consistent. All ports involved in a session must be added to the VLAN. Do not add common ports to an RSPAN VLAN.
- Do not configure a port that is connected to an intermediate device or a destination device as an RSPAN source port. Otherwise, traffic on the network may be in chaos.
- To achieve 1:N port mirroring, configure a port on a source device as a loopback port. The loopback function on the output port will transmit mirrored packets to multiple intermediate devices or destination devices.
- The loopback port cannot serve as a normal port to forward packets. You are advised to configure a port in Down state as the loopback port, and not to add other configurations for this port.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the VLAN configuration mode.

vlan *vlan-id*

(4) Configure a remote VLAN.

remote-span

By default, no remote VLAN is configured.

(5) Exit the VLAN configuration mode.

exit

(6) Configure an RSPAN source device.

monitor session *session-number* **remote-source**

By default, no source device is configured for an RSPAN session.

(7) (Optional) Configure the MAC loopback function on the source device.

a Enter the Layer 2 Ethernet interface configuration mode or Layer 3 Ethernet interface configuration mode.

interface *interface-type interface-number*

b Enable the MAC loopback function of the interface.

mac-loopback

By default, MAC loopback is disabled for an interface.

(8) Exit the Layer 2 Ethernet interface configuration mode or Layer 3 Ethernet interface configuration mode.

exit

(9) Configure a SPAN source port. Configure at least one of the following tasks.

- Specify an interface as the data source of SPAN.

  monitor session *session-number* **source interface** *interface-type interface-number* [**both** | **rx** [**acl** *acl-name* | **acl** *acl-number*] | **tx**]

- (Optional) Configure some VLANs as the data source of SPAN.

  monitor session *session-number* **filter vlan** *vlan-id-list* **rx**

  This command must be configured together with the **monitor session source interface** command. When this command and the **monitor session source interface acl** command are both configured, only the configuration of the **monitor session source interface acl** command takes effect.

- Specify one or more VLANs as the data source of SPAN.

  monitor session *session-number* **source vlan** *vlan-id-list* **rx**

  This function is mutually exclusive with the preceding two configurations.

By default, no source port on the source device is configured for an RSPAN session.

(10) Configure an RSPAN destination device.

monitor session *session-number* **remote-destination**

By default, no destination device is configured for an RSPAN session.

(11) Configure an output port on the source device or a destination port on the destination device.

monitor session *session-number* **destination remote vlan** *remote-vlan-id* **interface** *interface-type interface-number* [**switch**]

By default, no output port on the RSPAN source device or no destination port on the RSPAN destination device is configured.

1.6 Configuring ERSPAN

1.6.1 Restrictions and Guidelines

When you add the source interface of an ERSPAN session to a flow egress group, the interface will exit the session, and an interface exit notification will be displayed.

1.6.2 Configuration Tasks

ERSPAN configuration includes the following tasks:

(1) Configuring Basic Functions of ERSPAN

(2) (Optional) Configuring ERSPAN Attributes

1.6.3 Configuring Basic Functions of ERSPAN

1. Overview

After ERSPAN is configured, a network analyzer can be used to monitor data streams of network devices. Devices can normally exchange data with each other.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an ERSPAN session.

monitor session *session-number* **erspan-source**

No ERSPAN session is configured by default.

(4) Specify an interface as the data source of ERSPAN.

source interface *interface-type interface-number* [**both** | **rx** [**acl** { *acl-name* | *acl-number* }] | **tx**]

By default, no source port is configured. If a source port is configured, the default mirroring direction is bidirectional.

When a sub-interface is configured as the source port, mirroring is supported only in the inbound direction.

(5) Configure the source IP address for encapsulation.

original ip address *ipv4-address*

By default, no source IP address is configured for GRE encapsulation.

(6) Configure the destination IP address for encapsulation.

destination ip address *ipv4-address*

By default, no encapsulation type or destination IP address is configured.

1.6.4 Configuring ERSPAN Attributes

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an ERSPAN session.

monitor session *session-number* **erspan-source**

(4) Configure attributes of an ERSPAN session. The following configurations are optional. Select at least one of the configurations as actually needed.

(5) (Optional) Configure the TTL of the encapsulated IP packet.

ip ttl *ttl-value*

The default TTL of the encapsulated IP packet is **64**.

(6) (Optional) Configure the DSCP of the encapsulated IP packet.

ip dscp *dscp-value*

The default DSCP of the encapsulated IP packet is **0**.

(7) (Optional) Associate ERSPAN with a VRF.

vrf *vrf-name*

By default, no VRF is associated with ERSPAN.

When this function is configured, the VRF must be already configured.

(8) (Optional) Shut down the ERSPAN session.

shutdown

The session is enabled by default.

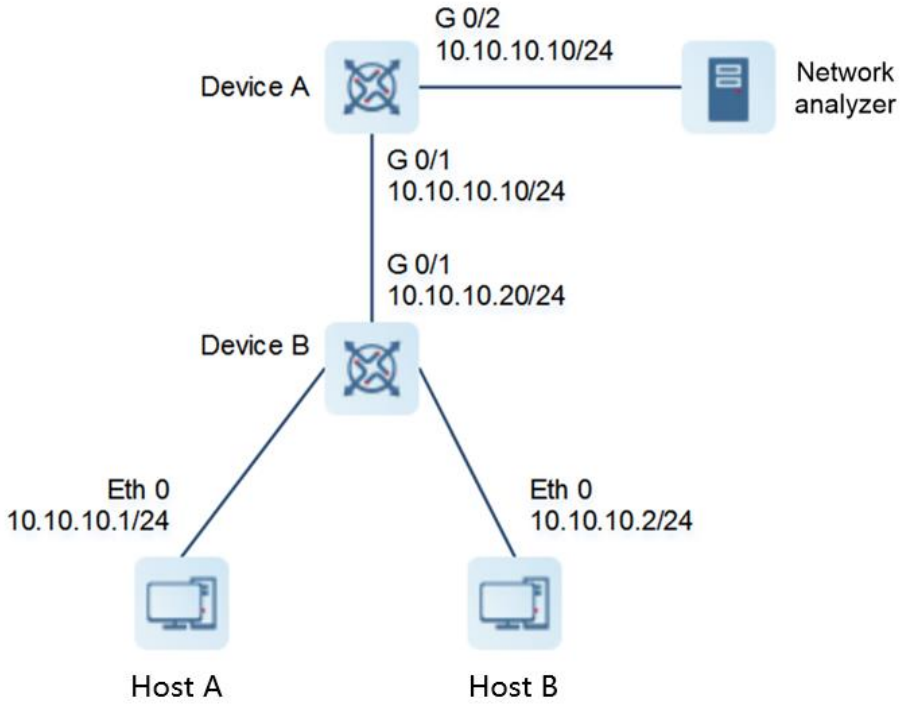
1.7 Monitoring

Run the **show** command to check the configuration.

Table 1-1 Monitoring

Command	Purpose
show monitor [**session** *session-number*]	Displays the SPAN session information.
show span-info information { **acl-ref** | **client** | **data-sync** | **global-info** | **memory** }	Displays debugging information of the SPAN module.

1.8 Configuration Examples



1.8.1 Configuring SPAN

1. Requirements

As shown in Figure 1-6, after appropriate configuration, the network analyzer can monitor all data streams forwarded by device A to device B and specified data streams of device B (for example, data streams from Host A and Host B).

2. Topology

Figure 1-6 SPAN Topology

3. Notes

- Add GigabitEthernet 0/1 and GigabitEthernet 0/2 of Device A to VLAN 1. Create SVI 1 and set the address of SVI 1 to 10.10.10.10/24.
- Add GigabitEthernet 0/1 of Device B to VLAN 1. Create SVI 1 and set the address of SVI 1 to 10.10.10.20/24.
- Set the IP addresses of Host A and Host B to 10.10.10.1/24 and 10.10.10.2/24, respectively.
- Configure SPAN for Device A and configure GigabitEthernet 0/1 and GigabitEthernet 0/2 as the source port and destination port of SPAN respectively. Monitor all data streams forwarded by Device A to Device B and specified data streams of Device B.

4. Procedure

GigabitEthernet 0/1 and GigabitEthernet 0/2 of Device A belong to VLAN 1 by default.

On Device A, create SVI 1 and set the address of SVI 1 to 10.10.10.10/24.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface vlan 1
DeviceA(config-if-VLAN 1)# ip address 10.10.10.10 255.255.255.0
DeviceA(config-if-VLAN 1)# exit
```

Add GigabitEthernet 0/1 of Device B to VLAN 1. The configuration details are not mentioned here.

On Device B, create SVI 1 and set the address of SVI 1 to 10.10.10.20/24.

```
DeviceB# configure terminal
```

```
DeviceB(config)# vlan 1
Device B (config)# interface vlan 1
DeviceB(config-if-VLAN 1)# ip address 10.10.10.20 255.255.255.0
DeviceB(config-if-VLAN 1)# exit
```

On Device A, configure an ACL to match packets with the source address 10.10.10.20.

```
DeviceA(config)# access-list 100 permit ip host 10.10.10.20 any
```

On Device A, configure GigabitEthernet 0/1 as the SPAN source port, and monitor all data streams forwarded by device A to Device B and specified data streams of Device B.

```
DeviceA(config)# monitor session 1 source interface gigabitethernet 0/1 tx
DeviceA(config)# monitor session 1 source interface gigabitethernet 0/1 rx acl
100
```

On Device A, configure GigabitEthernet 0/2 on Device A as the SPAN destination port.

```
DeviceA(config)# monitor session 1 destination interface gigabitethernet 0/2
```

5. Verification

Run the **show monitor** command to check whether the SPAN configuration is correct.

```
DeviceA# show monitor
sess-num: 1
span-type: LOCAL_SPAN
src-intf:
  GigabitEthernet 0/1        frame-type TX Only
src-intf:
  GigabitEthernet 0/1        frame-type RX Only
rx acl id 100
dest-intf:
  GigabitEthernet 0/2
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ip access-list extended 100
 10 permit ip host 10.10.10.20 any
!
interface VLAN 1
 ip address 10.10.10.10 255.255.255.0
!
monitor session 1 destination interface GigabitEthernet 0/2
monitor session 1 source interface GigabitEthernet 0/1 tx
monitor session 1 source interface GigabitEthernet 0/1 rx acl 100
!
end
```

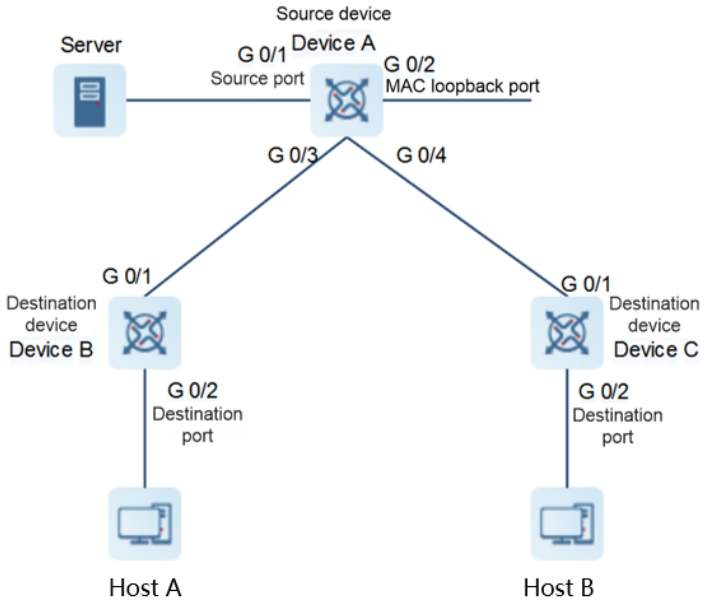
- Device B configuration file

```
hostname DeviceB
```

```
!
interface VLAN 1
 ip address 10.10.10.20 255.255.255.0
!
end
```

1.8.2 Configuring RSPAN to Realize One-to-Many SPAN

Caution



When deploying One-to-Many SPAN, you must run the **switchport trunk allowed vlan remove** *vlan-list* command to remove the broadcast VLANs from a trunk interface on each SPAN device. Otherwise, the trunk interface may be fully occupied by the broadcast traffic, causing service interruption.

1. Requirements

As shown in Figure 1-7, the RSPAN function enables the network analyzer to monitor bidirectional data streams of the source device A from the destination devices B and C. The devices can normally exchange data with each other.

2. Topology

Figure 1-7 Topology of RSPAN Used to Realize One-to-Many SPAN

3. Notes

- Configure device A as the source device. Configure an RSPAN VLAN. Configure GigabitEthernet 0/1 as the source port, GigabitEthernet 0/3 and GigabitEthernet 0/4 connected to the destination device as the output ports, and GigabitEthernet 0/2 as the MAC loopback port to realize the reflection function of 1:N SPAN. Configure the switching function of the output port.
- Configure devices B and C as the destination devices. Configure an RSPAN VLAN. Configure

GigabitEthernet 0/1 connected to the source device as the source port. Configure a trunk port. Configure GigabitEthernet 0/2 connected to the network analyzer as the SPAN destination port, and configure the switching function for the SPAN destination port.

4. Procedure

(1) Configure device A as the source device.

a. Configure a remote VLAN.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan 7
DeviceA(config-vlan)# remote-span
DeviceA(config-vlan)# exit
```

b. Configure a source port.

```
DeviceA(config)# monitor session 1 remote-source
DeviceA(config)# monitor session 1 source interface gigabitethernet 0/1 both
```

c. Configure an output port.

```
DeviceA(config)# monitor session 1 destination remote vlan 7 interface
gigabitethernet 0/2 switch
```

d. Configure a loopback port.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if)# mac-loopback
DeviceA(config-if)# switchport access vlan 7
DeviceA(config-if)# exit
DeviceA(config)# interface range gigabitethernet 0/3-4
DeviceA(config-if-range)# switchport mode trunk
```

(2) Configure device B as the destination device.

a. Configure a remote VLAN.

```
Device B> enable
DeviceB# configure
DeviceB(config)# vlan 7
DeviceB(config-vlan)# remote-span
DeviceB(config-vlan)# exit
```

b. Configure a destination port.

```
DeviceB(config)# monitor session 1 remote-destination
DeviceB(config)# monitor session 1 destination remote vlan 7 interface
gigabitethernet 0/2 switch
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if)# switchport mode trunk
```

(3) Configure device C as the destination device.

a. Configure a remote VLAN.

```
DeviceC> enable
DeviceC# configure
DeviceC(config)# vlan 7
```

```
DeviceC(config-vlan)# remote-span
DeviceC(config-vlan)# exit
```

b. Configure a destination port.

```
DeviceC(config)# monitor session 1 remote-destination
DeviceC(config)# monitor session 1 destination remote vlan 7 interface
gigabitethernet 0/2 switch
DeviceC(config)# interface gigabitethernet 0/1
DeviceC(config-if)# switchport mode trunk
```

5. Verification

Run the **show monitor** command on device A to view the SPAN source device configurations.

```
DeviceA# show monitor
sess-num: 1
span-type: SOURCE_SPAN
src-intf:
GigabitEthernet 0/1     frame-type Both
dest-intf:
GigabitEthernet  0/2
Remote vlan 7
mtp_switch on
```

Run the **show monitor** command on devices B and C to view the SPAN destination device configurations. Device B is taken as an example below:

```
DeviceB# show monitor
sess-num: 1
span-type: DEST_SPAN
dest-intf:
GigabitEthernet  0/2
Remote vlan 7
mtp_switch on
```

6. Configuration Files

- Device A configuration file of

```
hostname DeviceA
!
vlan 7
!
 remote-span
!
interface GigabitEthernet 0/2
 mac-loopback
 switchport access vlan 7
!
interface GigabitEthernet 0/3
switchport mode trunk
interface GigabitEthernet 0/4
```

```
switchport mode trunk
!
monitor session 1 remote-source
monitor session 1 source interface GigabitEthernet 0/1 both
monitor session 1 destination remote vlan 7 interface GigabitEthernet0/2
switch
!
end
```

- Device B configuration file

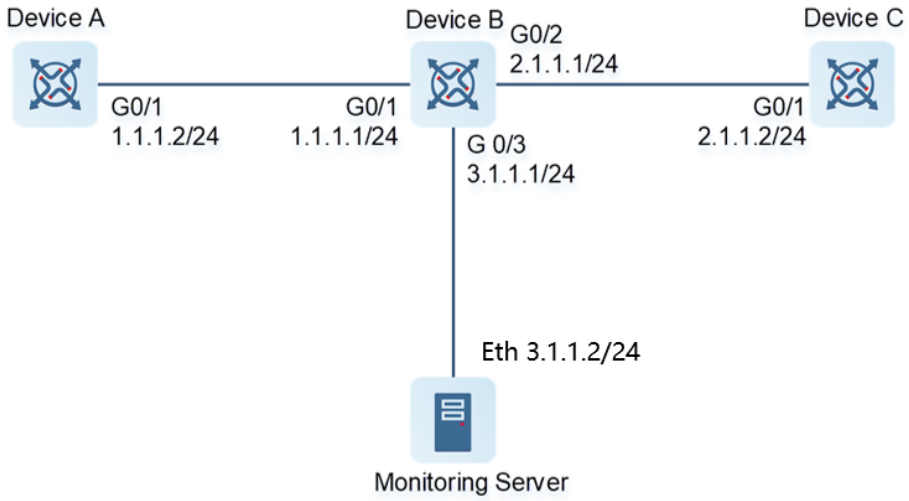
```
hostname DeviceB
!
vlan 7
 remote-span
!
interface GigabitEthernet 0/1
 switchport mode trunk
!
monitor session 1 remote-destination
monitor session 1 destination remote vlan 7 interface GigabitEthernet0/2
switch
!
end
```

- Device C configuration file

```
hostname DeviceC
!
vlan 7
 remote-span
!
interface GigabitEthernet 0/1
 switchport mode trunk
 !
monitor session 1 remote-destination
monitor session 1 destination remote vlan 7 interface GigabitEthernet 0/2
switch
!
end
```

7. Common Errors

- A remote VLAN must be configured on the source device, intermediate device, and destination device, and their VLAN IDs must be consistent.
- Packet loss may occur if packets of a port with large bandwidth are mirrored to a port with small bandwidth.



1.8.3 Configuring Basic Functions of ERPSAN

1. Requirements

As shown in Figure 1-8, the network administrator wants to use the network analyzer to monitor traffic on devices A and C. The network administrator monitors bidirectional packets of device A. For device B, the network administrator monitors only some incoming packets.

2. Topology

Figure 1-8 Topology of ERSPAN

3. Notes

- Configure reachable L3 routes between devices.
- Configure device B as the source device. Configure GigabitEthernet 0/1 and GigabitEthernet 0/2 as the source ports to mirror packets in both directions on GigabitEthernet 0/1, mirror packets with the destination IP address 2.1.1.1 on GigabitEthernet 0/2, and configure GigabitEthernet 0/3 as the output port.

4. Procedure

Configure the IP address of Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# ip address 1.1.1.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
DeviceB(config)# interface gigabitethernet 0/2
DeviceB(config-if-GigabitEthernet 0/1)# ip address 2.1.1.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
DeviceB(config)# interface gigabitethernet 0/3
DeviceB(config-if-GigabitEthernet 0/1)# ip address 13.1.1.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Configure the IP address of device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip address 1.1.1.2 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Configure the IP address of device C.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# interface gigabitethernet 0/1
DeviceC(config-if-GigabitEthernet 0/1)# ip address 2.1.1.2 255.255.255.0
DeviceC(config-if-GigabitEthernet 0/1)# exit
```

Configure an ACL on Device B.

```
DeviceB(config)#access-list 1 permit host 2.1.1.1
```

Create ERSPAN Session 1, and configure Device as the source device. Configure GigabitEthernet 0/1 as the source port, and mirror bidirectional packets. Configure GigabitEthernet 0/2 as the source port, and mirror packets with the destination IP address 2.1.1.1.

```
DeviceB(config)# monitor session 1 erspan-source
DeviceB(config-mon-erspan-src)# source interface gigabitethernet 0/1 both
DeviceB(config-mon-erspan-src)# source interface gigabitethernet 0/2 rx acl acl1
DeviceB(config-mon-erspan-src)# origin ip address 2.1.1.2
DeviceB(config-mon-erspan-src)# destination ip address 3.1.1.2
```

5. Verification

Check that the L3 route between Device B and Device A is reachable.

```
DeviceB# ping 1.1.1.2
Sending 5, 100-byte ICMP Echoes to 1.1.1.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/3/8 ms.
```

Check that the L3 route between Device B and Device C is reachable.

```
DeviceB# ping 2.1.1.2
Sending 5, 100-byte ICMP Echoes to 2.1.1.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/3/8 ms.
```

Check that the L3 route between Device B and the network analyzer is reachable.

```
DeviceB# ping 3.1.1.2
Sending 5, 100-byte ICMP Echoes to 3.1.1.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/3/8 ms.
```

Run the **show access-lists** command to check that the ACL configuration takes effect.

```
DeviceB# show access-lists
```

```
ip access-list standard 1
 10 permit host 1.1.1.1
```

Run the **show monitor** command to check that the ERSPAN session is in Active state in the configuration result.

```
DeviceB# show monitor
sess-num: 1
span-type: ERSPAN_SOURCE
src-intf:
  GigabitEthernet 0/1        frame-type: Both       TX status: Active   RX status:
Active
src-intf:
  GigabitEthernet 0/2        frame-type: RX Only    Rx acl id: 1
status: Active
original ip address: 2.1.1.2
destination ip address: 3.1.1.2
ip ttl: 64
ip dscp: 0
vrf: default
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 ip address 1.1.1.2 255.255.255.0
!
end
```

- Device C configuration file

```
hostname DeviceC
!
interface GigabitEthernet 0/1
 ip address 2.1.1.2 255.255.255.0
!
end
```

- Device B configuration file

```
hostname DeviceB
!
ip access-list standard 1
 10 permit host 1.1.1.1
!
interface GigabitEthernet 0/1
 ip address 1.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
```

```
 ip address 2.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/3
 ip address 3.1.1.1 255.255.255.0
!
monitor session 1 erspan-source
 source interface gigabitEthernet 0/1 both
 source interface gigabitEthernet 0/2 rx acl acl1
 origin ip address 10.1.1.2
 destination ip address 3.1.1.2
!
end
```

7. Common Errors

- The session ID used to configure ERSPAN is already configured with RSPAN or LOCAL SPAN.
- The L3 route between the source device and destination device is unreachable.

1 Configuring RNS

1.1 Introduction

The reliable network service (RNS) tests the services provided by a peer device to monitor the service availability, integrity of the end-to-end connection, and service quality. With the RNS test results, you can learn the network performance in time and take measures accordingly to handle related network performance problems. Meanwhile, you can diagnose and locate network faults.

1.1.1 Principles

1. RNS Test

An RNS test can be regarded as an RNS process. Before performing an RNS test, you must create an RNS test. In the RNS test, you need to configure RNS parameters, such as the test type, test destination address, and test frequency. The instance ID is globally unique. You need to configure test parameters based on the test type. The detection types include ICMP echo test, UDP echo test, TCP connect test, DHCP test, and DNS test.

2. ICMP Echo Test

The Internet Control Message Protocol (ICMP) echo test is a basic function of the RNS, and is implemented in compliance with the RFC 2925. An ICMP packet is sent to check whether the destination is reachable and to calculate the network response time and packet loss rate.

An ICMP echo request packet is sent to the destination IP address based on the preset test time and frequency. Upon receipt of the ICMP echo request packet, an ICMP echo reply packet is returned from the destination IP address. Through the ICMP echo test, the response time and packet loss rate is calculated based on the information relating to the received ICMP echo reply packet, for example, the receipt time and number of packets. In this way, the current network performance and status are reflected. The ICMP echo test results and historical records are saved, and you can use the command line to display them.

Caution

The prerequisite for a successful ICMP echo test is that destination devices can correctly respond to ICMP echo request packets.

3. UDP Echo Test

User Datagram Protocol (UDP) echo is used to test the network accessibility and delay. When UDP packets are used to test the network accessibility and delay, the RNS server must be enabled on the peer end with the UDP port enabled, or the RNS server must be able to respond to ICMP port unreachable packets.

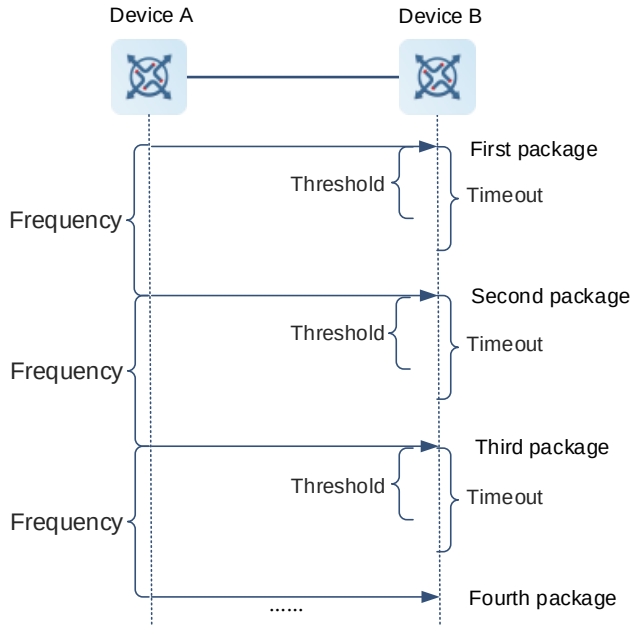
A UDP packet is sent to the destination IP address based on the preset test time and frequency. Upon receipt of the UDP packet, the device of the destination IP address replies by using such packet. Through the UDP echo test, the time required for packet round trip and packet loss rate are calculated based on the information relating to the received UDP packet from the server to reflect the current network performance and network conditions. The UDP echo test results and historical records are saved, and you can use the command line to display them.

4. DHCP Test

The Dynamic Host Configuration Protocol (DHCP) test is used to test the DHCP service function of the peer device and the network accessibility and delay. When DHCP packets are used to test the network accessibility and delay, the RNS service must be enabled on the peer end.

5. TCP Test

The Transmission Control Protocol (TCP) test is used to test the availability of a TCP connection. A TCP connection can be established based on the configured destination IP address and port ID. If the TCP connection is established successfully, the test succeeds; otherwise, the test fails.



6. DNS Test

In a DNS test, a DNS client is simulated to send a domain name resolution request to a specified DNS server. You can determine whether the DNS server is available and the domain name resolution speed by checking the domain name resolution result and the time required for domain name resolution. In the DNS test, the domain name resolution process is simulated, and the mapping between the resolved domain name and the IP address is not saved. The DNS test results and historical records are saved in the test group. You can use the command line to view them.

7. Test Packet Sending Mechanism

- Continuous test
  - Definition: Packets are sent at a specified frequency within the specified lifetime, and the timeout interval of each packet is specified, which are used for collecting the delay, jitter, and packet loss rate.
  - Applicable test types: ICMP Echo, UDP Echo, TCP Connect, DHCP, and DNS
  - Details: If no response packet is received within the timeout interval after a request packet is sent, the request packet is lost and marked as lost. Figure 1-1 illustrates the packet sending mechanism.
  - Constraint: Threshold ≤ Timeout < Frequency

Figure 1-1 Continuous Test Packet Sending Mechanism

1.1.2 Protocols and Standards

RFC 2925: Definitions of Managed Objects for Remote Ping, Traceroute, and Lookup Operations.

1.2 Restrictions and Guidelines

- In IP RNS configuration mode, if you do not configure the test type, the RNS test instance is not created.
- After configuring an RNS test instance, you need to run the **ip rns schedule** command to configure a policy for enabling the instance. Otherwise, the test will not be executed.
- ICMP Echo test, TCP Connect test, and UDP Echo test support IPv4 and IPv6, but DNS test and DHCP test support only IPv4.

1.3 Configuration Task Summary

RNS configuration includes the following tasks:

(1) Configuring Basic Features of RNS

(2) Configuring the ICMP Echo Test

(3) Configuring the UDP Echo Test

(4) Configuring the TCP Connection Test

(5) Configuring the DHCP Test

(6) Configuring the DNS Test

1.4 Configuring Basic Features of RNS

1.4.1 Overview

Configure details of an RNS test instance to complete basic configuration of the RNS instance. Brief configuration is also available. Configure and start an RNS instance at a time.

1.4.2 Restrictions and Guidelines

- In detailed configuration mode, if you do not configure the test type after entering the IP RNS mode by running the command, the RNS instance is not created.
- In detailed configuration mode, after configuring an RNS instance, you need to run the **ip rns schedule** command to configure the startup policy; otherwise, the test is not implemented.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Define an RNS operation object.

ip rns *operation-number* [{ **dns** *destination-hostname* **name-server** *ipv4-address* | **icmp-echo** *destination-ipv4-address* | **tcp-connect** *destination-ipv4-address port-number* } [**frequency** *interval*] [**timeout** *interval*] [**threshold** *interval*]]

No track operation object is created by default.

(4) Configure the proactive threshold monitoring and triggering mechanism for the RNS test. Select at least one of the following configuration tasks.

- Configure the threshold monitoring and triggering mechanism when monitoring all elements fails.

  ip rns reaction-configuration *operation-number* **react allfail** [**action-type track** | **threshold-type** { **average** [*number-of-measurements*] | **consecutive** [*occurrences*] | **immediate** | **never** | **xofy** [*x-value y-value*] }] *

- Configure the threshold monitoring and triggering mechanism when the packet round trip time is not within the threshold range.

  ip rns reaction-configuration *operation-number* **react rtt** [**action-type** { **trigger** | **none** } | **threshold-type** { **average** [*number-of-measurements*] | **consecutive** [*occurrences*] | **immediate** | **never** | **xofy** [*x-value y-value*] } | **threshold-value** *upper-threshold lower-threshold*]*

- Configure the threshold monitoring and triggering mechanism based on the timeout in either direction.

  ip rns reaction-configuration *operation-number* **react timeout** [**action-type** { **trigger** | **none** } | **threshold-type** { **average** [*number-of-measurements*] | **consecutive** [*occurrences*] | **immediate** | **never** | **xofy** [*x-value y-value*] }] *

The proactive threshold monitoring and triggering mechanism is not configured for the test by default.

(5) Trigger another test in pending state to activate when the monitoring threshold exceeds the expectation during a test.

ip rns reaction-trigger *source-operation-number target-operation-number*

The trigger mechanism when the monitoring threshold exceeds the expectation is not configured for the test by default.

(6) Configure scheduling parameters of an RNS instance.

ip rns schedule *operation-number* [**life** { **forever** | *period* }] [**start-time** { *hh:mm* [*:ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh:mm:ss* }] [**recurring**]

No scheduling policy is configured for the test by default.

(7) Configure the **ip rns restart** command to restart an RNS instance.

ip rns restart *operation-number*

To restart an IP RNS instance in pending status of scheduling, perform this configuration (or directly configure scheduling start: **ip rns schedule** *operation-number* **start-time now**).

The test restart function is not configured by default.

(8) Run the **ip rns reset** command to clear the RNS test configuration.

ip rns reset

Perform this configuration if you need to clear configurations of all the RNS instances, for example, when a lot of instances are configured but configuration errors are found.

The RNS test clearing function is not configured by default.

(9) Configure the **ip rns server** command to enable the server function.

ip rns-server udp-echo *port-number*

This configuration is mandatory when you need to enable the RNS server for UDP echo tests.

The server function of UDP echo test is not configured by default.

1.5 Configuring the ICMP Echo Test

1.5.1 Overview

Create an RNS test instance of ICMP echo type.

1.5.2 Restrictions and Guidelines

You must first configure the RNS basic features.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the IP RNS configuration mode.

ip rns operation-*number*

(4) Create an RNS test instance of ICMP echo type.

IPv4 network:

icmp-echo { **oob** { *destination-ipv4-address* | *destination-hostname* [**name-server** *ipv4-address*] } [**source-ipaddr** *ipv4-address*] **via** *interface-type interface-number* **next-hop** *ipv4-address* } | { { *destination-ipv4-address* | *destination-hostname* [**name-server** *ipv4-address*] } [[**af-direct**] **out-interface** *interface-type interface-number* [**next-hop** *ipv4-address*] | **source-ipaddr** *ipv4-address*] * }

IPv6 network:

icmp-echo { **oob** { *destination-ipv6-address* | *destination-hostname* [**name-server** *ipv6-address*] } [**source-ipaddr** *ipv6-address*] **via** *interface-type interface-number* **next-hop** *ipv6-address* } | { { *destination-ipv6-address* | *destination-hostname* [**name-server** *ipv6-address*] } [[**af-direct**] **out-interface** *interface-type interface-number* [**next-hop** *ipv6-address*] | **source-ipaddr** *ipv6-address*] * }

No test of ICMP echo type is created by default.

(5) (Optional) Configure the repeat test interval.

frequency *interval*

The default test interval is 60 seconds.

(6) (Optional) Configure the tag parameter.

tag *tag-name*

No test tag is configured by default.

(7) (Optional) Configure the time threshold parameter.

threshold *interval*

The default upper threshold of test is 5 seconds.

(8) (Optional) Configure the timeout period.

timeout *interval*

The default timeout interval of a test is 5 seconds.

(9) (Optional) Configure the type of service (TOS) parameter.

tos *tos-values*

The default TOS value for IPv4 packet of the test is 0.

(10) (Optional) Configure the virtual routing and forwarding (VRF) of an RNS test.

vrf *vrf-name*

No VRF name is configured for the test by default.

(11) Configure the protocol payload size for the test.

request-data-size *bytes*

The default protocol payload size is 36 bytes for the tests of ICMP echo and UDP echo types.

1.6 Configuring the UDP Echo Test

1.6.1 Overview

Create an RNS test instance of UDP echo type and implement the UDP echo test.

1.6.2 Restrictions and Guidelines

- You must first configure the basic features of the RNS and RNS server.
- The RNS server must be enabled to provide server functions.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the IP RNS configuration mode.

ip rns operation-*number*

(4) Create an RNS test instance of UDP echo type.

IPv4 network:

udp-echo { **oob** { *destination-hostname* | *destination-ipv4-address* } *port-number* **via** *interface-type interface-number* **next-hop** *next-hop-ipv4* | { *destination-hostname* | *destination-ipv4-address* } *port-number* [**out-interface** *interface-type interface-number* **next-hop** *next-hop-ipv4*] }

IPv6 network:

udp-echo { **oob** { *destination-hostname* | *destination-ipv6-address* } *port-number* **via** *interface-type interface-number* **next-hop** *next-hop-ipv6* | { *destination-hostname* | *destination-ipv6-address* } *port-number* [**out-interface** *interface-type interface-number* **next-hop** *next-hop-ipv6*] }

No test object of UDP echo type is configured by default.

Caution

For the commands (**frequency**, **tag**, **threshold**, **timeout**, **tos** and **vrf**) of configuring common optional parameters of a test, see 1.5 Configuring the ICMP Echo Test. They are omitted here.

1.7 Configuring the TCP Connection Test

1.7.1 Overview

Create an RNS test instance of TCP type to implement a TCP connection test.

1.7.2 Restrictions and Guidelines

- You must first configure the RNS basic features.
- The target host must be able to respond to the TCP connection request.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the IP RNS configuration mode.

ip rns operation-*number*

(4) Create an RNS test instance of TCP type.

IPv4 network:

tcp-connect { *destination-ipv4-address* | *destination-hostname* [**name-server** *ipv4-address*] } *port-number* [**source-ipaddr** *ipv4-address*] [[**af-direct**] **out-interface** *interface-type interface-number* **next-hop** *ipv4-address*]

IPv6 network:

tcp-connect { *destination-ipv6-address* | *destination-hostname* [**name-server** *ipv6-address*] } *port-number* [[**af-direct**] **out-interface** *interface-type interface-number* [**next-hop** *ipv6-address*] | **source-ipaddr** *ipv6-address*] *

No test of TCP type is configured by default.

Caution

For the commands (**frequency**, **tag**, **threshold**, **timeout**, **tos**, and **vrf**) of configuring common optional parameters of a test, see 1.5 Configuring the ICMP Echo Test. They are omitted here.

1.8 Configuring the DHCP Test

1.8.1 Overview

Create an RNS test instance of DHCP type to implement a DHCP test.

1.8.2 Restrictions and Guidelines

You must first configure the basic features of RNS and the IP address of the outbound port.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the IP RNS configuration mode.

ip rns operation-*number*

(4) Create an RNS test instance of DHCP type.

dhcp *destination-ipv4-address* **out-interface** *out-interface* **next-hop** *next_ip_address*

Caution

For the commands (**frequency**, **tag**, **threshold**, **timeout**, **tos** and **vrf**) of configuring common optional parameters of a test, see 1.5 Configuring the ICMP Echo Test. They are omitted here.

1.9 Configuring the DNS Test

1.9.1 Overview

Create an RNS test instance of DNS type.

1.9.2 Restrictions and Guidelines

You must first configure the RNS basic features.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the IP RNS configuration mode.

ip rns operation-*number*

(4) Create an RNS test instance of DNS type.

dns { **oob** *destination-hostname* **name-server** *ipv4-address* [**source-ipaddr** *ipv4-address*] **via** *interface-type interface-number* **next-hop** *ipv4-address* | *destination-hostname* **name-server** *ipv4-address* [[**af-direct**] **out-interface** *interface-type interface-number* [**next-hop** *ipv4-address*] | **source-ipaddr** *ipv4-address*] }

No test of DNS type is created by default.

Caution

For the commands (**frequency**, **tag**, **threshold**, **timeout**, **tos** and **vrf**) of configuring common optional parameters of a test, see 1.5 Configuring the ICMP Echo Test. They are omitted here.

1.10 Monitoring

Run the **show** command to check the configuration.

Run the **debug** command to display debugging information.

Caution

Debugging occupies system resources, so disable it immediately if not required.

Table 1-1 RNS Monitoring

Command	Purpose
show ip rns configuration [**json**] [*operation-number*]	Displays the configuration of one or more RNS instances.
show ip rns collection-statistics [*operation-number*]	Displays the detailed statistics of one or more RNS instances.
show ip rns operational-state [*operation-number*]	Displays the current status of one or more RNS instances.
show ip rns-server udp-echo	Displays the RNS server configuration.
show ip rns reaction-configuration [*operation-number*]	Displays the proactive threshold monitoring information of one or more RNS instances.
show ip rns reaction-trigger [*operation-number*]	Displays information about the test triggered by one or more RNS instances.
show ip rns statistics [**json**] [*operation-number*]	Displays the brief statistics of one or more RNS instances.
debug rns { **all** | **interface** | **lib** | **rdnd-event** | **restart** | **rns_id** [**0, 500**] }	Debugs the RNS module.
debug rns-server {udp-echo} { event | fail | packet }	Debugs the RNS server module.

1.11 Configuration Examples

1.11.1 Configuring Basic Functions of the ICMP Echo Test

1. Requirements

Configure an RNS test of ICMP echo type, which must be started immediately and take effect permanently.

2. Topology

Figure 1-2 Topology for Configuring the ICMP Echo Test

3. Notes

Configure RNS test 1 and related parameters on Device A.

4. Procedure

(1) Configure interface IP addresses and an IPv4 unicast routing protocol (for example, OSPF) on each device to ensure that routes between the devices are reachable.

(2) Configure RNS test 1 and parameters.

Perform the following configuration on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# ip rns 1
DeviceA(config-ip-rns)# icmp-echo 10.2.2.2
DeviceA(config-ip-rns-icmp-echo)# exit
DeviceA(config)# ip rns schedule 1 start-time now life forever
```

5. Verification

Run the **show ip rns configuration** command to display the instance configuration.

```
DeviceA# show ip rns configuration 1
Entry number: 1
Tag:
Type of operation to perform: icmp-echo
Operation timeout (milliseconds): 5000
Operation frequency (milliseconds): 60000
Threshold (milliseconds): 5000
Recurring (Starting Everyday): FALSE
Life (seconds): foerver
Next Scheduled Start Time:Start Time already passed
Target address/Source address: 10.2.2.2/0.0.0.0
Request size (ARR data portion): 36
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ip rns 1
 icmp-echo 10.2.2.2
!
ip rns schedule 1 start-time now life forever
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.1.1.1 255.255.0.0
!
end
```

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.2.2.2 255.255.0.0
!
end
```

1.11.2 Configuring Basic Functions of the UDP Echo Test

1. Requirements

Configure an RNS test of UDP echo type, which must be started immediately and take effect permanently.

2. Topology

Figure 1-3 Topology for Configuring the UDP Echo Test

3. Notes

Configure RNS test 1 and related parameters on Device A.

4. Procedure

(1) Configure interface IP addresses and an IPv4 unicast routing protocol (for example, OSPF) on each device to ensure that routes between the devices are reachable.

(2) Configure RNS test 1 and parameters.

Perform the following configuration Device A.

```
DeviceA> enable
```

```
DeviceA# configure terminal
DeviceA(config)# ip rns 1
DeviceA(config-ip-rns)# udp-echo 10.2.2.2 1025
DeviceA(config-ip-rns-udp-echo)# exit
DeviceA(config)# ip rns schedule 1 start-time now life forever
```

(3) Configure the server of the UDP echo test.

Perform the following configuration on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ip rns-server udp-echo 1025
```

5. Verification

Run the **show ip rns configuration** command to display the test configuration.

```
DeviceA# show ip rns configuration 1
Entry number: 1
Tag:
Type of operation to perform: udp-echo
Operation timeout (milliseconds): 5000
Operation frequency (milliseconds): 60000
Threshold (milliseconds): 5000
Target Address: 10.2.2.2
Target Port: 1025
Request size (ARR data portion): 36
```

Run the **show ip rns-server udp-echo** command to display the RNS server configuration.

```
DeviceA# show ip rns-server udp-echo
   UDP-Echo-Server:10000
   Receive packets number: 0
   Reflect packets success number: 0
   Reflect packets fail number: 0
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ip rns 1
 udp-echo 10.2.2.2 1025
!
ip rns schedule 1 start-time now life forever
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.1.1.1 255.255.0.0
!
end
```

- Device B configuration file

```
hostname DeviceB
!
ip rns-server udp-echo 1025
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.2.2.2 255.255.0.0
!
end
```

7. Common Errors

The UDP server port configured on the client is not correct.

1.11.3 Configuring Basic Functions of the TCP Connect Test

1. Requirements

Configure an RNS test of TCP type, which must be started immediately and take effect permanently.

2. Topology

Figure 1-4 Topology for Configuring the TCP Connect Test

3. Notes

Configure RNS test 1 and related parameters on Device A.

4. Procedure

(1) Configure interface IP addresses and an IPv4 unicast routing protocol (for example, OSPF) on each device to ensure that routes between the devices are reachable.

(2) Configure RNS test 1 and parameters.

Perform the following configuration on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# ip rns 1
DeviceA(config-ip-rns)# tcp-connect 10.2.2.2 8000
DeviceA(config-ip-rns-tcp)# exit
DeviceA(config)# ip rns schedule 1 start-time now life forever
```

5. Verification

Run the **show ip rns configuration** command to display the test configuration.

```
DeviceA# show ip rns configuration 1
Entry number: 1
Tag:
```

```
Type of operation to perform: tcp-connect
Operation timeout (milliseconds): 5000
Operation frequency (millseconds): 60
Threshold (milliseconds): 5000
Recurring (Starting Everyday): FALSE
Life (seconds): foerver
Next Scheduled Start Time:Start Time already passed
Target Address: 10.2.2.2
Target Port: 8000
```

6. Configuration Files

- Device A configuration file

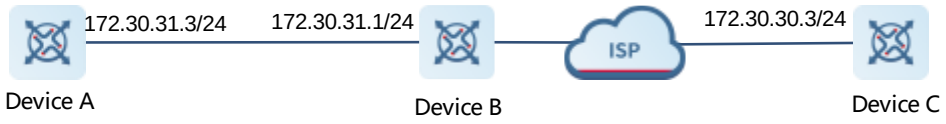
```
hostname DeviceA
!
ip rns 1
 tcp-connect 10.2.2.2 8000
!
ip rns schedule 1 start-time now life forever
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.1.1.1 255.255.0.0
!
end
```

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.2.2.2 255.255.0.0
!
end
```

7. Common Errors

- The target host does not respond to the TCP connection request.
- The configured TCP port for the RNS test is incorrect.



1.11.4 Configuring Basic Functions of the DHCP Test

1. Requirements

Configure an RNS test of DHCP type, which must be started immediately and take effect permanently.

2. Topology

Figure 1-5 Topology for Configuring the DHCP Test

3. Notes

Configure RNS instance 1 and related parameters on Device A.

4. Procedure

(1) Configure interface IP addresses and an IPv4 unicast routing protocol (for example, OSPF) on each device to ensure that routes between the devices are reachable.

(2) Enable the DHCP server and configure address pool parameters.

Perform the following configuration on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# service dhcp
DeviceB(config)# ip dhcp pool test
DeviceB(dhcp-config)# network 10.2.0.0 255.255.0.0
DeviceB(dhcp-config)# end
```

(3) Configure RNS test 1 and parameters.

Perform the following configuration on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# ip rns 1
DeviceA(config-ip-rns)# dhcp 172.30.30.3 out-interface gigabitethernet 0/1
next-hop 172.30.31.1
DeviceA(config-ip-rns-dhcp)# exit
DeviceA(config)# ip rns schedule 1 start-time now life forever
```

5. Verification

Run the **show ip rns configuration** command to display the test configuration.

```
DeviceA# show ip rns configuration 1
Entry number: 1
Tag:
Type of operation to perform: dhcp
Operation timeout (milliseconds): 5000
Operation frequency (milliseconds): 60000
Threshold (milliseconds): 5000
Recurring (Starting Everyday): FALSE
Life (seconds): forever
```

```
Next Scheduled Start Time: Start Time already passed
Target address/Source address: 172.30.30.3/172.30.31.252
Out-interface: GigabitEthernet 0/1
Next-hop address: 172.30.31.1
```

1. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ip rns 1
 dhcp 172.30.30.3 out-interface GigabitEthernet 0/1 next-hop 172.30.31.1
!
ip rns schedule 1 start-time now life forever
!
interface GigabitEthernet 0/1
 no switchport
 ip address 172.30.31.3 255.255.0.0
!
end
```

- Device B configuration file

```
hostname DeviceB
!
service dhcp
!
ip dhcp pool test
 network 10.2.0.0 255.255.0.0
!
interface GigabitEthernet 0/1
 no switchport
 ip address 172.30.30.1 255.255.0.0
!
End
```

- Device C configuration file

```
hostname DeviceC
!
interface GigabitEthernet 0/1
 no switchport
 ip address 172.30.30.3 255.255.0.0
!
end
```

6. Common Errors

- The DHCP service is not enabled on the server.
- No IP address is configured for the outbound interface of the client.

1.11.5 Configuring Basic Functions of the DNS Test

1. Requirements

Configure an RNS test of DNS type, which must be started immediately and take effect permanently.

2. Topology

Figure 1-6 Topology for Configuring the DNS Test

3. Notes

Configure RNS instance 1 and related parameters on Device A.

4. Procedure

(1) Configure interface IP addresses and an IPv4 unicast routing protocol (for example, OSPF) on each device to ensure that routes between the devices are reachable.

(2) Configure RNS test 1 and parameters.

Perform the following configuration on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# ip rns 1
DeviceA(config-ip-rns)# dns www.abc.com name-server 10.2.2.2
DeviceA(config-ip-rns-dns)# exit
DeviceA(config)# ip rns schedule 1 start-time now life forever
```

(3) Enable the DNS proxy function.

Perform the following configuration on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# ip dns proxy enable
DeviceB(config)# exit
```

5. Verification

Run the **show ip rns configuration** command to display the test configuration.

```
DeviceA# show ip rns configuration 1
Entry number: 1
Tag:
Type of operation to perform: dns
Operation timeout (milliseconds): 5000
Operation frequency (milliseconds): 60000
Threshold (milliseconds): 5000
Recurring (Starting Everyday): FALSE
Life (seconds): foerver
```

```
Next Scheduled Start Time:Start Time already passed
Target host name: www.abc.com
Name Server: 10.2.2.2
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
ip rns 1
 dns www.abc.com name-server 10.2.2.2
!
ip rns schedule 1 start-time now life forever
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.1.1.1 255.255.0.0
!
end
```

- Device B configuration file

```
hostname DeviceB
!
ip dns proxy enable
!
interface GigabitEthernet 0/1
 no switchport
 ip address 10.2.2.2 255.255.0.0
!
end
```

7. Common Errors

The DNS IP address is incorrect.

1.12 Common Misconfigurations

1.12.1 No Packet Is Obtained After RNS Configuration Is Completed

- Symptom

  After the RNS configuration is configured, no packet is obtained. The **show ip rns collection** command cannot be used to obtain detailed test information, or the number of sent or received packets is 0.

- Solution
  - Check whether the ping operation succeeds.

    Run the **ping** command to check connectivity of the destination path.
  - Check whether scheduling is configured and whether packets are sent at the specified scheduling time.

Run the **ip rns schedule** *operation-number* **start-time now** command to enable scheduling. If no scheduling is performed, the configuration can be performed. Otherwise, a message indicating that the RNS test is running is displayed.

1 Configuring sFlow

1.1 Introduction

1.1.1 Overview

Sampled Flow (sFlow) is a network monitoring technology based on message sampling. It is mainly used for traffic statistics analysis when the network traffic is huge.

sFlow has the following advantages:

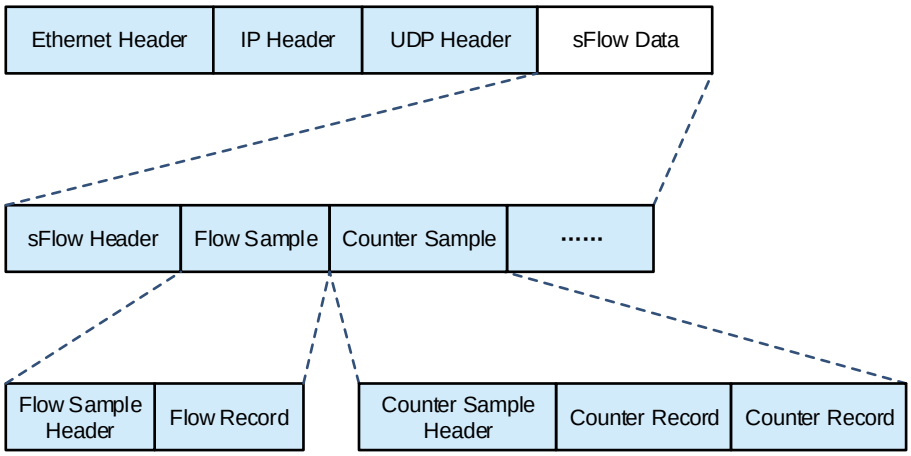
- Accurate: sFlow supports accurate monitoring of traffic on a Gigabit network or a network with higher bandwidth.
- Scalable: One sFlow Collector can monitor thousands of sFlow Agents, and it has high scalability.
- Low cost: sFlow Agent is embedded in a network device, and its cost is low.

1.1.2 Principles

The sFlow system consists of an sFlow Agent embedded in a device and a remote sFlow Collector. The sFlow Agent obtains interface statistics and data from the network device by using specific sampling technologies, encapsulates the information into sFlow packets, and sends them to the sFlow Collector. The sFlow Collector analyzes sFlow packets and displays the analysis results.

- **sFlow Agent**

  An sFlow Agent is embedded in a network device. Generally, one network device serves as an sFlow Agent.



- **sFlow Collector**

  An sFlow Collector can be a PC or server that receives and analyzes sFlow packets from the sFlow Agent. A PC or server installed with the software used for sFlow packet analysis can be regarded as an sFlow Collector.

  The sFlow Agent performs flow sampling and counter sampling, encapsulates sampled data into sFlow packets, and sends them to the sFlow Collector.

  sFlow packets are encapsulated in UDP. Figure 1-1 shows the sFlow packet format.

Figure 1-1 sFlow Packet Format

Note

One sFlow packet may contain one or more flow samples and counter samples.

Figure 1-2 sFlow Header

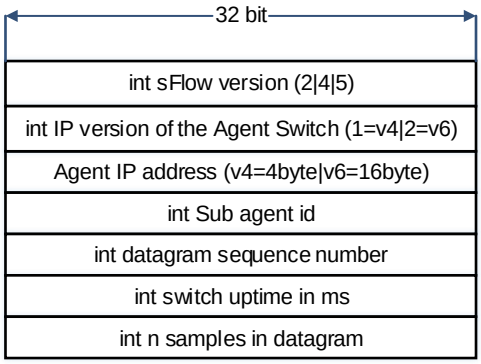


Table 1-1 sFlow Header Description

Field	Description
sFlow version	sFlow version. V2, V4, and V5 are available. Currently, the product supports V5 only.
IP version of the agent/switch	IP address version of the sFlow Agent
Agent IP address	IP address of the sFlow Agent
Sub agent id	Sub agent ID
Datagram sequence number	Serial number of an sFlow packet
Switch uptime	Duration from device startup to the current time

Field	Description
n samples in datagram	Number of samples in an sFlow packet. One sFlow packet contains one or more flow samples and counter samples.

1. Flow sampling

Based on the sampling rate configured for the specified interface, the sFlow Agent device performs flow sampling on packets through this interface, including copying the packet header, extracting the Ethernet header and IP header of each packet, and obtaining the route information of each packet. Then, the sFlow Agent encapsulates the flow sampling result into sFlow packets and sends them to the sFlow Collector for analysis.

Table 1-2 Description of Fields in the Flow Record Part of the sFlow Packet

Field	Description
Raw packet	All or part of the header of the original packet (the extracted length depends on the configuration) is extracted and encapsulated into an sFlow packet and then sent to the Collector.
Extended Switch Data	For an Ethernet packet, the Ethernet header is parsed and encapsulated into an sFlow packet and then sent to the Collector.

2. Counter sampling

In counter sampling, the sFlow Agent periodically obtains the statistics and CPU usage from a specified interface. The sFlow Agent periodically performs interface polling, obtains the statistics from an interface where the counter sampling timer expires, encapsulates the statistics into an sFlow packet, and sends it to the sFlow Collector for analysis.

Table 1-3 Description of Fields in the Counter Sampling Result

Field	Description
Generic Interface Counters	General interface statistics, including basic interface information and general interface traffic statistics
Ethernet Interface Counters	Ethernet-related traffic statistics of an Ethernet interface

1.1.3 Protocols and Standards

- sFlow Version 5: sFlow V5
- RFC 1014: XDR: External Data Representation standard

1.2 Configuration Task Summary

sFlow configuration includes the following tasks:

(1) Configuring Basic Functions of sFlow

(2) (Optional) Configuring Optional Parameters of sFlow

1.3 Configuring sFlow

1.3.1 Configuring Basic Functions of sFlow

1. Overview

- sFlow Agent and sFlow Collector can communicate with each other.
- Traffic flowing through the interface are sampled based on the default sampling rate and sent to the sFlow Collector for analysis.
- Statistics of the interface are periodically sent to the sFlow Collector based on the default sampling interval for analysis.

2. Restrictions and Guidelines

- The forwarding performance of an interface may be affected after flow sampling is enabled.
- To enable the sFlow Collector to analyze the flow sampling results, you must configure the IP address of the sFlow Collector on the sFlow Agent device.
- The sFlow Agent address must be a valid address. That is, the sFlow Agent address cannot be a multicast or broadcast address. It is recommended that the IP address of the sFlow Agent device be used.
- When the **vrf** parameter is configured, the corresponding VRF instance must exist. If you configure a VRF instance for an sFlow Collector address and later remove this VRF instance, the sFlow Collector address will be removed as well.
- When the **oob** parameter is configured, a packet is sent to the sFlow Collector through the management port.
- You can enable flow sampling on an Ethernet interface or a link aggregation.
- **sFlow enable**
  - If the direction is not specified, flow sampling is enabled in both the inbound and outbound directions.
  - Counter sampling is enabled when flow sampling is enabled in any direction of an interface.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the sFlow Agent address.

sflow agent { { **address** *ipv4-address* | **address ipv6** *ipv6-address* } | **interface** [**ipv6**] *interface-type interface-number* }

No sFlow Agent address is configured by default.

(4) Configure the sFlow Collector address.

sflow collector *collector-id* **destination** { *ipv4-address* | **ipv6** *ipv6-address* } *udp-port-number* [**vrf** *vrf-name* | **oob** [**via mgmt** *interface-number*]] [**description** *collector-description*]

No sFlow Collector address is configured by default.

(5) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(6) Configure the ID of the sFlow Collector for flow sampling. Configure at least one of the following task.

- Configure the ID of the sFlow Collector for flow sampling.

  sflow flow collector *collector-id*

  No ID of the sFlow Collector is configured for flow sampling by default.

- Configure the ID of the sFlow Collector for counter sampling.

  sflow counter collector *collector-id*

  No ID of the sFlow Collector is configured for counter sampling by default.

(7) Enable the sampling functions.

sflow enable [**ingress** | **egress**]

The sFlow sampling function is disabled by default.

1.3.2 Configuring Optional Parameters of sFlow

1. Overview

You can adjust the data sampling accuracy by modifying relevant parameter attributes of sFlow.

2. Restrictions and Guidelines

- You can run the **sflow collector** command to configure the payload size of an sFlow packet, excluding the Ethernet header, IP header, and UDP header. One or more flow samples and counter samples can be encapsulated to an sFlow packet. When the maximum sFlow packet size is configured, different numbers of sFlow packets may be output after the same number of flow samples or counter samples are processed. If the maximum size is greater than MTU, the output sFlow packet is segmented.
- The **sflow sampling-rate** command is used to configure the global flow sampling rate. This configuration applies to all interfaces. The flow sampling rate may affect the sFlow sampling accuracy. A lower sampling rate indicates a higher accuracy and a larger CPU consumption, which may affect the forwarding performance of the interface.
- You can run the **sflow flow max-header** command to modify the configuration of packets sent to the sFlow Collector. For example, if you are concerned about the IP header of a packet, set the length to 56 bytes.

During flow sampling, the first 56 bytes of a sample packet are encapsulated to the sFlow packet.

- This command is used to configure the maximum number of bytes that can be copied from the header of the original packet. The copied content is recorded in the generated sample. The protocol requires byte alignment during packet encapsulation, that is, the actual length of a sent packet is a multiple of 4. Therefore, the length of a collected packet may exceed the configured length. For example, when the maximum length is set to any of 21, 22, 23, and 24, the actual output packet length is 24.
- The **sflow counter interval** command is used to configure the global sFlow counter sampling interval. This configuration applies to all interfaces.
- The **sflow source** command is used to configure the source IP address of output packets. The default source address of output sFlow packets is the local device IP address which is used to ping the destination IP address. If the source interface is specified, the primary address (or the first global IPv6 address if any) of the interface is the source IP address of output packets. If the source interface is not specified, the default source address is used.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the maximum size of the output sFlow packet.

sflow collector *collector-id* **max-datagram-size** *datagram-size*

By default, the maximum size of the output sFlow packet is **1400**.

(4) (Optional) Configure the sFlow flow sampling rate.

sflow sampling-rate *sampling-rate*

The default sFlow flow sampling rate is **8192**.

(5) (Optional) Configure the maximum length of the packet header copied during flow sampling.

sflow flow max-header *sampling-length*

By default, the maximum length of the packet header copied during sFlow flow sampling is **64**.

(6) (Optional) Configure the sampling interval.

sflow counter interval *sampling-interval-time*

The interface where counter sampling is enabled sends the interface statistics to the sFlow Collector at the sampling interval.

(7) (Optional) Configure the source address of output sFlow packets.

sflow source { { **address** *ipv4-address* | **address ipv6** *ipv6-address* } | **interface** [**ipv6**] *interface-type interface-number* }

By default, the source address of output sFlow packets is the local device IP address which is used to ping the destination IP address.

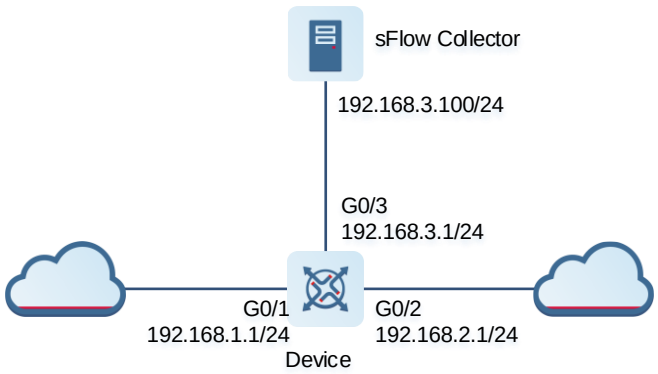
1.4 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Table 1-4 sFlow monitoring

Command	Purpose
show sflow	Displays the sFlow configuration.
show sflow capacity	Displays the sFlow capacity supported by the device.

1.5 Configuration Examples



1.5.1 Configuring Basic Functions of sFlow

1. Requirements

Start the device that serves as the sFlow Agent, enable flow sampling and counter sampling on port GigabitEthernet 0/1, monitor the traffic in the 192.168.1.0 network segment, encapsulate the sampling result into sFlow packets at regular intervals or when the buffer is full, and send these packets to the sFlow Collector for traffic analysis.

2. Topology

Figure 1-3 Network of Basic sFlow Configuration

3. Notes

- Configure the L3 network reachable between the sFlow Agent and the sFlow Collector.
- Configure the sFlow function.

4. Procedure

Configure the L3 network reachable between the sFlow Agent and the sFlow Collector.

```
Device> enable
Device#configure terminal
Device(config)# interface GigabitEthernet 0/1
```

```
Device(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
Device(config)# interface GigabitEthernet 0/2
Device(config-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
Device(config)# interface GigabitEthernet 0/3
Device(config-if-GigabitEthernet 0/1)# ip address 192.168.3.1 255.255.255.0
```

Configure 192.168.1.1 as the sFlow Agent address.

```
Device(config)# sflow agent address 192.168.1.1
```

Configure 192.168.3.100 as the address of sFlow Collector 1, and 6343 as the port number.

```
Device(config)# sflow collector 1 destination 192.168.3.100 6343
```

Configure the interface GigabitEthernet 0/1 to output flow samples and counter samples to sFlow Collector 1, and enable sFlow sampling on this interface.

```
Device(config)# interface GigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# sflow flow collector 1
Device(config-if-GigabitEthernet 0/1)# sflow counter collector 1
Device(config-if-GigabitEthernet 0/1)# sflow enable
```

5. Verification

Run the **show sflow** command to check whether the command output is consistent with the configuration.

```
Device# show sflow
sFlow datagram version 5
Global information:
Agent IP: 192.168.1.1
sflow counter interval:30
sflow flow max-header:64
sflow sampling-rate:65536
Collector information:
ID   IP                      Port Size VPN
1    192.168.3.100             6343 1400
2    NULL                    0    1400
Port information
Interface                   CID  FID  Enable
TenGigabitEthernet 0/1        1    1    B
```

Figure 1-4 shows the Top N tab of sFlowTrend, which displays the flow sampling result and the source IP addresses with the Top 5 traffic. The inbound traffic 450 kpps, and the outbound traffic is also 450 kpps, which is consistent with the actual traffic.

Figure 1-5 is the Counters tab of sFlowTrend, which displays the counter sampling result. The inbound traffic is 450 kpps, and the outbound traffic is also 450 kpps. All packets are unicast packets.

1 Configuring IPFIX

1.1 Introduction

1.1.1 Overview

IP Flow Information Export (IPFIX) is a standard protocol published by IETF for statistics and analysis of network traffic. It standardizes the format of traffic statistics on the network to allow interworking of network devices and servers of different vendors.

IPFIX provides information about the network, including the rate and traffic of interfaces and traffic of different applications, based on which network optimization, security testing, and traffic charging can be achieved.

1.1.2 IPFIX Sampling

Network devices receive packets from one interface and send packets from another. When using IPFIX for packet analysis, specify for which interface you need to collect statistics of incoming or outgoing packets. You can specify sampling of packets in the incoming or outgoing direction or in both directions for a certain interface.

1.1.3 IPFIX Flow

Forwarding devices forward packets one by one based on their destinations. They do not need to be aware of association between packets, while in fact some of the packets are associated, for example, they may belong to the same TCP session.

A packet consists of a series of attributes, such as the IP address and TCP port ID. Continuous packets that have the same attributes and flow through a detection point within a period of time are called a packet flow. Attributes used to determine whether packets belong to the same flow are called key attributes of the flow. If the key attributes of packets are the same, these packets belong to the same flow. These attributes can be fields of the IP packet header, for example, the source IP address, ToS fields, or any combination of these fields. A flow is determined by the common combination of the following key fields:

- Source IP address
- Destination IP address
- Source port ID
- Destination port ID
- L3 protocol type
- ToS
- Packet sampling interface index

These seven key fields determine a unique flow. Packets with the same seven fields belong to the same flow. If a packet has one key field that is different from that of another packet, they belong to different flows. A flow also contains other statistical fields, such as the number of packets, next-hop IP address, and total number of bytes in the flow. Flow information also includes:

- Flow start time
- Flow end time

- Total number of packets
- Total number of bytes
- Flow ingress interface index (for sampling in the ingress direction)
- Flow egress interface index (for sampling in the egress direction)

Note

The IPFIX flow here are also called the IPFIX basic flow or primary flow.

1.1.4 IPFIX Flow Table

A flow table stores measured IP flow information. For an IP packet, the device first looks up the corresponding flow record in the main cache based on key fields of its flow. If the flow record is not configured, the device creates a new flow record, and records the flow information. If the flow record is already configured, the device updates the flow statistics in the flow record, such as the number of packets and the number of bytes in the flow.

Note

The IPFIX flow table here is also called the IPFIX basic flow table or primary flow table, and used to store basic flows.

The basic functions of an IPFIX device include:

- Flow statistics: Obtains attributes from transmitted packets, and looks up the flow table based on the seven key fields. If no matched record is found in the flow table, the packet belongs to a new flow, and a flow record is created to record the flow statistics. If the packet belongs to an existing flow, the flow statistics is updated.
- Exporting flow information to the server: Sends the flow statistics to the server for analysis at the appropriate time.

Note

The IPFIX specification defines only how an IPFIX device exports flow records, but not how to save and analyze flow records.

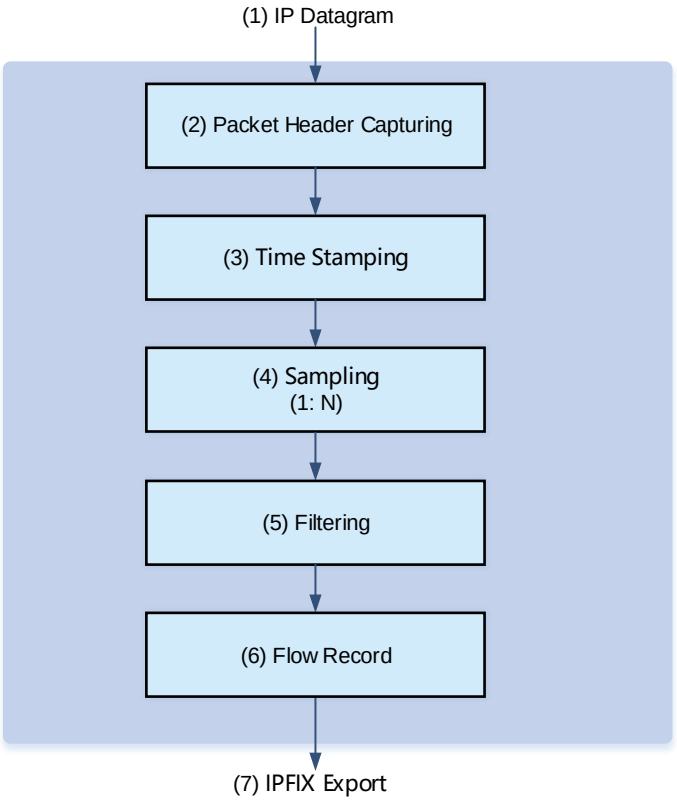
1.1.5 IPFIX Flow Statistics

IPFIX flow statistics is used to build flow tables, extract information in packets, and count traffic in the network. Figure 1-1 shows the IPFIX flow statistics process.

(1) A network device forwards packets normally. A packet is input from one interface and output from another interface after being forwarded.

(2) The IPFIX module of the device extracts the packet-related attributes, such as the IP address and packet length, from the packet header.

(3) It also adds a time stamp to the packet to record the start time, end time, and duration of the flow.



(4) Perform packet sampling according to the configuration, that is, process one in every n packets.

For example, if the sampling rate is 1:100, one packet is selected out of every 100 packets for processing by subsequent modules; if the rate is 1:1, all packets will be processed.

(5) The device save flow information. If the flow record is not configured, the device adds a flow record. If the flow record already is configured, the device updates the flow information, such as the number of packets and the number of bytes.

(6) The flow record is deleted at the specified time, and the flow record information is sent to the IPFIX server.

Figure 1-1 Flowchart of IPFIX Flow Statistics

1.1.6 IPFIX Flow Aging

Flow records are deleted from the flow table under certain circumstances. Before deletion, the statistical information is exported to the server. This process is called flow aging. Flow aging prevents the flow table from increasing indefinitely, while ensuring that the IPFIX server can obtain flow statistics.

- Principles of flow aging
  - The flow is already aged and should be output if no packet of the flow is detected within a certain period of time (non-activity aging time).
  - To avoid continuous recording of flow information as a flow proceeds, set a period (activity aging time). When the flow time exceeds it, the flow is forced to age.
  - When the IPFIX mode changes or the template configuration changes, a new template is used to analyze and collect packets and create new flow records, and the existing flow records are forced to age.
  - When the flow forced aging command is executed, related flow records are forced to age. When a flow record is aged and deleted, and a packet with the same seven key fields as the aged flow is immediately received, no matched flow record exists in the flow table. Therefore, the packet is processed as a new

flow, and a new flow record is created.

1.1.7 IPFIX Flow Export

IPFIX flow export means that aged flow records are exported to the IPFIX server for analysis.

- Principles
  - When an aged flow record needs to be exported to the server, the information of the flow record is encapsulated into a UDP or TCP packet based on the format defined in IPFIX, sent to the configured server, and processed by the collector on the server. The collector is a software tool for processing flow records. It displays the network status and analyzes network traffic based on collected flow record information.
  - IPFIX transfer flow records with a template. When sending flow records, create a template containing the record format and send the template to the server. The template specifies the attributes and length of data record fields. IPFIX defines lots of field attributes, and each attribute has an identifier to indicate the meaning of the attribute, for example, identifier 8 indicates the attribute is the source IP address. After receiving the template, the server learns the format of the subsequent flow records based on the template, and interprets the subsequent IPFIX flow records based on the flow record format defined in the template. The template and flow record information can co-exist in the same packet, or a packet can be accompanied by multiple flow records or templates.
  - The IPFIX device can send only the key attributes of a flow, and the software on the server can also extract only the useful flow attributes from flow records, and ignore other flow attributes. For example, a device may determine that the TCP flag can be used to analyze network security, and therefore include the TCP flag in the flow export information. However, some server software support only traffic analysis, but not network analysis. Therefore, the software can ignore the TCP flag sent by the device. There is no compatibility issue between the device and the server.
  - Similarly, when the network device expands a new field (attribute) in the flow record, it only needs to recreate the corresponding template. The server can interpret the flow record information based on the new template, without upgrading the server software. This greatly improves the scalability.

1.1.8 Flexible IPFIX Flow Sampling

A template and flow record can be selected based on configurations. The concept of flexible sampling is introduced based on the basic sampling function of IPFIX. You can flexibly configure keywords of the flow record and customize the template based on your requirements.

1.1.9 Protocols and Standards

- RFC 5470: Architecture for IP Flow Information Export
- RFC 5472: IP Flow Information Export (IPFIX) Applicability
- RFC 5103: Bidirectional Flow Export Using IP Flow Information Export (IPFIX)
- RFC 5153: IP Flow Information Export (IPFIX) Implementation Guidelines
- RFC 5102: Information Model for IP Flow Information Export
- RFC 5101: Specification of the IP Flow Information Export (IPFIX) Protocol for the Exchange of IP Traffic Flow Information
- RFC 3917: Requirements for IP Flow Information Export

- RFC 3954: Cisco Systems NetFlow Services Export Version 9

1.2 Configuration Task Summary

IPFIX configuration includes the following tasks:

(1) Configuring IPFIX Flow Statistics

(2) Configuring IPFIX Flow Export

(3) (Optional) Configuring Parameters of the IPFIX Flow Table

(4) Configuring Flexible Sampling

1.3 Configuring IPFIX Flow Statistics

1.3.1 Overview

By configuring IPFIX flow statistics, you can obtain statistics of the following types of packets in the network:

- IP packets
- IPv6 packets
- L2 packets
- MPLS packets

1.3.2 Restrictions and Guidelines

- Assume that the sampling function is configured under a link aggregation and link aggregation loading balancing is not configured. If the member ports of a link aggregation are not on the same line card, and packets with the same seven key attributes are collected from different line cards, the number of IPFIX packets received by the server from the link aggregation within the unit aging time is the same as the total number of IPFIX packets received by the member ports from different line cards. In addition, the flow aging time of the AP is the same as that on a single line card.
- If IPFIX ACL-based sampling is enabled on a port, the ACL is used to match the IP packets; otherwise, sampling does not take effect on the port. If IPFIX sampling based on the IPv4 ACL is enabled on a port, the ACL is used to match the IPv4 packets. If IPFIX sampling based on the IPv6 ACL is enabled on a port, the ACL is used to match the IPv6 packets. For more information about ACL configuration, see *Configuring ACL*.
- The **flow-sampler-map** command is configured in global configuration mode. You can enter the IPFIX sampler configuration mode, and then configure the sampler. If you enter the sampler mode, but do not configure any sampler, the IPFIX sampler configuration mode is not displayed when you run **show running-config**.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure IPFIX flow statistics for global MPLS packets.

{ **ip** | **ipv6** } **flow-cache mpls label-positions** *label-position&<1-3>*

(4) Configure a sampler map (sampling rule table).

flow-sampler-map *sampler-map-name*

No sampler map is configured by default.

(5) Configure a random sampler.

mode random one-out-of *packet-interval*

No random sampler is configured by default.

(6) Exit the IPFIX sampler configuration mode.

exit

(7) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(8) Enable IPFIX in the ingress direction of an interface.

{ **ip** | **ipv6** } **flow ingress**

By default, IPFIX is disabled in the ingress direction of an interface.

(9) Enable IPFIX in the egress direction of an interface.

{ **ip** | **ipv6** } **flow egress**

By default, IPFIX is disabled in the egress direction of an interface.

(10) Apply a sampler to an interface.

[**ipv6**] **flow-sampler** *sampler-map-name* [**egress** | **acl** { *acl-name* | *acl-number* }]

No sampler is applied to an interface by default.

1.4 Configuring IPFIX Flow Export

1.4.1 Overview

This section describes how to send the aged flow records to the server.

1.4.2 Restrictions and Guidelines

- The configured IPFIX server address must be reachable; otherwise, it cannot be displayed after the **show ip flow export** or **show ipv6 flow export** command is executed.
- If the type of interface used for exporting flow records is changed from port to VLAN and the interface is an SVI, you also need to configure IPFIX on the VLAN interface.

- Packets can be exported to a maximum of two IPFIX servers.
- You can configure an IPv4 or IPv6 address as the server address for IPv4 or IPv6 IPFIX. When the configured source port and the IPFIX server are not in the same VRF, the IP address of the specified source port cannot be used as the source IP address for packet transmission. The system obtains the best-matched local address as the source address based on the server address. The management port has a default VRF. If you want to use the management port to send packets, configure the source port and the management port in the same VRF.
- The **ip flow-export template** and **ipv6 flow-export template** commands are used to configure the template retransmission frequency. The IPFIX server parses the IPFIX packets based on the template. When the device just starts to use the IPFIX function, the template retransmission frequency can be decreased, so that the IPFIX server can receive the IPFIX template in a short time. For example, you can set the template retransmission frequency to 1 minute.
- The **ip flow-export source** and **ipv6 flow-export source** commands are used to configure the source IP address of an exported packet. By default, the source address of an exported IPFIX packet is the local device IP address which is used to ping the destination IP address. If the source interface is specified, the primary address (or the first global IPv6 address if any) of the interface is the source IP address of the exported IPFIX packet.
- If the source interface is not specified, the default source address is used. You can configure an IPv4 or IPv6 address, or both as the IPFIX server address. If you specify the source interface and configure an IPv6 or IPv4 address as the IPFIX server address, make sure that an IPv6 or IPv4 address is configured for the source interface. Otherwise, the system obtains the best-matched local address as the source address based on the server address. Make sure that the source interface and the IPFIX server are in the same VRF; otherwise, the system obtains the best-matched local address as the source address based on the server address.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the IPFIX server address.

(IPv4 main mode)

ip flow-export destination { **ipv6** *ipv6-address* | *ipv4-address* | *hostname* } *port-number* [**vrf** *vrf-name* | **oob** [**via mgmt** *mgmt-name*]

(IPv6 main mode)

ipv6 flow-export destination { **ipv6** *ipv6-address* | *ipv4-address* | *hostname* } *port-number* [**vrf** *vrf-name* | **oob** [**via mgmt** *mgmt-name*]

By default, no IPFIX flow record is exported to the server.

(4) (Optional) Configure the exported packet format.

(IPv4 main mode)

ip flow-export version { **9** | **10** }

(IPv6 main mode)

ipv6 flow-export version { **9** | **10** }

By default, the exported packet format is version 10.

(5) (Optional) Configure the source interface for packet export.

(IPv4 main mode)

ip flow-export source *interface-type interface-number*

(IPv6 main mode)

ipv6 flow-export source *interface-type interface-number*

By default, no destination address and port are configured, and the local interface address that best-matches the server address is adopted.

(6) (Optional) Configure parameters related to the export template.

(IPv4 main mode)

ip flow-export template { **model** *model-id* | **options** { **export-stats** | **refresh-rate** *refresh-rate* | **timeout-rate** *time-rate* } | **refresh-rate** *refresh-rate* | **timeout-rate** *timeout-rate* }

(IPv6 main mode)

ipv6 flow-export template { **model** *model-id* | **options** { **export-stats** | **refresh-rate** *refresh-rate* | **timeout-rate** *time-rate* } | **refresh-rate** *refresh-rate* | **timeout-rate** *timeout-rate* }

By default, the template retransmission frequency is 20 packets in 10 minutes.

1.5 Configuring Parameters of the IPFIX Flow Table

1.5.1 Overview

The parameters adjust the number of cache entries and the aging time of flow records in the IPFIX flow table.

1.5.2 Restrictions and Guidelines

- If the global IPFIX function is enabled, the modification of cache entries does not take effect immediately. To make the modification effective, you need to reconfigure the global IPFIX function or restart the device.
  a To disable the global IPFIX function, run the **no ip flow ingress** or **no ip flow egress** command.
  b To restart the IPFIX flow statistics function, run the **ip flow ingress** command.
- The number of cache entries for IPv4 and IPv6 entries is shared.
- To modify the aging time of an active or inactive entry, run the **ip flow-cache timeout** command.
  - Modification of the aging time affects the duration that a flow record exists in the flow table. A longer aging time indicates that a flow record exists longer in the flow table, and it takes longer for the IPFIX server to receive the flow record information.
  - To display the flow information in real time on the server, you are advised to set the aging time to a small value. For example, set the aging time of an active entry to 1 minute.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the number of cache entries in the flow table.

(IPv4 main mode)

ip flow-cache entries *number*

(IPv6 main mode)

ipv6 flow-cache entries *number*

(4) (Optional) Configure the aging time of a flow record.

(IPv4 main mode)

ip flow-cache timeout { **active** *active-time* | **inactive** *inactive-time* }

(IPv6 main mode)

ipv6 flow-cache timeout { **active** *active-time* | **inactive** *inactive-time* }

By default, the aging time is **30** minutes for an active entry and **15** seconds for an inactive entry.

1.6 Configuring Flexible Sampling

1.6.1 Overview

This section describes how to flexibly create flow entries and construct a template.

1.6.2 Restrictions and Guidelines

- To enable the flow-key function, ensure that the IPFIX function is already enabled.
- Multiple flow entries can be configured for flexible sampling at the same time.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the flow-key configuration mode.

(IPv4 main mode)

ip flow-key

(IPv6 main mode)

ipv6 flow-key

By default, the flow-key function is disabled.

(4) Configure the flow table matching conditions for flexible sampling.

match { **flow direction** | **interface** { **input** | **output** } | **ip** { **protocol** | **tos** } | **ipv4** { **destination-address** | **source-address** } | **transport** { **destination-port** | **source-port** } | **vlan** }

(5) Enter the template-key configuration mode.

(IPv4 main mode)

ip template-key

(IPv6 main mode)

ipv6 template-key

By default, the template-key function is disabled.

This command can be configured only after the collect function is enabled.

(6) Configure parameters of the IPFIX template for flexible sampling.

collect { **counter** { **bytes** | **packets** } | **timestamp sys-uptime** { **first** | **last** } | **transport tcp flags** }

By default, no parameter of the IPFIX template is configured for flexible sampling.

(7) Enable the flow-key and template-key modes.

enable

In flow-key configuration mode, this command is used to enable the flexible sampling function. In template-key configuration mode, this command is used to enable the flexible template function.

1.7 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

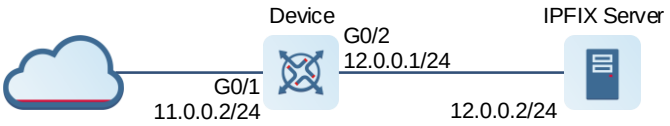
Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-1 IPFIX monitoring

Command	Purpose
clear { **ip** | **ipv6** } **flow stats**	Clears the flow table information.
show { **ip** | **ipv6** } **flow cache**	Displays the IPFIX flow table information.
show { **ip** | **ipv6** } **flow export**	Displays the IPFIX server information.
show ip flow interface	Displays the IPFIX configurations of an interface.
show flow-sampler [*sampler-map-name*]	Display the random sampler and its sampling statistics.

1.8 Configuration Examples



1.8.1 Configuring the IPv4 IPFIX Function

1. Requirements

The device is connected to the network through GigabitEthernet 0/1, and needs to monitor and analyze the IPv4 traffic passing through GigabitEthernet 0/1. Therefore, enable the IPv4 IPFIX function on the device, and configure the IPFIX sampling function in the ingress direction of GigabitEthernet 0/1.

2. Topology

Figure 1-2 Topology for the IPv4 IPFIX Function

3. Notes

- Configure the IP address of the device so that the device and the IPFIX server are mutually reachable at layer 3.
- Configure the sampling function.
- Export the IPv4 IPFIX flow records.
- Configure parameters of the IPv4 IPFIX flow table.

4. Procedure

(1) Configure the IP address of the device.

a. Set the IPv4 address of GigabitEthernet 0/1 to 11.0.0.2/24.

```
Device> enable
Devcie# config terminal
Device(config)# interface gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# ip address 11.0.0.2 255.255.255.0
Device(config-if-GigabitEthernet 0/1)#exit
```

b. Set the IPv4 address of GigabitEthernet 0/2 to 12.0.0.1/24.

```
Device(config)# interface gigabitEthernet 0/2
Device(config-if-GigabitEthernet 0/2)# ip address 12.0.0.1 255.255.255.0
Device(config-if-GigabitEthernet 0/2)#exit
```

(2) Configure the IPFIX sampling function.

a. Configure a sampler map "zxw".

```
Device(config)#flow-sampler-map zxw
```

b. Set the random sampling rate to 4096.

```
Device(config-sampler)#mode random one-out-of 4096
Device(config-sampler)#exit
```

c. Apply the sampler map to GigabitEthernet 0/1.

```
Device(config)# interface gigabitEthernet 0/1
Devcie(config-if-GigabitEthernet 0/1)#flow-sampler zxw
```

d. Enable IPv4 packet sampling in the ingress direction of GigabitEthernet 0/1.

```
Devcie(config-if-GigabitEthernet 0/1)#ip flow ingress
Devcie(config-if-GigabitEthernet 0/1)#exit
```

(3) Export the IPv4 IPFIX flow records to the server.

a. Export the flow records to the server with the IPv4 address 12.0.0.2 and port ID 9996.

```
Devcie(config)# ip flow-export destination 12.0.0.2 9996
```

b. Configure the IP address of GigabitEthernet 0/1 as the source IP address for packet export.

```
Devcie(config)# ip flow-export source gigabitEthernet 0/2
```

c. Set the template retransmission frequency to 40 minutes.

```
Devcie(config)# ip flow-export template timeout-rate 40
```

d. Configure the export option **export-stats**.

```
Devcie(config)# ip flow-export template options export-stats
```

e. Set the export option **refresh-rate** to 35 packets.

```
Devcie(config)# ip flow-export template options refresh-rate 35
```

f. Set the export option **timeout-rate** to 45 minutes.

```
Device(config)# ip flow-export template options timeout-rate 45
```

g. Export packets using the standard format of Netflow V9.

```
Devcie(config)# ip flow-export version 9
```

(4) Configure parameters of the IPv4 IPFIX flow table.

a. Set the number of cache entries in the flow table to 32768.

```
Device(config)# ip flow-cache entries 32768
```

b. Set the aging time of an active entry to 2 minutes.

```
Device(config)# ip flow-cache timeout active 2
```

c. Set the aging time of an inactive entry to 20 seconds.

```
Device(config)# ip flow-cache timeout inactive 20
```

5. Verification

Run the **ping** command to verify L3 reachability between the device and the IPFIX server.

```
Device# ping 12.0.0.2
Sending 5, 100-byte ICMP Echoes to 12.0.0.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/2 ms.
```

Run the **show ip flow export** command to display the IPFIX server information.

```
Devcie# show ip flow export
```

```
IPV4 main Cache:
       Exporting flows to 12.0.0.2 (9996)
       Exporting using source IP address 12.0.0.1
       Version 9 flow records
       IPV4 Template ID = 266
       IPV4 Template ID = 292
              Template timeout = 40 Minute(s)
              Template refresh rate = 30
       0 flows exported in 0 udp datagrams
       0 flows failed to export
       0 messages failed to export
```

Run the **show ip flow interface** command to display the IPFIX configurations of the interface.

```
Devcie# show ip flow interface
interface GigabitEthernet0/1
  flow-sampler zxw
  ip flow ingress
```

Run the **show ip flow cache** command to display the information about the IPv4 IPFIX flow table.

```
Devcie# show ip flow cache
IPFIX CACHE(slot-0/1):
       IPV4 Flow Switching Cache, 0 bytes
       0 active, - inactive, 0 added

!
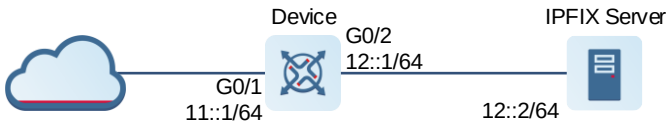
end
```



1.8.2 Configuring the IPv6 IPFIX Function

1. Requirements

The device is connected to the network through GigabitEthernet 0/1, and needs to monitor and analyze the IPv6 traffic passing through GigabitEthernet 0/1. Therefore, enable the IPv6 IPFIX function on the device, and configure the IPFIX sampling function in the ingress direction of GigabitEthernet 0/1.

2. Topology

Figure 1-3 Topology for the IPv6 IPFIX Function

3. Notes

- Configure the IP address of the device so that the device and the IPFIX server are mutually reachable at layer 3.
- Configure the sampling function.
- Export the IPv6 IPFIX flow records.
- Configure parameters of the IPv6 IPFIX flow table.

4. Procedure

(1) Configure the IP address of the device.

a. Set the IPv6 address of GigabitEthernet 0/1 to 11::1/64.

```
Device> enable
Devcie# config terminal
Device(config)# interface gigabitEthernet 0/1
Device(config-if-GigabitEthernet 0/1)# ipv6 address 11::1/64
Device(config-if-GigabitEthernet 0/1)#exit
```

b. Set the IPv6 address of GigabitEthernet 0/2 to 12::1/64.

```
Device(config)# interface gigabitEthernet 0/2
Device(config-if-GigabitEthernet 0/2)# ipv6 address 12::1/64
Device(config-if-GigabitEthernet 0/2)#exit
```

(2) Configure the IPFIX sampling function.

a. Configure a sampler map "zxw".

```
Device(config)#flow-sampler-map zxw
```

b. Set the random sampling rate to 4096.

```
Device(config-sampler)#mode random one-out-of 4096
Device(config-sampler)#exit
```

c. Apply the sampler map to GigabitEthernet 0/1.

```
Device(config)# interface gigabitEthernet 0/1
Devcie(config-if-GigabitEthernet 0/1)#ipv6 flow-sampler zxw
```

d. Enable IPv6 packet sampling in the ingress direction of GigabitEthernet 0/1.

```
Devcie(config-if-GigabitEthernet 0/1)#ipv6 flow ingress
Devcie(config-if-GigabitEthernet 0/1)#exit
```

(3) Export the IPv6 IPFIX flow records to the server.

a. Export the flow records to the server with IPv6 address 12::2 and port ID 9996.

```
Devcie(config)# ipv6 flow-export destination 12::2 9996
```

b. Configure the IP address of GigabitEthernet 0/2 as the source IP address for packet export.

```
Devcie(config)# ipv6 flow-export source gigabitEthernet 0/2
```

c. Set the template retransmission frequency to 40 minutes.

```
Devcie(config)# ipv6 flow-export template timeout-rate 40
```

d. Configure the export option **export-stats**.

```
Devcie(config)# ipv6 flow-export template options export-stats
```

e. Set the export option **refresh-rate** to 35 packets.

```
Devcie(config)# ipv6 flow-export template options refresh-rate 35
```

f. Set the export option **timeout-rate** to 45 minutes.

```
Device(config)# ipv6 flow-export template options timeout-rate 45
```

g. Export packets using the standard format of Netflow V9.

```
Devcie(config)# ipv6 flow-export version 9
```

(4) Configure parameters of the IPv6 IPFIX flow table.

a. Set the number of cache entries in the flow table to 32768.

```
Device(config)# ipv6 flow-cache entries 32768
```

b. Set the aging time of an active entry to 2 minutes.

```
Device(config)# ipv6 flow-cache timeout active 2
```

c. Set the aging time of an inactive entry to 20 seconds.

```
Device(config)# ipv6 flow-cache timeout inactive 20
```

5. Verification

Run the **ping** command to verify L3 reachability between the device and the IPFIX server.

```
Device# ping 12::2
Sending 5, 100-byte ICMP Echoes to 12::2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/2 ms.
```

Run the **show ipv6 flow export** command to display the IPFIX server information.

```
Devcie# show ipv6 flow export

IPV6 main Cache:
       Exporting flows to 12::2 (9996)
       Exporting using source IP address 12::1
       Version 9 flow records
       IPV6 Template ID = 5000
       IPV6 Template ID = 5026
              Template timeout = 40 Minute(s)
              Template refresh rate = 30
```

```
      0 flows exported in 0 udp datagrams
      0 flows failed to export
      0 messages failed to export
```

Run the **show ip flow interface** command to display the IPFIX configurations of the interface.

```
Devcie# show ip flow interface
interface GigabitEthernet0/1
  ipv6 flow-sampler zxw
  ipv6 flow ingress
```

Run the **show IPv6 flow cache** command to display the information about the IPv6 IPFIX flow table.

```
Devcie# show ipv6 flow cache
Devcie# show ipv6 flow cache
IPFIX CACHE(slot-0/1):
      IPV6 Flow Switching Cache, 0 bytes
      0 active, - inactive, 0 added
      0 flow alloc failures
      0 displayed
      Exporting flows to 12::2 (9996)
      0 ipv6 flows exported in 0 udp datagrams, 0 failed
      And Exporting flows to 0.0.0.0 (0)
      0 ipv6 flows exported in 0 udp datagrams, 0 failed
      Last clearing of statistics 0 Days 00:00:18

1 Configuring Python

1.1 Introduction

1.1.1 Overview

Python is an object-oriented interpretive computer programming language and is pure free software. Its source code and interpreter Cpython comply with GNU general public license (GPL) protocol. The Python shell component can debug and run Python scripts through CLI commands.

1.1.2 Principles

1. Python Script Debugging

Python script debugging refers to debugging or running a script to be run on a device. A Python script is debugged with two methods:

- One is to copy the Python script to a device and debug the script on the Python console.
- The other is to copy the Python script to a device and run the script. Check whether the expected effect is achieved. If not, modify and debug the script.

Regardless of methods, the user runs an open source Python command and the debugging method is consistent with that of the open source Python. The Python shell component redirects the input and output of the open source Python process to the current terminal.

2. Permission Control

Permission control indicates that Python CLI commands are not allowed to operate directories or files other than **flash:** and **tmp:** and risky operations such as popen and system are not allowed in a script.

Permissions are controlled at the entry of Python. So long as a Python script is run on a device, permissions are controlled to control the risk caused by running of the Python script.

1.2 Restrictions and Guidelines

Permission control: Python commands and scripts can be run on only files in the **flash:** and **tmp:** directories.

1.3 Configuring Basic Features

1.3.1 Overview

This section describes how to run a Python script.

1.3.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Debug a Python script.

python [*file-name* [*args*]]

1 Configuring Tech-Support 1

1.1 Introduction 1

1.1.1 Overview 1

1.1.2 Principles 1

1.2 Enabling the Tech-Support Function 2

1.2.1 Overview 2

1.2.2 Restrictions and Guidelines 2

1.2.3 Procedure 3

1 Configuring Tech-Support

1.1 Introduction

1.1.1 Overview

Tech-Support is an information collection function that provides diversified information collection triggering modes according to requirements of the administrator, and collects information on faulty equipment in different modes.

1.1.2 Principles

1. Basic collection

In basic collection mode, the directory files registered by the log framework are collected, including configuration files, Syslog, and CLI operations.

2. Full collection

In full collection mode, the following fault information is collected:

- All fault log files
- Coredump files
- Service realtime fault information

3. Hotkey collection

When the console fails, you can use the hotkey @@@@f to trigger one-click collection. For details about the collected content, see Full collection.

4. Reset key collection

Press the Reset key on the panel for less than 5s to collect the fault information. Five minutes later, the device is reset. For details about the collected content, see Full collection.

5. Storage of the collected content

During the running process of the device, all the files required (such as configuration files and system software) are stored in the storage media of the device. Each storage medium supported by the device is called a file system **USB:**, **Flash:**, or **Tmp:**. The storage medium of the USB drive type is called **USB:**; the storage medium of the flash type is called **Flash:**; the storage medium of the Tmp type is called **Tmp:**.

The collected fault information is stored in the descending order of USB flash drive, **Flash:/**, and **Tmp:/**.

If the collected fault information is not stored on the USB flash drive, at most two compressed packages are stored.

6. Collection of real-time diagnostic information

When a fault occurs, you can run the **show system diag-info** command in debug support mode to view the CLI commands that cause the fault, and collect the related fault information and save it in the **diag-info.txt** file on the Flash.

1.2 Enabling the Tech-Support Function

1.2.1 Overview

You can use the Tech-Support function to collect detailed fault information of a device and use it for fault location.

1.2.2 Restrictions and Guidelines

- When the device is connected to the console port, you can also use the hotkey **@@@@f** to collect detailed fault information of the device. The @@@@f hotkey operation is often performed when the console crashes. The fault information is packaged in a way similar to the **tech-support package** command.
- Before enabling the Tech-Support function, you are advised to check whether the device has sufficient space to store the fault information.
- To avoid an information collection failure due to insufficient storage space, you are advised to insert the USB flash drive into the device before enabling Tech-Support to avoid information loss. You can use the TFTP function to transfer the compressed packages of the final fault information to a PC.
- If the collected files are too large, it takes a long time to collect the information and services may be affected. To prevent this problem, if the collected coredump files exceed 200 MB or the number of files is too large, a collection failure notification will be displayed. In this case, you need to use other commands to collect coredump files separately.
- The specific procedure is as follows:

  a Run the **show coredump files** command to display the coredump file names.

```
Device# show coredump files
Directory of /xxx/xxx/xxx/ :
 core-xxx-xxx
```

  b Enter the debug support mode, run the **execute diagnose-cmd copy** command to copy the coredump files to the **data** directory, and upload the files to the specified TFTP server.

```
Device# debug support
Device(support)# execute diagnose-cmd copy xxx/xxx/xxx/core-xxx-xxx /data
This operation will modify file? [Y/N]:y
Device(support)# exit
Device# copy flash:/ xxx/xxx/xxx/core-xxx-xxx tftp://xxx.xxx.xxx.xxx/
This operation may overwrite file[tftp:// xxx.xxx.xxx.xxx /core-xxx-xxx]? [Y/N]:y
Press Ctrl+C to quit
!!!!!!!!!!!!!!!!!!!!!!!!!!!!
Copy success.
```

- The compressed packages of fault information are stored as follows:
  - USB flash drive

    If a USB flash drive is inserted into the device, the compressed packages are stored in the root directory of the USB flash drive. You can run the **dir usb0:** command to view these compressed packages.
  - Flash directory

    If no USB flash drive is inserted into the device, the compressed packages are preferentially stored in the Flash directory. You can run the **dir flash:** command to view these compressed packages.

- **Tmp** directory (memory)

  If no USB flash drive is inserted into the device and the Flash has insufficient space, the compressed packages are stored in the **Tmp** directory. You can run the **dir tmp:** command to view these compressed packages.

- To prevent excessive consumption of space on the storage media after the fault information is collected for multiple times, a maximum of three compressed packages of fault information can be stored on the same storage medium.

1.2.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the debug support mode.

debug support

(3) Enable the Tech-Support function. The configuration tasks below are mutually exclusive. Please configure only one task.

- Run the following command to enable the Tech-Support function:

  tech-support package [*component-name* | **basic**]

- Use the hotkey to enable the Tech-Support function.

  @@@@f

  This command takes effect only when the device is connected to the console port, and is invalid for remote connections, for example, Telnet or SSH connection.

1 Configuring Hotkeys 1

1.1 Introduction 1

1.1.1 Overview 1

1.1.2 Principles 1

1.2 Restrictions and Guidelines 2

1 Configuring Hotkeys

1.1 Introduction

1.1.1 Overview

Hotkeys provide a method of device debugging and maintenance. When the device is abnormal or cannot be controlled, the network administrator can use hotkeys to view the memory information, interrupt information, lock occupancy and process information of the device. You can also use hotkeys to perform one-click collection, enable and disable the logging function of the console, obtain key debugging information of the device, locate the causes of the device errors, and restore the normal operation of the device.

1.1.2 Principles

Currently supported hotkeys include 4@ key combination and 4$ key combination. For details about the key combination, see *Hotkey Commands*.

Note

Hotkeys only support input in the serial terminal of the device, other types of terminals cannot take effect.

1. 4@ Key Combination

Note

4@ key combination can also be replaced with 4Esc (that is, press the **Esc** key on the keyboard 4 times continuously), and then press the relevant character or number keys.

4@ key combination means that you can press the @ key on the keyboard 4 times continuously, and then press the relevant character keys. The characters represent the following functions:

- **b**: restarts the device.
- **c**: starts and stops the console.
- **d**: displays occupation information of all locks.
- **h**: displays hotkey help information.
- **i**: displays CLI debugging information.
- **j**: displays interrupt information.
- **l**: displays the started process information.
- **m**: displays memory statistics of the device.
- **n**: enables periodic output of interrupt information.
- **o**: disables periodic output of interrupt information.
- **p**: disables the console from outputting logs.
- **q**: displays the context switch time and running time of all threads.

- **r**: displays the current stack information of all CPU cores.
- **s**: displays the status of all threads.
- **t**: displays the kernel stack information of all threads.
- **x**: enables the console to output dots.
- **y**: disables the console from outputting dots.

2. 4$ Key Combination

4$ key combination means that you can press the **$** key on the keyboard 4 times continuously, and then press the relevant character or number keys. The characters or numbers represent the following functions:

- 0-9: sets the log output level of the kernel.
- **b**: restarts the device.
- **c**: constructs abnormal crash of the system.
- **d**: prints all lock information of the kernel.
- **e**: uses SIGTERM to kill all processes.
- **f**: actively triggers Out Of Memory (OOM) to kill a low-priority process.
- **i**: uses SIGKILL to kill all processes.
- **j**: unfreezes the file system forcibly.
- **k**: shuts down the process that uses the current Teletypes (TTY).
- **h**: displays system hotkey help information.
- **l**: displays the active CPU stack information.
- **m**: displays memory information of the device.
- **n**: configures the real-time process as a common process.
- **o**: shuts down the system.
- **p**: displays register information of the device.
- **q**: displays timer information of the device.
- **r**: restores the keyboard mode to character mode.
- **s**: synchronizes the files in cache to the disk.
- **t**: displays the kernel stack information of all threads.
- **u**: mounts all file systems in read-only mode.
- **w**: displays the blocked thread information on the device.
- **z**: prints the Function Tracer (Ftrace) cache information.

1.2 Restrictions and Guidelines

- Only serial port terminals support the hotkeys, but other remote terminals (such as Telnet and SSH) do not support the hotkeys.

1.4.1 Configuring the Function of Obtaining Packets Sent to the CPU 3

1 Configuring PCAP

1.1 Introduction

1.1.1 Overview

Packet Capture (PCAP) is used to obtain packets received by or sent from a device for fault analysis. As network technologies develop, network deployment becomes more complex. The PCAP function can be configured on a device to remotely locate faults, facilitating network maintenance.

When the PCAP function is configured on a device, the network administrator can view the obtained packets on the command line interface (CLI) or save the obtained packets as a *.pcap file on the storage medium of the device and then download the file to a local PC to view the packets using related software. The PCAP function allows you to analyze the causes of network failures with simplified deployment of packet analysis and network monitoring equipment. This improves network maintenance efficiency and reduces costs.

1.1.2 Principles

The device can obtain the following packets:

1. Packets Sent to the CPU

You can configure a packet obtaining point to specify the packet obtaining location, direction, matching rules, number of obtained packets, and file name. By analyzing the packets of various types sent to the CPU, you can locate the cause of the CPU exception and handle it in a timely manner to ensure the smooth operation of the CPU.

1.2 Configuring the Function of Obtaining Packets Sent to the CPU

1.2.1 Overview

When a CPU exception occurs (for example, the CPU usage is high), the device obtains and analyzes the packets sent to the CPU to locate the cause of the CPU exception and handle it promptly to ensure smooth CPU operation.

1.2.2 Restrictions and Guidelines

- To obtain packets of various types, you can configure a maximum of eight packet obtaining points with different names on the device simultaneously.
- You can configure packet obtaining rules to obtain required packets. The packet obtaining rules include:
  - Specify the location where packets are obtained. You can specify a physical port or CPU as the packet obtaining location. Only one packet obtaining location can be defined for a packet obtaining point but multiple packet obtaining points can be defined for a single packet obtaining location.
  - Specify the direction of the packets to be obtained. You can configure the device to obtain packets in the inbound, outbound, or both directions.
  - Obtain specific packets by matching the packet information. The packet information includes the source

MAC address, destination MAC address, Layer 2 protocol type, source IP address, destination IP address, Layer 3 protocol type, and TCP/UDP port information.

- Specify the name of the file that saves the obtained packets. You can save obtained packets as a *.pcap file on the storage medium of the device.
- Specify the conditions for automatically stopping packet obtaining: the number of packets to be obtained, the size of the file to save the obtained packets, or the duration of packet obtaining. After the PCAP function is enabled, the device automatically stops packet obtaining when any of the automatic stop conditions is met. When you run the **packet capture stop** command, the device immediately stops packet obtaining regardless of whether the stop condition is met.
- The device supports multiple packet obtaining rules with different names. A packet obtaining policy takes effect only when it is referenced by a packet obtaining point.
- Before deleting a packet obtaining rule, you need to delete all the packet obtaining points that reference this rule.

1.2.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Configure packet obtaining rules.

packet capture rule *rule-name* **filter** [**dst-mac** *mac-address* | **etype** *type* | **icmpv4_code** *icmpv4-code* | **icmpv4_type** *icmpv4-type* | **icmpv6_code** *icmpv6-code* | **icmpv6_type** *icmpv6-type* | **ipv4_dip** { *ipv4-address mask* | **host** *ipv4-address* } | **ipv4_dport eq** *port-number* | **ipv4_sip** { *ipv4-address mask* | **host** *ipv4-address* } | **ipv4_sport eq** *port-number* | **ipv6_dip** *ipv6-address prefix-length* | **ipv6_dport eq** *port-number* | **ipv6_sip** *ipv6-address prefix-length* | **ipv6_sport eq** *port-number* | **src-mac** *mac-address* | **v4_protocol** *protocl* | **v6_protocol** *protocol*] *

By default, no packet obtaining rule is configured.

(3) Configure a packet obtaining point.

packet capture point *name* **rule** *rule-name* **location** { **control-plane** | **interface** *interface-type interface-number* }{ **both** | **in** | **out** }

By default, no packet obtaining point is configured.

(4) Configure the name of the file where the obtained packets are saved.

packet capture file { **flash:** | **tmp: | usb0:** } *filename* [**buffer-size** *size*] [**packet-num** *number*] [**timeout** *timeout*]

By default, the name of the file where the obtained packets are saved is not configured.

(5) Enable the PCAP function.

packet capture start

By default, the PCAP function is disabled.

(6) (Optional) Disable the PCAP function manually.

packet capture stop

By default, the device automatically stops packet obtaining when the configured stop condition is met.

1.3 Monitoring

Run the **show** command to check the configuration.

Table 1-1 Monitoring

Command	Purpose
show packet capture status	Displays packet obtaining information.

1.4 Configuration Examples

1.4.1 Configuring the Function of Obtaining Packets Sent to the CPU

1. Requirements

The TCP connection fails on GigabitEthernet 0/1. Obtain TCP packets on this port for one minute.

2. Procedure

The following example configures a packet obtaining rule named tcp, and sets the Layer 2 protocol type to IPv4 and the Layer 3 protocol type to TCP for packet matching.

```
Device> enable
Device# packet capture rule tcp filter etype ip v4_protocol tcp
```

The following example associates the packet obtaining rule tcp with the packet obtaining point named tcppoint, and obtains bidirectional packets on port GigabitEthernet 0/1.

```
Device# packet capture point tcppoint rule tcp location interface gigabitethernet
0/1 both
```

The following example saves the obtained packets in the tcp.pcap file in the flash directory. The automatic stop condition is met when the size of the tcp.pcap file is 2 MB, the number of obtained packets reaches 1500, or the packet obtaining duration is 1 minute.

```
Device# packet capture file flash:tcp.pcap buffer-size 2 packet-num 1500 timeout
1
```

The following example enables the PCAP function.

```
Device# packet capture start
```

3. Verification

Run the **show packet capture status** command to display the configuration of the PCAP function.

```
Device# show packet capture status

Capture rules:
  Capture rules tcp:
    Etype: 0x0800
    Protocol: 0x6

Capture points:
```

```
  Capture point tcppoint:
    Capture rules: tcp
    Location: Gi0/1
    Direction: all
    Packets captured(all): 0

Capture file:
  Filename: flash:tcp.pcap
  Buffer size: 2(MB)

Capture Statistic:
  Status: running
  Start time: 2021-04-12 10:00:03
  Timeout: 1(minutes)
  Packets limit: 1500
  Write file packet count: 0
```

After packet obtaining ends, run the **show packet capture status** command to display the status of the PCAP function.

```
Device# show packet capture status

Capture rules:
  Capture rules tcp:
    Etype: 0x0800
    Protocol: 0x6

Capture points:
  Capture point tcppoint:
    Capture rules: tcp
    Location: Gi0/1
    Direction: all
    Packets captured(all): 60

Capture file:
  Filename: flash:tcp.pcap
  Buffer size: 2(MB)

Capture Statistic:
  Status: stopped
  Stopped reason: Timeout
  Start time: 2021-04-12 10:00:03
  End time  : 2021-04-12 10:01:03
  Timeout: 1 (minutes)
  Packets limit: 1500
  Write file packet count: 60
```

1.2 Monitoring.....1

1 Configuring Cluster Packet Tracing

1.1 Introduction

1.1.1 Overview

Cluster packet tracking includes a comprehensive set of mechanisms for packet tracing within a cluster. By configuring matching conditions for target packets and running the **display** command, you can trace the flow of target packets in a cluster and identify packet loss locations and causes through fault symptom analysis. Cluster packet tracking enhances problem localization efficiency and simplify fault location.

1.1.2 Principles

During packet processing, the cluster monitors packets based on the configured packet matching rules. The information monitored by the cluster includes the nodes traversed by packets, number of packets, and packet delays at each node. Ultimately, the cluster packet tracing component collects the monitoring results and outputs them on the Command Line Interface (CLI). This function is typically used by developers to locate faults, such as packet loss and delay in a cluster.

1.2 Monitoring

Run the **show** command to check the configuration.

Run the **clear** command to clear information.

Table 1-1 Monitoring

Command	Purpose
clear pkt configure	Clears the configured packet matching rules.
clear pkt statistic	Clears the packet matching results and restarts counting.
show pkt configure	Displays the configured packet matching rules.
show pkt statistic	Displays the packet matching results.

1 Configuring Alarm and Event Management

1.1 Introduction

1.1.1 Overview

Network device faults cause exceptions of services. When a fault occurs, you need to locate the fault quickly and troubleshoot it. An alarm is a notification generated by a device when a fault is detected. Checking an alarm with fault information is one of the most effective ways to locate the fault.

As the network grows in size and complexity, the failure of a service module may cause a large number of alarms. If all alarms are sent to the network management server or recorded and output through Syslog, system resources will be consumed and effective fault information cannot be collected.

You can manage the statistics and reports of alarms and events by the alarm management function. The alarms will be more effective and accurate, which helps a network manager to locate and troubleshoot faults efficiently.

- The alarm masking function masks alarms that users are not interested in to help them quickly obtain valuable fault information.
- The alarm suppression function controls the number of flapping alarms reported within a short period of time, and filters unstable alarms, to ensure that the user receives effective alarm information.

1.1.2 Principles

1. Basic Concepts

- Active Alarm

  An active indicates a persistent alarm. The active alarm persists if the fault is not fixed. When a service module detects a fault, it will send a notification to the alarm management module to inform the fault. The notification is displayed as an active alarm on the device.

- Historical Alarm

  Historical alarms record resolved alarms for fault location.

  When the service module reports the information about a resolved alarm, the alarm management module deletes the corresponding active alarm, records the recovery time, creates a historical alarm record, and updates the count and serial number of alarms. If the number of historical alarm records reaches the upper limit, the alarm management module deletes the earliest historical alarm record from the database.

- Event

  When an object or a status changes on the device, the notification generated by the device is called an event. Different from a persistent alarm, an event only displays a current change.

2. Active Alarm Report

If the service module reports that an active alarm is generated, the alarm management module checks the database to confirm the alarm. If the active alarm exists, the alarm management module does not handle the alarm notification. If the alarm does not exist, the alarm management module confirms whether the number of active alarms on the device reaches the upper limit. If the number of active alarms does not reach the upper

limit, the alarm management module sends the alarm to the network management server, or records and outputs the alarm through Syslog. If not, the alarm management module discards the alarm and records the alarm information in an internal log.

1.2 Configuration Task Summary

The configuration tasks of alarm and event management are as follows. The following configuration tasks are optional. Select the configuration tasks as required.

- Configuring Alarm Masking
- Configuring Alarm Suppression

1.3 Configuring Alarm Masking

1.3.1 Overview

Redundant alarms make it difficult for users or O&M personnel to locate faults. You can configure the alarm masking function to mask the alarms that users are not interested in.

1.3.2 Restrictions and Guidelines

- If you cancel the masking for a specified alarm, the service module can report the alarm only when the alarm matches no masking rules.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the alarm masking function and configure masking rules.

alarm mask { **alarm-name** *alarm-name* | **all** | **slot** *slot-id* }

The alarm masking function is disabled by default.

1.4 Configuring Alarm Suppression

1.4.1 Overview

For some service modules, the underlying state fluctuates frequently, which causes the alarm state to flap between alarm and recovery repeatedly within a short period of time. The alarm is not resolved during flapping. The actual state is unstable. In this case, if each alarm or alarm clearance is reported, the alarm notifications may flood, which affects user experience.

The alarm suppression function suppresses the report of flapping alarms. The service module does not report two alarm records with the same source during suppression, to improve the accuracy of alarms.

For the alarms that cannot be ignored in the application scenario, you can disable the alarm suppression function to obtain all alarms.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable the alarm suppression function.

alarm jitter suppress disable

The alarm suppression function is enabled by default.

1.5 Monitoring

Run the **show** command to display the configuration.

Run the **clear** command to clear information.

Note

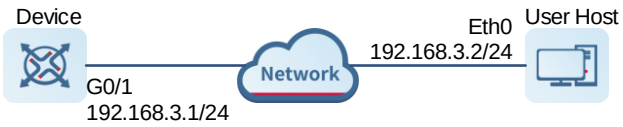
Running the **clear** command may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
clear alarm { **active** | **history** } [**sequence-number** *alarm-number*]	Clears alarm information.
clear alarm statistic	Clears all alarm statistics.
clear event { **all** | **sequence-number** *event-number* }	Clears event information.
show alarm active [**list**] [**above-severity** *severity* | **alarm-name** *alarm-name* | **module** *module-name* | **slot** *slot-id*] [**all**]	Displays the information about active alarms.
show alarm config	Displays the global configuration of the alarm module.
show alarm config alarm-name *alarm-name*	Displays the configuration of a specified alarm.
show alarm config event-name *event-name*	Displays the configuration of a specified event.
show alarm config list	Displays the information about all alarms.
show alarm history [**list**] [**above-severity** *severity* | **alarm-name** *alarm-name* | **module** *module-name* | **slot** *slot-id*]	Displays the information about historical alarms.
show alarm mask [**alarm-name** *alarm-name* | **slot**	Displays the information about masked alarms.

Command	Purpose
slot-id] [**all**]	
show alarm statistic [**alarm-name** *alarm-name* **slot** *slot-id*]	Displays the statistics of the alarm modules.
show event { **all** | **event-name** *event-name* | **slot** *slot-id* }	Displays the information about events.

1.6 Configuration Examples



1.6.1 Configuring Alarm and Event Management

1. Requirements

The alarm and event management function enables the network administrator to obtain valid fault information of the device in a timely manner and efficiently locate the device fault.

2. Topology

Figure 1-1 Topology

3. Note

- Enable the alarm masking function.
- Enable the alarm suppression function when the function is disabled.

4. Procedure

(1) Enable the alarm masking function and specify masking rules.

```
Device> enable
Device# configure terminal
Device(config)# alarm mask alarm-name ruijieLogicCpldRwError
Device(config)# alarm mask slot 0
```

(2) Enable the alarm suppression function.

```
Device> enable
DeviceA# configure terminal
Device(config)# no alarm jitter suppress disable
```

5. Verification

Run the **show alarm config** command to display the global configuration of the alarm module.

```
Device# show alarm config
```

```
Alarm state    : ALL READY
Mask flag      : enable
Active count    : 65536
History count   : 2000
Event count     : 0
Mask config set : 0
Active sequence num  : 65536
History sequence num : 65542
Event sequence num   : 0
Old master nodeid    : 0
Slot exist flag     : 0x40000000 (dev1) 0x40000000 (dev2)
Slot online flag    : 0x40000000 (dev1) 0x40000000 (dev2)
Slot mask flag      : 0x40000000 (dev1)
Jitter suppress flag : enable
```

6. Configuration Files

1.1.1 Overview.....1

1.1.2 Principles.....1

1.2 Restrictions and Guidelines.....1

1.3 Monitoring.....2

1 Configuring the Function of Displaying Device Restart Reasons

1.1 Introduction

1.1.1 Overview

Diversified availability detection functions are implemented to ensure the availability of all system functions. While the self-healing mode of killing the target process or restarting the line card can ensure system availability, it also brings certain risks since such self-healing behaviors cannot be tracked and controlled uniformly. When a process is killed or a line card is restarted, it is difficult to locate the service that triggers the event. Once the logic of a detection service fails, the process is frequently killed or the line card is frequently restarted, which may cause more serious system exceptions. To address this issue, a component is required to track and control the self-healing of services. Level-2 Protect and Self-healing (PSH) provides a method of viewing the device restart cause on the CLI. When a device restarts, you can view the device restart reasons by using the command provided by the PSH module on the device.

A device restart may be caused by logical exceptions of service functions or serious errors that cannot be processed by the system kernel, such as a device crash. When the system kernel encounters an exception, the system outputs some error information and actively restarts the device to recover normal operation of the system. The output error information includes the causes of kernel crashes, function stack, and registers. The exception and crash recording module is responsible for saving the system output containing the preceding error information and providing methods to facilitate locating causes of device crashes.

1.1.2 Principles

The PSH module collects information about the process that triggers restart of the device before the device restarts, and saves the restart reason locally. You can either run a command on a device to view the locally stored restart reason of the device, or run a command on the primary device of a cluster to view the restart reasons of all devices in the cluster.

1.2 Restrictions and Guidelines

Queries can only be performed on the active supervisor module of a device.

The card in the specified slot must be in position. Otherwise, the card cannot be queried.

Real-time queries can be performed only on the active supervisor module of a device, and only the active supervisor module and cards can be queried. The standby supervisor module does not support real-time queries.

In real-time queries, cards in the specified slot must be in position. Otherwise, the card cannot be queried.

The PSH module records only self-healing events of the system, and service components cannot use it as an internal logging tool to record logs of the running process in a log file.

1.3 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring of the Function of Displaying Device Restart Reasons

Command	Purpose
clear exception [**slot** *slot-id* | **slot all**]	Clears the records of exceptions that cause device crashes.
show exception [**slot** *slot-id* | **slot all**]	Displays the records of exceptions that cause device crashes.
show reboot-reason [**all**]	Displays the device restart reason.
show psh selfhealing	Displays system logs recorded by the PSH module.

1.4 Monitoring....2

1 Configuring Component Diagnostic Logs

1.1 Introduction

1.1.1 Overview

Component diagnostic logs display the log information of key events generated during the operation of the specified component on each card, facilitating quick and effective fault locating.

- Component operation logs of any card based on filter criteria
- Logs of the specified component and module based on filter criteria
- All operation logs of the specified component during a specific period
- All operation logs of the specified component and module during a specific period
- Statistics on the specified card, module, instance type, and instance
- Multi-instance logs at the specified level of the specified card, module, and instance type

1.1.2 Basic Concepts

1. Component Module Logs

Component module logs include the component logs and the core event logs generated by shared open files during the component operation.

2. Operation Logs

Operation logs refer to event logs generated by components during normal system operation.

3. Multi-Instance Logs

Multi-instance logs are classified logs of service components.

1.1.3 Principles

Each component and its modules save key events and processing information to the component log file during the component operation. Diagnostic log commands are used to display the operation data of each service module, the logs of the specified component and module, and the logs of all modules in a component in a chronological sequence.

1.2 Restrictions and Guidelines

- The command output is displayed when the command is run on the supervisor module to query logs of a specified component on a specified line card. Only the logs of explicit components can be queried.

1.3 Configuring Logging at the Specified Level

1.3.1 Overview

The log framework outputs logs with all severity levels by default. You can enable or disable logging at the specified level.

1.3.2 Restrictions and Guidelines

- This function takes effect globally and cannot be configured for a single service.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable logging at the specified level.

rg-log level *log-level* **log disable**

Logging at all levels except the debugging level is enabled by default.

1.4 Monitoring

Run the **show** command to check the configuration.

Run the **debug** command to output debugging information.

Caution

Debugging occupies system resources, so disable it immediately if not required.

Run the **clear** command to clear information.

Caution

During device operation, running the clear command may cause service interruption due to key information loss.

Table 1-1 Monitoring

Command	Purpose
clear log-file slot *slot-id* **component** *component-name*	Clears logs of the specified component in a slot.
debug log-center slot *slot-id* **component** *component_name* **flash config-info**	Displays the total log capacity in the var directory for the specified component in a slot.
debug log-center slot *slot-id* **component** *component_name* **flash statistic-info**	Displays the used log capacity in the var directory for the specified component in a slot.
debug log-center slot *slot-id* **component** *component_name* **memory config-info**	Displays the total log capacity in the tmp directory for the specified component in a slot.
debug log-center slot *slot-id* **component** *component_name* **memory statistic-info**	Displays the used log capacity in the tmp directory for the specified component in a slot.

Command	Purpose
debug log-center slot *slot-id* **flash config-info**	Displays the total log capacity in the var directory for all components in the specified slot.
debug log-center slot *slot-id* **flash statistic-info**	Displays the used log capacity in the var directory for all components in the specified slot.
debug log-center slot *slot-id* **memory config-info**	Displays the total log capacity in the tmp directory for all components in the specified slot.
debug log-center slot *slot-id* **memory statistic-info**	Displays the used log capacity in the tmp directory for all components in the specified slot.

1 Configuring Interface Link Diagnostics.....1

1.1 Introduction.....1

1.1.1 Overview.....1

1.1.2 Working Principle.....1

1.2 Monitoring.....1

1 Configuring Interface Link Diagnostics

1.1 Introduction

1.1.1 Overview

Linklayer Service Module (LSM) process is a physical link layer service module. Interface link diagnosis organizes and maintains interface information through the LSM and provides other modules with the services of querying interface information and notifying interface events. The LSM collects and displays details of interface information, data source registration information, client registration information, and MOM database status for fault locating.

1.1.2 Working Principle

- When the interface status or configuration changes, the interface table information is updated. You can run the **show lsm interface** command to display all information about the current interface.
- When the LSM process starts, it obtains the capability values supported by the device. You can determine whether a function is supported by running the **show lsm capacity** command to display the capability values related to the interface.
- When the LSM process starts, other services register as the LSM client and monitor events related to the interface. Run the **show lsm client** command to display interface events that are monitored by each client. This is to determine whether to send the interface event to the client when the interface information changes.
- The LSM sends messages to other services through the MOM database. Run the **show lsm mom** command to display the messages that are sent.

1.2 Monitoring

Run the **show** command to check the configuration.

Run the **clear** command to clear statistics.

Table 1-1 Monitoring

Command	Purpose
show lsm apinfo [*ap-number*]	Displays information about LSM aggregate interfaces.
show lsm capacity	Displays information about LSM capability values.
show lsm client [**detail** | **pid** *client-pid*]	Displays information about LSM clients.
show lsm database [**data-source** | **interface**]	Displays information about the LSM internal database.
show lsm data-source	Displays information about the LSM data source.
show lsm debug-performance	Displays debugging information about LSM performance.

Command	Purpose
show lsm hook	Displays registration information about LSM preprocessing.
show lsm interface [*interface-index* | *interface-type interface-number*]	Displays details of LSM interfaces.
show lsm kernel [**apinfo** [*ap-number*] | **hook** | **interface** [*interface-index* | *interface-type interface-number*] [**statistic**] | **memory** | **timer** | **vrf**]	Displays information about the LSM kernel.
show lsm lib pid *pid* [**apinfo** [*ap-number*] | **hook** | **interface** [*interface-index* | *interface-type interface-number*] [**statistic**] | **memory** | **timer** | **vrf**]	Displays information about the LSM library.
show lsm linux	Displays native Linux messages configured by using the LSM.
show lsm memory	Displays information about LSM memory usage.
show lsm mom { **app_db** | **local_db** | **tunner_db** } [**cap_agg_global** | **cap_eth_glb** | **cap_ethif** | **cap_ifportrange** | **cap_stormctrl** | **data_agg_global** | **data_agg_intf** | **data_agg_mbr** | **data_ether_global** | **data_ether_drv** | **data_ethif** | **data_if_counters** | **data_ifname_map** | **data_intf** | **data_stormctrl** | **dev_port** | **dev_port_static** | **fiber_state** | **port_det_result** | **ras_dsoverevt** | **state_agg_global** | **state_eth_split** | **state_ethif** | **state_fiber_info** | **state_ifattri** | **state_ifcreate** | **state_intf** | **state_intflimit** | **task_eee** | **task_fiber** | **task_line_detect**] [*interface-type interface-number* | *db-index*]	Displays information about the LSM MOM database.
show lsm mom sub-counts	Displays the number of database subscriptions.
show lsm net-client	Displays information about LSM NET client events.
show lsm redundancy	Displays information about LSM hot standby.
show lsm rpc_agent	Displays information about the LSM RPC proxy.
show lsm split_cache_info	Displays information about LSM split interfaces.
show lsm timer	Displays information about the LSM timer.

Command	Purpose
show lsm troubleshooting	Displays information about LSM diagnosis.
show lsm vrf	Displays information about LSM VRF.
clear lsm redundancy statistics	Clears LSM hot standby statistics.
