Personal Data Statement

During the operation or troubleshooting of the products, services, or features you have purchased, certain personal data of users may be collected or used. Therefore, it is essential for you to establish and implement appropriate privacy policies, in compliance with the relevant laws and regulations of the applicable countries or regions, to ensure the complete protection of users' personal data.

If Ruijie Networks is involved in this process, we will strictly adhere to the relevant laws and regulations of the applicable countries or regions and take all necessary actions to safeguard users' personal data.

When discarding, reclaiming, or reusing a device, please ensure to back up or clear any stored data to avoid data leakage. For assistance, please contact our after-sales technical support.

Preface

Intended Audience

This document is intended for:

- Network engineers
- Technical support and servicing engineers
- Network administrators

Technical Support

- Ruijie Networks website: https://www.ruijie.com/

Conventions

1. Conventions

Convention	Description
Boldface	The keywords of a command line are in **boldface**.
Italic	Command arguments are in *italics*.
[ ]	Items in square brackets are optional.
[x | y]	Optional items are grouped in braces and separated by vertical bars. One item or no item is selected.
{ x | y }	Optional items are grouped in brackets and separated by vertical bars. One item is selected.
[x | y | ...] *	Optional items are grouped in braces and separated by vertical bars. Several items or no item can be selected.
{ x | y | ... } *	Optional items are grouped in brackets and separated by vertical bars. A minimum of one item or a maximum of all items can be selected.
&<1-n>	The parameter before the & sign can be repeated for consecutive 1-n times.

Convention	Description
//	A line starting with double slashes is comments.

2. Signs

The signs used in this document are described as follows:

Warning

An alert that calls attention to important rules and information that if not understood or followed can result in data loss or equipment damage.

Caution

An alert that calls attention to essential information that if not understood or followed can result in function failure or performance degradation.

Note

An alert that contains additional or supplementary information that if not understood or followed will not lead to serious consequences.

Specification

An alert that contains a description of product or version support.

3. Notes

The manual provides configuration information, including models, port types, and command line interfaces, for reference purposes only. In the event of any discrepancy or inconsistency between the manual and the actual version, the actual version shall take precedence.

Basic Configuration

1. Configuring CLI
2. Configuring ZAM
3. Configuring Basic Management
4. Configuring RBAC
5. Configuring Lines
6. Configuring File System
7. Configuring USB

1 Configuring CLI

1.1 Introduction

The command line interface (CLI) is a window for text instruction interaction between users and network devices. Users can enter commands in the CLI to configure and manage network devices.

1.1.1 Accessing the CLI

Before using the CLI, you need to connect a terminal or PC to a network device. After you start the network device and initialize the hardware and software of the network device, you can use the CLI. If you use the network device for the first time, you can connect it only through the console port. This is called out-of-band management. After performing relevant configuration, you can connect and manage the network device by telnetting to the virtual terminal.

1.1.2 Command Modes

Since the device has many commands, you can classify them by function to facilitate their use. The CLI provides several commands modes, and all commands are registered in one or several command modes. You must enter the mode of a command before using this command. Command modes are related with each other but differ from each other.

As soon as a new session is set up between a user and the management interface of a network device, you enter user EXEC mode. In this mode, you can use a few commands and the command functions are limited, such as the **show** command. Execution results of commands in user EXEC mode are not saved.

To use more commands, enter privileged EXEC mode. Generally, you must enter a password to enter privileged EXEC mode. In privileged EXEC mode, you can use all commands registered in this command mode, and further enter global configuration mode.

Using commands in configuration modes (such as global configuration mode and interface configuration mode) affects configurations in use. If you save the configurations, these commands are saved and run when the system restarts. To enter another configuration mode, enter global configuration mode. If you perform configuration in global configuration mode, you can enter various configuration sub-modes, such as interface configuration mode.

Table 1-1 Description of the Command Modes (suppose that the name of the network device is "Device")

Command Mode	Access Method	Prompt	Exit or Entering Next Mode	Function Description of the Mode
User EXEC mode	A user enters user EXEC mode by default when accessing a network device.	Device>	Run the **exit** command to exit this mode. Run the **enable** command to enter privileged EXEC mode.	Use this command mode to conduct basic tests or display system information.
Privileged EXEC mode	In User EXEC mode, run the **enable** command to enter privileged EXEC mode.	Device#	Run the **disable** command to return to user EXEC mode. Run the **configure** command to enter global configuration mode.	Use this command mode to check whether the configurations take effect. This mode is password-protected.
Global configuration mode	In Privileged EXEC mode, run the **configure** command to enter global configuration mode.	Device(config)#	Run the **exit** or **end** command, or press **Ctrl+C** to return to privileged EXEC mode. Run the **interface** command to enter interface configuration mode. In the **interface** command, you must specify the interface configuration sub-mode you want to enter. Run the **vlan** *vlan-id* command to enter VLAN configuration mode.	Use commands in this mode to configure global parameters that affect the entire network device.

Command Mode	Access Method	Prompt	Exit or Entering Next Mode	Function Description of the Mode
Interface configuration mode	In global configuration mode, run the **interface gigabitethernet 0/1** command to enter interface configuration mode.	Device(config-if-gigabitethernet 0/1)#	Run the **end** command or press **Ctrl+C** to return to privileged EXEC mode. Run the **exit** command to return to global configuration mode. In the **interface** command, you must specify the interface configuration sub-mode you want to enter.	Use this command mode to configure various interfaces of the network device.
Config-vlan (VLAN configuration mode)	In global configuration mode, run the **vlan** *vlan-id* command to enter VLAN configuration mode.	Device(config-vlan)#	Run the **end** command or press **Ctrl+C** to return to privileged EXEC mode. Run the **exit** command to return to global configuration mode.	Use this command mode to configure VLAN parameters.

1.1.3 System Help

When entering commands in the CLI, you can obtain help information by using the following methods:

- At the command prompt in any mode, enter a question mark (?) to list the commands supported in current command mode and command description.

```
Device> ?
Exec commands:
  <1-99>     Session number to resume
  disable    Turn off privileged commands
  disconnect  Disconnect an existing network connection
  enable     Turn on privileged commands
  exit       Exit from the EXEC
  help       Description of the interactive help system
  lock       Lock the terminal
  ping       Send echo messages
  show       Show running system information
```

```
  telnet     Open a telnet connection
  traceroute  Trace route to destination
```

- Enter a space and a question mark (?) after a keyword of a command to list the next keyword or variable associated with the keyword.

```
Device(config)# interface ?
  Aggregateport    Aggregate port interface
  GigabitEthernet   Gigabit Ethernet interface
  Loopback         Loopback interface
  Null            Null interface
  Tunnel           Tunnel interface
  VLAN            Vlan interface
  range           Interface range command
```

Note

If a keyword is followed by a parameter value, the value range and description of this parameter are displayed as follows:

```
Device(config)# interface vlan ?
  <1-4094>  Vlan port number
```

- Enter a question mark (?) after an incomplete string of a command keyword to list all command keywords starting with the string.

```
Device# d?
debug  delete  dir  disable  disconnect do
```

- After an incomplete command keyword is entered, if the suffix of this keyword is unique, press the **Tab** key to displaythe complete keyword.

```
Device# show conf<Tab>
Device# show configuration
```

- In any command mode, you can run the **help** command to obtain brief description of the help system.

```
Device(config)# help
Help may be requested at any point in a command by entering
a question mark '?'. If nothing matches, the help list will
be empty and you must backup until entering a '?' shows the
available options.
Two styles of help are provided:
1. Full help is available when you are ready to enter a
   command argument (e.g. 'show ?') and describes each possible
   argument.
2. Partial help is provided when an abbreviated argument is entered
   and you want to know what arguments match the input
   (e.g. 'show pr?'.)
```

1.1.4 Abbreviated Commands

If a command is long, you can enter a part of the command keyword characters that are used to identify the command keyword.

For example, the **interface gigabitethernet 0/1** command for entering the configuration mode of interface GigabitEthernet 0/1 is abbreviated as follows:

```
Device(config)# int g0/1
Device(config-if-GigabitEthernet 0/1)#
```

1.1.5 No and Default Options of Commands

Most commands have the **no** option. Generally, the **no** option is used to disable a feature or function, or perform an operation opposite to a command. For example, run the **no shutdown** command on an interface to perform the operation opposite to the **shutdown** command, that is, enable the interface. The keyword without the **no** option is used to enable a disabled feature or a feature that is disabled by default.

Most configuration commands have the **default** option. The **default** option is used to restore settings of a command to default values. Default values of most commands are used to disable this function. Therefore, in most cases, the function of the **default** option is the same as that of the **no** option. For some commands, however, the default values are used to enable this function. In this case, the function of the **default** option is opposite to that of the **no** option. At this time, the **default** option is used to enable the function of this command and set the variables to default values.

Note

For specific function of the **no** or **default** option of each command, see the command reference.

1.1.6 Prompts for Incorrect Commands

If an incorrect command is entered, an error prompt is displayed.

Table 1-2 Common CLI Errors

Error	Description	How to Obtain Help
% Ambiguous command: "show c"	The characters entered are too few to identify a unique command.	Enter the command again, and enter a question mark (?) after the ambiguous word. All the possible keywords are displayed.
% Incomplete command.	The mandatory keyword or variable is not entered in the command.	Enter the command again, and enter a space and a question mark (?). All the possible keywords or variables are displayed.

% Invalid input detected at '^' marker.	An incorrect command is entered. The symbol (^) indicates the position of the wrong word.	At the current command mode prompt, enter a question mark (?). All the command keywords allowed in this command mode are displayed.

1.1.7 History Commands

The system automatically saves commands that are entered recently. You can use shortcut keys to query or call history commands.

Table 1-3 Operation Methods

Operation	Result
Ctrl+P or the Up key	The previous command in the history command list is displayed. Starting from the latest record, you can repeatedly perform this operation to query earlier records.
Ctrl+N or the Down key	After pressing **Ctrl+P** or the Up key, you can perform this operation to return to a command that is more recently executed in the history command list. You can repeatedly perform this operation to query more recently executed commands.

Specification

The standard terminals, such as the VT100 series, support the direction keys.

1.1.8 Featured Editing

When editing commands, you can use the keys or shortcut keys listed in the following table:

Table 1-4 Description of Shortcut Keys

Function	Key or Shortcut Key	Description
Move the cursor in a line.	Left key or **Ctrl+B**	Move the cursor to the left by one character.
	Right key or **Ctrl**+**F**	Move the cursor to the right by one character.
	Ctrl+**A**	Move the cursor to the head of the command line.

	Ctrl+**E**	Move the cursor to the end of the command line.
Delete an entered character.	Backspace key	Delete one character to the left of the cursor.
	Delete key	Delete one character to the right of the cursor.
Move the output by one line or one page.	Enter key	When the output is displayed, press the **Enter** key to move the output one line upward and display the next line. Use this key only when the output does not end yet.
	Space key	When the output is displayed, press the **Space** key to page down and display the next page. Only when the output does not end, use this key.

When the cursor is close to the right boundary, the entire command line moves to the left by 20 characters, and the hidden front part is replaced with a dollar ($) sign. You can use related keys or shortcut keys to move the cursor to the characters in the front or return to the head of the command line.

For example, the entire **access-list** command may be wider than the screen. When the cursor is first close to the end of the command line, the entire command line moves to the left by 20 characters, and the hidden front part is replaced with a dollar sign ($). Each time the cursor is close to the right boundary, the entire command line moves to the left by 20 characters.

```
access-list 199 permit ip host 192.168.180.220 host
$ost 192.168.180.220 host 202.101.99.12
$0.220 host 202.101.99.12 time-range tr
```

Press **Ctrl+A** to return to the head of the command line. At this time, the hidden tail part of the command line is replaced with a dollar sign ($).

```
access-list 199 permit ip host 192.168.180.220 host 202.101.99.$
```

Note

The default line width of terminals is 80 characters.

1.1.9 Searching and Filtering of the Show Command Output

- To search specified content in the output of the **show** command, run the following command:

Table 1-5 Searching for Specified Content in the Output of the show Command

Command	Purpose
show *any-command* | [**regexp**] **begin** *regular-expression*	Searches for specified content in the output of the **show** command, and outputs the first line containing the content and all information that follows this line.

- To filter specified content in the output of the **show** command, run the following commands:

Table 1-6 Filtering Specified Content in the Output of the show Command

Command	Purpose
show *any-command* | [**regexp**] **exclude** *regular-expression*	Filters the output of the **show** command to filter out lines containing the specified content, and outputs other information.
show *any-command* | [**regexp**] **include** *regular-expression*	Filters the output of the **show** command to output only the lines containing the specified content, and filters out other information.

Note
- The **show** command can be executed in any mode.
- Searched content is case-sensitive.

When the **regexp** keyword is specified, a regular expression can be used for filtering content. The following table describes the usages of special characters in a regular expression.

Table 1-7 Description of Usages of Special Characters in a Regular Expression

Character	Symbol	Special Meaning
Period	.	Matches any single character.
Plus sign	+	Matches one or any sequence in a string.

Caret	^	Matches the start of a string.
Underline	_	Matches commas, brackets, start and end of a string, and spaces.
Square brackets	[ ]	Matches a single character within a range.

To search or filter the output of the **show** command, you must enter a vertical line (|). After the vertical line, specify the search or filter rules and content to be searched or filtered (characters or strings). Content to be searched and filtered is case-sensitive.

```
Device# show running-config | include interface
interface GigabitEthernet 0/0
interface GigabitEthernet 0/1
interface GigabitEthernet 0/2
interface GigabitEthernet 0/3
interface GigabitEthernet 0/4
interface GigabitEthernet 0/5
interface GigabitEthernet 0/6
interface GigabitEthernet 0/7
interface Mgmt 0
Device# show running-config | regexp include GigabitEthernet [0-9]/1
interface GigabitEthernet 0/1
```

1.1.10 Redirection of the show Command Output

- To redirect the **show** command output to a file, run the following command.

Table 1-8 Redirection of the show Command Output

Command	Description
show any-command > file_path	Redirects the show command output to a file.

To redirect the **show** command output to a file, enter the greater than sign (>) and add the file name (Flash, Tmp, and USB partitions are supported) following this sign.

```
Device# show running-config > flash:output.txt
```

1.1.11 Command Alias

You can specify any word as the alias of a command to simplify the input of the command string.

1. Default aliases in the system

In configuration mode or privileged EXEC mode, default aliases are available for some commands. You can run the **show aliases** command to display these default aliases.

```
Device(config)# show aliases
Exec mode alias:
  h                 help
  p                 ping
  s                 show
  u                 undebug
  un                undebug
```

Note

Default aliases in the system cannot be deleted.

2. System help regarding command aliases

- The system provides help information for command aliases. An asterisk (*) is displayed in front of an alias in the following format:

  ```
  *command-alias=original-command
  ```

  For example, in privileged EXEC mode, the default command alias "s" represents the keyword **show**. If you enter "s?", help information of the keywords and aliases starting with "s" is displayed.

  ```
  Device# s?
  *s=show  show  start-chat  start-terminal-service
  ```

- If the command represented by an alias contains more than one word, the command is displayed in a pair of quotation marks.

  For example, in privileged EXEC mode, configure the alias "sv" to replace the **show version** command. If you enter "s?", help information of the keywords and aliases starting with "s" is displayed.

  ```
  Device# s?
  *s=show  *sv="show version" show  start-chat
  start-terminal-service
  ```

- You can use an alias to obtain help information of the command represented by the alias.

  For example, if you configure the alias "ia" in interface configuration mode to represent the **ip address** command, you can enter "ia?" in interface configuration mode to obtain help information of "**ip address**?", and replace the alias with the actual command.

  ```
  Device(config-if)# ia ?
    A.B.C.D  IP address
    dhcp     IP Address via DHCP
  Device(config-if)#ip address
  ```

Caution

If you enter a space in front of a command alias, the command represented by this alias is displayed.

1.1.12 Character Set Encoding

The function of character set encoding enables the device to use a unified character set encoding format by configuring character set encoding. After a command is entered in the CLI of a terminal, the command is automatically converted into a command in the unified character set encoding format before delivery.

Note

When hybrid formats exist in current running configurations, you must manually delete running configurations containing the encoding format different from the target format before modifying the character set encoding format.

1.2 Restrictions and Guidelines

You can adopt UTF-8/GBK to perform configuration in Chinese. When you use the cursor to process words or delete **Backspace** in the CLI, the interface may display errors or garbled characters. You are advised to delete all current characters and then configure a unified character set encoding format. Upon word processing or Backspace deletion, you can run the **show running-config** command to check whether the configurations are correct. (To delete a Chinese character, you must press the **Backspace** key twice in the case of GBK, but must press the **Backspace** key three times in the case of UTF-8.)

1.3 Configuration Task Summary

CLI configuration includes the following tasks: All the configuration tasks below are optional. Select the configuration tasks as required.

- Operating the Python Script
- Configuring a Command Alias
- Configuring the Privilege Level of a Command
- Configuring the Character Set Encoding Format

1.4 Operating the Python Script

1. Overview

This section describes how to load and unload the Python script of CLI.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Operate the Python script. The configuration steps below are mutually exclusive. Select one of them for configuration.

- Load the Python script.

  cli-python insmod *python-filename*

- Unload the Python script.

  cli-python rmmod *python-filename*

1.5 Configuring a Command Alias

1. Overview

You can specify any word as the alias of a command to simplify the input of the command string.

2. Restrictions and Guidelines

- The command replaced with an alias must start from the first character of the command line.
- The command replaced with an alias must be complete.
- An alias must be entered in full; otherwise, it cannot be identified.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an alias to replace the front part of a command.

alias *mode command-alias original-command*

Default aliases are available for some commands in global configuration mode or privileged EXEC mode by default.

1.6 Configuring the Privilege Level of a Command

1. Overview

This section describes how to configure the privilege level of a command.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the privilege level of a command.

privilege *mode* [**all**] { **level** *level* | **reset** } *command-string*

1.7 Configuring the Character Set Encoding Format

1. Overview

This section describes how to configure a unified character set encoding format for the device.

2. Restrictions and Guidelines

- When hybrid formats exist in current running configurations of the device, you must manually delete running configurations containing the encoding format different from the target format before modifying the character set encoding format.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the character set encoding format.

language character-set { **default** | **GBK** | **UTF-8** }

By default, hybrid formats are supported.

1.8 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Table 1-9 Monitoring of the CLI

Command	Purpose
show aliases [*mode*]	Displays all command aliases or the command aliases in specific command mode.
show cli session	Displays information about running CLI sessions.
show cli model state	Displays the CLI service module readiness status.

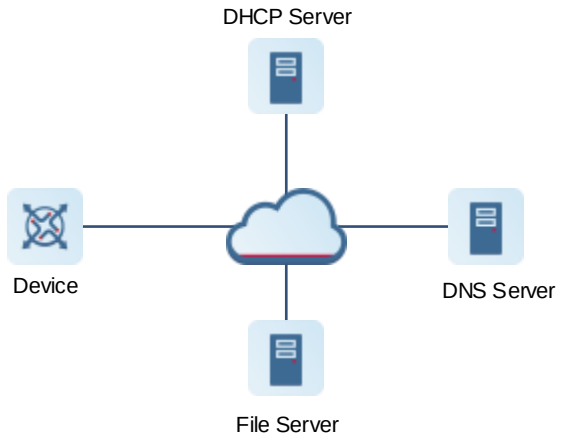
1 Configuring ZAM



1.1 Introduction

1.1.1 Overview

The zero automatic manager (ZAM) function enables the device to automatically download the software version, upgrade the device version, and apply configuration files when the device has no configuration and the network administrator is not in contact with the field devices. ZAM simplifies the operation, maintenance, and deployment of massive devices, lowers the labor cost, reduces human errors, and improves the efficiency of network deployment.

1.1.2 Principles

Figure 1-1 ZAM Automatic Go-Online Solution

ZAM go-online and deployment include four stages as follows:

(1) Initialization

At this stage, a device that goes online without configurations connects to a network and completes initialization. The device automatically pre-deploys the ZAM environment. During the pre-deployment, the MGMT port or service port must be used as the ZAM interface. The device automatically performs configuration, without any need of extra configuration by the administrator.

(2) DHCP

Upon the pre-deployment above, the ZAM interface requests an IP address from the Dynamic Host Configuration Protocol (DHCP) server via the DHCP protocol. In a reply packet, the reply packet carries Option 66 (containing the IP address of the file server) and Option 67 (containing the name of the Python script to be downloaded). The requirements are as follows:

- The ZAM interface supports DHCP.

- Configure the ZAM interface with a DHCP-allocated IP address. DHCP requests support Option 66 and Option 67, and Option 66 and Option 67 have been configured in the address pool of the DHCP server.
- The device analyzes and deploys the IP address of the ZAM interface, and analyzes the content of Option 66 and Option 67.

(3) TFTP

Based on the file name of the Python script and the IP address of the ZAM server (on which the TFTP server function will be deployed) obtained during DHCP, the device downloads the corresponding configuration script from the ZAM server.

Upon downloading above, the device executes the configuration script and downloads the corresponding configuration file or version from the ZAM server.

(4) Configuration loading

After the Python script is executed, the device restarts automatically to update the device version and load the configuration file.

1.2 Restrictions and Guidelines

- An automatic retry is available after a ZAM failure. In this case, check whether the network functions properly and whether the DHCP server is correctly configured based on the ZAM failure prompt.
- For a product version with ZAM disabled by default, please manually enable this function.

1.3 Configuring ZAM

1.3.1 Overview

This section describes how to configure ZAM to enable a device with no configurations to implement automatic deployment.

1.3.2 Restrictions and Guidelines

To use the ZAM function, deploy the ZAM server and DHCP server.

1.3.3 Prerequisites

- Configure the address pool, Option 66, and Option 67 for the DHCP server. The configuration example is as follows:

```
ip dhcp pool poap
 option 67 ascii zam.py
 option 66 ascii 100.1.1.2
```

- Deploy the TFTP server function on the ZAM server. Store the Python script file in the root directory of the ZAM server, and create the folders listed in Table 1-1 in the root directory to store the files required during the ZAM configuration.

Table 1-1 Description of Folders to Be Created on the ZAM Server

Folder Name	Content	Function
POAP_CFG	● xxxx.cfg ● xxxx.params	● xxxx.cfg: Indicates the configuration file of the device. The configuration file of each device is named after the sn value of the device and uses .cfg as the suffix. ● xxxx.params: Indicates the parameter file of the device. It contains the path to the downloaded configuration file, path to the file used for version upgrade, and the name of the version file. ● The device automatically downloads the files.
POAP_IMAGE	Version binary file	● The folder stores the version file of the device. ● The device automatically downloads the file.
POAP_LOG	Log file	● The folder stores the log files uploaded during the ZAM configuration of the device. The log files of each device are named after the sn value of the device. ● The device automatically uploads the files.
POAP_STARTUP	Device sn value files	● The folder stores the sn value file of the device where ZAM needs to be configured. ● The device automatically uploads the file.
POAP_STATUS	-	● The folder stores the ZAM result log files, which are named after the sn value. ● The device automatically uploads the files.

1.3.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable ZAM.

zam

The ZAM function is enabled by default.

1.4 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

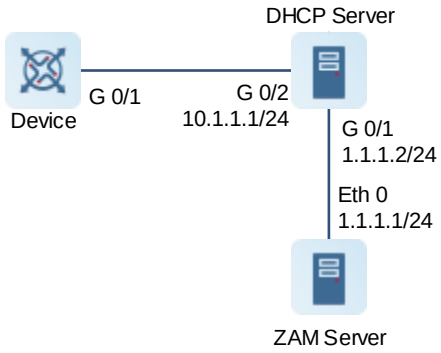
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-2 ZAM Monitoring

Command	Purpose
debug zam	Enables the ZAM framework event debugging.
show zam	Displays the current configurations and status of ZAM.

1.5 Configuration Examples



1.5.1 Configuring ZAM

1. Requirements

Manage and control onboarding and deployment of all devices in the network in a unified manner. Realize the unified management of onboarding and deployment of all devices.

2. Topology

Figure 1-2 ZAM Topology

3. Notes

- Configure the DHCP server.

- Configure the ZAM server.
- Enable the ZAM function on the devices.

4. Procedure

(1) Configure the DHCP server.

Set the IP address of interface GigabitEthernet 0/1 of the DHCP server to 1.1.1.2/24.

```
Dhcp_Server> enable
Dhcp_Server# configure terminal
Dhcp_Server(config)#interface gigabitEthernet 0/1
Dhcp_Server(config-if-GigabitEthernet 0/1)# ip address 1.1.1.2 255.255.255.0
```

Set the IP address of interface GigabitEthernet 0/2 of the DHCP server to 10.1.1.1/24.

```
Dhcp_Server(config)#interface gigabitEthernet 0/2
Dhcp_Server(config-if-GigabitEthernet 0/2)# ip address 10.1.1.1 255.255.255.0
```

Enable the DHCP server function.

```
Dhcp_Server(config)# service dhcp
```

Configure the address pool of the DHCP server.

```
Dhcp_Server(config)# ip dhcp pool zam
Dhcp_Server(dhcp-config)# network 10.1.1.1 255.255.255.0
Dhcp_Server(dhcp-config)# default-router 10.1.1.1
```

Configure Option 66.

```
Dhcp_Server(dhcp-config)# option 66 ascii 1.1.1.1
```

Configure Option 67.

```
Dhcp_Server(dhcp-config)# option 67 ascii zam.py
```

(2) Configure the ZAM server. Store the intermediate file (Python script named **zam.py**), and the configuration files and version files to be delivered to the devices on the ZAM server. For details, see 1.3.3 Prerequisites.

(3) Enable the ZAM function on the devices.

Delete the configuration files from the devices.

```
Device# delete config.text
Do you want to delete [flash:/config.text]? [Y/N]:y
Delete success.
```

Run the **reload** command to restart the devices to enable the ZAM function.

```
*May 13 15:47:36: %ZAM-6-EVENT: Get tftp server ip 1.1.1.1.

5. Verification

Run the **show dhcp lease** command to display the obtained IP address.

```
Device# show dhcp lease
Temp IP addr: 0.0.0.0  for peer on Interface: Mgmt 0
Temp  sub net mask: 0.0.0.0
   DHCP Lease server: 0.0.0.0, state: 3 Init-proc
   Retry count: 7   Client-ID: 01300588aba05e4D670D7430
Temp IP addr: 10.1.1.2  for peer on Interface: VLAN 1
Temp  sub net mask: 255.255.255.0
   DHCP Lease server: 10.1.1.1, state: 9 Inform-proc
   DHCP transaction id: 75cf492b
   Lease: 16400 secs,  Renewal: 43200 secs,  Rebind: 75600 secs
   Next timer fires after: 43054 secs
   Retry count: 0   Client-ID: 01300588aba05d564C414E31
```

Run the **show zam** command to check the execution status of the ZAM function.

```
Device# show zam
ZAM state           :enable
ZAM status          :Now is waiting for do shell exec
Server ip           :1.1.1.1
Usb path            :NULL
Interface name       :VLAN 1
Interface type       :SVI
Succ Interface name   :VLAN 1
Script URL          :tftp://1.1.1.1/zam.py
```

6. Configuration Files

- DHCP server configuration file

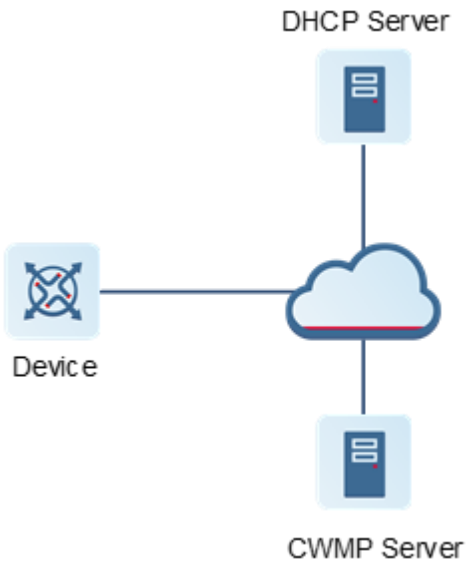
```
hostname Dhcp_Server
!
ip dhcp pool zam
 option 66 ascii 1.1.1.1
 option 67 ascii zam.py
 network 10.1.1.0 255.255.255.0
 default-router 10.1.1.1
!
end
```

7. Common Errors

- The network connection between the device and the ZAM server is abnormal.
- The configuration file on the device is not deleted.
- When ZAM obtains scripts and configuration files for zero-configuration startup, the scripts and configuration

files can be downloaded only through SVI 1 interface and the MGMT port of the active supervisor module. The MGMT ports of non-active supervisor modules cannot automatically obtain the configuration files.

2 O&M Automatic Deployment Application



2.1 Introduction

2.1.1 Overview

The Operation and maintenance (O&M) automatic deployment application is also a zero-configuration automatic deployment solution. Unlike ZAM, it allows the unconfigured device that is started to automatically connect to the CPE WAN Management Protocol (CWMP)server and to complete device login and application configuration template functions. It also simplifies O&M of large-scale devices, reduces labor costs, minimizes human errors, and improves network deployment efficiency.

2.1.2 Principles

Figure 2-1 Networking of O&M automatic deployment application

The O&M automatic deployment application involves four phases:

(1) Initialization

When an unconfigured device goes online, the device is powered on, is connected to a network device, and loads the configuration. Then the CWMP service, loop prevention, and dynamic IP address application are automatically enabled. This process does not require additional configuration by a network administrator.

(2) DHCP phase

After the pre-deployment in the initialization phase is complete, the device will apply for an IP address from the DHCP server through DHCP on the interface of VLAN 1. The Option 43 field in the DHCP Reply packet contains the address of the INC server and the **ruijie_inc_acc_zcm** field. The requirements are as follows:

- The O&M automatic deployment application interface can be enabled with DHCP, and dynamic IP address application is enabled in VLAN 1 by default.
- The DHCP server should be configured with only one login mode. Different login modes use the management network for isolation.

(3) CWMP phase

The device connects to the CWMP server based on the CWMP server's address obtained from the DHCP phase to obtain the device configuration template or customized configuration.

(4) Configuration loading

After the configuration file is downloaded, the device automatically restarts.

2.2 Restrictions and Guidelines

2.2.1 Onboarding of the O&M Automatic Deployment Application

- The O&M automatic deployment application is enabled based on product features, and no additional configuration is required.
- Before starting the O&M automatic deployment application, configure the address pool and Option 43 on the DHCP server. The configuration example is as follows.

```
ip dhcp pool poap
 option 43 ascii https://172.18.149.122:8089/vlan/cwmp/inform/ruijie_inc_acc_zcm
 network 10.1.1.1 255.255.255.0
 default-router 10.1.1.1
```

- When the O&M automatic deployment application is started, the unconfigured device can be automatically deployed.
- When the O&M automatic deployment application is provisioned, first deploy a CWMP server configuration template.
- If the device cannot be connected to the CWMP server, the device automatically re-applies for an IP address.
- To implement onboarding in different modes, you need to use different management networks for isolation.
- The DHCP server and CWMP server can be deployed on the same device.

2.2.2 Loop Prevention Detection

- When an unconfigured device goes online through O&M automatic deployment application or ZAM, loop prevention detection is enabled by default. The loop prevention detection function relies on RLDP protocol and storm traffic statistics collection methods. When a loop occurs on the device or storm traffic occurs on an interface, the **shutdown** command is is automatically configured on the corresponding interface.
- The warning action of RLDP is enabled by default.
- When a user enters the configuration mode, automatic loop prevention detection is disabled.

- When the device detects a loop on an interface, it automatically configures the **shutdown** command on the interface to eliminate possible loops on the network. If you save the configuration of the device and perform the **write** operation, the **shutdown** command configuration exists on the corresponding interface of the device. To enable this interface, enter the configuration mode before performing the write operation. In this case, the loop prevention detection function is disabled. Or, perform the write operation, and then run the **no shutdown** command on the interface.

2.3 Configuring Network Access With No SN Input or Approval

2.3.1 Overview

Before an unconfigured device goes online\, you need to manually collect the device's SN. The device can go online only after the device's SN is recorded on the controller. The site ID is introduced to achieve fast onboarding. The site ID is equivalent to the SN for onboarding. After learning the site ID, the device registers with the CWMP server and goes online with the site ID.

The controller selects several seed devices on a network. A seed device is a device whose SN has been manually entered and is bound to a site ID. When the seed device goes online, the controller delivers the site ID through the CWMP RPC method. The device resolves CWMP packets to obtain the site ID and periodically broadcasts the site ID through Layer 2 broadcast packets.

A non-seed device learns the site ID through Layer 2 broadcast and registers with the CWMP server to go online with the site ID. However, a non-seed device does not broadcast the site ID by default.

If the device learns the site ID through Layer 2 broadcast and the site ID is inconsistent with the local site ID, the device only generates a syslog.

2.3.2 Restrictions and Guidelines

- On the controller, you need to enter the SN of one or more devices and create a site ID as the seed device. Otherwise, other devices cannot go online.
- Ensure that the device has no other site ID information.

  Run the **show amaint-app network-id detail** command to check whether the device has a site ID. If the device has other site ID information, the device may fail to go online. Run the **no amaint-app network-id** command to clear the site ID.
- By default, a device can learn the site ID from CWMP packets sent by a controller or Layer 2 broadcast packets. To manually being the device to go online, run the **amaint-app network-id** command to configure a network ID for the device.

2.3.3 Configuration Procedure

(1) Enter the privileged EXEC mode.
enable

(2) Enter the global configuration mode.
configure terminal

(3) (Optional) Configure the site ID and name of the device.
amaint-app network-id *network-id* **network-name** *network-name*

By default, no site ID or site name is configured for an unconfigured device.

(4) (Optional) Enable the device to periodically learn the site ID from broadcast packets.
amaint-app idcp broadcast

By default, a seed device broadcasts the site ID, and a non-seed device does not broadcast the site ID.

(5) (Optional) Configure the interval for broadcasting the site ID.
amaint-app idcp interval time

The default interval for broadcasting the site ID is 30 seconds.

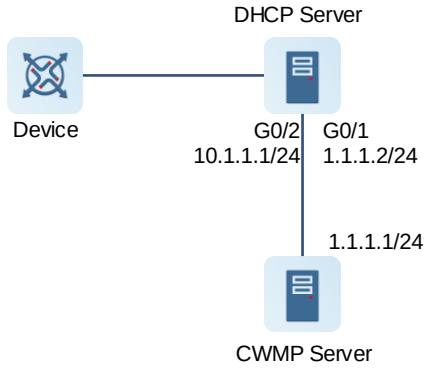
2.4 Monitoring

Run the **show** command to check the configuration.

Table 2-1 Monitoring

Command	Purpose
show amaint-app loop-detect	Displays loop information of the device.
show amaint-app network-id detail	Displays the site ID of the device.

2.5 Configuration Examples



2.5.1 Configuring Basic Functions of O&M Automatic Deployment Application

1. Requirements

Uniformly manage and control the deployment and onboarding process of all devices on a network.

2. Topology

Figure 2-2 Topology for Basic Functions of O&M Automatic Deployment Application

3. Notes

- Configure the DHCP server.
- Configure the CWMP server.
- Start the unconfigured device.

4. Procedure

(1) Configure the DHCP server.

Set the IP address of GigabitEthernet 0/1 of the DHCP server to 1.1.1.2/24.

```
Dhcp_Server> enable
Dhcp_Server# configure terminal
Dhcp_Server(config)# interface gigabitEthernet 0/1
Dhcp_Server(config-if-GigabitEthernet 0/1)# ip address 1.1.1.2 255.255.255.0
```

Set the IP address of GigabitEthernet 0/2 of the DHCP server to 10.1.1.1/24.

```
Dhcp_Server(config)# interface gigabitEthernet 0/2
Dhcp_Server(config-if-GigabitEthernet 0/2)# ip address 10.1.1.1 255.255.255.0
```

Enable the DHCP server function.

```
Dhcp_Server(config)# service dhcp
```

Configure the address pool of the DHCP server.

```
Dhcp_Server(config)# ip dhcp pool inc
Dhcp_Server(dhcp-config)# network 10.1.1.1 255.255.255.0
Dhcp_Server(dhcp-config)# default-router 10.1.1.1
```

Configure Option 43.

```
Dhcp_Server(dhcp-config)# option 43 ascii
http://172.29.101.91:8096/vlan/cwmp/inform/ruijie_inc_acc_zcm
```

(2) Configure the CWMP server configuration template.

(3) Start the unconfigured device.

Delete the configuration file from the device.

```
Device# delete config.text
Do you want to delete [flash:/config.text]? [Y/N]:y
Delete success
```

Run **reload** to restart the device.

```
Device# reload
Reload system?(Y/N)y
```

5. Verification

Run the **show dhcp lease** command to display the result of obtaining an IP address.

```
Device# show dhcp lease
Temp IP addr: 0.0.0.0  for peer on Interface: Mgmt 0
```

```
Temp  sub net mask: 0.0.0.0
   DHCP Lease server: 0.0.0.0, state: 3 Init-proc
   Retry count: 7   Client-ID: 01300588aba05e4D670D7430
Temp IP addr: 10.1.1.2  for peer on Interface: VLAN 1
Temp  sub net mask: 255.255.255.0
   DHCP Lease server: 10.1.1.1, state: 9 Inform-proc
   DHCP transaction id: 75cf492b
   Lease: 16400 secs,  Renewal: 43200 secs,  Rebind: 75600 secs
   Next timer fires after: 43054 secs
   Retry count: 0   Client-ID: 01300588aba05d564C414E31
```

Run the **show amaint-app loop-detect** command to check the loop prevention configuration.

```
Device# show amaint-app loop-detect
Loop-detect configuration:
    source:AMAINT
    source:zam
Loop-detect loop list:
Interface            State       Module    Loop-time     Recover     Loop-cnt
---------------------- ------------ ---------- -------------- ------------ --------
Gi1/0/1              up          NONE      0            0          0
Gi1/0/2              up          NONE      0            0          0
Gi1/0/3              up          NONE      0            0          0
Gi1/0/4              up          NONE      0            0          0
Gi1/0/5              up          NONE      0            0          0
```

Run the **show amaint-app neighbor** command to display neighbor information on the device.

```
Device#  show amaint-app
neighbor----------------------------------------------------------------
Neighbor-information of port [Gi1/0/9]
  Neighbor Port                 : Gi0/16
  Neighbor MAC                  : 00d0.f016.6668
  Neighbor SerialNum             :
  Neighbor IPv4                 : 192.168.1.130
  Neighbor Chassis ID            : 00d0.f016.6668
  Multi-service neighbor         : false
  Neighbor has been alive        : 19 s
```

6. Common Errors

- The network connection between the device and CWMP server is abnormal.
- The configuration file on the device is not deleted.

1 Configuring Basic Management

1.1 Overview

To reduce the inconvenience caused by on-site maintenance, IT devices are widely managed remotely. Even initial deployment can be carried out remotely. Remote management needs to consider the various operational needs of network administrators and the security of device management. A series of functions of basic management address security, maintenance and monitoring issues.

- Security: Basic management provides permissions, encryption authentication and access control to ensure device security.
- Maintenance: Basic management provides flexible configuration management methods, such as backup, rollback and batch execution, etc.
- Monitoring: Basic management provides various software and hardware monitoring functions to display information of memory, CPU, bus, session, etc..

1.2 Basic Concepts

Table 1-1 Basic Concepts

Concept	**Description**
TFTP	The Trivial File Transfer Protocol (TFTP) is a protocol used for simple file transfer between a client and a server in the Transmission Control Protocol (TCP)/Internet Protocol (IP) suite.
AAA	Authentication, Authorization and Accounting (AAA), including: Authentication: Verifies user identities and available network services. Authorization: Grants network services to users according to authentication results. Accounting: Records the network service consumption of users and to send the records to the billing system. After the AAA mode is enabled, some servers (or the local user database) are used to authenticate users' management permissions according to their usernames and password at terminal login and the configured AAA login authentication method list. For details about AAA, see *Configuring AAA*.
RADIUS	The Remote Authentication Dial in User Service (RADIUS) is the most widely used AAA protocol.

Concept	**Description**
Telnet	Telnet is a terminal emulation protocol in the TCP/IP protocol suite which provides a connection to a remote host by creating a virtual terminal. It is a standard protocol at Layer 7 (application layer) of the Open System Interconnection (OSI) model and is used on the Internet for remote login. During remote login through telnet, users must enter the usernames and passwords for authentication. Telnet sets up a connection between the local personal computer (PC) and a remote host.
System information	System information includes the system description, system power-on time, system hardware and software versions, control-layer software version, and boot-layer software version.
Hardware information	Hardware information includes the physical device information as well as information about pluggable modules on the device. The device information includes the device description and slot quantity. The slot information includes the slot ID, module description (which is empty if a slot does not have a module), number of physical ports on a module inserted into a slot, and maximum number of ports supported by a slot.
System configurations	System configurations include: Running configurations: Configurations running on all component modules of the system. Startup configurations: Configurations stored in the non-volatile random-access memory (NVRAM) of the system.

1.3 Protocol Specification

RFC 874: Telnet Protocol Specification

1.4 Restrictions and Guidelines

- Pay attention to the following when entering a string:
  - If the string is in double quotation marks, any characters can be inside the quotation marks. To include quotation marks in the string, you must translate the character prefix “\”. For example, if the input string is "hello my friend \"Haha\"", the saved string is as follows: hello myfriend "Haha".
  - If the string does not contain a right quotation mark, the string ends at the end of the command line. For example, if the string is “hello my friend \"Haha\", the string is saved as follows: hello my friend "Haha".
  - A string without quotation marks cannot carry delimiters, such as spaces and tabs. The valid value is a string of ha-ha or Haha.

1.5 Configuration Task Summary

All the following configuration tasks are optional and maybe selected as needed.

Basic functions:

- Configuring Basic System Parameters
  - Configuring Connection to the Supervisor Module or Member Device
  - Configuring a System Name and Command Prompt
  - Configuring System Notifications
  - Configuring the System Clock
- Enabling or Disabling a Specific Service

Permission and login control:

- Configuring Passwords and Privilege Levels
- Configuring Telnet Login
  - Configuring the Telnet Service
  - Configuring Telnet Access Security
  - Configuring Logging in to Other Devices through Telnet

Configuration and maintenance:

- Configuring Management
  -
  - Running Batch File Commands
  - Configuring Multiple-configuration Booting
  - Configuring Automatic Configuration File Backup to a Remote Server
  - Rolling Back System Configurations
  - Saving the Configuration
  - Configuring the Login Failure Recording Function
- Configuring a Restart Policy
  - Configuring Immediate Restart
  - Configuring Scheduled Restart

1.6 Configuring Basic System Parameters

1.6.1 Configuration Tasks

Basic system parameter configuration includes the following tasks:

- Configuring Connection to the Supervisor Module or Member Device
- Configuring the System Clock
- Configuring a System Name and Command Prompt
- Configuring System Notifications

1.6.2 Configuring Connection to the Supervisor Module or Member Device

1. Overview

By configuring this function, the administrator can connect to the supervisor module or member device in the VSU active-standby (chassis device) environment.

This function allows an administrator to connect to a member device in a VSU environment that involves multi-device stacking.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Connect to the supervisor module or member device.

(Standalone mode)

session master

(VSU mode))

session { **device** *device-number* | **master** }

1.6.3 Configuring a System Name and Command Prompt

1. Overview

To facilitate management, you can configure a system name for each device to identify the device. The default system name is **Ruijie**, and acts as the default command prompt. The command prompt changes with the system name. A system name longer than 32 characters is truncated to keep only the first 32 characters.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a system name.

hostname *hostname*

The default system name is **Ruijie**.

(4) Configure a command prompt.

prompt *prompt-string*

(5) No CLI prompt is configured by default, and the system name is used as the command prompt.

1.6.4 Configuring System Notifications

1. Overview

System notifications are prompts displayed after user login and are classified into the following two types:

- Message of the day (MOTD): Displays MOTD messages on the terminal after user login.
- Login banner: Provides some common login prompts and appears after MOTD information.

2. Restrictions and Guidelines

After entering a delimiter and pressing **Enter**, you can enter text, and then enter a delimiter and press **Enter** again to stop entering the text. Any characters following the ending delimiter are dropped. Text in the notification information must not contain the delimiter letter.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure MOTD information.

banner motd *c message c*

No MOTD information is configured by default.

(4) Configure login banner information.

banner login *c message c*

No login banner information is configured by default.

(5) Configure a prompt indicating the establishment of a reverse telnet connection.

banner incoming *c message c*

No prompt for the establishment of a reverse telnet connection is configured by default.

(6) Configure a prompt for the access to the privileged EXEC mode.

banner privilege-mode *c message c*

No prompt for the access to the privileged EXEC mode is configured by default.

(7) Configure a prompt for SLIP/PPP line connection.

banner slip-ppp *c message c*

No prompt for SLIP/PPP line connection is configured by default.

(8) Configure a prompt for user login authentication timeout.

banner prompt-timeout *c message c*

No prompt for user login authentication timeout is configured by default.

(9) Configure a welcome prompt indicating that a user has entered the user EXEC mode of a line.

banner exec *c message c*

No welcome prompt indicating that a user has entered the user EXEC mode of a line is configured by default.

(10) (Optional) Enter the line configuration mode.

line { **console** | **vty** } *first-line* [*last-line*]

(11) (Optional) Configure a prompt indicating that the function of displaying EXEC prompt information is forbidden for a specific line.

no exec-banner

The function of displaying EXEC prompt information is activated for all lines by default.

1.6.5 Configuring the System Clock

1. Overview

The system clock includes the date (year, month, and day), time (hour, minute, and second), and week information. This function is used to record event occurrence time, such as the system logging. When you use a device for the first time, set its system time to the current date and time manually.

2. Restrictions and Guidelines

- For a device with the hardware clock, the device clock starts from the configured time and keeps running even when the device is powered off.
- If a device has no hardware clock, the manually configured time becomes invalid when the device is powered off.
- If daylight saving time and time zone need to be configured at the same time, configure them by running commands in the following order: **clock timezone** and then **clock summer-time**. Otherwise, the daylight saving time configuration exists but does not take effect.
- If both daylight saving time and time zone configurations exist on the device, when you run the **no clock timezone** command to delete the time zone configuration, the daylight saving time configuration is also deleted. In this case, you need to reconfigure the daylight saving time.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Configure the system date and clock.

clock set *hh:mm:ss* [*MM* [*DD* [*YY*]]]

The default system clock is 1970-01-01 00:00:00.

(3) (Optional) Configue the system to synchronize the hardware time with the software time.

clock update-calendar

The system is not configured to synchronize the hardware time with the software time by default.

(4) (Optional) Configure the hardware clock of the device

calendar set *hh:mm:ss* [*MM* [*DD* [*YY*]]]

The default hardware time of the device is 1970-01-01 00:00:00.

(5) (Optional) Configure the system to synchronize the software time with the hardware time.

clock read-calendar

The system is not configured to synchronize the software time with the hardware time by default.

(6) Enter the global configuration mode.

configure terminal

(7) (Optional) Configure the summer time.

clock summer-time *summer-time-zone* **start** *start-month* [*week* | **last**] *start-date hh:mm* **end** *end-month* [*week* | **last**] *end-date hh:mm* [**ahead** *hours-offset* [*minutes-offset*]]

The summer time is not configured by default.

(8) (Optional) Configure the time zone.

clock timezone *timezone hours-offset* [*minutes-offset*]

The time zone is set as Universal Time Coordinated (UTC) by default.

1.7 Enabling or Disabling a Specific Service

1. Overview

When the system is running, you can dynamically adjust system services, including SSH server service, Telnet server service, and Web server service.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable a specific service.

enable service { **ssh-server** | **telnet-server** | **web-server** [**http** | **https** | **all**] }

The Secure Shell (SSH) server, Telnet server, and Web server are disabled by default.

1.8 Configuring Passwords and Privilege Levels

1. Overview

Privilege levels and passwords for different privilege levels can be configured to distinguish access needs of different users' devices.

16 privilege levels from 0 to 15 are defined for users in the command line interface (CLI) of network devices. Users of various privilege levels can run different commands. A smaller value indicates a lower privilege level. Level 0 is the lowest level and users of this level can run only a few commands, whereas level 15 is the highest level and users of this level can run all commands. Levels 0 and 1 are common user levels without the device configuration permission (users are not allowed to enter the global configuration mode). Levels 2 to 15 are privileged user levels with the device configuration permission.

Password protection is configured for each privilege level on the device so that users of different levels can use different command collections. An increase in privilege level requires the input of the correct password of the target privilege level, whereas a reduction in privilege level does not require password input.

Passwords fall into two types: passwords and secrets.

- Passwords are simple encrypted passwords. You can set them for privilege levels 1 to 15.
- Secrets are secure encrypted passwords. You can set them for privilege levels 1 to 15.

Passwords must be stored in encryption mode. Passwords use simple encryption, and secrets use secure encryption.

Caution

- If a privilege level is configured with both a password and a secret, the password does not take effect.
- If no password is configured for a privileged user level, you do not need to input a password to enter this level. For security purposes, it is recommended that a password be configured for privileged user levels.

2. Restrictions and Guidelines

- When a password or secret is configured for the first time and the plaintext string is less than eight characters or contains only one type of characters, the system prompts you that it is a weak password.
- After logging in to a device, a user can run the **enable** or **disable** command to raise or lower his/her privilege level to access commands at different privilege levels. An increase in privilege level requires the input of the correct password of the target privilege level by default.
- You can specify the **level** keyword in the password configuration command to configure a password for a specific privilege level. After you set a password for a specific privilege level, the password works for the users who need to access commands of this level.
- The **enable** commands include **enable** (for role switching), **enable password**, and **enable secret**. If no role is specified, these three commands are used to set the role configured by running the **enable** command.
- **enable password**
  - This command is used to configure passwords only for level 15 and takes effect only when no secret is configured. If you use this command to configure a password for a non-15 level, the system displays a warning and the password is automatically converted into a secret.
  - If the password and secret set for level 15 are the same, the system displays a warning.
  - If you specify an encryption type but enter a plaintext password during password configuration, you cannot enter the privileged EXEC mode again.

3. Procedure

(1) Enter user EXEC mode.

(2) Change the user privilege level.

- Increase the privilege level.

  enable [*privilege-level*]

  When the RBAC function is enabled, you can run this command to switch the role of the current terminal. By default, the role is switched to network-admin.

- Lower the privilege level.

  disable [*privilege-level*]

  The privilege level specified in this command must be lower than the current level.

  When the RBAC function is enabled, this command is unavailable.

(3) Enter the privileged EXEC mode.

enable

(4) (Optional) Display help information.

help

(5) Change the privilege level.

- Raise the privilege level.

  enable [*privilege-level* | **role** *role-name*]

  When the role-based access control (RBAC) function is enabled, this command can be used to switch the terminal role. If no role is specified, the system switches to role **network-admin** by default.

- Lower the privilege level.

  disable [*privilege-level*]

  The privilege level specified in this command must be lower than the current level.

  When the RBAC function is enabled, this command is unavailable.

(6) Enter the global configuration mode.

configure terminal

(7) Configure a password.

enable password [**level** *password-level* | **role** *role-name*] [[**0**] *password* | **7** *encrypted-password*]

Preamble spaces are allowed in front of the password but the spaces are ignored. Intermediate and trailing spaces are recognized.

(8) Configure a secret.

enable secret { [**level** *secret-level*] | [**role** *role-name*] } { [**0**] *password* | { **5** | **8** } *encrypted-secret* }

When the RBAC function is enabled and no role is specified, this command is used to set a password for role **network-admin** by default.

(9) (Optional) Configure a handling policy when the number of consecutive authentication failures to enter the privileged EXEC mode reaches the limit.

enable user-block { **disable** | **failed-times** *times* **period** *period* | **reactive** *time* }

The allowed maximum number of consecutive authentication failures is 3, the period for resetting the consecutive authentication failure count is 10 minutes, and a user will be locked for 10 minutes after the number of consecutive authentication failures reaches the limit. You can run the **enable user-block disable** command to disable the function.

(10) (Optional) Configure the algorithm used for encryption.

enable algorithm-type { **md5** | **sha256** }

The SHA-256 algorithm is used for encryption by default.

(11) (Optional) Configure the role for running the **enable** commands.

enable default role *role-name*

The default role for running **enable** commands is **network-admin**.

Only when the RBAC function is enabled, this command is available.

(12) (Optional) Enable level increase logging.

login privilege log

The level increase or role switching logging function is disabled by default.

(13) Configure command privilege levels.

privilege *mode* { **all** | **level** *level* | **reset** } *command-string*

(14) Enter the line configuration mode.

line { **console** | **vty** } *first-line* [*last-line*]

(15) Configure a password for line-based login.

password { [**0**] *password* | **7** *encrypted-password* }

(16) Verify the password for line-based login.

login

The verification function of simple login passwords is disabled for the console line and enabled for the virtual terminal lines by default.

(17) Exit the configuration mode and return to the upper-level mode or exit the command line interface (CLI) from the privileged EXEC mode.

exit

1.9 Configuring Telnet Login

1.9.1 Configuration Tasks

Telnet login includes the following tasks, which are all optional and can be chosen according to the actual situation:

- Configuring Telnet Service
- Configuring Telnet Access Security

1.9.2 Configuring the Telnet Service

1. Overview

As an application-layer protocol in the TCP/IP protocol suite, telnet provides the standard for remote login and virtual terminal communication on the Internet.

The telnet client service allows a local or remote login user of the device to access other remote system resources on the Internet. As shown in the following figure, a user uses a PC to connect to device A by using the terminal emulation program or telnet program and then logs in to device B by running the **telnet** command to configure and manage device B.

Figure 1-1 Telnet Service

Telnet allows you to use IPv4 and IPv6 addresses for communication. The telnet server can accept connection requests sent from a telnet host with an IPv4 or IPv6 address. The telnet client can initiate connection requests to a host configured with an IPv4 or IPv6 address.

When the telnet server service is enabled on the device, you can use the telnet client to connect to the device securely and configure the following functions:

- Configure an access control list (ACL) for the telnet server.

- Disable the IP address blocking function of the telnet server.
- Configure the number of authentication failures, beyond which an IP address is blocked, and the time period for counting consecutive authentication failures on the telnet server.
- Configure the period for awakening blocked IP addresses on the telnet server.
- Clear entries about blocking and authentication failures of all or specific IP addresses.

2. Restrictions and Guidelines

- When the number of authentication failures of telnet login meets the IP address blocking conditions in the authentication failure count period, source IP address blocking is triggered. That is, the telnet client of this source IP address is not allowed to log in to the device to prevent the device from being attacked. The telnet client can log in to the device only after the IP address awakening period expires.
- With the IP address blocking function enabled, a user logs in to the device through telnet. When the number of consecutive authentication failures reaches the configured count within the authentication failure count period, source IP address blocking is triggered. When such number does not reach the configured count or one authentication operation is successful within the authentication failure count period, the authentication failures are cleared.
- After the time for awaking a blocked source IP address comes, entries about the IP address blocking are cleared. The blocked IP address is awakened immediately and can be used to log in to the device through the telnet client.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(1) Configure the listening port of the Telnet server.

ip telnet-server port *port-number*

The default port number is 23.

(2) Configure an ACL for the telnet server.

ip telnet access-class { *acl-name* | *acl-number* }

No IPv4 ACL filtering rule is configured by default.

ipv6 telnet access-class *ipv6-acl-name*

No IPv6 ACL filtering rule is configured by default.

(3) Disable the IP address blocking function of the telnet server.

ip telnet ip-block disable

The IP address blocking function of the telnet server is enabled by default.

(4) Configure the number of authentication failures, beyond which an IP address is blocked, and the period for counting consecutive authentication failures on the telnet server.

ip telnet ip-block failed-times *failed-times* **period** *period-time*

The allowed maximum number of authentication failures is 6, and the period for counting consecutive authentication failures is 5 minutes by default.

(5) Configure the period for awakening blocked IP addresses on the telnet server.

ip telnet ip-block reactive *reactive-period-time*

The default period for awakening blocked IP addresses is 5 minutes.

(6) Enter the line configuration mode.

line vty *line-number*

(7) (Optional) Configure the connection timeout time.

exec-timeout *exec-timeout-minutes* [*exec-timeout-seconds*]

The default connection timeout time of the device on a line is 10 minutes.

If there is no input information during the specified time, the server interrupts the established connection.

(8) (Optional) Configure the session timeout time.

session-timeout *session-timeout-time* [**output**]

The default session timeout time is 0 minute for remote terminals. That is, the sessions never time out. If there is no input information during the specified time, the device closes sessions established to a remote terminal on the current line and restores the terminal to the idle state.

(9) (Optional) Enable EXEC prompt information display for a specific line.

exec-banner

EXEC prompt information display is enabled for all lines by default.

(10) (Optional) Enable MOTD prompt information display for a specific line.

motd-banner

MOTD prompt information display is enabled for all lines by default.

1.9.3 Configuring Telnet Access Security

1. Overview

When AAA is disabled, you can configure a line password or local user authentication to control users to log in to and manage the device. When login authentication (via the **login** command) is configured for a line, only users who pass the line password verification are allowed to log in. When local user authentication (via the **login local** command) is configured for a line, the username and password entered by a user are checked against those stored in the local user database. If they are matched, the user can access the device with proper management permissions.

When AAA is enabled, some servers can be used to authenticate users' management permissions by their usernames and passwords at their login. Only authenticated users are allowed to log in. For example, a RADIUS server can authenticate usernames and passwords and control users' permissions to manage the device. Thus, instead of using locally stored password information for authentication, the device sends encrypted user information to the RADIUS server for verification. The server configures unified usernames, passwords, shared passwords, and access policies of users to manage and control user access and improve the security of user information.

Caution

After AAA is enabled, line password verification and local user authentication do not take effect.

2. Restrictions and Guidelines

- In the enabled AAA authentication mode, set line-based login for this authentication, and use the AAA authentication methods, including RADIUS authentication, local authentication, and no authentication.
- In the enabled AAA security service, to perform non-AAA authentication for a line run the **login access non-aaa** command. The configuration is valid for all terminals.
- The **username** command is used to create a local user database for authentication. The encryption type **7** needs to be specified only when encrypted passwords are copied and pasted. If the value **7** is specified as the encryption type, the entered ciphertext string must consist of an even number of characters. The login user cannot delete his/her account.
- To lock a session, enable locking on the terminal connected to a line in line configuration mode, and run the **lock** command in the EXEC mode of the terminal to lock the terminal. When a user enters any character on the locked terminal, the password prompt is displayed. The terminal will be automatically unlocked if the entered password is correct.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) (Optional) Import user information from a file.

username import *file-name*

(3) (Optional) Export user information to a file.

username export *file-name*

(4) Enter the global configuration mode.

configure terminal

(5) Configure a local user account and optional authorization information.

username *username* [**algorithm-type** { **md5** | **sha256** }] [**login mode** { **console** | **ssh** | **telnet** | **ftp** }] [**online amount** *amount-number*] [**permission** *oper-mode path*] { [**privilege** *privilege-level*] | [**role** *text-string*] } [**reject remote-login**] [**vid** *vid-number*] [**web-auth**] [**pwd-modify**] [**nopassword** | **password** [**0** | **7**] *text-string* | **secret** [**0** | **5** | **8**] *text-string*]

No local user account or authorization information is configured by default.

(6) Enter the line configuration mode.

line { **console** | **vty** } *first-line* [*last-line*]

(7) Configure the encryption type for line-based login.

algorithm-type { **md5** | **sha256** }

The default encryption type for line-based login is SHA256.

(8) Configure an MD5/SHA-256 irreversible encrypted password for line-based login.

secret { [**0**] *password* | { **5** | **8** } *encrypted-secret* }

No encrypted password is configured for line-based login by default.

(9) Configure a password for line-based login.

password { [**0**] *password* | **7** *encrypted-password* }

No password is configured for line-based login by default.

(10) (Optional) Enable locking on a terminal connected to a line.

lockable

The function of locking terminals connected to the current line is disabled by default.

(11) Configure local authentication for line-based login.

login local

When AAA is enabled, no local user authentication is configured for lines by default,

(12) (Optional) Configure AAA authentication for line-based login.

login authentication { **default** | *list-name* }

When AAA is enabled, the **default** authentication method is used by default.

(13) (Optional) Configure non-AAA authentication for line-based login when AAA is enabled.

a Return to the global configuration mode.

exit

b (Optional) Configure non-AAA authentication for line-based login when AAA is enabled.

login access non-aaa

When AAA is enabled, non-AAA authentication is disabled by default.

1.10 Configuring Logging in to Other Devices through Telnet

1.10.1 Overview

As an application-layer protocol in the TCP/IP protocol suite, telnet provides the standard for remote login and virtual terminal communication on the Internet. The telnet client service allows a local or remote login user of the device to access other remote system resources on the Internet.

1.10.2 Restrictions and Guidelines

- If you have run the **telnet** command to initiate a telnet client session, you can press **Ctrl+Shift+6+X** (press **Ctrl+Shift+6**, release the buttons, and then press **X**) to temporarily exit the session. To restore this session, run the <**1**–**99**> command. To display information about established sessions, run the **show sessions** command.
- Before you remotely log in to the device through Telnet, you can run the **enable service telnet-server** command to enable the Telnet server service on the device.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Run the **telnet** command to log in to the telnet server.

telnet [**oob**] { *hostname* | *ipv4-address* | *ipv6-address* } [*port-number*] [**/source** { **interface** *interface-type interface-number* | **ip** *ipv4-address*| **ipv6** *ipv6-address* | **interface** *interface-type interface-number* }] [**/vrf** *vrf-name*] [**via mgmt** *mgmt-name*] *

(3) Run the **do telnet** command to log in to the telnet server.

do telnet [**oob**] { *hostname* | *ipv4-address* | *ipv6-address* } [*port-number*] [**/source** { **ip** *ipv4-address* | **ipv6** *ipv6-address* | **interface** *interface-type interface-name* }] [**/vrf** *vrf-name*] [**via mgmt** *mgmt-name*] *

(4) (Optional) Restore the established telnet client session.

1–99

(5) (Optional) Disconnect a suspended telnet client session.

disconnect *session-id*

(6) (Optional) Specify the IP address of an interface as the source IP address of a Telnet connection. .

ip telnet source-interface *interface-type interface-number*

The Telnet source interface is the reachable outbound interface of the Telnet server by default.

(7) (Optional) Return to the privileged EXEC mode.

end

(8) (Optional) Lock the current terminal connected to a line.

lock

1.11 Configuring Management

1.11.1 Configuration Tasks

Management Configuration includes the following tasks. All the following configuration tasks are optional and may be selected as needed.

-
- **Running Batch File** Commands
- **Configuring Multiple-configuration Booting**
- **Configuring Automatic Configuration File Backup to a Remote Server**
- **Rolling Back System Configurations**
- **Saving the Configuration**
- **Configuring the Login Failure Recording Function**

1.11.2 Running Batch File Commands

1. Overview

To management system functions, it may take a long time to enter many commands on the CLI. This process is prone to errors and omissions. You can put the commands in a batch file according to configuration steps, and execute the file to complete related configurations.

2. Restrictions and Guidelines

- You can specify the name and content of the batch file on your PC and transfer the file to the flash memory

of the device through TFTP. The content of the batch file simulates user input. Therefore, you must edit the content according to the configuration sequence of the CLI commands. For some interactive commands, you must write the responses in the batch file to ensure that the commands are normally run.

- The batch file must not exceed 128 KB in size; otherwise, it will fail to be executed. You can divide a large batch file into multiple files smaller than 128 KB in size each.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Run the **execute** command to execute the batch file.

execute flash: *file-name*

1.11.3 Configuring Multiple-configuration Booting

1. Overview

Multiple-configuration booting allows users to modify the saving paths and names of startup configuration files of the device. This function saves configurations to an extended flash memory or an extended Universal Serial Bus (USB) flash drive of the device only.

2. Restrictions and Guidelines

- The startup configuration file name can be a file name or an existing path. For example, if the startup configuration file name is set to **flash:/Hostname/Hostname.text** or **usb0:/Hostname/Hostname.text**, **flash:/Hostname.** The file folder **flash:/Hostname** and **usb0:/Hostname** must exist, or the **write** command will fail to save the configurations. In the master-slave mode, the paths must exist on all devices.
- To save configurations to an extended USB flash drive, the device must support at least one USB port. If the device supports two or more USB ports, this function saves startup configurations to USB 0 only.
- To save the startup configuration file to a USB flash drive, the device must provide a USB port with a USB flash drive inserted. Otherwise, the **write** command will fail to save the configurations. In the master-slave mode, all devices must have a USB flash drive inserted.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Modify the saving path and name of startup configuration file.

boot config { **flash:***file-name* | **usb0:***file-name* }

The saving path and name of the startup configuration file is **flash:/config.text** by default.

1.11.4 Configuring Automatic Configuration File Backup to a Remote Server

1. Overview

By configuring the specific information and interval, you can automatically back up the configuration file of the device to the remote server.

2. Restrictions and Guidelines

- If no configuration file exists during command execution, an error is displayed.
- If the configuration file is deleted after the configuration command takes effect, the system stops backing up the configuration file to the remote server after the preset time expires.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure automatic backup of the configuration file backup to a remote server.

auto-backup configuration [**oob**] { **ftp** *server* [**port** *port-number*] **username** *username* **password** { [0] *password* | 7 *encrypted-password* } | **tftp** *server* } **interval** *interval-time* [**path** *folder*] [**via** *mgmt_name*] [**vrf** *vrf_name*]

The automatic configuration file backup function is not configured by default.

1.11.5 Rolling Back System Configurations

1. Overview

The configuration rollback feature allows a network administrator to create a snapshot of the current configuration, which is a copy or checkpoint of the current running configuration. The checkpoint configuration is re-applied to the device without the need for a restart.

2. Restrictions and Guidelines

- Configuration rollback is used in the following scenarios:
  - You need to copy the configuration file from another device to the new device and apply the configuration without restarting the device.
  - When current system configuration contains too many errors and it is difficult to locate faults or roll back the configuration one by one, you must roll back the current configurations to the previously correct state.
  - When the device application environment changes and the device needs to run the configuration in a configuration file, you can roll back the current configuration to the specified configuration file state without restarting the device.
- When configuration rollback is performed, the system compares and processes the current configuration with the configuration in the rollback checkpoint or configuration file:
  - For the same commands in both configurations, the system does not process them.
  - For the commands only in the current configuration, the system cancels them.
  - For commands that exist in the rollback checkpoint or configuration file but not in the current configuration, these commands will be executed.
  - For the different commands between both the current configuration and checkpoint configuration, the system cancels the configuration, and then runs related commands in the checkpoint configuration.

- This command is used to roll back the configuration from the configuration file. Commands are identified by indentation during rollback. Incorrect indentation may cause a rollback exception. Therefore, the indentation format of the configuration file must be consistent with the format displayed in the command output of the **show running-config** command.
- Only one user can create checkpoints and configure rollback on a device at a time.
- It is recommended that you check whether the baud rate of the serial port is consistent between the current system configuration and checkpoint configuration before you perform rollback. If they are inconsistent, you are advised to change the baud rate of the serial port to that of the checkpoint configuration. Otherwise, the baud rate may change during rollback, causing a failure to display the rollback process information.
- During configuration rollback, do not hot swap any supervisor module or line card, and ensure that the device topology environment is the same as the environment for checkpoint creation. For example, if the device topology is a standalone environment during checkpoint creation but a virtual switching unit (VSU) environment during rollback, configuration rollback may fail.
- If the system displays the message "Increased configuration:" after rollback, the configuration increases compared with the checkpoint configuration. This is because some commands cannot be reversed or fail to be reversed. For details, see the corresponding command reference, and manually reverse these commands.
- If the system displays the message "Decreased configuration:" after rollback, the configuration decreases compared with the checkpoint configurations. This is because some commands fail to be executed during rollback. For details, see the corresponding command reference, and manually run these commands.

3. Configuration Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Roll back configurations. Perform either of the following configurations.

- Roll back the configuration through the configuration file.

  Copy the configuration file to the device.

  copy *source-url destination-url*

  The configuration is rolled back from the configuration file.

  rollback running-config config-file *file-name* [**display-differences** | **ignore-results**]

- Roll back the configuration through the checkpoint configuration.

  Create a checkpoint.

  checkpoint [*checkpoint-name*] [**description** *description*]

  No checkpoint is configured by default.

  Roll back the configuration through the checkpoint configuration.

  rollback running-config checkpoint *checkpoint-name* [**display-differences** | **ignore-results**]

1.11.6 Saving the Configuration

1. Overview

The device supports manual saving and automatic saving. The running configuration is not saved by default, and the device will use the startup configuration file after restarting. Therefore, you are advised to use this function in time to save the running configuration to the startup configuration file

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Save system configurations (**running-config**) to a specific position.

write [**auto-save** { **interval** *interval-time* | **reset** } | **memory** [**auto-save interval** *interval-time*] | **terminal**]

1.11.7 Configuring the Login Failure Recording Function

1. Overview

The login failure recording function is enabled by default. You can run the **show login fail-record** command to display the login failure information recorded. You can also configure the maximum number of entries that can be recorded and disable the recording function.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable the login failure recording function.

no login fail-record enable

The login failure recording function is enabled by default.

(4) Configure the maximum number of entries that can be recorded.

login fail-record size

The maximum number of login failure records is 512 by default.

1.12 Configuring a Restart Policy

1.12.1 Configuration Tasks

The restart policy configuration includes the following tasks:

- Configuring Immediate Restart
- Configuring Scheduled Restart

1.12.2 Configuring Immediate Restart

1. Overview

Immediate restart applies when the device needs to be restarted immediately.

2. Restrictions and Guidelines

- A restart may interrupt services. Exercise caution.
- If the device to be restarted is being upgraded, it does not perform the restart.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Configure immediate device restart.

reload

1.12.3 Configuring Scheduled Restart

1. Overview

A restart policy enables the device to restart as scheduled. The following two scheduled restart functions are supported:

- Configure the system to restart after an interval. The interval is in the format of *mmm* or *hhh*:*mm*, in minutes. You can select either of the formats. You can specify an interval name to reflect the restart purpose.
- Configure the system to restart at a future time point.

2. Restrictions and Guidelines

- A restart may interrupt services. Exercise caution.
- If the device to be restarted is being upgraded, the system does not perform the restart.
- The restart time must be later than the current system time but cannot be more than 31 days later than the current system time. After you configure a restart schedule, do not change the system clock (for example, change the system time to a time after the restart time). Otherwise, the configuration may fail.
- To restart the system at a future time point, the system must support the clock function and the input time value must be a future time point. A new restart schedule overwrites the existing one. If the system is restarted before a restart schedule takes effect, the schedule will be lost.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Configure scheduled device restart.

- Configure a scheduled restart schedule.

  reload at *hh*:*mm*:*ss* [*MM* [*DD* [*YY*]]]

- Configure a countdown restart schedule.

  reload in [*hh* :] *mm*

  No restart function is configured by default.

(3) (Optional) Cancel the restart schedule.

reload cancel

1.13 Configuring a Memory Usage Threshold

1.13.1 Overview

A memory usage threshold is used to monitor the memory status of a device. Excess of this threshold may cause service exceptions. If the actual memory usage exceeds this threshold, a syslog alarm is generated. For example, if the configured memory usage threshold is 90%, when this threshold is exceeded, a syslog alarm is generated.

1.13.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a memory usage threshold.

memory low-watermark set *memory-threshold*

The default memory usage threshold is **90%**.

1.14 Configuring a CPU Usage Threshold

1.14.1 Overview

When the CPU usage of the device is above the upper threshold, a CPU usage overlimit alarm is triggered. The default CPU usage upper threshold is 85%. When the CPU usage of the device drops below the lower threshold, a CPU usage restore notification is triggered. The default CPU usage lower threshold is 75%. If the default upper threshold and lower threshold for the CPU usage do not need actual needs, you can adjust the thresholds accordingly.

1.14.2 Restrictions and Guidelines

- The configuration takes effect immediately.
- The upper threshold and lower threshold for the CPU usage are synchronized to all cards in-position. All the cards use the same upper threshold and lower threshold for the CPU usage.

1.14.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the upper threshold and lower threshold for the CPU usage.

cpu high-watermark set [**down** *down-value* | **up** *up-value*] *****

The default upper threshold and lower threshold for the CPU usage are 85% and 75%, respectively.

1.15 Configuring System Version Monitoring

1.15.1 Overview

After you enable system version monitoring, the device can detect the version number changes of all the cards in the cluster. If the version number of a card changes, a Syslog alarm is generated. System version monitoring helps you determine whether the versions of cards on the device are reliable.

1.15.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enable or disable system version monitoring.

monitor-version { **disable** | **enable** }

System version monitoring is disabled by default.

1.16 Monitoring and Maintenance

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** command to delete all types of information.

Caution

Running the **clear** command while a device is running may cause service interruption due to the loss of important information.

Table 1-2 Monitoring and Maintenance of Basic Management

Command	Function
clear checkpoint database	Clears checkpoints and related data.
clear enable user-block { **all** | **no-user** | *user* }	Unlocks users who are locked because the number of consecutive authentication failures to enter the privileged EXEC mode exceeds the limit.
clear telnet ip-block { **all** | [*ipv4-address* | *ipv6-address*] }	Clears entries about blocked IP addresses and authentication failures.
memory history clear { **all** | **half** | **one-forth** }	Clears historical memory usage records.
memory low-watermark set *memory-threshold*	Enables the monitoring of memory usage threshold.
show boot config	Displays the saving path and name of startup configuration file.
show calendar	Displays the hardware time of the system.

Command	Function
show checkpoint { checkpoint-name [**all**] | **summary** }	Displays all information about a checkpoint or a summary of all checkpoints.
show clock	Displays the current system time.
show configuration change running-config startup-config	Displays the differences between the running configuration file and startup configuration file.
show cpu [**core** | **slot** [*slot-id* | **all-info**]]	Displays CPU usage information of system tasks on control cores and non-virtual cores.
show cpu-monitor history [**slot** { *slot-id* | **all-info** }]	Displays the CPU usage excess history of the device.
show cpurule all	Displays the CPU rule configuration.
show debugging	Displays information about enabled debugging functions.
show enable user-block { **all** | **list** }	Displays users who are blocked from privileged EXEC mode authentication on the device.
show hostname	Displays the host name of the device.
show language character-set	Displays the current character set encoding format of the device.
show line { **console** *line-number* **| vty** *line-number* **|** *line-number* }	Displays the line configurations.
show login fail-record	Displays the device login failure information recorded.
show memory [*process-id* | *process-name* | **history** | **low-watermark** | **slot** [*uslot* [**sorted total**] | *all-info* [**sorted total**]] | **sorted total**]	Displays memory information.
show memory vsd *vsd-id*	Displays Virtual Storage Director (VSD) information.
show memory-monitor history [**slot** { *slot-id* | **all-info** }]	Displays the memory usage excess history of the device.
show pci-bus	Displays information about devices mounted on the Peripheral Component Interconnect (PCI) bus.
show processes cpu [[**15min** | **1min** | **5min** | **5sec**] [**nonzero**] [**record**] | **history** [**table**]]	Displays system tasks by VSD.
show processes cpu detailed { *process-id* | *process-name* }	Displays details about a specific task.
show reload	Displays system restart settings.

Command	Function
show running-config [**interface** *interface-type interface-number* | **router** { **bgp** | **isis** | **ospf** }]	Displays the running configurations of the device system or configurations of an interface.
show service	Displays the service status (enabled/disabled).
show sessions	Displays information about established Telnet client instances.
show startup-config	Displays the device configurations stored in the NVRAM.
show sysmon grpc info	Displays information about the gRPC function registered in the system monitoring process.
show telnet ip-block { **all** | **list** }	Displays information about blocked IP addresses and authentication failures.
show this	Displays effective system configurations in current mode.
show usb-bus	Displays information about devices mounted on the USB bus.
show version [**detail**]	Displays system information.
show monitor-version status	Displays whether system version monitoring is enabled.

1.17 Configuration Examples

1.17.1 Configuring Login Authentication and Telnet Service

1. Requirements

You can use Device A as a jump server through the workstation to manage Device B remotely.

- Establish a telnet session to a remote device.
- Complete login identity authentication.

2. Topology

Figure 1-1 Configuring the Telnet Service

3. Notes

- Establish a Telnet session to the remote device whose IPv4 address is 192.168.65.119.
- Establish a Telnet session to the remote device whose IPv6 address is 2AAA:BBBB::CCCC.

4. Procedure

(1) Configure user and authorization information on Device B.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# line vty 0
Hostname(config-line)# password Abc123456
Hostname(config-line)# login
```

(2) Establish a telnet session to a remote device on Device A.

Run the **telnet** command in privileged EXEC mode, or run the **do telnet** command in user EXEC mode, privileged EXEC mode, global configuration mode, or interface configuration mode.

```
Hostname# telnet 192.168.65.119
Trying 192.168.65.119 ... Open
User Access Verification
Password: Abc123456
Hostname# telnet 2AAA:BBBB::CCCC
Trying 2AAA:BBBB::CCCC ... Open
User Access Verification
Password: Abc123456
Hostname(config)# do telnet 2AAA:BBBB::CCCC
Trying 2AAA:BBBB::CCCC ... Open
User Access Verification
Password: Abc123456
```

5. Verification

- Run the **ping** command to display the configurations. If the remote device can be pinged, the telnet service is configured.
- Verify the login identity. If the login is successful, login authentication is configured.

1.17.2 Configuring Basic System Parameters

1. Notes

- Configure the system time.
- Configure MOTD information.
- Configure login banner information.
- Set the serial port baud rate to 57,600 bps.

2. Procedure

(1) Configure the system time.

Set the system time to June 20, 2003, 10:10:12.

```
Hostname> enable
Hostname# clock set 10:10:12 6 20 2003
```

(2) Configure MOTD information.

Set the MOTD content to "Notice: system will shutdown on July 6th." with the pound key (#) as the delimiter.

```
Hostname# configure terminal
Hostname(config)# banner motd #
Enter TEXT message.  End with the character '#'.
Notice: system will shutdown on July 6th.#
Hostname(config)#
```

(3) Configure login banner information.

Set the login banner content to "Access for authorized users only. Please enter your password." with the pound key (#) as the delimiter.

```
Hostname(config)# banner login #
Enter TEXT message.  End with the character '#'
Access for authorized users only. Please enter your password.
```

(4) Set the serial port baud rate to 57,600 bps.

```
Hostname# configure terminal
Hostname(config)# line console 0
Hostname(config-line)# speed 57600
```

3. Verification

- Verify the system time.

  Run the **show clock** command in privileged EXEC mode to display the system time.

```
Hostname# show clock
clock: 2003-6-20 10:10:54
```

- Verify MOTD information.

  Connect to the local device through the console, telnet, or SSH, and check whether the MOTD information is displayed before the CLI appears.

```
Hostname# telnet 192.168.65.236
Notice:  system will shutdown on July 6th.
Access for authorized users only. Please enter your password.
 User Access Verification
Password:
```

- Verify login banner information.

  Connect to the local device through the console, telnet, or SSH, and check whether the login banner information is displayed before the CLI appears.

```
Hostname# telnet 192.168.65.236
Notice:  system will shutdown on July 6th
Access for authorized users only. Please enter your password
 User Access Verification
Password:
```

- Verify that the serial port baud rate is set to 57,600 bps.

  Run the **show line** command to display the configurations.

```
Hostname# show line console 0
```

```
CON    Type    speed   Overruns
* 0    CON    57600   0
Line 0, Location: "", Type: "vt100"
Length: 25 lines, Width: 80 columns
Special Chars: Escape  Disconnect  Activation
            ^^x    none       ^M
Timeouts:     Idle EXEC    Idle Session
            never       never
History is enabled, history size is 10
Total input: 22 bytes
Total output:  115 bytes
Data overflow:  0 bytes
stop rx interrupt:  0 times
Modem: READY
```

1.5 Monitoring 9

1.6 Configuration Examples 10

1.6.1 Configuring Role Permissions 10

1 Configuring RBAC

1.1 Introduction

1.1.1 Overview

Role-based access control (RBAC) associates roles with permissions. Users are assigned with appropriate roles with -permissions. The authorization structure of user-role-permission is formed to simplify permission management. Roles are defined to complete various tasks, and a device administrator can predefine all the roles and their permissions. To change a user's permission, use RBAC to change only the permission of his role. This process reduces the authorization workload and device management overhead.

1.1.2 Basic Concepts

- Feature

  Features vary with CLI commands. CLI commands with the same features constitute one feature.

- Feature group

  A feature group is composed of features. Different features are classified as needed to form one feature group. In short, a feature group is composed of several types of CLI commands.

- User

  By default, a user does not have any permissions to operate a device. Only after you specify a proper role to a user, the user has the permission of this role. There are local users and remote AAA server users. Local users are used for local authentication while remote AAA server users are used for remote AAA authentication.

- Role

  There are predefined system roles and user-defined roles. The system predefines 18 roles, including **network-admin**, **network-operator**, and **priv-***n* (0–15). Each role is granted with specific operation permissions. Table 1-1 lists these roles and their permissions.

Table 1-1 Roles and Permissions

Role	Default Permission
network-admin	Administrator role, with all operation permissions.
network-operator	Operator role, with the following permissions: ● Permission control: ○ CLI commands: allowed to run the **ping**, **show**, **ssh**, **telnet**, **traceroute**, **ssh-session**, and **terminal** commands and the command to change the current local user password. The **show** command displays all information. ● Resource control: ○ Interfaces: allowed to operate all interfaces. ○ Virtual local area networks (VLANs): allowed to operate all VLANs.

	○ VPN routing and forwarding (VRF): allowed to operate all VRF instances.
priv-0	Level-0 role, assigned with the following permissions: ● Permission control: ○ CLI commands: allowed to run the **ping**, **ssh**, **telnet**, **traceroute**, **ssh-session**, and **enable** commands. ● Resource control: ○ Interfaces: allowed to operate all interfaces. ○ VLANs: allowed to operate all VLANs. ○ VRF: allowed to operate all VRF instances.
priv-n (1-13)	Level-1 to level-13 roles, without any permission
priv-14	Level-14 role, with the following permissions: ● Permission control: ○ CLI commands: allowed to run CLI commands other than the **more**, **upgrade**, and **debug** commands that are executable only by an administrator. ● Resource control: ○ Interfaces: allowed to operate all interfaces. ○ VLANs: allowed to operate all VLANs. ○ VRF: allowed to operate all VRF instances.
priv-15	Level-15 role, with the same all operation permissions as the role **network-admin**.

- Permission

  Permissions fall into three modes - read, write, and execute - or into two types - rule permissions and resource permissions. Rule permissions include those of command-based rules, those of feature-based rules, and those of feature group-based rules. Resource permissions include those of interface resources, those of VLAN resources, and those of VRF resources.

  Rule permissions configured for user roles are divided into the following categories:

  - Prohibit a role from running or allow a role to execute a specific command line.
  - Prohibit a role from running or allows a role to run one or several types of commands for specified or all features.
  - Prohibit a role from running or allows a role to run one or several types of commands for all features in a feature group.

  Resources permissions configured for user roles are divided into the following categories:

  - Prohibit a role from operating or allow a role to operate all or some interfaces.
  - Prohibit a role from operating or allow a role to operate all or some VLANs.
  - Prohibit a role from operating or allow a role to operate all or some VRF instances.

1.2 Configuration Task Summary

RBAC configuration includes the following tasks:

(1) (Optional) Configuring a Feature Group

(2) Configuring Role Permissions

a Enabling the RBAC Function

b Configuring Roles

c Configuring Rule Permissions for a Role

d (Optional) Configuring Description of a Role

e (Optional) Prohibiting a Role from Operating All Interface Resources

f (Optional) Allowing a Role to Operate a Specific Interface Resource

g (Optional) Prohibiting a Role from Operating All VLAN Resources

h (Optional) Allowing a Role to Operate a Specific VLAN Resource

i (Optional) Prohibiting a Role from Operating All VRF Resources

j (Optional) Allowing a Role to Operate a Specific VRF Resource

1.3 Configuring a Feature Group

1.3.1 Overview

This section describes how to create a feature group and add features to the feature group.

1.3.2 Restrictions and Guidelines

- Feature groups predefined in the system cannot be deleted or modified.
- Up to 64 feature groups can be customized.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a feature group and enter the feature group configuration mode.

role feature-group name *group-name*

The system predefines feature groups **L2** and **L3** by default. Feature group **L2** contains all commands for functions related to L2 protocols. Feature group **L3** contains all commands for functions related to L3 protocols.

(4) Add features to the feature group.

feature *feature-name*

By default, a system predefined feature group contains default features while a user-defined feature group contains no feature.

1.4 Configuring Role Permissions

1.4.1 Overview

This section describes how to create a user role and configure its operation permissions. After a user is authenticated to get a proper role, he has operation permissions.

1.4.2 Configuration Tasks

User role permission configuration includes the following tasks:

(1) Enabling the RBAC Function

(2) Configuring Roles

(3) Configuring Rule Permissions for a Role

(4) (Optional) Configuring Description of a Role

(5) (Optional) Prohibiting a Role from Operating All Interface Resources

(6) (Optional) Allowing a Role to Operate a Specific Interface Resource

(7) (Optional) Prohibiting a Role from Operating All VLAN Resources

(8) (Optional) Allowing a Role to Operate a Specific VLAN Resource

(9) (Optional) Prohibiting a Role from Operating All VRF Resources

(10) (Optional) Allowing a Role to Operate a Specific VRF Resource

1.4.3 Enabling the RBAC Function

1. Overview

This section describes how to enable the RBAC function.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the RBAC function.

role enable

The RBAC function is disabled by default.

1.4.4 Configuring Roles

1. Overview

This section describes how to customize a role.

2. Restrictions and Guidelines

- System predefined roles cannot be deleted by running the **no** command. The default permission of only the **priv**-*n* (0–13) role can be restored by running the **default** command.
- Permissions can be added to the **priv**-*n* (0–13) role only.

- Users can customize up to 64 roles and configure permissions for the roles..

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a role and enter the role configuration mode.

role name *role-name*

By default, the system predefines 18 roles, including **network-admin**, **network-operator**, and **priv**-*n* (0–15). Each role is granted with specific operation permissions.

1.4.5 Configuring Rule Permissions for a Role

1. Overview

This section describes how to configure the rule permissions for a role.

2. Restrictions and Guidelines

- By default, system predefined roles have predefined rule permissions while user-defined roles have no rule permission.
- During rule configuration, if the specified rule number does not exist, create a rule; otherwise, modify the rule corresponding to the specified rule number. The modified rule supports newly authenticated users only.
- A user role is allowed to create multiple rules, and permissions executable by this role is a union set of these rules. If permissions defined by these rules conflict with each other, rules with larger serial numbers prevail. For example, if command A is prohibited by rule 1, and command B is prohibited by rule 2, but command A is allowed by rule 3, rule 2 and rule 3 finally take effect. Specifically, command A is allowed and command B is prohibited.
- Predefined rules for predefined roles in the system cannot be deleted or modified. If there is a conflict between system predefined rules and user-defined rules, user-defined rules prevail.
- Up to 256 rules can be configured for each role. A maximum of 1024 rules can be configured for all roles on the device.
- To configure command-based rules, follow the rules below:
  - Division of segments. To describe a multi-level mode command, divide the command character string into multiple segments by a semicolon (;). Each segment represents one or a series of commands. The command in the latter segment is used to execute the mode of a command in the preceding segment. A segment must contain at least one printable character.
  - Use of semicolons. To describe a multi-level mode command, separate the command segments with a semicolon. For example, the character string **config ; logging on** is used to grant a permission over the **logging on** command in configuration mode. The semicolon in the last command segment indicates that the permission is granted over the current mode command. For example, the character string **config ; interface *** is used to grant a permission over only the command to enter the interface configuration mode. The absence of a semicolon in the last command segment indicates that permissions are granted over the current command mode and all commands in this mode. For example,

the character string **config ; interface *** is used to grant permissions over all commands in interface mode.

- Use of asterisks. Each command segment contains at least one asterisk (*). An asterisk resides either in the middle or at both ends of a command segment. Each asterisk serves to fuzzily match a command. For example, the character string **config ; *** is used to grant permissions over all the commands in configuration mode. The character string **config ; logging * flush** is used to grant a permission over a command starting with **logging** and ending with **flush** in configuration mode. The character string **config ; logging *** is used to grant permissions over all commands starting with **logging on** in configuration mode. When an asterisk resides in the middle of a command segment and the asterisk is used to match the command, the command is matched up to only the first asterisk in the middle, and the subsequent command segments are all considered matched. An execution command must be fully matched.
- Matching of keyword prefixes. A prefix matching algorithm is used for the matching between the command keyword and the command character string. That is, if the first several consecutive characters or all characters of a keyword in the command line match the keyword defined in a rule, the command line matches this rule. Therefore, a command character string may include a partial or complete command keyword. For example, if the rule **rule 1 deny command show ssh** is effective, the **show ssh** command and the **show ssh-session** command are disabled.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the role configuration mode.

role name *role-name*

(4) Configure rule permissions for a role.

rule *rule-number* { **permit** | **deny** } { **command** *command-string* | { **read** | **write** | **execute** }* { **feature** [*feature-name*] | **feature-group** *feature-group-name* } }

By default, predefined roles have predefined rule permissions while user-defined roles have no rule permission.

1.4.6 Configuring Description of a Role

1. Overview

This section describes how to configure the description for a role.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the role configuration mode.

role name *role-name*

(4) Configure the description for a role.

description *description*

By default, a predefined role is provided with a default description with the user-defined role is provided with no description.

1.4.7 Prohibiting a Role from Operating All Interface Resources

1. Overview

This section describes how to prohibit a role from -creating, deleting or applying all interface resources.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the role configuration mode.

role name *role-name*

(4) Prohibit a role from operating all interface resources and enter the interface configuration mode of the role.

interface policy deny

By default, a role has the permission to operate all interface resources.

1.4.8 Allowing a Role to Operate a Specific Interface Resource

1. Overview

This section describes how to allow a role to create, delete or apply a specific interface resource.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the role configuration mode.

role name *role-name*

(4) Prohibit a role from operating all interface resources and enter the interface configuration mode of the role.

interface policy deny

(5) Enable the role to operate a specific interface resource.

permit interface *interface-type interface-number-list*

By default, a role is prohibited from operating all interface resources.

1.4.9 Prohibiting a Role from Operating All VLAN Resources

1. Overview

This section describes how to prohibit a role from creating, deleting or applying all VLAN resources.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the role configuration mode.

role name *role-name*

(4) Prohibit a role from operating all VLAN resources and enter the VLAN configuration mode of the role.

vlan policy deny

By default, a role has the permission to operate all VLAN resources.

1.4.10 Allowing a Role to Operate a Specific VLAN Resource

1. Overview

This section describes how to allow a role to create, delete, and apply a specific VLAN resource.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the role configuration mode.

role name *role-name*

(4) Prohibit a role from operating all VLAN resources and enter the VLAN configuration mode of the role.

vlan policy deny

(5) Allow a role to operate a specific VLAN resource.

permit vlan *vlan-list*

By default, a role is prohibited from operating all VLAN resources.

1.4.11 Prohibiting a Role from Operating All VRF Resources

1. Overview

This section describes how to prohibit a role from creating, deleting or applying all VRF resources.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the role configuration mode.

role name *role-name*

(4) Prohibit a role from operating all VRF resources and enter the VRF configuration mode of the role.

vrf policy deny

By default, a role has the permission to operate all VRF resources.

1.4.12 Allowing a Role to Operate a Specific VRF Resource

1. Overview

This section describes how to allow a role to create, delete or apply a specific VRF resource.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the role configuration mode.

role name *role-name*

(4) Prohibit a role from operating all VRF resources and enter the role VRF configuration mode.

vrf policy deny

(5) Enable a role to operate a specific VRF resource.

permit vrf *vrf-name*

By default, a role is prohibited from operating all VRF resources.

1.5 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** command to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Run the **debug** command to output various debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-2 RBAC Monitoring

Command	Purpose
debug rbac	Debugs the RBAC module.
show role [**name** *role-name*]	Displays the information about a specific role or all roles.
show role feature [**detail** | **name** *feature-name* [**detail**]]	Displays the basic information or details about a specific feature or all features.
show role feature-group [**name** *group-name*] [**detail**]	Displays the basic information or details about a specific feature group or all feature groups.

1.6 Configuration Examples

1.6.1 Configuring Role Permissions

1. Requirements

(1) Create the role **test**, set the description to "test role", and configure permissions to:

- Check all device information.
- Execute all commands of features snmpd and syslogd.
- Execute commands to create and delete interfaces, VLANs and VRF instances.
- Prohibit the role from operating all interface resources, but allow the role to operate interface VLAN 1.
- Prohibit the role from operating all VLAN resources, but allow the role to operate VLAN 1.
- Prohibit the role from operating all VRF resources, but allow the role to operate the VRF instance **test**.

(2) Create a user with username **user**, password **Abc123456**, and role **test**.

(3) Configure username and password-based authentication for telnet login.

(4) Let a user log in to a device from a PC in telnet mode, and perform authentication with username **user** and password **Abc123456**. Upon login, the user is assigned with role **test** and has permissions of role **test**.

2. Topology

Figure 1-1 Configuring Role Permissions

3. Notes

- Enable the RBAC function.
- Create a role and configure its description.

- Configure role permissions to:
  - Operate all **show** commands.
  - Operate all read, write, and execution commands of features snmpd and syslogd.
  - Execute interface, VLAN and VRF commands, as well as all commands in corresponding modes.
  - Prohibit the role from operating all interface resources, but allow it to operate interface VLAN 1.
  - Prohibit the role from operating all VLAN resources, but allow it to operate VLAN 1.
  - Prohibit the role from operating all VRF resources, but allow it to operate VRF instance **test**.
  - Create a user with username **user** and password **Abc123456**, and assign the user with the role **test**.
  - Configure username and password-based authentication for Telnet login.

4. Procedure

(1) Enable the RBAC function.

Enable the RBAC function for device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# role enable
```

(2) Create a role and configure its description.

Create the role **test** for device A and set the description for the role.

```
DeviceA(config)# role name test
DeviceA(config-role)# description test role
```

(3) Configure the role permissions.

Allow the role to run all **show** commands.

```
DeviceA(config-role)# rule 1 permit command show *
```

Allow the role to operate all read, write, and execute commands of features snmpd and syslogd.

```
DeviceA(config-role)# rule 2 permit read write execute feature snmpd
DeviceA(config-role)# rule 3 permit read write execute feature syslogd
```

Allow the role to execute interface, VLAN and VRF commands, as well as all commands in corresponding modes.

```
DeviceA(config-role)# rule 4 permit command config;interface *
DeviceA(config-role)# rule 5 permit command config;vlan *
DeviceA(config-role)# rule 6 permit command config;vrf definition *
```

Prohibit the role from operating all interface resources, but allow it to operate interface VLAN 1.

```
DeviceA(config-role)# interface policy deny
DeviceA(config-role-interface)# permit interface vlan 1
DeviceA(config-role-interface)# exit
```

Prohibit the role from operating all VLAN resources, but allow it to operate VLAN 1.

```
DeviceA(config-role)# vlan policy deny
DeviceA(config-role-vlan)# permit vlan 1
DeviceA(config-role-vlan)# exit
```

Prohibit the role from operating all VRF resources, but allow it to operate the VRF instance **test**.

```
DeviceA(config-role)# vrf policy deny
DeviceA(config-role-vrf)# permit vrf test
DeviceA(config-role-vrf)# exit
DeviceA(config-role)# exit
```

Create a user with username **user** and password **Abc123456**, and assign the user with the role **test**.

```
DeviceA(config)# username user password Abc123456
DeviceA(config)# username user role test
```

Configure local username and password-based authentication for remote telnet login.

```
DeviceA(config)# line vty 0 4
DeviceA(config-line)# login local
```

5. Verification

View the role information.

```
DeviceA# show role name test
Role: test
  Description: test role
  Interface policy: deny
  Permit interfaces:
  VLAN1
  VLAN policy: deny
  Permit VLANs: 1
  Vrf policy: deny
  Permit vrfs: test
  ------------------------------------------------------------------
  Rule    Perm   Type  Scope       Entity
  ------------------------------------------------------------------
  1       permit      command     show *
  2       permit RWX   feature     snmpd
  3       permit RWX   feature     syslogd
  4       permit      command     config;interface *
  5       permit      command     config;vlan *
  6       permit      command     config;vrf definition *
  R:Read W:Write X:Execute
```

Run any **show** command.

```
DeviceA# show privilege
Current privilege role is test
Ruijie# show users
Line           User       Host(s)            Idle      Location
---------------- ------------ -------------------- ---------- ------------------
*  1 vty 0      user        idle               00:00:00   172.30.31.16
```

Run all read, write, and execution commands of features snmpd and syslogd.

```
DeviceA# show logging
Syslog logging: enabled
  Console logging: level debugging, 46 messages logged
```

```
  Monitor logging: level debugging, 19 messages logged
  Buffer logging: level debugging, 46 messages logged
  Standard format:false
  Timestamp debug messages: datetime
  Timestamp log messages: datetime
  Sequence-number log messages: disable
  Sysname log messages: disable
  Count log messages: disable
  Trap logging: level informational, 46 message lines logged,0 fail
Log Buffer (Total 1048471 Bytes): have written 4462
*Oct 16 07:23:17: %CLI-6-STARTUP: Cli server process startup.
*Oct 16 07:23:17: %LOCALEAP-6-PKIMANAGE: Self-Signed PKI is activated
DeviceA# show snmp
Chassis: 60FF60
0 SNMP packets input
       0 Bad SNMP version errors
       0 Unknown community name
       0 Illegal operation for community name supplied
       0 Encoding errors
       0 Number of requested variables
       0 Number of altered variables
       0 Get-request PDUs
       0 Get-next PDUs
       0 Set-request PDUs
       0 Drop PDUs
       0 UDP parse errors
0 SNMP packets output
       0 Too big errors (Maximum packet size 1472)
       0 No such name errors
       0 Bad values errors
       0 General errors
       0 Response PDUs
       0 Trap PDUs
SNMP global trap: disabled
SNMP logging: disabled
SNMP agent: enabled
SNMP v1: enabled
```

Run the interface access command. Then, a prompt for no permission appears.

```
DeviceA(config)# snmp-server community test rw
DeviceA(config)# logging server 1.1.1.1
DeviceA(config)# interface vlan 1
DeviceA(config-if-VLAN 1)# description test
DeviceA(config-if-VLAN 1)# exit
DeviceA(config)# interface gigabitethernet 0/1
% User doesn't have sufficient privilege to execute this command.
DeviceA(config)# vlan 1
```

```
DeviceA(config-vlan)# name test
DeviceA(config-vlan)# exit
DeviceA(config)# vlan 2
% User doesn't have sufficient privilege to execute this command.
DeviceA(config)# vrf definition test
DeviceA(config-vrf)# description test
DeviceA(config-vrf)# exit
DeviceA(config)# vrf definition test1
% User doesn't have sufficient privilege to execute this command.
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
username user password $10$184$HItkSIIBDRBo$
username user role test
!
role enable
!
role name test
 description test role
 rule 1 permit command show *
 rule 2 permit read write execute feature snmpd
 rule 3 permit read write execute feature syslogd
 rule 4 permit command config;interface *
 rule 5 permit command config;vlan *
 rule 6 permit command config;vrf definition *
 interface policy deny
  permit interface VLAN 1
 vlan policy deny
  permit vlan 1
 vrf policy deny
  permit vrf test
!
line vty 0 4
 login local
```

1 Configuring Lines

1.1 Introduction

1.1.1 Overview

There are various types of terminal lines on network devices. You can group and manage terminal lines by types. Configurations of these terminal lines are called line configurations. On network devices, terminal lines are classified into multiple types such as CTY and virtual type terminal (VTY).

1.1.2 Principles

1. Basic Concepts

- CTY

  The CTY line is a line connected to the console port. Most network devices have one console port. You can access the local system through the console port.

- VTY

  A VTY line is a virtual terminal line not connected to any hardware. It is used for telnet or Secure Shell (SSH) connection.

1.2 Configuration Task Summary

Line configuration includes the following tasks.

The following tasks are optional. Select them based on your requirements.

- (Optional)Configuring the Number of VTY Terminals
- (Optional)Configuring Line Attributes
- (Optional)Configuring Terminal Attributes

1.3 Configuring the Number of VTY Terminals

1.3.1 Overview

This section describes how to enter the line configuration mode to configure other functions.

1.3.2 Restrictions and Guidelines

- The **line vty** command allows you to enter the VTY line configuration mode and specify the number of VTY connections.
- To reduce the number of available VTY connections, run the **no line vty** *line-number* command.
- To configure the allowed maximum number of VTY connections, run the **line maximum-vty** command. If the allowed maximum number of VTY connections is set to **0**, all remote connections fail. If the allowed maximum number of VTY connections is set to a value less than the number of online remote connections, the configuration fails and a prompt appears.

Note

- Remote connections include telnet, SSH, and session connections.
- The allowed maximum number of VTY connections and the number of available VTY connections are separately managed. A remote connection is established successfully only when both conditions are met.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the allowed maximum number of VTY connections.

line maximum-vty *max-number*

The default maximum number of VTY connections is **36**.

(4) Enter the line configuration mode.

line { **console** | **vty** } *first-line* [*last-line*]

(5) Increase or decrease VTY connections.

line vty *line-number*

There are five VTY connections, numbered from 0 to 4 by default. You can increase the number of VTY connections to 36, with new ones numbered from 5 to 35.

VTY connections numbered from 0 to 4 are default connections of the system, which cannot be deleted. Only new connections can be deleted.

1.4 Configuring Line Attributes

1.4.1 Overview

This section describes how to configure line attributes in line configuration mode.

1.4.2 Restrictions and Guidelines

- When the absolute timeout time set for a line expires, the device immediately disconnects the line even if a user is operating the line terminal. Before the line is disconnected, the system displays the remaining time and a prompt, indicating that the terminal will exit.
- After a user acts as a dumb terminal to connect to the device through an asynchronous serial port, the user remotely logs in to the specified host through telnet specified in the **autocommand** command or obtains the specified application-based terminal service by running the **autocommand** command.
- The asynchronous hardware of the device generates seven data bits with parity check in flow communication mode. If parity is generated, specify seven data bits per character. If no parity is generated, specify eight data bits per character. Only early devices support five or six data bits, which are seldom used.
- By running the **flowcontrol** command, you can specify the flow control mode to keep the Tx rate of one end the same as the Rx rate of the peer end. Since terminals cannot receive data while sending data, flow control can prevent data loss. When high-speed data processing devices communicate with low-speed data

processing devices (for example, a printer communicates with a network port), you also need to enable flow control to prevent data loss. Ruijie General Operating System (RGOS) provides the following two flow control modes:

- Software flow control, also called soft flow control, which uses control keys for control. The default stop and start characters for software flow control are **Ctrl+S** (XOFF, ASCII value 19) and **Ctrl+Q** (XON, ASCII value 17), respectively. You can run the **stop-character** and **start-character** commands to configure them.
- Hardware flow control, also called hard flow control, which uses hardware for control.

- In telnet connection scenarios, you can run the **terminal-type** command to configure the type of terminals simulated on the terminal connected to a line as required. Upon telnet connection, one end negotiates with the other end about the terminal type based on its terminal type configuration (telnet negotiation ID: 0x18). For details, see RFC 854. You can run the **terminal-type vt100** command to restore the default terminal type.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the allowed maximum number of VTY connections.

line maximum-vty *max-number*

The default maximum number of VTY connections is **36**.

(4) Enter the line configuration mode.

line { **console** | **vty** } *first-line* [*last-line*]

(5) (Optional) Configure an access control list (ACL) to control terminal login.

Note

The **access-class** and **ipv6 access-class** commands cannot be run on **line console 0**.

(IPv4 network)

access-class { *acl-number* | *acl-name* } { **in** | **out** }

(IPv6 network)

ipv6 access-class *acl-name* { **in** | **out** }

No ACL is configured for controlling terminal login by default.

(6) (Optional) Enable accounting for a line. All the following configurations are optional and may be selected as needed.

- Enable command accounting for a line.

  accounting commands *level* { *list-name* | **default** }

  The command accounting function is disabled by default.

- Enable user access accounting for a line.

accounting exec { **default** | *list-name* }

The user access accounting function is disabled by default.

- Enable command authorization for a line.

  authorization commands *authorization-commands-level* { **default** | *list-name* }

  The command authorization function is disabled by default.

(7) (Optional) Enable EXEC authorization for a line.

authorization exec { **default** | *list-name* }

The EXEC authorization function is disabled by default.

(8) Configure the access to the CLI through a line.

exce

Accessing the CLI through lines is enabled by default.

(9) Configure line attributes. The following configurations are optional. Select them based on your requirements.

- Configure the absolute timeout time for a line.

  absolute-timeout *absolute-timeout-time*

  No absolute timeout time is configured for a line by default.

- Configure the character for activating a null terminal session.

  activation-character *ascii-value*

  The default character for activating a terminal session is the carriage return character (ASCII value 13).

- Enable automatic command execution.

  autocommand *autocommand-command*

  Automatic command execution for a line is disabled by default.

- Configure the hotkey for disconnecting terminal connections.

  disconnect-character *ascii-value*

  The default hotkey for disconnecting terminal connections is **Ctrl+D** (ASCII value 4).

- Configure the character for exiting a line.

  escape-character *escape-value*

  The default character for exiting a line is **Ctrl+Shift+6** (ASCII value 30).

- Configure the access to the CLI through a line.

  exce

  Accessing the CLI through lines is enabled by default.

- Enable historical command recording for a specified line terminal and configure the allowed maximum number of recorded historical commands for the current terminal.

  history [**size** *size*]

  The historical command recording function is enabled by default, and the default number of recorded historical commands is **10**.

- Configure the maximum number of lines that are displayed on a single screen on a specified line terminal.

length *screen-length*

The maximum number of lines that are displayed on a single screen is **24** by default.

- Configure location description for a specific line.

  location *location*

  No location description is configured for a specific line by default.

- Enable logging display on terminals.

  Monitor

  Logging display on terminals is disabled by default.

- Configure a privilege level for line-based login.

  privilege level *privilege-level*

  The default privilege level for line-based login is **1**.

- Configure the prompt for refusing line-based login.

  refuse-message [*c message c*]

  No prompt is configured for refusing line-based login by default.

- Configure the baud rate for the current terminal.

  terminal speed *baudrate*

  The default baud rate is **9600**.

- Configure the maximum number of columns that are displayed in a single line on the terminal connected to a specified line, that is, the line width.

  width *screen-width*

  The line width is **79** by default.

(10) Configure asynchronous line attributes. The following configurations are optional. Select them based on your requirements.

- Configure the number of data bits per character for asynchronous lines in flow communication mode.

  databits *bit*

  The default number of data bits per character for asynchronous lines in flow communication mode is **8**.

- Configure the CLI character encoding format for asynchronous lines.

  exec-character-bits { **7** | **8** }

  The system selects a full 8-bit ASCII character set as the CLI character set by default.

  To enter Chinese characters or display Chinese characters, images, or other international characters in the CLI, run the **exec-character-bits 8** command.

- Configure the flow control mode for asynchronous lines.

  flowcontrol { **hardware** | **none** | **software** }

  No flow control is configured for asynchronous lines by default.

- Configure the parity bit for asynchronous lines.

  parity { **even** | **none** | **odd** }

When using certain hardware (such as an asynchronous serial port and console port) for communication, you usuallyneed to configure a parity bit.

- Configure the start character for software flow control for asynchronous lines.

  start-character *ascii-value*

  The default start character for software flow control for asynchronous lines is **Ctrl+Q** (ASCII value 17).

  After software flow control is enabled for an asynchronous line, the start character indicates the start of data transmission.

- Configure the stop character for software flow control for asynchronous lines.

  stop-character *ascii-value*

  The default stop character for software flow control for asynchronous lines is **Ctrl+S** (ASCII value 19).

  After software flow control is enabled for an asynchronous line, the stop character indicates the end of data transmission.

- Configure the number of stop bits in each byte transmitted through asynchronous lines.

  stopbits { **1** | **2** }

  The default number of stop bits in each byte transmitted through asynchronous lines is **2**.

  You should configure the stop bits for communication between an asynchronous line and the connected network device (such as a conventional numb terminal and modem).

- Configure the type of terminals simulated by an asynchronous line terminal.

  terminal-type *terminal-type-string*

  The default type of terminals simulated by a line is **vt100**.

1.5 Configuring Terminal Attributes

1.5.1 Overview

This section describes how to configure terminal attributes.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Configure terminal attributes. The following configurations are optional. Select them based on your requirements.

- Configure the number of data bits per character for asynchronous lines in flow communication mode.

  terminal databits *bit*

  The default number of data bits per character for the current terminal in flow communication mode is **8**.

- Configure the character for exiting the current terminal.

  terminal escape-character *escape-value*

  The default character for exiting the current terminal is **Ctrl+Shift+6** (ASCII value 30).

- Configure the CLI character encoding format for the current terminal.

  terminal exec-character-bits { **7** | **8** }

To enter Chinese characters or display Chinese characters, images, or other international characters in the CLI, run the **terminal exec-character-bits 8** command.

- Configure the flow control mode for the current terminal.

  terminal flowcontrol { **hardware** | **none** | **software** }

  No flow control is configured for asynchronous lines by default.

- Enable historical command recording for the current terminal and configure the allowed maximum number of recorded historical commands.

  terminal history [**size** *size*]

  The historical command recording function is enabled by default, and the default number of recorded historical commands is **10**.

- Configure the maximum number of lines that are displayed on a single screen on the current terminal.

  terminal length *screen-length*

  The maximum number of lines that are displayed on a single screen is **24** by default.

- Configure location description for the current terminal.

  terminal location *location*

  No location description is configured for the current terminal by default.

- Configure the parity bit for the asynchronous line corresponding to the current terminal.

  terminal parity { **even** | **none** | **odd** }

  No parity bit is configured for the asynchronous line corresponding to the current terminal by default.

  When using certain hardware (such as an asynchronous serial port and console port) for communication, you usually need to configure a parity bit.

- Configure the baud rate for the current terminal.

  terminal speed *baudrate*

  The default baud rate is **9600**.

- Configure the start character for software flow control for the current terminal.

  terminal start-character *ascii-value*

  The default start character for software flow control for the current terminal is **Ctrl+Q** (ASCII value 17).

- Configure the stop character for software flow control for the current terminal.

  terminal stop-character *ascii-value*

  The default stop character for software flow control for the current terminal is **Ctrl+S** (ASCII value 19).

- Configure the number of stop bits in each byte transmitted through the current terminal.

  terminal stopbits { **1** | **2** }

  The default number of stop bits in each byte transmitted through the current terminal is **2**.

- Configure the type of terminals simulated by the current terminal.

  terminal terminal-type *terminal-type-string*

  The default terminal type is **vt100**.

- Configure the maximum number of columns that are displayed in a single line on the current terminal,

that is, the line width.

terminal width *screen-width*

The maximum number of columns that are displayed in a single line is **79** by default.

(3) Enter the global configuration mode.

configure terminal

(4) Enter the line configuration mode.

line { **console** | **vty** } *first-line* [*last-line*]

(5) (Optional) Configure the login authentication timeout time for the current terminal.

timeout login response *response-timeout-time*

The default authentication timeout time for line-based login is **30** seconds.

(6) (Optional) Configure communication protocols supported by the current terminal.

transport input { **all** | **ssh** | **telnet** | **none** }

All communication protocols are supported by default. That is, both SSH and telnet are supported.

(7) (Optional) Configure the prompt for terminal logout.

vacant-message [*c message c*]

No prompt is configured for terminal logout by default.

(8) (Optional) Configure the maximum number of columns that are displayed in a single line on the current terminal, that is, the line width.

width *screen-width*

The maximum number of columns that are displayed in a single line is **79** by default.

1.6 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
clear history all-users	Clears historical records.
clear line { *line-number* | **console** *console-line-number* | **vty** *vty-line-number* }	Clears the connection status of a line.
show enable password	Displays the authorization password in JSON format.
show history	Displays historical command records of a line.

Command	Purpose
show history all-users	Displays all historical command records.
show line { *line-number* | **console** *console-line-number* | **vty** *vty-line-number* }	Displays the line configurations.
show privilege	Displaythe privilege level of a line.
show user [**all**]	Displays login user information of a line.
show web-api line vty info	Displays the VTY configuration information in JSON format.

1.7 Configuration Examples

1.7.1 Configuring Line Attributes

1. Requirements

When users use VTY connections to remotely log in to the device through telnet, the network administrator can configure VTY line attributes based on the use and security requirements of the device. Configure an ACL to control terminal login, set the privilege level of VTY line users to **14**, and require users of VTY line-based login to enter a password. Set the absolute timeout time of VTY connections to 30 minutes.

2. Topology

Figure 1-1 Configuring Line Attributes

3. Notes

- Set the maximum number of VTY line users to **6**.
- Configure an ACL to allow users of some IP addresses to access the device.
- Configure attributes of VTY line user.
- Configure the privilege level, login verification method, and verification password of VTY line users.

4. Procedure

(1) Configure an ACL named **acl1** to control terminal login.

```
Device> enable
Device# configure terminal
Device(config)# ip access-list standard acl1
Device(config-std-nacl)# permit 192.168.1.0 0.0.0.255
Device(config-std-nacl)# exit
```

```
Device(config)# line vty 0 6
Device(config-line)# access-class acl1 in
```

(2) Set the maximum number of VTY line users to **6**.

```
Device(config)# line vty 0 6
```

(3) Set the baud rate to 115200 bps.

```
Device(config-line)# speed 115200
```

(4) Set the number of data bits to **8**.

```
Device(config-line)# databits 8
```

(5) Set the parity bit to **even**.

```
Device(config-line)# parity even
```

(6) Set the number of stop bits to **1**.

```
Device(config-line)# stopbits 1
```

(7) Set the absolute timeout time of VTY connections to 30 minutes.

```
Device(config-line)# absolute-timeout 30
```

(8) Configure software flow control.

```
Device(config-line)# flowcontrol software
```

(9) Set the maximum number of lines that are displayed on a single screen to **100**.

```
Device(config-line)# length 100
```

(10) Set the maximum number of columns that are displayed in a line to **256**.

```
Device(config-line)# width 256
```

(11) Enable historical command recording and set the number of recorded historical commands to **200**.

```
Device(config-line)# history size 200
```

(12) Set the privilege level of line-based login to **14**.

```
Device(config-line)# privilege level 14
```

(13) Configure the user verification method.

```
Device(config-line)# login local
Device(config-line)# exit
```

(14) Configure a username.

```
Device(config)# username Device privilege 15 password Abc123456
```

5. Verification

Users of the IP address 192.168.1.100 can log in to the device through tenet. Users beyond the IP addresses in the 192.168.1.0/24 network segment cannot log in to the device. Run the **show users** command to display users who log in to the device.

```
Device# show users
Line           User        Host(s)            Idle      Location
---------------- ------------ -------------------- ---------- ------------------
*  0 con 0      ---         idle              00:00:00   ---
   1 vty 0      Device      idle               00:00:04   192.168.1.100
```

Run the **show line vty** command to display the line status of the console.

```
Device# show line vty 1

VTY    Type    speed   Overruns
  1    VTY    115200  0
Line 2, Location: "", Type: "vt100"
Length: 100 lines, Width: 256 columns
Special Chars: Escape  Disconnect  Activation
            ^^x    ^D        ^M
Timeouts:     Idle EXEC    Idle Session
            00:10:00    never
History is enabled, history size is 200.
Total input: 0 bytes
Total output: 0 bytes
Data overflow: 0 bytes
stop rx interrupt: 0 times
```

6. Configuration Files

Device configuration file

```
hostname Device
!
username Device privilege 15 password $10$184$HItkSIIBDRBo$

1.6 Configuration Examples 7

1.6.1 Configuring Basic Features of File System Management 7

1 Configuring File System Management

1.1 Introduction

1.1.1 Overview

Files required for running a device, including configuration files and system software, are saved in the storage media of the device. File system management refers to the management of directories and files in storage media, including creation, deletion, modification and viewing of files.

1.1.2 Basic Concepts

The storage media supported by devices include fixed media (Flash) and pluggable media (USB flash drive). Each storage medium is called a file system.

1. Storage media and file system name

- The file system of Flash-type storage media is named as "flash:".
- The file system of USB drive-type storage media is named as "usb:".

2. Default file system

The file system used by default after a user logs in to the device when multiple storage media are available for the device.

3. Name of folder and file

The name of a folder or file can contain numbers, letters or special characters except asterisk (*), vertical bar symbol (|), backslash (\), slash (/), question mark (?), angle brackets (<>), quotation mark ("), and colon (:).

4. Root directory

The root directory is the default directory once the user logs in to the device. It is expressed by a slash (/). For example, "flash:/" indicates the root directory of Flash.

5. Working directory

The working directory is also called the current working directory. The default working directory is the root directory of Flash.

6. Path

The location of a file or folder.

Note

filesystem: specifies the uniform resource locator (URL) of a file system, followed by a colon (:). File systems include **flash:**, **usb:**, and **tmp:**. In addition, *directory* indicates a file name with the path, or specifies a path name. If the name starts with a slash (/), the path is an absolute path; otherwise, the path is a relative path.

1.1.3 Way to Manage Files

To manage files, log in to the system directly or use File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP).

Table 1-1 Way to Manage Files

Way to Manage Files	Application Scenario
Direct login to the system	A device fails to access information, and you need to repair the device or manage the files and directories in the device.
FTP	FTP is applicable to file transfer scenarios which do not require high security of network, and widely used for version upgrade.
TFTP	In laboratory LAN with good network conditions, use TFTP to load and upgrade versions online.

1.2 Configuration Task Summary

Configuration of file system management includes the following tasks: All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring a Directory
  - Displaying the Working Directory
  - Changing the Working Directory
  - Displaying Directory Information
  - Creating a Directory
- Configuring a File
  - Displaying File Content
  - Displaying File Information
  - Copying a File
  - copy source-url dstination-url
  - Renaming a File
  - Deleting a File
  - Ejecting a USB Device
  - Erasing a File System
  - Configuring Prompt Level
  - Formatting a Flash Memory Disk

1.3 Configuring a Directory

1.3.1 Displaying the Working Directory

1. Overview

This feature displays the complete path of the current working directory.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Display the complete path of the current working directory.

pwd

1.3.2 Changing the Working Directory

1. Overview

This feature changes the current working directory.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Change the current working directory.

cd [*filesystem*:] [*directory*]

1.3.3 Displaying Directory Information

1. Overview

This feature displays the list of files and sub-directories under a directory.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Display the files under a directory.

dir [*filesystem*:] [*file-url*]

1.3.4 Creating a Directory

1. Overview

This feature creates a directory.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Create a directory.

mkdir [*filesystem*:] *directory*

1.3.5 Deleting a Directory

1. Overview

This feature deletes a directory.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Delete an empty directory.

rmdir [*filesystem*:] *directory*

1.4 Configuring a File

1.4.1 Displaying File Content

1. Overview

This feature displays the content of a file.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Displaythe content of a file.

more [**/ascii** | **/binary**] [*filesystem*:] *file-url*

1.4.2 Displaying File Information

1. Overview

This feature displays the information of a file.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Displaythe information of a file.

file [*filesystem*:] *file-url*

1.4.3 Copying a File

1. Overview

This feature copies a file.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Copy a file.

copy *source-url dstination-url*

1.4.4 Renaming a File

1. Overview

This feature renames a file.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Rename a file or folder.

rename *source-url destination-url*

1.4.5 Deleting a File

1. Overview

This feature deletes a file.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Delete a file.

delete { [*filesystem*:] *file-url* | **startup-config** }

1.4.6 Ejecting a USB Device

1. Overview

This feature ejects a USB device.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Eject a USB device.

eject usb0

1.4.7 Erasing a File System

1. Overview

This feature erases a file system of a device.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Erase the file system of a USB device.

erase usb0

1.4.8 Configuring Prompt Level

1. Overview

This feature configures the prompt level for executing a file or folder.

- When the prompt level is set to **noisy**, the system asks you to confirm all the files.
- When the prompt level is set to **quiet**, the system seldom gives a prompt.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Configure the prompt level for operating a file.

file prompt [**noisy** | **quiet**]

The prompt level for operating a file is **noisy** by default.

1.4.9 Formatting a Flash Memory Disk

1. Overview

This feature formats a Flash memory disk.

2. Restrictions and Guidelines

The device restarts after this feature is executed. After that, the Flash partition is formatted. Then, all files except the configuration files in the flash partition are deleted. Before formatting the flash disk, you are advised to back up important files in the flash partition.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Format a Flash memory disk.

format flash

1.5 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-2 File System Management Monitoring

Command	Purpose
show coredump files	Displays the Coredump file information of a card in-position.
show disk usb	Displays the USB flash drive or Flash information.
show file systems	Displays information about file systems.
show mount	Displays information about the file system mounted on the device.

1.6 Configuration Examples

1.6.1 Configuring Basic Features of File System Management

1. Requirements

Operate the files in the device after logging in to the device through the Console port or with a Telnet connection.

2. Notes

- Display the files and sub-directories under the current directory.
- Create the **test** directory.
- Copy the **config.text** file to the **test** directory and name it **test.text**.

3. Procedure

(1) Display the files and sub-directories under the current directory.

```
Device# dir flash:/
Directory of flash:/
Number  Properties    Size           Time                  Name
------  ----------  ----------  ----------------------  --------------------
1       -rw-     9.9k       Fri Jan  3 02:49:39 2020  Hostname.text
2       -rw-     113.3M      Sat Jun 13 14:15:17 2020
3       -rw-     5.3k       Wed Jun 10 14:12:45 2020  cfgmpls
4       drwx     4.0k       Mon Jan  6 21:12:20 2020  startup
5       -rw-     2.6k       Sat Jun 13 16:13:12 2020  cfgpol
6       -rwx     1.6k       Thu May 21 13:39:30 2020  rsa1_private.bin

8       -rw-     3.9k       Thu Jan  1 10:53:27 1970  virtual_switch.text
9       drwx     4.0k       Mon Jan  6 21:13:23 2020  uft
10       drwx     4.0k       Fri Nov 15 00:31:04 2019  rg_licns
11       -rw-     7.5k       Wed Jun 30 10:33:50 2021  config.text
…
33 files, 22 directories
1,939,972,096 bytes data total (383,688,704 bytes free)
3,959,422,976 bytes flash total (383,688,704 bytes free)
```

(2) Create the **test** directory. Copy the **config.text** file to the **test** directory and name it **test.text**.

```
Device# mkdir test
```

(3) Copy the **config.text** file to the **test** directory and name it **test.text**.

```
Device# copy config.text flash:/test/test.text
Copying, press Ctrl+C to quit
!
Accessing flash:/config.text finished, 7652 bytes prepared
Flushing data to flash:/test/test.text...
Flush data done
Copy success.
```

4. Verification

Enter the **test** directory.

```
Device# cd test
```

Displaythe currentworking path.

```
Device# pwd
flash:/test
```

Displaythe files underthe **test** directory.

```
Device# dir
Directory of flash:/test
Number  Properties    Size           Time                  Name

1 Configuring USB

1.1 Introduction

1.1.1 Overview

Universal Serial Bus (USB) is an external bus standard. In this document, it refers to peripheral devices in line with the USB standard, such as USB flash drives. USB devices are hot-swappable. They serve to copy files (such as configuration files and log files) from a communication device or copy external data (such as system upgrade files) to an internal storage device.

USB devices are applied in scenarios such as file system management and upgrade. The detailed scenarios are specified in configuration guides for different features. This document describes only the identification, viewing, use, and removal of USB devices.

1.2 Configuration Task Summary

USB configuration includes the following tasks:

(1) Using a USB

(2) Ejecting a USB Device

1.3 Using a USB Device

1.3.1 Overview

When you insert a USB device into a USB port, the system automatically finds the USB device. The driver module of the system, upon identifying the USB device, initializes the device and loads the file system in it. Then, the system reads and writes the USB device. Run commands (**cd**, **copy, delete** or **dir**) of the file system to operate the USB device.

1.3.2 Restrictions and Guidelines

- The system only uses products that support standard Small Computer System Interface (SCSI) commands (generally USB flash drives). Other products, including USB flash drives attached to USB network interface cards (NICs) and those with virtual USB drives, are not supported.
- A USB device supports file allocation tables (FATs) only. Other file systems can be used on a USB device only after they are converted to FATs through a PC.

1.3.3 Prerequisites

Insert a USB device.

1.3.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Run commands of the file system to operate the USB device. Configure one of the following tasks.

- Enter the USB device partition.

  cd usb: [*directory*]

  The path name, if not specified, is the name of the root path of the USB device partition by default.

- Copy files between file systems.

  copy *source-url dstination-url*

  When the file to be copied exists on the target URL, the target file system determines the action, for example, reporting an error, overwriting the file, or asking users to make the choice.

- Delete a file in the USB device.

  delete usb: [*file-url*]

- Check whether the file is in the USB device.

  dir usb: [*file-url*]

  The path name, if not specified, is the name of the root path of the USB device partition by default.

Note

- When multiple partitions exist in the USB device, only the first FAT partition is accessible.
- The concept of parent directory is not available for the USB device path. After accessing the USB device by running **cd usb*:**, return to the flash file system by running **cd flash:**.

1.4 Ejecting a USB Device

1.4.1 Overview

This feature ejects a USB device while keeping the data stored in the device intact.

1.4.2 Restrictions and Guidelines

- Do not remove a USB device when the system is using it. Otherwise, the data stored in the device will be damaged. Therefore, disconnect the USB device from the system before removing it.
- Upon successful disconnection, the system prints a prompt. After that, remove the device. USB device disconnection failure indicates that the system is using the device. Remove the device when the system is not using it.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Remove the USB device.

usb remove *device-id*

1.5 Monitoring

Run the **show** command to check the USB device.

Table 1-1 USB Monitoring

Command	Purpose
show usb	Displays the information about the inserted USB device.

1.6 Configuration Examples

1.6.1 Configuring USB Basic Features

1. Requirements

Operate the files in the device as follows after logging in to the device through the Console port or with a Telnet connection.

- Insert the USB flash drive into the port.
- Copy the **config.txt** file in the drive to **Flash**.
- Run the **usb remove** command to remove the USB device.

2. Notes

- After you insert a USB flash drive into the port, the system displays a prompt of successful loading of the drive.
- Before removing the USB device, run the corresponding command to eject it. This is to avoid an error resulted from the system using the device.

3. Procedure

(1) After you insert a USB flash drive into the port, the system finds the USB device and loads the drive. After that, the system prints the following prompt information:

```
*Jan  1 00:09:42: %USB-5-USB_DISK_FOUND: USB Disk <Mass Storage> has been inserted
to USB port 0!
*Jan  1 00:09:42: %USB-5-USB_DISK_PARTITION_MOUNT: Mount usb0 (type:FAT32),size :
15789711360B(15789.7MB)
```

Note

Mass Storage specifies the name of the identified device. "**usb0**" specifies the first USB device. **Size** specifies the size of the partition. As shown above, the USB flash drive has a space of 15789.7 MB.

(2) Copy the **config.txt** file in the drive to Flash.

```
Hostname# dir usb0:/
Directory of usb0:/
   1 -rwx           4  Tue Jan  1 00:00:00 1980  fac_test
   2 -rwx           1  Mon Sep 30 13:15:48 2013  config.txt
2 files, 0 directories
15,789,711,360 bytes total (15,789,686,784 bytes free)
Hostname#
```

```
Hostname# copy usb0:/config.txt flash:/
Copying: !
Accessing usb0:/config.txt finished, 1 bytes prepared
Flushing data to flash:/config.txt...
Flush data done
```

(3) Remove the USB device.

```
Hostnam# usb remove 0
OK, now you can pull out the device 0.
```

4. Verification

Insert the USB flash drive to check the USB device.

```
Hostname> enable
Hostname# show usb
Device: Mass Storage
ID: 0
URL prefix: usb0
Disk Partitions:
usb0(type:vfat)
Size:15789711360B(15789.7MB)
Available size:15789686784B(15789.6MB)
```

Run the **dir** command to check whether the **config.txt** file in the flash is copied successfully.

```
Hostname# dir flash:/
Directory of flash:/
  20 ----           1  Thu Jan  1 00:04:51 2020  config.txt
1 files, 0 directories
5,095,424 bytes total (4,960,256 bytes free)
```

Run the **show usb** command to check whether the USB device is removed. The device with ID 0 is not displayed when the **show usb** command is run.

```
Hostname# show usb
  No partition found.
```

5. Common Errors

- A device that uses non-standard SCSI is inserted into the USB port.
- The system cannot identify the USB device as the device is not a FAT.

1 Configuring the FTP Server

1.1 Introduction

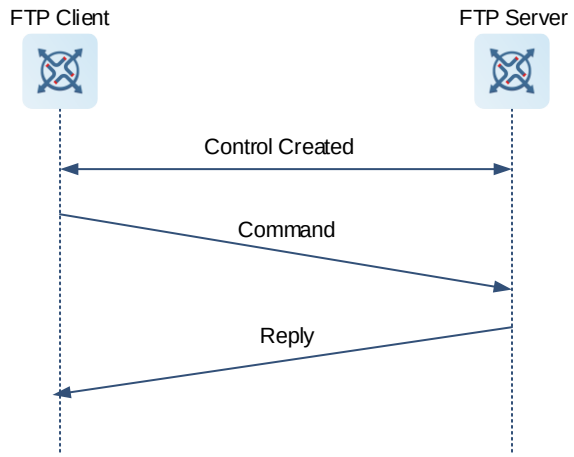
1.1.1 Overview

File Transfer Protocol (FTP) is a standard application layer protocol formulated by the IETF Network Working Group. It implements file transfer based on Transmission Control Protocol (TCP). FTP is a major method for transferring files on the Internet.

FTP adopts the client/server model. As shown in Figure 1-1, a device can act as an FTP server to provide remote client access and program operations. By issuing commands to the server through the client, you can view the files in the FTP server directory, copy files from a remote computer to the local device, and transfer local files to the server. In addition, FTP provides functions, such as login authentication and read/write access control.

Figure 1-1 FTP Client/Server Mode

1.1.2 Principles



1. FTP Connection

FTP sets up two TCP connections between the client and the server, namely the control connection and the data connection.

- The control connection uses port 21 to transmit control commands, and is always in enabled state.
- The data connection uses port 20 to transmit data. The server can proactively enable or disable the data connection. It sets up a new data connection every time a file or directory is transferred.

For some simple sessions, only the control connection needs to be enabled, the client sends a command to the server, and the sever returns a response after receiving the command. The process is shown in Figure 1-2.

Figure 1-2 Control Connection

When the client sends a command for uploading or downloading data, both the control connection and data connection must be established.

2. User Login and Authentication

To access files on the FTP server, the FTP client must have a user account authorized by the FTP server. By default, a device supports configuration of up to 10 users, 2 connections per user, and 10 connections with the server.

In addition, the read and write permissions of files can be defined to effectively prevent unauthorized users from accessing internal files. When the number of a user's FTP login failures reaches the upper limit, the IP address or username used for login is locked. Within a certain period of time, all users cannot log in to the FTP server properly using this IP address or username.

3. Supported FTP Commands

After receiving an FTP connection request, the FTP server requires the client to provide the username and password for authentication.

If the client passes the authentication, the FTP client commands can be executed. The following table lists the FTP client commands supported by the FTP server.

Table 1-1 FTP Client Commands Supported by the FTP Server

ascii	close	mdelete	mput	quit	size
bin	delete	mdir	nlist	recv	system
bye	dir	mget	passive	rename	type
cd	get	mkdir	put	rmdir	user
cdup	ls	mls	pwd	send	

For how to use these FTP client commands, refer to the documentation of the FTP client software used. In addition, many FTP client tools, such as CuteFTP and FlashFXP, provide the graphic user interface (GUI), which allows users to perform operations without configuring FTP commands.

1.1.3 Protocols and Standards

- RFC 959: File Transfer Protocol (FTP)
- RFC 3659: Extensions to FTP
- RFC 2228: FTP Security Extensions
- RFC 2428: FTP Extensions for IPv6 and NATs
- RFC 1635: How to Use Anonymous FTP

1.2 Configuration Task Summary

FTP server configuration includes the following tasks:

(1) Configuring Basic Functions of the FTP Server

(2) (Optional) Configuring FTP Session Management

(3) (Optional) Configuring the FTP Lock Function

(4) (Optional) Enabling AAA on the FTP Server

(5) (Optional) Configuring Read/Write Permission Control of FTP Users

1.3 Configuring Basic Functions of the FTP Server

1.3.1 Overview

This section describes how to enable the FTP server and configure the username, password, and top-level directory to provide the FTP service for the FTP client.

1.3.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the FTP server.

ftp-server enable

The FTP server is disabled by default.

(4) Configure the top-level directory of the FTP server.

ftp-server topdir *directory*

By default, no top-level directory under which the FTP client can read and write files is configured, that is, the client is prohibited from accessing any directory on the FTP server.

(5) Configure a username and password for server login.

ftp-server username *username* [**privilege level**] **password** [*type*] *password*

By default, no username and password are configured for login to the FTP server, that is, no login users are restricted.

1.4 Configuring FTP Session Management

1.4.1 Overview

- The FTP login times refers to the number of times that the user's account and password can be verified when the user logs in to the FTP server.
- The FTP login timeout refers to the maximum time that the user can stay online after the username and password are verified. If the username and password are not verified again before login timeout, the session will be terminated to ensure that other users can log in to the FTP server.
- The idle timeout refers to the time from the completion of the last FTP operation to the start of the next FTP operation in an FTP session. After the server responds to an FTP client command (for example, after a file is completely transferred), the server starts to count the idle time again, and stops counting when the next FTP client command arrives. Therefore, the configuration of the idle timeout does not affect time-consuming file transfer operations.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure FTP session management. Configure at least one of the following tasks.

- Configure the FTP login times.

  ftp-server login times *times*

  By default, the FTP login times is 3, that is, a session will be terminated after you enter an incorrect username or password for three times so that other users can go online.

- Configure the FTP login timeout.

  ftp-server login timeout *time*

  By default, the FTP login timeout is 2 minutes.

- Configure the idle timeout.

  ftp-server timeout *time*

  By default, the idle timeout of an FTP session is 10 minutes.

- Configure the maximum number of FTP sessions.

  ftp-server max-sessions *number*

  By default, the maximum number of FTP sessions is 20.

1.5 Configuring the FTP Lock Function

1.5.1 Overview

- After the IP address lock function is enabled, if the cumulative number of login failures caused by entry of the incorrect username or password reaches the configured upper limit, the FTP session is terminated and the user's IP address is locked. In addition, all users cannot log in to the FTP server properly using this IP address or username.
- After the username lock function is enabled, if the cumulative number of login failures caused by entry of the incorrect password reaches the configured upper limit, the FTP session is terminated and the username is locked. The user cannot log in to the FTP server, but other users are not affected.
- The FTP lock time refers to the duration that a user needs to wait for automatic unlocking after the user is locked because the number of the user's login failures reaches the upper limit. The locked user can log in to the FTP server only after the login silence time expires.
- The maximum number of login verification times allowed by the FTP lock function refers to the maximum number of times that the username and password of a user can be verified after the FTP lock function is enabled. The default value is 3. If the number of verification failures exceeds the configured upper limit, the session is terminated and the user is locked.

1.5.2 Restrictions and Guidelines

After the IP address lock function is enabled, if the number of locked IP addresses reaches the upper limit, the full lock function is enabled. Then, the FTP server no longer accepts the connection request from any user until the number of locked IP addresses is smaller than the upper limit.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the FTP lock function. Configure at least one of the following tasks.

- Disable the IP address lock function.

  ftp-server login ip-block disable

  The IP address lock function is enabled by default.

- Configure the username lock function.

  ftp-server login username-block disable

  The username lock function is enabled by default.

- Configure the FTP lock time.

  ftp-server login silence-time *time*

  By default, the FTP lock time is 5 minutes.

- Configure the maximum number of IP addresses that can be locked after the IP address lock function is enabled.

ftp-server login max-block-limit *limit*

By default, up to 30 IP addresses can be locked.

- Configure the maximum number of login verification times allowed by the FTP lock function.

  ftp-server login block failed-times *times*

  By default, the maximum number of login verification times allowed by the FTP lock function is 3.

1.6 Enabling AAA on the FTP Server

1.6.1 Overview

By default, FTP does not support AAA login authentication. However, you can enable AAA on the FTP server through configuration.

1.6.2 Restrictions and Guidelines

This command takes effect only after FTP is enabled.

1.6.3 Prerequisites

Enable the AAA function before configuring this command. For details about how to enable AAA, see *Configuring AAA*.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable AAA on the FTP server.

ftp-server authentication { **default** | *name* }

By default, FTP does not support AAA login authentication.

1.7 Configuring Read/Write Permission Control of FTP Users

1.7.1 Overview

After the user read/write permission control function is enabled, the configured FTP user levels or AAA username levels can be used to control read/write permissions. By default, users of all levels have the read/write permissions. After permission control is enabled, if the user level is not configured, it is set to 1 by default and the user has only the read permission, that is, the user can only download data. You can configure FTP users of different levels as required for read/write permission control.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable read/write permission control of FTP users.

ftp-server login permission enable

By default, read/write permission control of FTP users is disabled.

1.8 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **clear** commands to clear information.

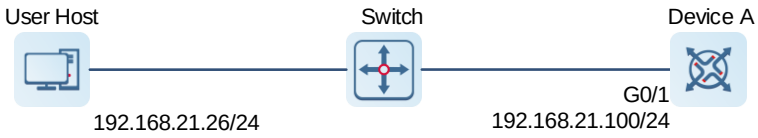
Caution

Running the **clear** command may lose vital information and thus interrupt services.

Table 1-2 FTP Server Monitoring

Command	Purpose
clear ftp-server block-list [**all** | **ip-address** { *ipv4-address* | *ipv6-address* } [**vrf** *vrf-name*] | **username** *user*]	Clears the user lock entries in the FTP lock list.
show ftp-server	Displays the FTP server status information.
show ftp-server { **ip-block** | **username-block** } **list**	Displays the user lock entries in the FTP lock list.
debug ftp-server err	Debugs the FTP server error events.
debug ftp-server pro	Debugs the FTP server message events.

1.9 Configuration Examples



1.9.1 Providing the FTP Service in a LAN

1. Requirements

As shown in Figure 1-3, a device in a LAN acts as the FTP server to provide the upload and download services for users. The switch is an access device. The required session idle timeout is 5 minutes.

2. Topology

Figure 1-3 Providing the FTP Service in a LAN

3. Notes

Configure device A as follows:

(1) Enable the FTP server function.

(2) Configure the top-level directory **/syslog**.

(3) Set the username to **user** and password to **Abc123456**.

(4) Set the session idle timeout to **5** minutes.

4. Procedure

(1) Configure device A.

a. Configure an IP address.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.168.21.100 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

b. Enable the FTP server function.

```
DeviceA(config)# ftp-server enable
```

c. Configure the top-level directory **/syslog**.

```
DeviceA(config)# ftp-server topdir /syslog
```

d. Set the username to **user** and password to **Abc123456**.

```
DeviceA(config)# ftp-server username user password Abc123456
```

e. Set the session idle timeout to **5** minutes.

```
DeviceA(config)# ftp-server timeout 5
```

(2) Configure the user host.

Set the IP address of the user host to 192.168.21.26/24.

5. Verification

Run the **show ftp-server** command to view the FTP server configurations.

```
DeviceA# show ftp-server
   ftp-server information
================================
enable : Y
```

```
topdir : /syslog
timeout: 5min
total connect: 0
username:user
password:(PLAINT)$10$184$HItkSIIBDRBo$
connect num[0]
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface gigabitEthernet 0/1
ip address 192.168.21.100 255.255.255
!
ftp-server enable
ftp-server topdir /syslog
ftp-server timeout 5
ftp-server username user password $10$184$HItkSIIBDRBo$
!
```

7. Common Errors

- No username is configured.
- No password is configured.
- No top-level directory is configured.

1 Configuring FTP Client

1.1 Introduction

1.1.1 Overview

File Transfer Protocol (FTP) is an application of TCP/IP. By setting up a connection-oriented and reliable TCP connection between the FTP client and server, a user can access a remote computer that runs the FTP server program.

An FTP client enables file transfer between a device and the FTP server over FTP. A user uses the client to send a command to the server. The server responds to the command and sends the execution result to the client. By means of command interaction, the user can view files in the server directory, copy files from a remote computer to a local computer, and transfer local files to a remote computer.

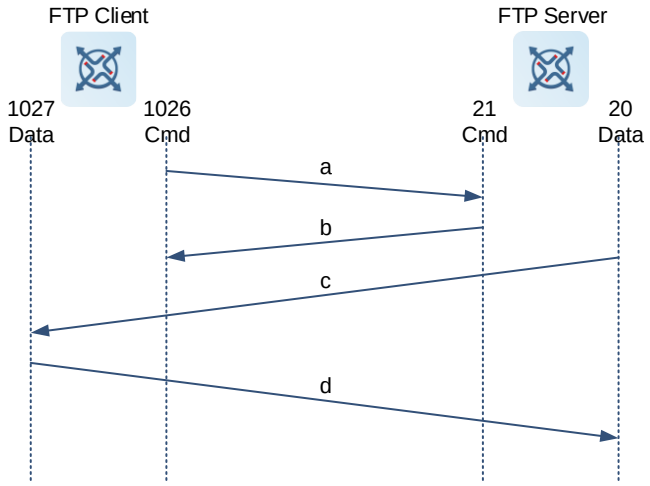
FTP facilitates sharing of program/data files and remote use of computers. Users can transfer data in an efficient and reliable manner without caring about differences between files sys tems on different hosts.

A Ruijie FTP client runs interactive commands in a way different from a standard FTP client. You enter the copy command in the CLI to automatically run commands related to the control connection, such as **open**, **user**, and **pass**. After a control connection is established, the file transfer process starts. Then, a data connection is established to upload or download files.

Note

For the principles of the connection between the FTP client and server, see *Configuring FTP Server*.

The following sections introduce only the FTP client.



1.1.2 Principles

1. FTP Connection Mode

FTP supports two data connection modes: active (PORT) and passive (PASV). The two modes differ only in the way that a data connection is established, and the control connection is the same.

- In PORT mode, when a data connection is established, the FTP server initiates a request to establish a new connection with the client for data transmission. The connection establishment process is as follows:
  - a The FTP client establishes a control channel through port 1026 and port 21 of the FTP server, and sends control commands through this channel.
  - b The client sends the **PORT** command through this channel when it needs to receive data. The **PORT** command contains the port information (1027) of the client data channel.
  - c When transmitting data, the server connects to port 1027 of the client through port 20 on the server to establish a data channel for data transmission and reception.
  - d The client sends a response. Data transmission ends.

Figure 1-1 PORT Mode

- In PASV mode, the FTP client initiates a request when a data connection is established. The connection establishment process is as follows:

  a The FTP client establishes a control channel through port 1026 and port 21 of the FTP server, and sends control commands through this channel.

  b The client sends the **PASV** command through this channel when it needs to receive data.

  c After receiving the **PASV** command, the FTP server randomly opens a high-end port 2024 and notifies the client of data transmission to this port.

  d The client uses port 1027 to connect to port 2024 of the FTP server, and then sends or receives data on this channel. The FTP server does not need to establish a new connection with the client.

Figure 1-2 PASV Mode

Note

The control connection for command and feedback transmission is always present whereas the data connection is established as required. Only the FTP client can select the PASV or PORT mode. The FTP mode supported by an FTP client depends on the actual FTP client software. A Ruijie FTP client uses the PASV mode by default.

2. FTP File Transmission Modes

FTP provides two file transmission modes:

- Binary transmission mode: It is used to transfer program files (for example, .app, .bin and .btm files), executable files, compressed files, image files, and all ASCII values. In this transmission mode, data is not processed, and therefore the transmission rate is faster than that of the text transmission mode.
- Text transmission mode (ASCII mode): It is used to transfer text files (such as .txt, .bat, and .cfg files). This mode is different from the binary mode in carriage return and line feed processing. In ASCII mode, carriage return and line feed are converted to local CRC characters. For example, \n in Unix is \r\n in Windows or \r in Mac. Assume that a file copied by a user contains ASCII text. If a remote computer does not run Unix, FTP automatically converts the file format accepted by the remote computer during file transfer.

3. Specifying the Source IP Address for FTP Transmission

You can configure a source IP address for the FTP client and use it to communicate with an FTP server. With this IP address, the FTP client can connect to the server and share files with the server.

4. Checking Sizes of Files Downloaded from an FTP Server

When the FTP client downloads a file, it checks the file size by default to detect file transfer errors (if any). You can also disable the file size check when downloading files from FTP servers that cannot reply to FTP clients with file sizes.

1.1.3 Protocols and Standards

- RFC 959: FILE TRANSFER PROTOCOL (FTP)

1.2 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring basic functions of the FTP client
  - Enabling the FTP Client to Upload Files
  - Enabling the FTP Client to Download Files
- Configuring extended functions of the FTP client
  - Configuring the FTP Connection Mode
  - Configuring the Transmission Mode of the FTP Client
  - Configuring the Source IP Address for FTP Connection

1.3 Enabling the FTP Client to Upload Files

1.3.1 Overview

You can use the FTP client to upload files to the FTP server.

1.3.2 Restrictions and Guidelines

During file transfer, do not insert or remove a storage medium or transmission medium to or from the device to avoid transmission errors.

1.3.3 Prerequisites

The user must have an account with the read and write permissions for the FTP server, and can use this account to access the target folder on the FTP server.

1.3.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Upload files.

copy flash:*local-file* { **ftp: | oob_ftp:** }***//****account-information@remote-file*

1.4 Enabling the FTP Client to Download Files

1.4.1 Overview

You can use the FTP client to download files from the FTP server.

1.4.2 Restrictions and Guidelines

During file transfer, do not insert or remove a storage medium or transmission medium to or from the device to avoid transmission errors.

1.4.3 Prerequisites

The user must have an account with the read permission for the FTP server, and can use this account to access the target files on the FTP server.

1.4.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) (Optional) Disable the size check of files downloaded from the FTP server.

- Enter the global configuration mode.

  configure terminal

- Disable the size check of files downloaded from the FTP server.

  ftp-client disable-size-check

  By default, the sizes of files downloaded from the FTP server are checked.

- Exit the global configuration mode.

  exit

(3) Download files.

copy { **ftp:** | **oob_ftp:** }***//****account-information@remote-file* **flash:***local-file*

1.5 Configuring the FTP Connection Mode

1.5.1 Overview

You can download or upload files in the specified FTP connection mode. The default FTP connection mode is PASV. You can set the FTP connection mode to PORT, in which the FTP server initiates a connection request to the client.

1.5.2 Restrictions and Guidelines

If you need to specify the **vrf** *vrf-name* parameter when configuring the FTP client, configure the VRF first. For details about the VRF, see *Configuring VRF*.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Set the connection mode to **PORT**.

ftp-client [**vrf** *vrf-name*] **port**

The default FTP connection mode is PASV.

1.6 Configuring the Transmission Mode of the FTP Client

1.6.1 Overview

You can download or upload files in the specified transmission mode of the FTP client. The default transmission mode is Binary. You can also set the transmission mode to ASCII according to your requirements.

1.6.2 Restrictions and Guidelines

If you need to specify the **vrf** *vrf-name* parameter when configuring the FTP client, configure the VRF first. For details about the VRF, see *Configuring VRF*.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Set the transmission mode to ASCII.

ftp-client [**vrf** *vrf-name*] **ascii**

The default transmission mode is Binary.

1.7 Configuring the Source IP Address for FTP Connection

1.7.1 Overview

You can download or upload files using the specified IP address of the FTP client. The FTP client is bound to the IP address of a port so that the client can use this IP address to connect to the server.

1.7.2 Restrictions and Guidelines

If you need to specify the **vrf** *vrf-name* parameter when configuring the FTP client, configure the VRF first. For details about the VRF, see *Configuring VRF*.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the source IP address for FTP connection.

ftp-client [**vrf** *vrf-name*] **source** { *ipv4-address* | *ipv6-address* | *interface-type interface-number* }

By default, no source IP address is bound to the FTP client. Instead, an IP address is selected for the client based on the route.

1.8 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

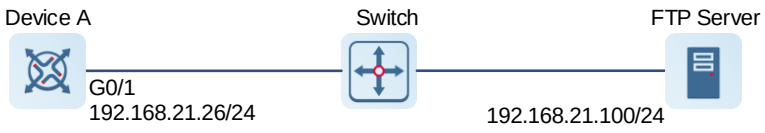
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
show ftp-client	Displays the FTP client configurations.
debug ftp-client	Debugs the FTP client.

1.9 Configuration Examples



1.9.1 Configuring the FTP Client

1. Requirements

As shown in Figure 1-3, in a LAN, a local device needs to share files with a remote FTP server, and FTP is required to work in the specified connection mode and transmission mode.

2. Topology

Figure 1-3 Topology of FTP Client

3. Notes

- Set the FTP connection mode to PORT.
- Set the transmission mode to ASCII.
- Use the username **user** and password **Abc123456** to log in to the FTP server, upload the **local-file** file in the **home** directory of the local device to the **root** directory of the FTP server, and rename the file **remote-file**.
- Use the username **user** and password **Abc123456** to log in to the FTP server, download the **remote-file** file from the **root** directory of the FTP server to the **home** directory of the local device, and rename this file **local-file**.

4. Procedure

(1) Configure the FTP server.

Set the IP address of the FTP server to 192.168.21.100/24.

(2) Configure device A.

a. Configure the IP address of device A.

```
Device A> enable
Device A# configure terminal
Device A(config)# interface gigabitethernet 0/1
Device A(config-if-GigabitEthernet 0/1)# ip address 192.168.21.26 255.255.255.0
Device A(config-if-GigabitEthernet 0/1)# exit
```

b. Set the transmission mode to ASCII.

```
Device A(config)# ftp-client ascii
```

c. Set the FTP connection mode to PORT.

```
Device A(config)# ftp-client port
Device A(config)# exit
```

d. Upload the file.

```
Device A# copy flash: home/local-file
ftp://user:pass@192.168.21.100/root/remote-file
```

e. Download the file.

```
Device A# copy ftp://user:pass@192.168.21.100/root/remote-file flash:
home/local-file
```

5. Verification

Run the **show ftp-client** command to view the FTP client configurations.

```
Device A> enabl
Device A# show ftp-client
      ftp-client information
==================================
type: ASCII
mode: PORT
```

6. Configuration Files

Device A configuration file

```
hostname Device A
!
interface gigabitEethernet 0/1
 ip address 192.168.21.26 255.255.255
!
 ftp-client ascii
 ftp-client port
!
```

7. Common Errors

- The command formats for uploading and downloading are incorrect.
- The username or password is incorrect.

1 Configuring TFTP Server

1.1 Introduction

1.1.1 Overview

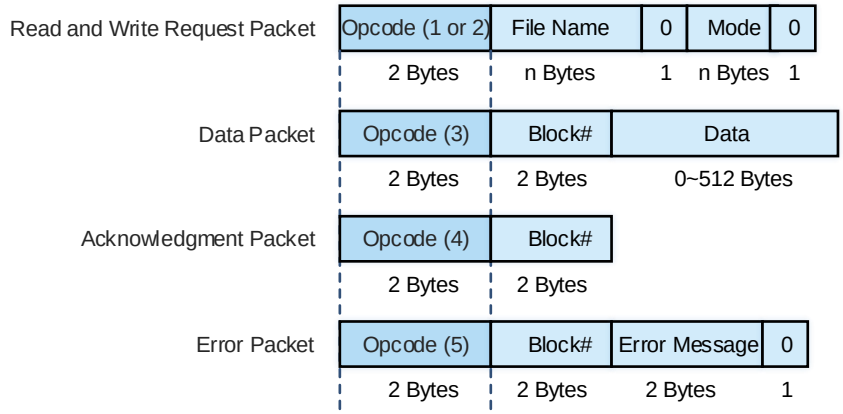
Trivial File Transfer Protocol (TFTP) is a standard application layer protocol formulated by the IETF Network Working Group. TFTP uses User Datagram Protocol (UDP) as its transport protocol, and the well known UDP port for TFTP traffic is 69.

TFTP provides the uncomplicated and inexpensive file transfer service. Many commonly used FTP features are unavailable in TFTP. TFTP can only upload or download files, but not list directories, perform authentication, or provide a security mechanism. TFTP employs a timeout and retransmission strategy to ensure data transmission. TFTP is described in RFC1350.

A TFTP client can conveniently download files (such as upgrade packages) on the device from the TFTP server, or upload files directly to the file system of the TFTP server.

1.1.2 Principles

1. TFTP Packet



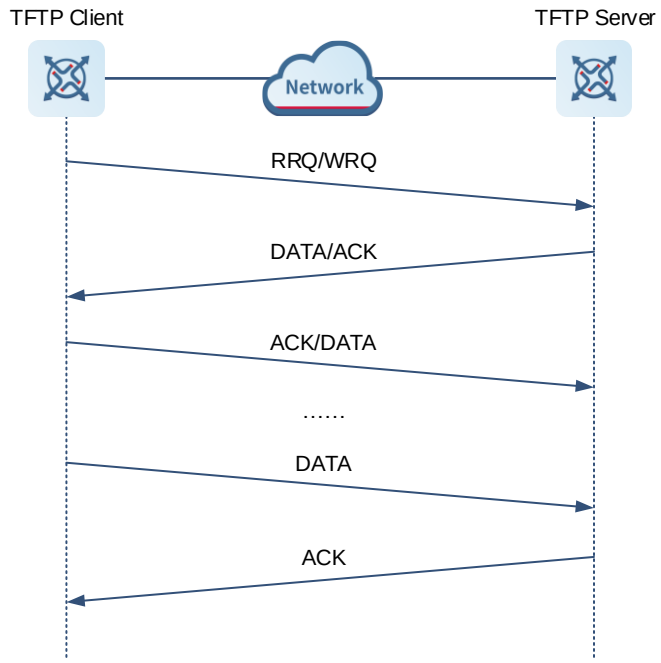
After the TFTP client initiates a file read or write request, and the TFTP server approves the request, TFTP transmits the data in 512-byte packets. A packet with less than 512 bytes indicates that the transmission is completed.

Each packet contains a data block, and the next packet can be sent only after an acknowledgment (ACK) packet is received from the peer. If the ACK packet is not received within the specified time, the last packet sent is retransmitted.

The header of a TFTP packet contains an Opcode field, which indicates the packet type. Opcodes 1 to 5 represent five types of packets:

- 1: Read Request (RRQ)
- 2: Write Request (WRQ)
- 3: Data (DATA)
- 4: Acknowledgment (ACK)
- 5: Error (ERROR)

Figure 1-1 TFTP Packet



The Error Message in an error packet contains 2 bytes in ASCII code. TFTP provides the following error codes:

- 0: Not defined;
- 1: File not found;
- 2: Access violation;
- 3: Disk full;
- 4: Illegal TFTP operation;
- 5: Unknown port;
- 6: File already exists;
- 7: No such user.

2. TFTP Working Modes

Figure 1-2 TFTP Working Modes

(1) The TFTP client initiates a read request (RRQ) or write request (WRQ) to the TFTP server.

(2) If the TFTP server receives an RRQ, it checks whether the read conditions are met (whether the file exists and whether the TFTP client has the access permission). If yes, the TFTP server sends a data packet (DATA) to the TFTP client. If the TFTP server receives a WRQ, it checks whether the write conditions are met (whether there is enough space and whether the FTP client has the write permission). If yes, the TFTP server sends an ACK packet to the TFTP client.

(3) If the TFTP client receives a DATA packet when preparing to download a file, it replies with an ACK packet. If the TFTP client receives an ACK packet when preparing to upload a file, it continues to send the DATA packet.

(4) The process of sending the ACK packet repeats until the last DATA packet with less than 512 bytes is received and indicates the end of the transmission.

(5) If an error is encountered in the transmission process, an ERROR packet is sent to the peer.

3. TFTP File Transmission Modes

TFTP supports the following transmission modes:

- Binary mode for transmitting program files
- ASCII mode for transmitting text files

1.1.3 Protocols and Standards

- RFC 1350: The TFTP Protocol (revision 2)
- RFC 2347: TFTP Option Extension
- RFC 2348: TFTP Blocksize Option
- RFC 2349: TFTP Timeout Interval and Transfer Size Options

1.2 Configuring Basic Functions of the TFTP Server

1.2.1 Overview

This section describes how to configure the TFTP server to provide the upload and download service for the TFTP client.

1.2.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the top-level directory of the TFTP server.

tftp-server topdir *directory*

By default, the TFTP client can read and write files in the Flash directory.

(4) Enable the TFTP server function.

tftp-server enable

The TFTP server is disabled by default. After the TFTP server is enabled, files can be transmitted only through the MGMT port.

1.3 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

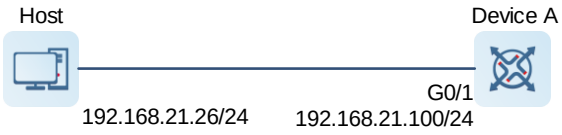
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
show tftp-server	Displays the TFTP server configurations.
show tftp-server updating-list	Displays the file download progress on the client.
debug tftp-server	Debugs the server.

1.4 Configuration Examples



1.4.1 Configuring the TFTP Server

1. Requirements

Configure a TFTP server in a LAN so that users can upload and download files.

2. Topology

Figure 1-3 Topology of TFTP Server

3. Notes

Configure Device A as follows:

(1) Enable the TFTP server.

(2) Configure the top-level directory.

4. Procedure

(1) Configure device A.

Configure the IP address of the Ethernet interface.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.168.21.100 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Configure the top-level directory of the TFTP server.

```
DeviceA(config)# tftp-server topdir /tmp
```

Enable the FTP server function.

```
DeviceA(config)# tftp-server enable
```

(2) Configure the host.

Set the IP address of the host to 192.168.21.26/24.

5. Verification

Run the **show tftp-server** command to view the FTP server configurations.

```
DeviceA# show tftp-server
   tftp-server information
==================================
enable : Y
topdir : /tmp
```

6. Configuration Files

TFTP server configuration file

```
hostname DeviceA
!
interface gigabitEthernet 0/1
ip address 192.168.21.100 255.255.255.0
!
tftp-server enable
tftp-server topdir /tmp
!
```

7. Common Errors

- No top-level directory is configured.

1.8 Configuration Examples 4

1.8.1 Configuring the TFTP Client.....4

1 Configuring TFTP Client

1.1 Introduction

1.1.1 Overview

Trivial File Transfer Protocol (TFTP) is a specific application of Transmission Control Protocol/Internet Protocol (TCP/IP). File transfer between TFTP client and server is implemented based on User Datagram Protocol (UDP), and the default port number is **69**. Compared with the TCP-based FTP protocol, TFTP does not require authentication or have complex packets. It is suitable for a stable network environment and small file transfer.

Note

TFTP is suitable for small file transfer, and FTP supports transfer of large files.

1.1.2 Principles

1. Specifying the Source Interface IP Address for TFTP Transmission

You can configure a source IP address for the TFTP client and use it to communicate with a TFTP server. With this IP address, the TFTP client can connect to the server and share files with the server. Specifying the egress interface of packets facilitates interface management.

2. Specifying a Port Number for Connection with the TFTP Server

You can specify a port number on the TFTP client to connect with the TFTP server and transfer files. Specifying a port number also prevents attacks.

1.1.3 Protocols and Standards

- RFC 783: Trivial FILE TRANSFER PROTOCOL (TFTP)

1.2 Configuration Task Summary

All the configuration tasks below are optional. Select the configuration tasks as required.

- Basic functions of the TFTP client
  - Enabling the TFTP Client to Upload Files
  - Enabling the TFTP Client to Download Files
- Extended functions of the TFTP client
  - Binding the Source IP Address to the TFTP Client
  - Configuring a Port Number for TFTP Connection

1.3 Enabling the TFTP Client to Upload Files

1.3.1 Overview

You can upload files from the TFTP client to the TFTP server.

1.3.2 Restrictions and Guidelines

During file transfer, do not insert or remove a storage medium or transmission medium to or from the device to avoid transmission errors.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Upload files.

copy flash:*local-file* { **tftp: | oob_tftp:** }***//****remote-file*

1.4 Enabling the TFTP Client to Download Files

1.4.1 Overview

You can download files from the TFTP server to the TFTP client.

1.4.2 Restrictions and Guidelines

During file transfer, do not insert or remove a storage medium or transmission medium to or from the device to avoid transmission errors.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Download files.

copy { **tftp:** | **oob_tftp:** }***//****remote-file* **flash:***local-file*.

1.5 Binding the Source IP Address to the TFTP Client

1.5.1 Overview

You can bind a source IP address to the TFTP client so that the client can use this IP address to communicate with the server for file upload or download.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Bind a source IP address to the TFTP client.

tftp-client source { **ip** *ipv4-address* | **ipv6** *ipv6-address* | interface-type interface-number }

By default, no source IP address is bound to the TFTP client. Instead, an IP address is selected for the client based on the route.

1.6 Configuring a Port Number for TFTP Connection

1.6.1 Overview

You can specify the port number used by the TFTP client to connect with the TFTP server for file upload and download.

1.6.2 Restrictions and Guidelines

The range of the port number configured for the TFTP client is from 20000 to 65534.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the port number used by the TFTP client to connect with the TFTP server.

tftp-client port *port-number*

The default port number used by the TFTP client to connect with the TFTP server is **69**.

1.7 Monitoring

Run the **debug** command to output debugging information.

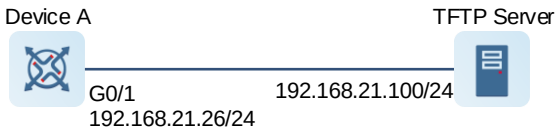
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
debug tftp	Debugs the TFTP client.

1.8 Configuration Examples



1.8.1 Configuring the TFTP Client

1. Requirements

A local device needs to upload a file to a remote TFTP server, and download another file from the TFTP server.

2. Topology

Figure 1-1 Topology of TFTP Client

3. Notes

- Upload the **local-file** file in the **Flash** directory on device A to the **root** directory of the TFTP server with an IP address 192.168.21.100, and rename the file **remote-file**.
- Download the **remote-file** file from the **root** directory of the TFTP server with the IP address 192.168.21.100 to the **Flash** directory on device A, and save the file as **download-file**.

4. Procedure

(1) Configure the TFTP server.

Set the IP address of the TFTP Server to 192.168.21.100/24.

(2) Configure device A.

a. Configure an IP address.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.168.21.26 255.255.255
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

b. Upload the file.

```
DeviceA# copy flash:local-file tftp://192.168.23.69/root/remote-file
```

c. Download the file.

```
DeviceA# copy tftp://192.168.23.69/root/remote-file flash: download-file
```

5. Verification

Check whether the **remote-file** file is configured on the TFTP server.

Run the **dir** command on device A to check whether the **download-file** file is configured in the **home** directory of the Flash.

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
 interface gigabitEthernet 0/1
 ip address 192.168.21.26 255.255.255.0
!
```

7. Common Errors

- The format of the uploaded or downloaded file is incorrect.

1.5.1 Configuring Basic Features of HTTP Service....3

1 Configuring HTTP

1.1 Introduction

1.1.1 Overview

The Hypertext Transfer Protocol (HTTP) is used to transmit Web page information on the Internet. It is at the application layer of the TCP/IP protocol stack. The transport layer adopts the connection-oriented Transmission Control Protocol (TCP).

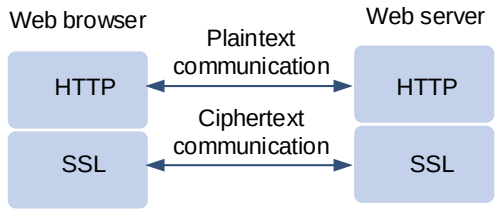
The Hypertext Transfer Protocol Secure (HTTPS) is an HTTP protocol supporting the Secure Sockets Layer (SSL) protocol. HTTPS is used to create a secure channel on an insecure network, to prevent information from being monitored and protect against man-in-the-middle attacks. HTTPS is widely used in secure and sensitive communication on the Internet, for example, electronic transaction payments.

1.1.2 Principles

1. HTTP Service

HTTP is a service provided for Web management. Users log in to devices through Web pages to configure and manage the devices.

Web management covers Web clients and Web servers. Similarly, the HTTP service adopts the client/server mode. The HTTP client is embedded in the Web browser of the Web management client. It sends HTTP packets and receives and processes HTTP response packets. The Web server (HTTP server) is embedded in devices. The information exchange between the client and the server is as follows:



- A TCP connection is established between the client and the server. The default port number of the HTTP service is 80 and the default port number of the HTTPS service is 443.
- The client sends a request to the server.
- The server parses the request sent by the client. The request content includes obtaining a Web page, running a CLI command, and uploading a file.
- After executing the request content, the server sends a response to the client.
- The TCP connection between the server and the client is closed.

2. HTTPS Service

The HTTPS service is an SSL-based HTTP service, as shown in Figure 1-1. The HTTPS service improves the device security through the following services provided by the SSL protocol:

- Mutual authentication is needed between the client and the server to ensure that data is sent to the correct client and server, and unauthorized users are prevented from attacking the device.
- The communication data between the client and the server is encrypted to prevent the data from being stolen midway, ensuring security and integrity of the data transmission and achieving security management of the device.

Figure 1-1 Principle of HTTPS Service

Caution

To run HTTPS properly, a server must have a Public Key Infrastructure (PKI) certificate while a client may not.

1.1.3 Protocols and Standards

- RFC 1945: Hypertext Transfer Protocol -- HTTP/1.0
- RFC 2616: Hypertext Transfer Protocol -- HTTP/1.1
- RFC 2818: Hypertext Transfer Protocol Over TLS -- HTTPS

1.2 Configuration Task Summary

HTTP service configuration includes the following tasks:

(1) Configuring Basic Features of HTTP Service

1.3 Configuring Basic Features of HTTP Service

1.3.1 Overview

After the HTTP service is enabled on a device, users can log in to the Web management page to manage the device after they pass authentication, and can monitor the device status, configure the device, upload and download files.

1.3.2 Restrictions and Guidelines

- Usernames and passwords involve three permission levels: Up to 10 usernames and passwords are configured for each permission level.
- By default, the system creates the account **admin**. The account cannot be deleted and only the password of the account can be changed. The administrator account **admin** corresponds to the level 0 privilege. Account **admin** owns all function privileges on the Web client and can edit other management accounts and authorize the accounts to access pages. All new accounts correspond to the level 1 privilege.
- Currently, the service supports multi-user management and simultaneous login for multiple accounts; you can use one account to log in to multiple ends simultaneously (multiple browsers and so on).
- Users can configure an HTTPS service port number to reduce attacks initiated by unauthorized users on HTTPS service.
- During the login, if you do not operate the Web page for more than 30 minutes, you will log out due to time out and need to log in again.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the HTTP service.

enable service web-server [**http** | **https** | **all**]

The HTTP and HTTPS service features are disabled by default.

(4) Configures an HTTP service port.

http port *port-number*

The default port number of the HTTP service is 80.

(5) Configures an HTTPS service port.

http secure-port *port-number*

The default port number of the HTTPS service is 443.

1.4 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 HTTP Service Monitoring

Command	Purpose
show web-server status	Displays the configuration and status of the Web service.

1.5 Configuration Examples

1.5.1 Configuring Basic Features of HTTP Service

1. Requirements

To manage a Ruijie device in Web mode, log in to the device through a Web browser and configure related features.

2. Topology

Figure 1-2 Topology for Basic Features of HTTP Service

3. Notes

- Configure L3 route reachable between the server and the device.

- To improve security, change the authentication username, HTTP service port, and HTTPS service port for login to the device. Moreover, configure redirection to HTTPS when accessing through HTTP. Thus, the Web browser can access the Web server through either HTTP or HTTPS.

4. Procedure

Configure the management IP address on the device to make the device reachable to the server via L3 routes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 1.1.1.1 255.255.255.0
```

Enable both the HTTP and HTTPS services.

```
Hostname(config)# enable service web-server
```

Set the HTTP service port number to 8080.

```
Hostname(config)# http port 8080
```

Set the HTTPS service port number to 4430.

```
Hostname(config)# http secure-port 4430
```

5. Verification

Run the **ping** command to check whether the L3 route between the server and the server is reachable.

```
Hostname# ping 1.1.1.10
Sending 5, 100-byte ICMP Echoes to 1.1.1.10, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/2 ms.
```

Run the **show web-server status** command to display the configuration of the HTTP service.

```
Hostname# show web-server status
http server status: enabled
http server port: 8080
https server status:enabled
https server port: 4430
```

6. Configuration Files

```
hostname Device
!
http port 8080
http secure-port 4430
enable service web-server http
enable service web-server https
!
interface GigabitEthernet 0/1
 no switchport
 ip address 1.1.1.10 255.255.255.0
!
end
```

7. Common Errors

If the HTTP service port is not the default port 80 or 443, you must enter a specific configured service port in the browser. Otherwise, you cannot access the device in Web mode.

1 Configuring Syslog

1.1 Introduction

1.1.1 Overview

If link status change or events such as receiving of exception packets and processing exception occur during the device running, a log packet in a fixed format is generated automatically. A log packet can be added with a timestamp and a sequence number, classified by the log priority, and output to the console, monitor terminal, log server, or other media. Logs are used by administrators to monitor the running status of the device, analyze the network conditions, and locate problems.

1.1.2 Classification of System Logs

System logs fall into two types:

- Common logs
- Debugging logs

Note

To generate debugging logs, you need to enable a debug command. Such logs are used to locate problems, and may be ignored by users.

1.1.3 Levels of System Logs

Eight severity levels are defined for system logs in a descending order, including emergency, alert, critical, error, warning, notification, informational, and debugging, which correspond to eight numerical values from 0 to 7 respectively. A smaller value indicates a higher level. Table 1-1 describes the log levels.

Note

Only logs with a level equal to or higher than the specified level are output. For example, if the level of logs is set to informational (level 6), logs of level 6 or higher are output.

Table 1-1 Description of Log Levels

Keyword	Level	Description
emergencies	0	Indicates that the system cannot run normally.
alerts	1	Indicates that corrective measures must be taken immediately.
critical	2	Indicates a critical circumstance.
errors	3	Indicates an error message.
warnings	4	Indicates a warning.

Keyword	Level	Description
notifications	5	Indicates a common but important message that requires attention.
informational	6	Indicates an informational message.
debugging	7	Indicates debugging information.

1.1.4 Output Direction of System Logs

System logs can be output to the console, monitor, server, buffer, and file. The default level and type of logs vary with the output direction. You can customize filtering rules for different output directions. Table 1-2 describes output directions of system logs.

Table 1-2 Description of System Log Output Directions

Name of Output Direction	Default Output Direction	Default Output Level	Description
console	Console	debugging (Level 7)	Outputs logs and debugging information.
monitor	Monitor terminal	debugging (Level 7)	Outputs logs and debugging information to facilitate remote maintenance.
server	Log server	informational (Level 6)	Outputs logs and debugging information.
buffer	Log buffer	debugging (Level 7)	Outputs logs and debugging information. The log buffer is used to store system logs during the device running.
file	Log file	informational (Level 6)	Outputs logs and debugging information, and periodicallywrites logs in the log buffer into files.

1.1.5 RFC3164 Log Format

Formats of system logs mayvary with the system log output direction.

1. Non-server Direction

When logs are output to the console, monitor terminal, log buffer, or log file, the system logs are in the following format:

```
seq no: *timestamp: sysname %module-level-mnemonic: content
```

The log format is described below:

Sequence number: *timestamp: system name %module name-severity-mnemonic: log text

For example, if you exit the configuration mode, the following log is displayed on the console:

```
001233: *May 22 09:44:36: Ruijie %SYS-5-CONFIG_I: Configured from console by console
```

2. Server Direction

When logs are output to the log server, the system logs are in the following format:

```
<priority>seq no: *timestamp: sysname %module-level-mnemonic: content
```

The log format is described below:

<Priority> sequence number: *timestamp: system name %module name-severity-mnemonic: log text

For example, if you exit the configuration mode, the following log is displayed on the log server:

```
<189>001233: *May 22 09:44:36: Ruijie %SYS-5-CONFIG_I: Configured from console by console
```

The following details each field in the log format:

- priority

  The priority is calculated using the following formula: Facility x 8 + Level. "Level" indicates the log level and "Facility" indicates the numerical code of the facility. The default facility value is local7 (23). Table 1-3 lists the value range of the facility.

Note

This field is valid only when logs are output to the log server.

Table 1-3 Description of the Log Priority Parameter

Numerical Code	Facility Keyword	Facility Description
0	kern	Kernel messages
1	user	User-level messages
2	mail	Mail system
3	daemon	System daemons
4	auth1	Security/Authorization messages
5	syslog	Messages generated internally by syslog
6	lpr	Line printer subsystem
7	news	Network news subsystem
8	uucp	UUCP subsystem
9	clock1	Clock daemon
10	auth2	Security/Authorization messages
11	ftp	FTP daemon
12	ntp	NTP subsystem

Numerical Code	Facility Keyword	Facility Description
13	logaudit	Log audit
14	logalert	Log alert
15	clock2	Clock daemon
16	local0	Local use 0 (local0)
17	local1	Local use 1 (local1)
18	local2	Local use 2 (local2)
19	local3	Local use 3 (local3)
20	local4	Local use 4 (local4)
21	local5	Local use 5 (local5)
22	local6	Local use 6 (local6)
23	local7	Local use 7 (local7)

- seq no (sequence number)

  The sequence number of a system log is a 6-digit integer, and increases with system logs. By default, the sequence number is not displayed. You can run a command to display or hide this field.

- timestamp

  The timestamp records the generation time of a system log to help you check and locate system events. The devices support two formats of system log timestamps: datetime and uptime.

  - Datetime format

  The complete datetime format is as follows:

```
Mmm dd yyyy hh:mm:ss.msec
```

  Table 1-4 describes each parameter of the timestamp in the datetime format.

  - uptime format:

  The complete uptime format is as follows:

```
dd:hh:mm:ss
```

  Table 1-5 describes each parameter of the timestamp in the uptime format.

Table 1-4 Description of Parameters in the Timestamp in the Datetime Format

Timestamp Parameter	Parameter Name	Description
Mmm	Month	Indicates the abbreviated month. The 12 months in a year are abbreviated as Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec.
dd	Day	Indicates the day in the current month.

Timestamp Parameter	Parameter Name	Description
yyyy	Year	Indicates the year, not displayed by default.
hh	Hour	Indicates the hour.
mm	Minute	Indicates the minute.
ss	Second	Indicates the second.
msec	Millisecond	Indicates the millisecond.

Note

By default, the timestamp in the datetime format in system logs does not contain the year and milliseconds. You can run a command to display or hide the year and millisecond in the timestamp in the datetime format.

Table 1-5 Description of Parameters in the Timestamp in the Uptime Format

Timestamp Parameter	Parameter Name	Description
dd	Day	Indicates the day in the month in which the device starts up.
hh	Hour	Indicates the hour at which the device starts up.
mm	Minute	Indicates the minute at which the device starts up.
ss	Second	Indicates the second at which the device starts up.

Note

If the device does not have a real time clock (RTC), which is hardware used to record the absolute time of the system, the device uses its startup time (in the uptime format) as the system log timestamp by default. If the device has an RTC, the device uses its absolute time (in the datetime format) as the system log timestamp by default.

- sysname (system name)

  This field records the name of the device that generates a log so that the log server can identify the host of such device. By default, the field is not displayed. You can run a command to display or hide this field.

- module (module name)

  This field indicates the name of the module that generates a log. The value is an upper-case string of 2 to 20 characters, which can contain upper-case letters, digits, and underscores. The **module** field is mandatory for common logs by default, and optional for debugging logs.

- level (log level)

Eight system log levels from 0 to 7 are defined. The level of system logs generated by each module is determined during development and cannot be changed.

- mnemonic

  This field indicates a summary of the generation of a log. The value is a string of 4 to 64 characters, which can contain upper-case and lower-case letters, digits, and underscores. The **mnemonic** field is mandatory for common logs by default, and optional for debugging logs.

- content (log text)

  This field indicates the content of a system log.

1.1.6 RFC5424 Log Format

All system logs are in the following format regardless of their output directions:

```
<priority>version timestamp sysname MODULE LEVEL MNEMONIC [structured-data]
description
```

The log format is described below:

<Priority>version timestamp system name module name level mnemonic structured parameter area log content

For example, if you exit the configuration mode, the following log is displayed on the console:

```
<133>1 2013-07-24T12:19:33.130290Z ruijie SYS 5 CONFIG - Configured from console by
console
```

The following details each field:

- priority

  The priority is calculated using the following formula: Facility x 8 + Level. "Level" indicates the log level and "Facility" indicates the facility value. The facility value can be set during log configuration. When the RFC5424 log function is enabled, the default facility value is local0 (16).

- version

  According to RFC5424, the version is always **1**.

- timestamp

  The timestamp records the generation time of a system log to help you check and locate system events. The devices use the following uniform timestamp format when the RFC5424 logging function is enabled:

  ```
  YYYY-MM-DDTHH:MM:SS.SECFRACZ
  ```

  Table 1-6 describes each parameter.

Table 1-6 Description of Timestamp Parameters

Timestamp Parameter	Parameter Name	Description
YYYY	Year	Indicates the year.
MM	Month	Indicates the month in the current year.
DD	Day	Indicates the day in the current month.
T	Separator	A date must end with "T".

Timestamp Parameter	Parameter Name	Description
HH	Hour	Indicates the hour.
MM	Minute	Indicates the minute.
SS	Second	Indicates the second.
SECFRAC	Millisecond	Indicates the millisecond (1–6 digits).
Z	End mark	Time must end with "Z".

- sysname (system name)

  This field indicates the name of the device that generates a log so that the log server can identify the host of such device.

- MODULE (module name)

  This field indicates the name of the module that generates a log. The value is an upper-case string of 2 to 20 characters, which can contain upper-case letters, digits, and underscores. The **module** field is mandatory for common logs by default, and optional for debugging logs.

- LEVEL (log level)

  Eight system log levels from 0 to 7 are defined. The level of system logs generated by each module is determined during development and cannot be changed.

- MNEMONIC

  This field indicates a summary of the generation of a log. The value is a string of 4 to 64 characters, which can contain upper-case and lower-case letters, digits, and underscores. The **mnemonic** field is mandatory for common logs by default, and optional for debugging logs.

- structured-data (structured parameter area)

  This field is introduced to RFC5424, to describe log parameters in a way that helps device parsing. Each log can contain 0 or multiple parameters. If no parameter exists, the placeholder (-) must be used. Each parameter is in the following format:

  ```
  [SD_ID@enterpriseID PARAM-NAME=PARAM-VALUE]
  ```

  Table 1-7 describes each parameter.

Table 1-7 Description of Structured Parameters

Structured Parameter	Parameter Name	Description
SD_ID	Name of parameter information	The name of parameter information is capitalized, and must be unique in a log.
@	Separator	"@enterpriseID" is necessary for the customized parameters, but not for parameters defined in RFC5424.

Structured Parameter	Parameter Name	Description
enterpriseID	Enterprise ID	The enterprise ID is maintained by the Internet Assigned Numbers Authority (IANA). The enterprise ID of devices is 4881. You can query the enterprise ID at the official website of IANA.
PARAM-NAME	Parameter name	The parameter name is capitalized, and must be unique in the structured parameter area of a log.
PARAM-VALUE	Parameter value	The parameter value must be enclosed in double quotation marks. Values of the IP address and MAC address must be capitalized, and values of other parameters are capitalized as required.

- description (log text)

  This field indicates the content of a system log.

1.1.7 System Log Filtering

By default, the logs generated by the system are output in all directions. The device provides the log filtering function, which allows you to filter logs by log output direction, log keyword, and matching rule. When you do not care about some logs or you care about some logs only, use the log filtering function to filter the logs.

- Filtering direction

  Four log filtering directions are defined:

  - **buffer**: Filters the logs sent to the log buffer, that is, the logs displayed by the **show logging** command.
  - **file**: Filters the logs written into logging files.
  - **server**: Filters the logs sent to the log server.
  - **terminal**: Filters the logs sent to the console and monitor terminal (including telnet and SSH).

Note

The four filtering directions can be used either collectively (logs in various directions are filtered) or separately (logs in one direction are filtered).

- Filtering Mode

  Two filtering modes are available:

  - **contains-only**: Indicates that only the logs that contain keywords specified in the filtering rules are output. When you care about some logs only, you can apply the contains-only mode on the device to output only the logs that match the filtering rules on the terminal. Thus, you can check whether any event occurs.
  - **filter-only**: Indicates that the logs that contain keywords specified in the filtering rules are filtered and are not output. Too many logs from a module may result in spamming on the terminal CLI. If you do not care about this type of logs, you can apply the filter-only mode and configure filtering rules to filter such logs.

Note

The two filtering modes are mutually exclusive, that is, you can configure only one filtering mode at a time.

- Filtering Rule

  Two log filtering rules are available:

  - **exact-match**: If exact-match is selected, you must select all the three filtering options (log module, log level, and log mnemonic). To filter a specific log, use the exact-match filtering rule.
  - **single-match**: If single-match is selected, you only need to select one of the three filtering options (log module, log level, and log mnemonic). To filter a specified type of log, use the single-match filtering rule.

Note

If the same module name, log level, or mnemonic is configured in both the single-match and exact-match rules, the single-match rule prevails.

1.1.8 Log Reporting

The log reporting functions falls into level-based reporting, delayed reporting, and periodical reporting, which are described as follows:

- Level-based reporting

  You can perform the level-based policy function to send logs of modules and severity levels to different destinations.

  For example, you can configure a command to send OSPF module logs of level 4 or lower to the log server, and OSPF module logs of level 5 or higher to local log files.

- Delayed reporting

  Delayed log reporting means that instead of being directly sent to the log server, system logs generated in the system are buffered in the log files in the device and then periodically sent to the log server. Delayed log reporting can be configured to reduce the packet transmission and interaction frequency between the device and the log server. In this way, the performance pressure on the device and the log server and the burden of the intermediate network is reduced.

- Periodical reporting

  Logs about device performance statistics are periodically sent. All timers for periodically sending logs are managed by the syslog module. When a timer expires, the syslog module calls the log processing function registered by each module to display and output the performance statistic logs to the remote syslog server in real time. The server analyzes these logs to evaluate the device performance.

Caution

- To configure log reporting, enable the RFC5424 log format function; otherwise, you cannot configure level-based reporting, delayed reporting, and periodical reporting.
- When the RFC5424 log format is enabled, logs can be output in all directions, and delayed reporting is enabled by default. At the same time, the periodical reporting function is disabled.

1.1.9 Configuring System Log Monitoring

System log monitoring means that the system monitors external connections to the device and records logs.

- After user login/logout logging is enabled, the system records the user's connections to the device. The recorded information includes the login username and source address.
- After user operation logging is enabled, the system records device configuration changes. The recorded information includes the operation username, source address, and operation content.

1.1.10 Protocols and Standards

- RFC 3164: The BSD syslog Protocol
- RFC 5424: The_Syslog_Protocol

1.2 Configuration Task Summary

Syslog configuration includes the following tasks:

(1) Configuring Basic Syslog Features

(2) (Optional) Configuring the System Log Format. The configurations below are mutually exclusive. Configure either of the tasks.

- Configuring the RFC3164 Log Format
- Configuring the RFC5424 Log Format
- Configuring a Space Next to <pri> in the Log Format

(3) Configuring Log Reporting Configure at least one of the functions.

- Configuring Level-based Log Reporting
- Configuring Delayed Log Reporting
- (Optional) Configuring Periodical Log Reporting

(4) (Optional) Configuring System Log Monitoring

(5) (Optional) Configuring the Output Direction of System Logs Configure at least one of the output directions.

- Configuring the Output of System Logs to the Console
- Configuring the Output of System Logs to the Monitor Terminal
- Configuring the Function of Writing System Logs into the Memory Buffer
- Configuring the Transmission of System Logs to the Log Server
- Configuring the Function of Writing System Logs into Log Files

(6) (Optional) Configuring System Log Filtering

(7) (Optional) Configuring System Log Redirection

(8) (Optional) Configuring Performance Logging Function

(9) (Optional) Configuring Synchronization of User Input and Log Output

1.3 Configuring Basic Syslog Features

1.3.1 Overview

This section describes how to enable the syslog function so that the system processes logs and users view the logs generated by the device.

1.3.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable logging.

logging on

By default, logging is enabled.

1.4 Configuring the System Log Format

1.4.1 Overview

By configuring system log display, you can adjust the display format of system logs.

1.4.2 Configuration Tasks

System log format configuration includes the following tasks. The following configurations are mutually exclusive. Configure either of the tasks.

- Configuring the RFC3164 Log Format
- Configuring the RFC5424 Log Format
- Configuring a Space Next to <pri> in the Log Format

1.4.3 Configuring the RFC3164 Log Format

1. Restrictions and Guidelines

- If the device does not have an RTC, which is hardware used to record the absolute time of the system, the system uses the device startup time (in the **uptime** format) as the log timestamp. In this case, the configured device time is invalid. If the device has an RTC, the system uses the device time (in the **datetime** format) as the log timestamp.
- Add a system name to logs to identify the device that generates a system log after the system log is sent to the server.
- Add a sequence number to logs. The sequence number starts from 1. After the sequence number is added, the system can monitor the loss and the generation sequence of logs. The log sequence number is a 6-digit integer. Each time a log is generated, the sequence number increases by one. When the sequence number increases from 1 to 1,000,000, or reaches 2^32, it starts from 000000 again.
- After the RFC3164 format is enabled, the **logging delay-send**, **logging policy**, and **logging statistic** commands that are applicable to the RFC5424 format will become invalid and be hidden.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the timestamp format for system logs.

service timestamps [*message-type* [**datetime** [**msec** | **year**] * | **uptime**]]

The system logs use the datetime timestamp format, and the timestamp does not contain the year and milliseconds by default.

(4) (Optional) Add the system name to system logs.

service sysname

By default, system logs do not contain the system name.

(5) (Optional) Add the sequence number to system logs.

service sequence-numbers

By default, system logs do not contain the sequence number.

(6) Configure the system log format. The configurations below are mutually exclusive. Configure one of the log formats.

- Set the system log format to the standard log format.

  service standard-syslog

- Set the system log format to the private log format.

  service private-syslog

1.4.4 Configuring the RFC5424 Log Format

1. Restrictions and Guidelines

- After the RFC5424 log format is enabled, a uniform timestamp format is adopted, and **uptime** and **datetime** are not differentiated.
- In the RFC5424 log format, the timestamp may or may not contain the time zone. Currently, only the timestamp without the time zone is supported.
- After the RFC5424 format is enabled, the **service sequence-numbers**, **service sysname**, **service timestamps**, **service private-syslog**, and **service standard-syslog** commands that are applicable to the RFC3164 format will become invalid and be hidden.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Set the system log format to the RFC5424 log format.

service log-format rfc5424

1.4.5 Configuring a Space Next to <pri> in the Log Format

1. Restrictions and Guidelines

- If there is no special requirement, configure a space on the device that needs a space next to <pri> in the log format.
- The default format of logs sent to a server are as follows:

```
<pri>*timestamp: %module-level-mnemonic: content
```

The order is as follows:

```
<pri>*timestamp: %module-level-mnemonic: content
```

If the function is enabled, the format of logs sent to a server are as follows:

```
<pri> *timestamp: %module-level-mnemonic: content
```

Compared with the default log format, a space is added next to <pri>.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a space next to <pri> in the log format.

logging priv-format private

By default, no space exists after <pri> in the log format.

1.4.6 Configuring the Log Format to Carry Identity Information

1. Restrictions and Guidelines

- Unless otherwise specified, configure this function to carry identity information in the log format in the RFC3164 format.
- The default format for logs sent from the device to the server is as follows:

```
<pri>*timestamp: %module-level-mnemonic: content
```

The following describes the preceding parameters:

```
<Priority>*Timestamp: %Module name-Level-Mnemonic: Log content
```

If this function is configured, the log sent from the device to the server is displayed in the following format:

```
<pri>Origin-id: *timestamp: %module-level-mnemonic: content
```

The following describes the preceding parameters:

```
<Priority>Identity information: *Timestamp: %Module name-Level-Mnemonic: Log
content
```

The identity information is added.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the log format to carry identity information.

logging origin-id { **hostname** | **string** *word* }

By default, logs do not carry identity information.

1.5 Configuring Log Reporting

1.5.1 Configuration Tasks

The log reporting configuration includes the following tasks. Configure at least one of the tasks.

- Configuring Level-based Log Reporting
- Configuring Delayed Log Reporting
- (Optional) Configuring Periodical Log Reporting

1.5.2 Restrictions and Guidelines

The log reporting function can be configured and takes effect only when the RFC5424 format is enabled.

1.5.3 Configuring Level-based Log Reporting

1. Overview

You can configure a level-based log reporting policy to output logs of different modules and severity levels to different destinations.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Set the system log format to the RFC5424 log format.

service log-format rfc5424

(4) Configure a level-based log reporting policy.

logging policy module *module-name* [**not-lesser-than**] *policy-level* **direction** { **all** | **buffer** | **console** | **file** | **monitor** | **server** }

No level-based log reporting policy is configured by default.

1.5.4 Configuring Delayed Log Reporting

1. Overview

Delayed log reporting means that, instead of being directly sent to the log server, system logs generated in the system are buffered in the log files in the device and then periodically sent to the log server. Delayed log reporting can be configured for system logs to reduce the message transmission and interaction frequency

between the device and the log server. In this way, the performance pressure on the device and the syslog server and the burden of the intermediate network is reduced.

2. Restrictions and Guidelines

- Generally, you are not advised to output logs reported in a delayed manner to the console or remote terminal. Otherwise, many logs reported in a delayed manner are displayed, increasing the burden on the device.
- The configured file name cannot contain any dot (.) because the system automatically adds the index and the file name extension (**.txt**) to the file name when generating a locally buffered file. The index increases each time a new file is generated. In addition, the file name cannot contain characters prohibited by the file system of your PC, such as \, /, :, *, ", <, >, and |. For example, the configured file name is **log_server**, the current index is 5, the file size is 1000 bytes, and the source IP address of the device sending the log file is 10.2.3.5. The name of the log file sent to the remote server is **log_server_1000_10.2.3.5_5.txt** while the name of the log file stored on the device is **log_server_5.txt**. If the source IP address is an IPv6 address, the colon (:) in the IPv6 address must be replaced by the hyphen (-) because the colon (:) is prohibited by the file system. For example, the file name is **log_server**, the current file index is 6, the file size is 1000 bytes, and the source IPv6 address of the device sending the log file is 2001::1. The name of the log file sent to the remote server is **log_server_1000_2001-1_6.txt** while the name of the log file stored on the device is **log_server_6.txt**.
- If few logs are generated on the device, you are advised to set the interval of delayed log reporting to a large value so that more logs are sent to the remote server at a time.
- By default, the log file sent to the remote server is named **File size_device IP address_index.txt**. If the name of the file for delayed log reporting is modified, the log file sent to the remote server is named **Configured file name prefix_file size_device IP address_index.txt**. The file stored on the local flash space of the device is named **Configured file name prefix_index.txt**. The default file name prefix is **syslog_ftp_server**, the interval for delayed log reporting is 3600s (1 hour), and the log file size is 128 KB.
- The maximum interval for delayed log reporting is 65535s (18 hours). If you set the interval for delayed log reporting to a larger value, the size of logs generated in this period may exceed the file size (128 KB). To prevent loss of logs, the logs are written into a new log file, and the index increases by 1. When the timer expires, all log files buffered in this period are sent to the log server at a time.
- The flash space for buffering local log files on the device is limited. Therefore, up to eight log files are buffered on the device. If more than eight log files are buffered on the device, all the log files generated earlier are sent to the log server at a time.
- You can send logs to the log server through File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP). The addresses of up to five log servers are configured for one device. Either FTP or TFTP is specified for each server.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Set the system log format to the RFC5424 log format.

service log-format rfc5424

(4) Configure delayed log reporting. The following configurations are optional. Configure at least one of them as actually needed.

- Configure delayed log reporting to the console and remote terminal.

  logging delay-send terminal

  Delayed log reporting to the console and remote terminal is disabled by default.

- Configure the name of the file for delayed log reporting.

  logging delay-send file flash: *delay-send-filename*

  The default format of the log file name is file size_device IP address_index.txt.

- Configure the interval for delayed log reporting.

  logging delay-send interval *delay-send-interval*

  The interval for delayed log reporting is 3600s (1 hour) by default.

- Configure the server address and reporting mode.

  logging delay-send server [**oob**] { *ipv4-address* | **ipv6** *ipv6-address* } [**vrf** *vrf-name*] [**via** *mgmt-name*] **mode** { **ftp user** *username* **password** [**0** | **7**] *password* | **tftp** }

  (Management port configuration)

  logging delay-send server oob { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } [**via mgmt** *interface-number*] **mode** { **ftp user** *username* **password** [**0** | **7**] *password* | **tftp** }

  (Non-management port configuration)

  logging delay-send server { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } [**vrf** *vrf-name*] **mode** { **ftp user** *username* **password** [**0** | **7**] *password* | **tftp** }

  Delayed log reporting is disabled by default.

1.5.5 Configuring Periodical Log Reporting

1. Overview

This section describes how to configure periodical log reporting so that the server can collect all the logs on the device at the same time point.

2. Restrictions and Guidelines

- The interval of periodical log reporting and the function of outputting logs to the console and remote terminal take effect only after periodical log reporting is enabled.
- You are advised to disable the function of outputting periodically reported logs to the console and remote terminal. Otherwise, when the reporting timer expires, many performance statistics logs are displayed, increasing the burden on the device.
- To ensure that the server collects all performance statistics logs from the device at the same time point, the timers of all statistical objects are restarted when you modify the interval of one statistic object.
- The default interval of periodical log reporting is 15 minutes. To enable the server to collect all performance statistics logs from the device at the same time point, you need to set the log reporting interval of different statistic objects to be a multiple of another interval. Currently, the interval can be set to 0, 15, 30, 60, or 120. Here, **0** indicates that periodical log reporting is disabled.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Set the system log format to the RFC5424 log format.

service log-format rfc5424

(4) Configure periodical log reporting.

logging statistic enable

Periodical log reporting is disabled by default.

(5) (Optional) Configure periodical log reporting to the console and remote terminal.

logging statistic terminal

Periodical log reporting to the console and remote terminal is disabled by default.

(6) (Optional) Configure the interval for periodical log reporting.

logging statistic mnemonic *mnemonic* **interval** *logging-statistic-interval*

The default interval of periodical log reporting is 15 min.

1.6 Configuring System Log Monitoring

1.6.1 Overview

System log monitoring enables the system to monitor the external connections to the device and record logs.

1.6.2 Restrictions and Guidelines

- If both the **logging userinfo** command and the **logging userinfo command-log** command are configured on the device, only the results shown by the **logging userinfo command-log** command are displayed when you run the **show running-config** command.
- The **logging userinfo** command is run in global configuration mode to enable login/logout logging. After this function is configured, the device displays logs when users access the devices through telnet, Secure Shell (SSH), or Hypertext Transfer Protocol (HTTP) so that the administrator monitors the device connection status.
- The **logging userinfo command-log** command is run in global configuration mode to enable user operation logging. After this function is configured, the system displays related logs to notify the administrator of configuration changes.
- User operations are logged when commands are configured and run. By default, the device does not generate operation logs when a user modifies the device configuration. If the 5424 log format is configured, that is, the **service log-format rfc5424** command is configured, you need to configure the **logging delay-send terminal** command so that operation logs are output to the terminal (because delayed log reporting is registered for operation logs).

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure system log monitoring. The following configurations are all optional. Configure at least one of them as actually needed.

- Enable user login/logout logging.

  logging userinfo

  User login/logout logging is disabled by default.

- Enable user operation logging.

  logging userinfo command-log

  User operation logging is disabled by default.

1.7 Configuring the Output Direction of System Logs

1.7.1 Configuration Tasks

System log output direction configuration includes the following tasks. Configure at least one of the tasks.

- (Optional) Configuring the Output of System Logs to the Console
- (Optional) Configuring the Output of System Logs to the Monitor Terminal
- (Optional) Configuring the Function of Writing System Logs into the Memory Buffer
- (Optional) Configuring the Transmission of System Logs to the Log Server
- (Optional) Configuring the Function of Writing System Logs into Log Files

1.7.2 Configuring the Output of System Logs to the Console

1. Overview

This section describes how to configure the output of system logs to the console so that the device can output logs generated by the system to the console. Then, administrator can monitor the running status of the system.

2. Restrictions and Guidelines

- If too many system logs are generated, you can limit the logging rate to reduce logs output to the console.
- By default, system logging is enabled. You are advised not to disable it. If too many system logs are displayed, you can configure the level of logs to be displayed on different devices to reduce the logs displayed.
- The **logging count** command is run to enable the log statistics function in global configuration mode. After this function is enabled, the system records the number of times logs are generated by each module and the generation time of the last log.
- The default level of logs that are displayed on the console is debugging (Level 7). You can run the **show logging config** command in privileged EXEC mode to display the level of logs that are displayed on the

console.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable log statistics collection.

logging count

Log statistics collection is disabled by default.

(4) (Optional) Configure the level of logs that are output to the console.

logging console [*severity-level*]

The default level of logs that are displayed on the console is 7 (debugging information).

(5) (Optional) Configure logging rate limiting.

logging rate-limit [**console**] [**all**] *number* [**except** [*severity-level*]]

Logging rate limiting is disabled by default.

1.7.3 Configuring the Output of System Logs to the Monitor Terminal

1. Overview

This section describes how to configure the output of system logs to the monitor terminal so that the device can output system logs to the remote monitor terminal. Then, the administrator can monitor the running status of the system.

2. Restrictions and Guidelines

- If too many system logs are generated, you can limit the logging rate to reduce logs output to the monitor terminal.
- By default, the current monitor terminal is not allowed to output logs after you remotely connect to the device. You need to manually run the **terminal monitor** command to allow the current monitor terminal to display logs. The **terminal monitor** command is valid only for the current connection. When the terminal reconnects to the device, the default settings of this command are restored.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enable log display on the current monitor terminal.

terminal monitor

Log display in the window of the monitor terminal is disable by default.

(3) Enter the global configuration mode.

configure terminal

(4) (Optional) Configure the level of logs to be output to the monitor terminal.

logging monitor [*severity-level*]

The default level of logs that are displayed in the window of the monitor terminal is 7 (debugging information).

1.7.4 Configuring the Function of Writing System Logs into the Memory Buffer

1. Overview

This section describes how to configure the function of writing system logs into the memory buffer so that the device can write generated system logs into the memory buffer. Then, the administrator can view recent system logs by running the **show logging** command.

2. Restrictions and Guidelines

- If the buffer is full, earlier logs are overwritten when system logs are written into the memory buffer.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the parameters for the memory buffer, into which logs are to be written.

logging buffered [*buffer-size*] [*severity-level*]

The buffer size is 10 mega-byte and the log severity level is 7 by default.

1.7.5 Configuring the Transmission of System Logs to the Log Server

1. Overview

This section describes how to configure the device to transmit generated system logs to the log server so that the administrator can monitor device logs on the server.

2. Restrictions and Guidelines

- The log timestamp or sequence number function must be enabled. Otherwise, the logs are not sent to the log server.
- If the device has an MGMT interface and is connected to the log server through the MGMT interface, you must add the **oob** option (indicating that system logs are sent to the log server through the MGMT interface) when configuring the **logging server** command. You can use the **via** parameter only when **oob** is specified in the command. In this case, **/vrf** is unavailable.
- The **logging server** command is used to specify the address of the log server that receives logs. You can specify multiple log servers, and logs are sent simultaneously to all these log servers.
- Up to five log servers are configured for a Ruijie product.
- When a domain name is entered to configure a log server, the **logging hostname** command is disabled.
- To track and manage logs, you can use the **logging source interface** command to set the source IP address of all log packets to the IP address of an interface. Thus, the administrator can identify the device that sends the logs based on the unique address. If this source interface is not configured or the IP address is not configured for this source interface, the source IP address of log packets is the IP address of the

interface that sends the log packets.

- The **logging trap** command is used to configure the severity level of logs that are sent to all syslog servers on a device. The log severity level configured in the **logging server** command is used for each device to determine whether to send logs to all syslog servers. Logs generated by the device can be sent to the corresponding log server only when the level is smaller than or equal to the log severity level specified in both the **logging trap** command and the **logging server** command. For details about the severity levels of logs, see Table 1-1. A smaller value indicates a higher severity level.
- The priority carried in the logs sent by the device to the log server is specified by the **facility-type** parameter in the **logging facility** command. The **facility-type** parameter in this command is only used to determine whether to send logs to the log server. If the value specified in this command is greater than or equal to the value specified in the **logging facility** command, the device can send system logs to the log server. Otherwise, the device cannot send system logs to the log server.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the transmission of logs to a specified log server.

Perform configuration on a management interface.

logging server oob { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } [**via mgmt** *interface-number*] [**udp-port** *port-number*] [**facility** *facility-type*] [**level** *inform-level*]

If the configuration is performed on a non-management interface, configure only one of the following tasks.

logging server { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } [**vrf** *vrf-name*] [**udp-port** *port-number*] [**facility** *facility-type*] [**level** *inform-level*]

logging { *ipv4-address* | **ipv6** *ipv6-address* } [**vrf** *vrf-name*] [**udp-port** *port-number*] [**facility** *facility-type*] [**level** *inform-level*]

No syslog server is specified to record logs by default.

(4) (Optional) Configure the severity level of logs that are sent to the syslog server.

logging trap [*severity-level*]

The default severity level of logs is 6 (informational messages). Logs of levels 0 to 6 can be sent to the log server.

(5) (Optional) Configure the facility value for logs to be sent to the log server.

logging facility *facility-type*

When the RFC5424 log format is enabled, the default facility value is 16 (Local0, Local use); when the RFC5424 log format is disabled, the default facility value is 23 (Local7, Local use).

(6) (Optional) Configure the source interface for logs to be sent to the log server.

logging source interface *interface-type interface-number*

No log source address is configured by default, and the source IP address of the log packets sent to the server is the IP address of the interface that sends the log packets.

(7) (Optional) Configure the source address for logs to be sent to the log server.

- Configure an IPv4 source address for the logs to be sent to the log server.

  logging source ip *ipv4-address*

- Configure an IPv6 source address for the logs to be sent to the log server.

  logging source ipv6 *ipv6-address*

No log source address is configured by default, and the source IP address of the log packets sent to the server is the IP address of the interface that sends the log packets.

1.7.6 Configuring the Function of Writing System Logs into Log Files

1. Overview

This section describes how to configure the function of writing system logs into log files so that the device can save generated system logs to the log files for viewing. Logs are saved in a log file buffer before being saved to the log file. The system writes the content in the log file buffer to the log file at the specified frequency, and you can also save the logs to a log file manually. After the logs are saved, the content in the log file buffer will be cleared. When logs need to be saved, the device automatically generates log files.

2. Restrictions and Guidelines

- System logs are not immediately written into log files. They are first buffered in the memory buffer, and then written into log files either periodically (at an interval of 1 hour by default) or when the buffer is full.
- When no log file is generated and the remaining space of the storage medium is insufficient, the device does not save the newly generated logs to a log file. Therefore, you must regularly clean up the storage space of the storage medium to ensure the log file function.
- The **logging file** command is used to create a log file with a specified file name on a specified file storage device. The file size increases with logs, but cannot exceed the configured value of **max-file-size**. If the value of **max-file-size** is not specified, the default size of a log file is 128 KB.
- After the **logging file** command is configured, the system saves logs to log files. A log file name does not contain any file type extension. The log file name extension is always **txt**, which cannot be changed.
- After this function is configured, logs will be written into log files at an interval of 1 hour. If you have run the **logging file flash:syslog** command, 16 log files are created, such as **syslog.txt**, **syslog_1.txt**, **syslog_2.txt**, …, **syslog_14.txt**, and **syslog_15.txt**. Logs are overwritten into the 16 log files in sequence and cyclically. For example, the system writes logs into **syslog_1.txt** after **syslog.txt** is fully occupied. When **syslog_15.txt** is fully occupied, logs are written into **syslog.txt** again.
- If no extended flash space is available, the **logging file flash** command is automatically hidden and is not configured.
- You can configure an upper alarm threshold for the system log storage space based on actual needs to back up historical logs in time and prevent log loss because some logs are overwritten. When the storage space accumulatively occupied by log files reaches the configured upper alarm threshold, the system generates Syslog and trap alarms and instructs you to back up the logs in time. After you back up and delete the logs, the system checks the occupied space again. If the occupied space is below the threshold, the system generates the Syslog and trap alarms for the restoration.
- The system will not delete the generated log files after the number of log files is modified. Therefore, to save the space of the extended flash space, you need to manually delete the log files generated in the system

(before deletion, you can transfer the log files to an external server through TFTP). For example, 32 log files are created by default after the function of writing logs into log files is enabled. If the device has generated 32 log files and if you want to change the number of log files to 2, new logs are overwritten into the log files with the index of 0 and 1 by turns. The existing log files with the index of 2 to 32 are retained. You can manually delete these log files as needed.

- After the time-based log storage is enabled, the system writes logs of the same level that are generated in the same day into the same log file. The log file is named **yyyy-mm-dd_filename_level.txt**, where **yyyy-mm-dd** indicates the absolute time of the day when the logs are generated, **filename** indicates the log file name configured by the **logging file flash** command, and **level** indicates the log level.
- After you specify the storage time for logs of a level, the system will delete the logs once the storage time expires. For better network management, the storage time ranges from 7 days to 365 days.
- If the time-based log storage is not enabled, logs are stored based on the file size to support old configuration commands.
- After the **logging flash flush** command is configured, the logs in the buffer are immediately written into a log file.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the parameters for the log file, into which logs are written.

logging file { **flash:***filename* | **usb0**:*filename* } [*max-file-size*] [*inform-level*]

(4) Configure the number of log files.

logging file numbers *file-numbers*

The default number of log files is 32.

(5) Configure an upper alarm threshold for the system log storage space.

logging file alarm-threshold *percent-number*

The upper alarm threshold for the system log storage space is 90% by default.

(6) Configure the interval for writing logs into log files.

logging flash interval *log-write-flash-interval*

By default, logs are written into flash files at an interval of 3600s.

(7) Configure the storage time of logs written into log files.

logging life-time level *inform-level life-time-days*

No storage time is configured by default. The storage time depends on the configured log file size.

(8) Configure the function of immediately writing logs in the buffer into log files.

logging flash flush

1.8 Configuring System Log Filtering

1.8.1 Overview

By default, all the logs generated by the system are displayed on the console or other terminals. By configuring log filtering, the network administrator can filter the generated system logs, select only the required logs to be displayed, or have the logs displayed on a specified terminal.

1.8.2 Restrictions and Guidelines

- Two filtering modes are available: **contains-only** and **filter-only**, which are mutually exclusive. You can configure only one filtering mode at a time.
- Log filtering rules fall into **exact-match** and **single-match**. The **single-match** rule prevails over the **exact-match** rule. If the same module, mnemonic, or information level is configured in both the **single-match** and **exact-match** rules, the logs complying with the **single-match** rule are filtered first.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the log filtering direction. The following configurations are optional. Select at least one of the configurations as actually needed.

- Configure the log filtering direction.

  logging filter direction { **all** | **buffer** | **file** | **server** | **terminal** }

  Logs sent to all the directions are filtered by default, namely, **all** is set.

- Configure the log filtering mode.

  logging filter type { **contains-only** | **filter-only** }

  The filtering type is set to **filter-only** by default.

(4) Configure the log filtering rule.

logging filter rule { **exact-match module** *module-name* **mnemonic** *mnemonic-name* **level** *inform-level* | **single-match** { **level** *inform-level* | **mnemonic** *mnemonic-name* | **module** *module-name* } }

No log filtering rule is configured by default.

1.9 Configuring System Log Redirection

1.9.1 Overview

In a virtual switching unit (VSU) environment, you can configure the system log redirection function to redirect the logs of the slave device to the active device so that the network administrator can manage the logs uniformly.

1.9.2 Restrictions and Guidelines

- The system log redirection function is used in a VSU active-standby environment only, and does not apply to

the standalone environment.

- You are advised to run the **logging rd rate-limit** command to limit the rate of the logs redirected to the active device. This is to limit the number of the logs that are redirected from the slave device to the active device per second. This prevents considerable logs on the slave device from burdening the system.
- In a VSU environment, logs on the slave device can be displayed in its console window, redirected to the active device for display in the console or virtual type terminal (VTY) window of the active device, or stored in the memory buffer of the active device, extended flash space or syslog server.
- In a VSU environment composed of box-type devices, after the log redirection function is enabled, logs on the slave or standby device will be redirected to the active device for output, and the role flag string "(*device ID)" will be added to the beginning of each log, to indicate that the log is a redirected log. Assume that four devices form a VSU. The ID of the active device is 1, the ID of the slave device is 2, and the IDs of two standby devices are 3 and 4. No role flag string is added to logs generated by the active device. The role flag string (*2) is added to logs redirected from the slave device to the active device. The role flag strings (*3) and (*4) are added respectively to logs redirected from the two standby devices to the active device.
- In a VSU environment composed of chassis-type devices, after the log redirection function is enabled, logs generated by the slave or standby Supervisor Engine will be redirected to the master Supervisor Module for output, and a role flag string "(*device ID/Supervisor Engine name)" will be added to each log to indicate that a log is a redirected log. If four Supervisor Engines are used in a VSU, the role flag strings are as follows: (*1/M1), (*1/M2), (*2/M1), and (*2/M2).

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the log redirection function.

logging rd on

(4) (Optional) Configure the rate limit on redirected logs.

logging rd rate-limit *number* [**except** [*severity-level*]]

The log redirection function limits the maximum number of logs to be redirected per second to 200 by default.

1.10 Configuring Performance Logging Function

1.10.1 Overview

After the performance logging function is enabled, the logs that are output through the performance logging interface will be transmitted through the performance logging channel.

1.10.2 Restrictions and Guidelines

The performance logging function needs to be configured only when massive logs are displayed on the server within a short period. Only several functional services require this function.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the performance logging function.

logging performance switch

The performance logging function is disabled by default.

1.11 Configuring Synchronization of User Input and Log Output

1.11.1 Overview

When the synchronization of user input and log output is enabled, even if logs are displayed during user input, the user input information is displayed after display, thereby ensuring the input integrity and continuity.

1.11.2 Restrictions and Guidelines

The **logging synchronous** command is configured in line configuration mode, and on each line that enables this function.

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the configuration mode of a specified line.

line { **console** | **vty** } *first-line* [*last-line*]

(4) Synchronize user input and log output.

logging synchronous

Synchronization of user input and log output is disabled by default.

1.12 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-8 Syslog Monitoring

Command	Purpose
clear logging	Clears logs in the memory buffer.
show logging	Displays log statistics and logs in the memory buffer based on the timestamp from earliest to latest.
show logging reverse [**timestamp** *YY MM DD hh:mm:ss*]	Displays log statistics and logs in the memory buffer based on the timestamp from latest to earliest.
show logging config	Displays system log configurations and statistics.
show logging count	Displays log statistics of each module in the system.

1.13 Configuration Examples

1.13.1 Configuring the RFC3164 Log Format

1. Requirements

The network administrator can check system logs to learn about the operation status of the device, better understand and manage the device, or locate problems.

2. Topology

Figure 1-1 Topology for RFC3164 Log Format Configuration

3. Notes

- Configure the L3 network reachable between the device and the server.
- Enable logging.
- Configure the log format.
  - Set the system log format to RFC3164 format.
  - Configure the log display format.
  - Set the timestamp format to datetime and add the millisecond and year to the timestamp.
  - Add the system name to the system log format.
  - Add the sequence number to the system log format.
- Configure log monitoring.
  - Configure log statistics collection.
  - Set the rate of outputting system logs to the console to 50 logs per second.

- Configure the display of logs on the monitor terminal.

- Synchronize user input and log output.
- Enable performance logging.
- Configure log filtering.
  - Set the filtering directions of logs to **terminal** and **server**.
  - Set the log filtering mode to **filter-only**.
  - Set the log filtering rule to **single-match** to filter the logs with a module name containing "SYS".
- Configure the output direction of system logs.
  - Configure the function of writing system logs into a log file named **syslog**.
  - Configure the transmission of system logs to the log server with the IPv4 address of 192.168.1.20.
  - Configure the size of the system logs to be written into the memory buffer to 128 KB (131072 bytes).

4. Procedure

(1) Configure the management IP address for the device.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet 0/1
Device(config-if-GigabitEthernet 0/1)# ip address 10.1.1.2 255.255.255.0
Device(config-if-GigabitEthernet 0/1)# exit
```

(2) Enable logging.

```
Device(config)# logging on
```

(3) Configure the system log format.

Set the system log format to RFC5424 log format.

```
Device(config)# no service log-format rfc5424
```

Set the log display format to standard log format.

```
Device(config)# service standard-syslog
```

Set the timestamp format to datetime and add the millisecond and year to the timestamp.

```
Device(config)# service timestamps log datetime year msec
Device(config)# service timestamps debug datetime year msec
```

Add the system name to the system log format.

```
Device(config)# service sysname
```

Add the sequence number to the system log format.

```
Device(config)# service sequence-numbers
```

(4) Configure log monitoring.

```
Device(config)# logging userinfo
Device(config)# logging userinfo command-log
```

Configure log statistics collection.

```
Device(config)# logging count
```

Configure the output of system logs to the console.

```
Device(config)# logging console informational
```

Set the rate of outputting system logs to the console to 50 logs per second.

```
Device(config)# logging rate-limit console 50
```

Configure the output of system logs to the monitor terminal.

```
Device(config)# logging monitor informational
Device(config)# line vty 0 4
Device(config-line)# monitor
```

(5) Synchronize user input and log output.

```
Device(config-line)#logging synchronous
Device(config-line)#exit
```

(6) Enable performance logging.

```
Device(config)# logging performance switch
```

(7) Configure log filtering.

Set the filtering directions of logs to **terminal** and **server**.

```
Device(config)# logging filter direction server
Device(config)# logging filter direction terminal
```

Set the log filtering mode to **filter-only**.

```
Device(config)# logging filter type filter-only
```

Set the log filtering rule to **single-match** to filter the logs with a module name containing "SYS".

```
Device(config)# logging filter rule single-match module SYS
```

(8) Configure the output direction of system logs.

Configure the function of writing system logs into a log file named **syslog**.

```
Device(config)# logging file flash:syslog debugging
Device(config)# logging flash interval 600
```

Configure the transmission of system logs to the log server with the IPv4 address of 192.168.1.20.

```
Device(config)# logging server 192.168.1.20
```

Configure the size of the system logs to be written into the memory buffer to 128 KB (131072 bytes).

```
Device(config)# logging buffered 131072 informational
```

5. Verification

Run the **ping** command to check whether the L3 route between the server and the log server is reachable.

```
Device# ping 192.168.1.20
Sending 5, 100-byte ICMP Echoes to 192.168.1.20, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/3 ms
```

Run the **show logging config** command to check the configuration.

```
Device# show logging config
Syslog logging: enabled
  Console logging: level informational, 82 messages logged
```

```
 Monitor logging: level informational, 0 messages logged
 Buffer logging: level debugging, 83 messages logged
 File logging: level debugging, 83 messages logged
 File name:syslog.txt, size 128 Kbytes, the 1 file is currently being written
 Standard format:true
 Timestamp debug messages: datetime
 Timestamp log messages: datetime
 Sequence-number log messages: enable
 Sysname log messages: enable
 Count log messages: enable
 Trap logging: level debugging, 82 message lines logged,8 fail
   logging to  192.168.1.20
```

6. Configuration Files

Device configuration file

```
hostname Device
!
service standard-syslog
service sysname
service sequence-numbers
service timestamps debug datetime msec year
service timestamps log datetime msec year
logging filter direction server
logging filter direction terminal
logging filter rule single-match module SYS
logging rate-limit console 50
logging count
logging userinfo command-log
logging buffered 131072 informational
logging file flash:syslog debugging
logging flash interval 600
logging console informational
logging monitor informational
logging server 192.168.1.20
logging performance switch
!
interface VLAN 1
 ip address 192.168.1.10 255.255.255.0
!
end
```

1.13.2 Configuring the RFC5424 Log Format

1. Requirements

The network administrator can check system logs to learn about the operation status of the device, better understand and manage the device, or locate problems.

2. Topology

Figure 1-2 Topology for RFC5424 Log Format Configuration

3. Notes

- Configure the L3 network reachable between the device and the server.
- Enable logging
- Set the system log format to RFC5424 format.
- Configure log reporting.
  - Configure level-based log reporting.
  - Configure delayed log reporting.
  - Configure periodical log reporting.
- Configure log monitoring.
  - Configure the log statistics collection.
  - Set the rate of outputting system logs to the console to 50 logs per second.
  - Configure the display of logs on the monitor terminal.
- Synchronize user input and log output.
- Enable performance logging.
- Configure log filtering.
  - Set the filtering directions of logs to **terminal** and **server**.
  - Set the log filtering mode to **filter-only**.
  - Set the log filtering rule to **single-match** to filter the logs with a module name containing "SYS".
- Configure the output direction of system logs.
  - Configure the function of writing system logs into a log file named **syslog**.
  - Configure the transmission of system logs to the log server with the IPv4 address of 192.168.1.20.
  - Configure the size of the system logs to be written into the memory buffer to 128 KB (131072 bytes).

4. Procedure

(1) Configure the management IP address for the device.

```
Device> enable
Device# configure terminal
Device(config)#interface gigabitethernet 0/1
Device(config-if-GigabitEthernet 0/1)# ip address 192.168.1.10 255.255.255.0
Device(config-if-GigabitEthernet 0/1)# exit
```

(2) Enable logging

```
Device(config)# logging on
```

(3) Set the system log format to RFC5424 format.

```
Device(config)# service log-format rfc5424
```

(4) Configure log reporting.

Configure delayed log reporting.

```
Device(config)# logging delay-send terminal
Device(config)# logging delay-send interval 7200
Device(config)# logging delay-send file flash:syslog
Device(config)# logging delay-send server 192.168.1.20 mode ftp user admin password
Abc123456
```

Configure level-based log reporting.

```
Device(config)# logging policy module SYS not-lesser-than 5 direction console
Device(config)# logging policy module SYS 3 direction buffer
```

Configure periodical log reporting.

```
Device(config)# logging statistic enable
Device(config)# logging statistic terminal
Device(config)# logging statistic mnemonic TUNNEL_STAT interval 30
```

(5) Configure log monitoring.

```
Device(config)# logging userinfo
Device(config)# logging userinfo command-log
```

Configure log statistics collection.

```
Device(config)# logging count
```

Configure the output of system logs to the console.

```
Device(config)# logging console informational
```

Set the rate of outputting system logs to the console to 50 logs per second.

```
Device(config)# logging rate-limit console 50
```

Configure the output of system logs to the monitor terminal.

```
Device(config)# logging monitor informational
Device(config)# line vty 0 4
Device(config-line)# monitor
```

(6) Synchronize user input and log output

```
Device(config-line)# logging synchronous
Device(config-line)# exit
```

(7) Enable performance logging.

```
Device(config)# logging performance switch
```

(8) Configure system log filtering.

Set the filtering directions of logs to **terminal** and **server**.

```
Device(config)# logging filter direction server
Device(config)# logging filter direction terminal
```

Set the log filtering mode to **filter-only**.

```
Device(config)# logging filter type filter-only
```

Set the log filtering rule to **single-match** to filter the logs with a module name containing "SYS".

```
Device(config)# logging filter rule single-match module SYS
```

(9) Configure the output direction of system logs.

Configure the function of writing system logs into a log file named **syslog**.

```
Device(config)# logging file flash:syslog debugging
Device(config)# logging flash interval 600
```

Configure the transmission of system logs to the log server with the IPv4 address of 192.168.1.20.

```
Device(config)# logging server 192.168.1.20
```

Configure the size of the system logs to be written into the memory buffer to 128 KB (131072 bytes).

```
Device(config)# logging buffered 131072 informational
```

5. Verification

(1) Run the **ping** command to check whether the L3 route between the server and the log server is reachable.

```
Device# ping 192.168.1.20
Sending 5, 100-byte ICMP Echoes to 192.168.1.20, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/3 ms.
```

(2) Run the **show logging config** command to check the configuration result.

```
Device# show logging config
Syslog logging: enabled
  Console logging: level informational, 84 messages logged
  Monitor logging: level informational, 0 messages logged
  Buffer logging: level debugging, 92 messages logged
  File logging: level debugging, 105 messages logged
  File name:syslog.txt, size 128 Kbytes, the 1 file is currently being written
  Statistic log messages: enable
  Statistic log messages to terminal: enable
  Delay-send log messages to terminal: enable
  Delay-send file name:syslog, Current write index:0, Current send index:0,
Cycle:7200 seconds
  Count log messages: enable
  Trap logging: level debugging, 84 message lines logged,10 fail
    logging to 192.168.1.20
  Delay-send logging: 0 message lines logged
    logging to 192.168.1.20 by ftp
```

6. Configuration Files

1 Configuring Software Upgrade

1.1 Introduction

Adopting a modular structure, Ruijie General Operating System (RGOS) supports overall system upgrade and subsystem upgrade, as well as the upgrade through patches. The package management module of RGOS is used to install, query, and maintain components of the device. By upgrading the software of the device, users can install software that is more stable or contains more features in the system.

1.2 Principles of System Version Upgrade

1. Basic Concepts

- Subsystem

  A subsystem exists on a device in the form of images. Subsystems include:

  - Uboot: After being powered on, the device loads and runs the Uboot subsystem. This subsystem initializes the device, and loads and runs system images.
  - Rboot: This subsystem is a set of dedicated programs used to install or upgrade the main program.
  - Basic Input Output System (BIOS): This subsystem is dedicated for devices running the X86 architecture.
  - Main program: This subsystem is a collection of Operating Systems (OSs) and applications in the system.

- Installation package

  The installation package used for the upgrade or downgrade of a subsystem contains the installation files of all subsystems. The installation package is used for overall system upgrade/degradation.

- BIOS package

  The BIOS package is used to upgrade the BIOS of the device. It is used on the devices running the X86 architecture only.

2. Upgrading/Degrading and Managing Subsystems

Subsystem upgrade/degradation aims to update the software functions by replacing the subsystem components in the device with the ones in an installation package. Redundancy design is adopted for subsystems, so subsystems of the device are often not directly replaced with the subsystems in the package during upgrade/degradation. Instead, subsystems are added to the device and then activated.

- Upgrade/Degradation

  Subsystems exist on the device in different forms. Therefore, they are upgraded or degraded differently.

  - Uboot: Generally, this subsystem exists in the NOR flash memory of the device in the form of images. It is upgraded/degraded by writing images into the NOR flash memory of the device.
  - Rboot: Generally, this subsystem exists in the NOR flash memory of the device in the form of images. It is upgraded/degraded by writing images into the NOR flash memory of the device.
  - BIOS: Generally, this subsystem exists in the flash memory of the device in the form of images. It is

upgraded/degraded by writing images into the flash memory of the device.

- Main program: Generally, this subsystem exists in the NAND flash memory of the device in the form of images. It is upgraded/degraded by writing images into the NAND flash memory of the device.

- Management

  During upgrade of the subsystem component of the main program, the upgrade/degradation module always records the subsystem component in use, the redundant subsystem components, and management information of various versions in the configuration file. The module queries the available subsystem components and then loads subsystem components as needed.

  The redundancy design is adopted for each subsystem component. During the upgrade/degradation:

  - Uboot: This subsystem contains a master boot subsystem and a slave boot subsystem. Only the master boot subsystem is upgraded, and the slave boot subsystem is always redundant.
  - Rboot: This subsystem contains one program. More redundancies are allowed if there is enough space.
  - BIOS: This subsystem contains a master BIOS and a slave BIOS. The two BIOSs can be upgraded.
  - Main program: One redundancy is allowed if there is enough space.

- Upgrade

  Put upgrade files in the local device, and then run the **upgrade** command.

3. Auto-Sync Upgrade

Auto-sync upgrade aims to coordinate multiple subsystems within one system. During software upgrade, the system automatically sends an upgrade package to all matched members, or upgrades the software version of new members to the specified version according to the specified upgrade policy to ensure that the software version of the entire system meets expectations.

- Select one from the following auto-sync upgrade policies:
  - Check the software version of a new member, and upgrade the member if its version is earlier than the version of the system installation package. Otherwise, no upgrade is performed.
  - Do not auto-sync new members.
  - Upgrade new members to the version of the system upgrade package regardless of the current version of the new members.
- Auto-sync upgrade check is performed in the following scenarios:
  - During upgrade, if no upgrade target is specified, the upgrade function module sends the upgrade package to all matched members for auto-sync upgrade.
  - When the device is started, the version of every member is checked, and auto-sync upgrade is performed according to the version check result and auto-sync upgrade policy.
  - When a new member is added, the version of the member is checked and auto-sync upgrade is performed according to the version check result and auto-sync upgrade policy.
- Management

  To perform auto-sync upgrade, configure an auto-sync upgrade policy and install an upgrade package.

- Configuring an auto-sync upgrade policy

  To perform the expected upgrade when a new member is added to the system, check the auto-sync upgrade configuration, such as preparation of the installation package.

If a module is not checked because the system is not configured with an auto-sync upgrade policy, you can upgrade the specific members.

1.3 Principles of Patch Version Upgrade

1.3.1 Basic Concepts

- Patch package

  A patch package contains several patches. You can upgrade the package to fix various problems for the main program. If a patch package contains hot patches, they take effect before you restart the device restart. If a patch package contains cold patches, they take effect only after the device is restarted.

1.3.2 Patch Package Management

Upgrade of cold patches is to expand the component files in a package into the device. The upgrade takes effect only after the device is restarted.

Such process is similar to the upgrade of hot patches. But in the latter upgrade, only the files to be revised are replaced and then the new files take effect automatically.

Patch management is to use the database to record the patch information. The query, installation, and uninstallation correspond to the insertion, query, and deletion of the database.

Patch management includes three states: installed, activated, and confirmed:

- A patch in the installed state only indicates that this patch exists on the device, but it has not taken effect.
- Only a patch in the activated state is effective, but it will automatically roll back to the previous state after the device is restarted.
- A confirmed patch is also an effective patch, and the patch will not roll back even if the device is restarted.

1.3.3 Patch Auto-Sync

Patch auto-sync aims to coordinate multiple subsystems within a system. During software upgrade, the system automatically sends the patch installed on the current supervisor module to all the members meeting component installation rules. When a new member is added, the system automatically synchronizes the patch installed on the supervisor module to the new member. Thus, no resolved patch problem occurs even if synchronization is omitted.

Patch auto-sync rules:

- The versions of all the subsystems must come from the same installation package before patch auto-sync is performed.
- The patch installed on the master device is used as the benchmark. If the same patch is installed on a newly connected member but the patch status is higher than that of the current master device, the patch on the new member is not be processed. The status order of patches is: add, active, and running.

1.4 Restrictions and Guidelines

If the password encryption type is 7 or 8, when the device version is downgraded to a version that does not support the AES128/SHA256 encryption algorithm, the password may not be identified. Therefore, before the

device is downgraded, you must reconfigure the password as a plaintext password or a type 7 password ciphertext generated on a lower version device.

- During device upgrade, the following error message may be reported: cannot open "/dev/ubi7_0". If the device is upgraded finally, the reported error is automatically rectified. If the device fails to be upgraded, try to upgrade the device again. If the error persists, check for hardware damage.

1.5 Configuration Task Summary

Software upgrade configuration includes the following tasks:

- Configuring System Version Upgrade
  a Configuring Subsystem Upgrade/Degrade
  b (Optional) Configuring Version Auto-sync
  c Configuring One-click Upgrade
- Configuring Patch Version Upgrade
  - Installing a Patch Package
  - (Optional) Activating a Patch Package by One Click
  - (Optional)Activating an EMB Patch Package by One Click
  - Uninstalling a Patch Package
  - Patch Auto-Sync

1.6 Configuring System Version Upgrade

1.6.1 Configuration Tasks

System version upgrade configuration includes the following tasks:

(1) Configuring Subsystem Upgrade/Degrade

(2) (Optional) Configuring Version Auto-sync

(3) Configuring One-click Upgrade

1.6.2 Configuring Subsystem Upgrade/Degrade

Warning

Boot upgrade is risky. If the device is powered off during upgrade, the device may be damaged and thus does not work. If the upgrade fails, do not power off the device, but attempt to upgrade the boot again.

1. Overview

After you upgrade the installation package corresponding to the device, all system software in the device is updated, and the overall software is enhanced.

2. Restrictions and Guidelines

- To upgrade a main package of the device, download the installation package to the local device and run the **upgrade** command.
- To upgrade a rack package, store the installation package in a USB flash drive of the device because the installation package is large, and then run the **upgrade** command.
- After running the **upgrade** command to complete the upgrade of the installation package, you need to run the **reload** command to restart the device to complete the update process. Otherwise, the installation package before the upgrade will be still running on the system.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Upgrade the installation package corresponding to the device.

upgrade { *url* [**slot** *slot-id* | **slot all**] | **download** { **ftp://path** [**slot** *slot-id* | **slot all**] [**vrf** *vrf-name*] | **https://path** [**slot** *slot-id* | **slot all**] [**vrf** *vrf-name*] | **oob_ftp:**//*path* [**slot** *slot-id* | **slot all**] [**via mgmt** *interface-number*] | **oob_https:**//*path* [**slot** *slot-id* | **slot all**] [**via mgmt** *interface-number*] | **oob_sftp:**//*path* [**slot** *slot-id* | **slot all**] [**via mgmt** *interface-number*] | **oob_tftp:**//*path* [**slot** *slot-id* | **slot all**] [**via mgmt** *interface-number*] | **sftp://path** [**slot** *slot-id* | **slot all**] [**vrf** *vrf-name*] | **tftp:**//*path* [**slot** *slot-id* | **slot all**] [**vrf** *vrf-name*] } } [**force**]

(3) Upgrade all Uboot and Rboot files on the device.

upgrade boot { *url* [**slot** *slot-id* | **slot all**] | **download** { **ftp:**//*path* [**slot** *slot-id* | **slot all**] [**vrf** *vrf-name*] | **https:**//*path* [**slot** *slot-id* | **slot all**] [**vrf** *vrf-name*] | **oob_ftp:**//*path* [**slot** *slot-id* | **slot all**] [**via mgmt** *interface-number*] | **oob_https:**//*path* [**slot** *slot-id* | **slot all**] [**via mgmt** *interface-number*] | **oob_sftp:**//*path* [**slot** *slot-id* | **slot all**] [**via mgmt** *interface-number*] | **oob_tftp:**//*path* [**slot** *slot-id* | **slot all**] [**via mgmt** *interface-number*] | **sftp:**//*path* [**slot** *slot-id* | **slot all**] [**vrf** *vrf-name*] | **tftp:**//*path* [**slot** *slot-id* | **slot all**] [**vrf** *vrf-name*] } } [**force**]

(4) Restart the device to complete the upgrade process.

reload

1.6.3 Configuring Version Auto-sync

1. Overview

This section describes how to configure a version auto-sync policy for a distributed system.

2. Restrictions and Guidelines

- To upgrade a new member in the system, check the version auto-sync upgrade configuration, such as preparation of the installation package.
- If a device member is not checked because the system is not configured with a version auto-sync policy, you can upgrade a specific member manually.
- After the path of an upgrade package used for version auto-sync is configured, the upgrade function module will determine the location of the installation package according to this path when new members join the

system. Each time the system is upgraded, the upgrade function module records the path of the installation package for this upgrade and uses it for version auto-sync. You can also use the **upgrade auto-sync package** command to set an upgrade package path.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Configure a version auto-sync policy.

upgrade auto-sync policy { **none** | **compatible** | **coordinate** }

(3) Configure the range of version auto-sync.

upgrade auto-sync range [**vsu**]

(4) Configure the path of the upgrade package for version auto-sync.

upgrade auto-sync package *url*

(5) Configure the status of the version auto-sync service.

upgrade sync-server [**close** | **open**]

Automatic version synchronization is enabled by default.

1.6.4 Configuring One-click Upgrade

1. Overview

UpgradeThe one-click upgrade function is a method used to easily and quickly upgrade the system software of a device. In the system, the traditional upgrade method requires a device restart after upgrade. ISSU upgrades the device by controlling the active/standby switchover of the device. The specific process is as follows: First, upgrade the version of the standby device and restart it. After the standby device starts with the new version, the active device becomes the new standby device. Then, upgrade the new standby device and restart it. After this, the VSU is upgraded to the target version. ISSU helps you reduce service interruption time and improve service forwarding reliability. VSU

2. Restrictions and Guidelines

- Ensure that the device is in powered-on state during upgrade.
- This command is supported in the VSU system on rack-type devices and box-type devices. If the number of VSU members in a box-type device exceeds 2, this command is not supported.

3. Procedure

(1) Enter the privileged EXEC mode.
enable

(2) Enable the ISSU function and install a package to upgrade the device.
upgrade auto { *url* [**delay-time** *time-number*] | **download** { **ftp:**//*path* [**delay-time** *time-number*] [**vrf** *vrf-name*] | **https:**//*path* [**delay-time** *time-number*] [**vrf** *vrf-name*] | **oob_ftp:**//*path* [**delay-time** *time-number*] [**via mgmt** *interface-number*] | **oob_https:**//*path* [**delay-time** *time-number*] [**via mgmt** *interface-number*] | **oob_sftp:**//*path* [**delay-time** *time-number*] [**via mgmt** *interface-number*] | **oob_tftp:**//*path* [**delay-time**

time-number] [**via mgmt** *interface-number*] | **sftp:**//*path* [**delay-time** *time-number*] [**vrf** *vrf-name*] | **tftp:**//*path* [**delay-time** *time-number*] [**vrf** *vrf-name*] } } [**force**]

(3) After all VSU members of the device restart, the device is upgraded.

1.7 Configuring Patch Version Upgrade

1.7.1 Overview

Besides the main program version, provides a patch mechanism to quickly fix the problems occurring on the main program version. Ahot patch package can fix software bugs before the device is restarted; but an installed cold patch package can take effect only after the device is restarted. This patch package fixes a specific software version only. After the main program version is upgraded, the corresponding patch will become invalid automatically. RGOS provides a patching mechanism in addition to the main program version to quickly fix bugs in the main program version. The patch package can only fix the bugs in specific software versions. After the main program version is upgraded, the corresponding patch will expire automatically.

1.7.2 Configuration Restrictions and Guidance

- After the hot patch package is installed, the patch will take effect directly without restarting the device. If a cold patch package is installed, the device must be restarted for the patch to take effect.

1.7.3 Configuration Tasks

Patch version configuration includes the following tasks:

(1) Installing a Patch Package

(2) Activating a Patch Package by One Click

(3) Activating an EMB Patch Package by One Click

(4) Uninstalling a Patch Package

1.7.4 Installing a Patch Package

1. Overview

This section describes how to install a patch package to fix software bugs. A patch package is used to upgrade a specific version of software only.

2. Restrictions and Guidelines

- Before installing a patch package, download it to a local directory of the device.

Caution

The downloaded patch package cannot be renamed. The name of the patch package is used as the operation keyword for the subsequent patch activation, deactivation, and uninstallation.

- The installed patch must be activated before it is used. You must activate the patch first temporarily and then permanently. If a patch is activated temporarily, the patch will roll back to the previous state after the device is restarted. You can activate a patch temporarily only when verifying the patch function temporarily.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Download a patch package.

install add *url* [**slot** *slot-id* | **slot all**]

(3) Install the patch package by performing either of the following operations:

- Run the general patch command to install the patch package.
  a Activate the installed patch temporarily.
  install activate *package_name* [**slot** *slot-id* | **slot all**]
  b Activate the patch permanently.
  install commit [**slot** *slot-id* | **slot all**]
- Run the **patch** command to install the patch package.
  a Activate the installed patch temporarily.
  patch active [**slot** *slot-id* | **slot all**]
  b Activate the patch permanently.
  patch running [**slot** *slot-id* | **slot all**]

(4) Activate the patch permanently by one click.

patch auto-running [**slot** *slot-id* | **slot all**]

(5) (Optional) Restart the device for the patch to take effect.

reload

Run this command only after a cold patch is installed.

1.7.5 Activating a Patch Package by One Click

1. Overview

This section describes how to install a patch package to fix software bugs. A patch package is used to upgrade a specific version of software only.

2. Restrictions and Guidelines

- To fix software bugs without upgrading the main program and perform temporary verification, activate the patch package temporarily by one click.
- To fix software bugs without upgrading the main program, activate the patch package permanently by one click.
- If you need to ignore the CPU and memory checks of the system when installing a patch, add the **ignore_cpu_mem** parameter to the one-click upgrade command. The CPU and memory waterlines are built-in by default in the system, and their values are both 85%.

Caution

The downloaded patch package cannot be renamed. The name of the patch package name is used as the operation keyword for the subsequent patch activation, deactivation, and uninstallation.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Activate the patch package by one click.

- Activate the patch package temporarily by one click.

  upgrade { *url* **patch-active** | **download** { **ftp:** *//path* **patch-active** [**vrf** *vrf-name*] | **https:** *//path* **patch-active** [**vrf** *vrf-name*] | **oob_ftp:** *//path* **patch-active** [**via mgmt** *interface-number*] | **oob_https:** *//path* **patch-active** [**via mgmt** *interface-number*] | **oob_sftp:** *//path* **patch-active** [**via mgmt** *interface-number*] | **oob_tftp:** *//path* **patch-active** [**via mgmt** *interface-number*] | **sftp:** *//path* **patch-active** [**vrf** *vrf-name*] | **tftp**: //path **patch-active** [**vrf** *vrf-name*] } } [**slot** *slot-id* | **slot all**] [**force**]

- Activate the patch package permanently by one click.

  upgrade { *url* **patch-running** | **download** { **ftp:** *//path* **patch-running** [**vrf** *vrf-name*] | **https:** *//path* **patch-running** [**vrf** *vrf-name*] | **oob_ftp:** *//path* **patch-running** [**via mgmt** *interface-number*] | **oob_https:** *//path* **patch-running** [**via mgmt** *interface-number*] | **oob_sftp:** *//path* **patch-running** [**via mgmt** *interface-number*] | **oob_tftp:** *//path* **patch-running** [**via mgmt** *interface-number*] | **sftp:** *//path* **patch-running** [**vrf** *vrf-name*] | **tftp**: //path **patch-running** [**vrf** *vrf-name*] } } [**slot** *slot-id* | **slot all**] [**force**]

- Perform upgrade by one click to activate the patch package permanently.
  patch autoload *url* [**slot** *slot-id* | **slot all**] [**ignore_cpu_mem**]

1.7.6 Activating an EMB Patch Package by One Click

1. Overview

You can install an EMB patch package to fix software bugs. An EMB patch package is used to upgrade a specific version of software only.

2. Restrictions and Guidelines

- To fix EMB bugs without upgrading the main program, activate the EMB patch package permanently by one click.
- If you need to ignore CPU and memory usage detection during EMB patch installation, add the **ignore_cpu_mem** parameter to the one-click upgrade command. The default CPU and memory usage thresholds are 85%.

Caution

The downloaded patch package cannot be renamed. The name of the patch package name is used as the operation keyword for the subsequent patch activation, deactivation, and uninstallation.

3. Procedure

(1) Enter the privileged EXEC mode

enable

(2) Activate an EMB patch package by one click.

- One-click upgrade: Activate the EMB patch package permanently.

feature patch autoload *url* [**slot** *slot-id* | **slot all**] [**ignore_cpu_mem**]

1.7.7 Uninstalling a Patch Package

1. Overview

This section describes how to deactivate the activated patches and remove the existing patches from the device, that is, the database information.

2. Restrictions and Guidelines

For users, only one patch is effective on the device. Therefore, only one patch to be activated is allowed on the device. To install another patch package of a function component, you need to uninstall the previous patch.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Uninstall a patch. Run one of the following commands to uninstall the patch package:

- Run the general patch command to uninstall a patch package.
  - a Deactivate an activated patch.

    install deactivate *package_name* [**slot** *slot-id* | **slot all**]
  - b Uninstall a patch.

    install remove *package_name* [**slot** *slot-id* | **slot all**]
- Run the **patch** command to uninstall a patch package.
  - a Deactivate an activated patch.

    patch deactivate *package_name* [**slot** *slot-id* | **slot all**]
  - b Uninstall a patch.

    patch delete [**slot** *slot-id* | **slot all**]

1.7.8 Patch Auto-Sync

1. Overview

Configure the patch auto-sync policy for the distributed architecture system or the VSU system that consists of fixed devices.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the patch auto-sync function.

install auto-sync { **disable** | **enable** }

The patch auto-sync function is enabled by default.

1.8 Monitoring

Run the **show** command to check the configuration.

Run the **check** command to check information.

Run the **clear** command to clear information.

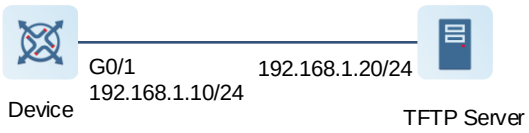
Caution

During device operation, running the **clear** command may cause service interruption due to key information loss.

Table 1-1 Software Upgrade Monitoring

Command	Purpose
show upgrade status	Displays the upgrade status of the device and the installation status of a patch.
show upgrade history	Displays the upgrade history.
show upgrade auto-sync	Displays the auto-sync upgrade configuration on the device.
check version	Checks the version matching.
clear install storage [**slot** *slot-id* | **slot all**]	Clears all the patch packages not running currently and corresponding database information.
show install	Displays information about the hot patch package already installed on the device in a multi-patch solution.
show patch	Displays information about the hot patch package already installed on the device in a single-patch solution.
show install auto-sync	Displays whether the device enables patch auto-sync.
show patch auto-sync	Displays information about all patch packages that need to be automatically synchronized on the current device.
show cmpnt { **auto_db** | **new_list** | **upgrade_db** | { **begin** | **client** | **server** } { **backup** | **current** } { **all_log** | **error_log** | **major_log** | **msg_log** | **trace_log** } }	Debugs the patch.

1.9 Configuration Examples



1.9.1 Configuring Subsystem Upgrade

1. Requirements

Upgrade a subsystem installation package to update all software in the device so that the overall software is enhanced and the known software bugs are fixed. Use Figure 1-1 as an example. The **upgrade download tftp://***path* command is used to upgrade the subsystems of the device by using the installation package file stored on the TFTP server.

2. Topology

Figure 1-1 Subsystem Upgrade Topology

3. Notes

- Configure an IP address for the network Ethernet interface on the device so that the L3 route is reachable between the device and the TFTP server.
- Run the **upgrade download tftp://***path* command to upgrade the installation package file stored on the TFTP server.

4. Procedure

(1) Configure the Ethernet interface IP address on the device.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 192.168.1.10 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# end
```

(2) Run the **upgrade download oob_tftp://***path* command to upgrade the device.

```
Hostname# upgrade download oob_tftp://192.168.1.20/main.bin force
*Nov 23 13:21:39: %UPGRADE-6-INFO: Copy to /tmp/vsd/0/upgrade_rep/
*Nov 23 13:21:39: %UPGRADE-6-INFO: Please wait for a moment......
Press Ctrl+C to quit
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!
< The terminal is locked by upgrade module >
```

```
Upgrade start
!!!!!!!!!!!!!!!!!!!!!!!!!!!!10%
< you can press Ctrl+C to unlock terminal >
!!!!!!!!!!!!!!!!!!!!!!!!!!!!20%
< you can press Ctrl+C to unlock terminal >
!!!!!!!!!!!!!!!!!!!!!!!!!!!!30%
< you can press Ctrl+C to unlock terminal >
!!!!!!!!!!!!!!!!!!!!!!!!!!!!100%
Upgrade success
< The terminal is unlocked by upgrade module >
[Slot 0]
       Device type    : CS88
       Status         : success
```

(3) After upgrading the subsystems, run the **reload** command to restart the device so that the configuration takes effect.

```
Hostname# reload
Reload system?(Y/N)y
*Dec 25 06:48:02: %SYSMON-5-RELOAD: Reset system from [CONSOLE] with reason
[Management port/Reset system by reload command]
Hostname#*Dec 25 06:48:02: %DP-3-RESET_DEV: Reset device 1 due to
SYSMON/3706/CONSOLE/Management port/Reset system by reload command.
*Dec 25 06:48:04: %DP-3-MACHINE_RESTART: MACHINE_RESTART.
```

5. Verification

(1) Run the **ping** command to check whether the L3 route between the device and the TFTP server is reachable.

```
Hostname# ping 192.168.1.20
Sending 5, 100-byte ICMP Echoes to 192.168.1.20, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/3 ms.
```

(2) Run the **show upgrade status** command to display the upgrade result.

```
Hostname# show upgrade status
upgrade global status: INIT
[Slot 0]
       Device type    : CS88
       Status         : success
```

(3) Check the running version on the device. If the version information changes, the upgrade is successful.

```
Hostname# show version
System description     : Ruijie 10G Ethernet Switch(CS88-08) By Ruijie
Networks
System start time      : 2020-11-23 13:13:59
System uptime          : 0:00:03:36
System hardware version : 1.0B
System software version : CS88_RGOS 12.6(3)B0204 (PL1)
```

```
System patch number     : NA
System serial number    : 1234942570025
System boot version     : 1.4.2(Master) 1.4.2(Slave)
Module information:
  Slot 1/0 : RG-CS88-08
    Hardware version    : 1.0B
    Boot version        : 1.4.2(Master) 1.4.2(Slave)
    Software version    : CS88_RGOS 12.6(3)B0204 (PL1)
    Serial number       : 1234942570025
  Slot 2/0 : RG-CS88-08
    Hardware version    : 1.00
    Boot version        : 1.4.2(Master) 1.4.2(Slave)
    Software version    : CS88_RGOS 12.6(3)B0204 (PL1)
    Serial number       : 1234942570022
```

6. Common Errors

If an error occurs during the upgrade, the system displays the cause of the upgrade failure. You can also run the **show upgrade status** command to display the result of the last upgrade.

The following describes several types of common error messages:

- Invalid installation package: The possible cause is that the package is damaged or is not an installation package. You are advised to obtain the correct installation package and perform the upgrade again.
- Installation package not supported by the device: The possible cause is that you use the installation package of other devices. You are advised to obtain the correct installation package, verify the package information, and perform the upgrade again.
- Insufficient device space: Generally, this error occurs on a rack-type device. You are advised to check whether the device is equipped with a USB flash drive . Rack-type devices often have USB flash drives.
- The TFTP server is not enabled.

1.9.2 Configuring Auto-sync Upgrade

1. Requirements

On devices using a distributed structure such as rack-type devices and VSUs, auto-sync upgrade can upgrade the software version of matched members according to a configured auto-sync upgrade policy when software is upgraded or new members are added. This function ensures the coordination of the entire system. In the example of the VSU system using rack-type devices, we auto-sync an installation package.

2. Procedure

Configure an auto-sync upgrade policy based on the software version of the controlling device.

```
Hostname> enable
Hostname# upgrade auto-sync policy coordinate
```

Set the auto-sync upgrade range to the VSU system.

```
Hostname# upgrade auto-sync range vsu
```

3. Verification

Displaythe current auto-sync upgrade policy.

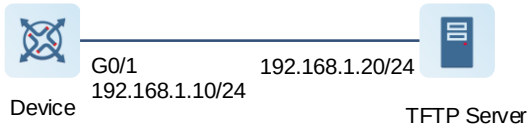
```
Hostname# show upgrade auto-sync
auto-sync range     : vsu
auto-sync policy    : coordinate
auto-sync package   : flash:install_file/install.bin
```

Check version matching of device nodes.

```
Hostname# check version
  Dev Slot State
  --- ---- ------------
  1   4    Compatible
  1   FE6  Compatible
  1   M1   Compatible
```

4. Common Errors

- The **url** parameter in the command used for configuring auto-sync upgrade does not point to a valid upgrade package.



1.9.3 Installing a Patch Package

1. Requirements

Install a patch package to fix software bugs without upgrading the main program version.

2. Topology

Figure 1-2 Patch Package Installation Topology

3. Notes

- Configure the L3 route reachable to the device.
- Copy the patch package to the device.
- Run the patch installation command.
- Activate a hot patch.
  - Activate a hot patch temporarily.
  - Activate a hot patch permanently.
- Configure patch auto-sync.

4. Procedure

(1) Configure the Ethernet interface IP address and default route on the device.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)#interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 192.168.1.10 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# end
```

(2) Install a patch package.

```
Hostname# install add tftp://192.168.1.20/smu_rf_hot1002_0118.bin
Press Ctrl+C to quit
!
< The terminal is lock >
Operating, please wait for a moment.....
!!!!!     100%
Patch operation finish!
Operate result information:
-------------------------------------
Slot          Result        Comment
1/0           Success       None
2/0           Success       None

< The terminal is unlock >
```

(3) Activate a patch.

- Run the **install** command to activate the patch.

  a Run the **install active** command to activate the hot patch temporarily.

```
Hostname# install activate smu_rf_hot1002_0118.bin
< The terminal is lock >
Operating, please wait for a moment.......
!!!!!     100%
Patch operation finish!
Operate result information:
-------------------------------------
Slot          Result        Comment
1/0           Success       None
2/0           Success       None

< The terminal is unlock >
```

  b Run the **install commit** command to activate the hot patch permanently.

```
Hostname# install commit
< The terminal is lock >
Operating, please wait for a moment...
!!!!!     100%
Patch operation finish!
Operate result information:
-------------------------------------
Slot          Result        Comment
```

```
1/0          Success       None
2/0          Success       None

< The terminal is unlock >
```

- Run the **patch** command to activate the patch.
  a Run the **patch active** command to activate the hot patch temporarily.

```
Hostname# patch active
< The terminal is lock >
Operating, please wait for a moment.......
!!!!!     100%
Patch operation finish!
Operate result information:
-------------------------------------
Slot         Result       Comment
1/0          Success      None
2/0          Success      None

< The terminal is unlock >
```

  b Run the **patch running** command to activate the hot patch permanently.

```
Hostname# patch running
< The terminal is lock >
Operating, please wait for a moment...
!!!!!     100%
Patch operation finish!
Operate result information:
-------------------------------------
Slot         Result       Comment
1/0          Success      None
2/0          Success      None

< The terminal is unlock >
```

(4) Configure automatic synchronization of the patch.

```
Hostname# configure
Enter configuration commands, one per line.  End with CNTL/Z.
Hostname(config)# install auto-sync enable
```

5. Verification

Run the **show install** command to display information about the hot patches installed on the current device.

```
Hostname# show install
Install information:
 [Slot 1/0]
    Name                     State        Flag      Effective time       Package
    smu_rf_hot1002_0118.bin     running      Hot       2019-09-17 19:00:02
```

```
 [Slot 2/0]
    Name                      State         Flag       Effective time        Package
    smu_rf_hot1002_0118.bin     running       Hot        2019-09-17 19:00:02
```

Run the **show patch** command to display information about the hot patches installed on the current device.

```
Hostname# show patch
 [Slot 1/0]
    Patch package SP1 installed in the system, version:5.0.0.0
    ----------------------------------------
    Patch      : SP1.bin
    Status     : active
    Version    : 5.0.0.0
    Size       : 1770
    Install time: 2021-09-03 10:00:24
    Description : test SP1

 [Slot 2/0]
    Patch package SP1 installed in the system, version:5.0.0.0
    ----------------------------------------
    Patch      : SP1.bin
    Status     : active
    Version    : 5.0.0.0
    Size       : 1770
    Install time: 2021-09-03 10:00:24
    Description : test SP1
```

6. Common Errors

- If you run the **install commit** command when a patch is not activated, an error is prompted. The **install commit** command takes effect only when the patch is in the active state.
- If you run the **patch running** command when a patch is not activated, an error is prompted. The **patch running** command takes effect only when the patch is in the active state.

1.9.4 Uninstalling a Patch Package

1. Requirements

One function component in one device can run one patch only. To install a new patch for this function component, you need to uninstall the previous patch before installation.

2. Notes

(1) Run the patch deactivation command.

(2) Run the patch uninstall command.

3. Procedure

(1) Uninstall a patch.

- Run the **install** command to uninstall a patch.

  a Run the **install deactivate** command to deactivate the patch.

```
Hostname# install deactivate smu_rf_hot1002_0118.bin
< The terminal is lock >
Operating, please wait for a moment.......
!        100%
Patch operation finish!
Operate result information:
-------------------------------------
Slot         Result       Comment
1/0          Success      None
2/0          Success      None

< The terminal is lock >
```

b Run the **install remove** command to uninstall the patch.

```
Hostname#install remove smu_rf_hot1002_0118.bin
< The terminal is lock >
Operating, please wait for a moment...
!        100%
Patch operation finish!
Operate result information:
-------------------------------------
Slot         Result       Comment
1/0          Success      None
2/0          Success      None

< The terminal is lock >
```

- Run the **patch** command to uninstall a patch.

a Run the **patch deactive** command to deactivate the patch.

```
Hostname# patch deactive
< The terminal is lock >
Operating, please wait for a moment.......
!        100%
Patch operation finish!
Operate result information:
-------------------------------------
Slot         Result       Comment
1/0          Success      None
2/0          Success      None

< The terminal is lock >
```

b Run the **patch delete** command to uninstall the patch.

```
Hostname# patch delete
< The terminal is lock >
Operating, please wait for a moment...
!        100%
```

```
Patch operation finish!
Operate result information:
-------------------------------------
Slot          Result        Comment
1/0           Success       None
2/0           Success       None

< The terminal is lock >
```

4. Verification

Run the **show install** command to displaythe patch uninstallation result.

```
Hostname#show install
Install information:
 [Slot 1/0]
    [No Install information]

 [Slot 2/0]
    [No Install information]
```

Run the **show patch** command to displaythe patch uninstallation result.

```
Hostname# show patch
 [Slot 1/0]
    [No patch package installed in the systemInstall information]

 [Slot 2/0]
    [No patch package installed in the systemInstall information]
```

1.1.4 Downloading X/Y/ZModem 3

1.1.5 Running the Main Program 6

1.1.6 Querying and Setting Other Functions 6

1 Configuring Rboot

1.1 Introduction

1.1.1 Overview

The Rboot menu includes all functions supported by Rboot, including booting the main program, updating the universal boot loader (Uboot), updating Rboot, and reinstalling the system.

1.1.2 Accessing the Rboot Menu

1. Connecting to the Client

Connect the COM port of a PC to the serial port of the device through a serial port cable, start the client software, and configure the following settings:

- Protocol type -for connection: Serial
- Port for connection: COM
- Bits per second: 9600
- Data bit: 8
- Parity check: N/A
- Stop bit: 1
- Data flow control: N/A

2. Starting the Device

After the device is started, the following information is displayed:

```
Press Ctrl+B to enter Boot Menu, Press Ctrl+C to enter Rboot
```

Press **Ctrl+C**.

When Rboot is started, the current version is displayed.

```
Rboot                        Version: 1.1.22
-----------------------------------------------
```

3. Accessing the Rboot Menu Interface

The interface displays the following:

```
====== Rboot Menu(Ctrl+Z to upper level) ======
   TOP menu items.
***********************************************
   0. Tftp utilities.
   1. X/Y/ZModem utilities.
   2. Run main.
   3. SetMac utilities.
   4. Scattered utilities.
***********************************************
```

```
Press a key to run the command:
```

After the device displays the menu interface, select a menu item to select the corresponding function.

Press the first character of the menu item to perform the function of the menu item. If the menu item is a submenu, the submenu is accessed. The device displays the interface of the submenu.

Press **Ctrl+Z** to exit the current submenu and return to the previous-level menu.

1.1.3 Downloading TFTP utilities

This is a submenu. After you access the submenu, the following information is displayed:

```
====== Rboot Menu(Ctrl+Z to upper level) ======
   Tftp utilities.
**********************************************
   0. Upgrade uboot/bios program.
   1. Upgrade rboot program.
   2. Upgrade main program.
   3. Upgrade the entire device by distribute package.
   4. Burn the total FlashROM by this downloaded file.
**********************************************
Press a key to run the command:
```

1. Upgrading Uboot/BIOS

This function downloads a Uboot or BIOS file to the flash memory to update the master or slave Uboot of the system or the master or slave BIOS of the system, depending on the specific requirement.

(1) Start the Trivial File Transfer Protocol (TFTP) server on the PC or supervisor module.

(2) Be sure to put the Uboot or BIOS upgrade image file to be downloaded in the TFTP server directory of the PC or supervisor module.

(3) Connect the device to the PC through an Ethernet cable.

(4) On the menu interface, select **Upgrade uboot/bios program**.

(5) Enter **Local IP** (IP address of the switch), **Remote IP** (IP address of the PC), and **Filename** (name of the Uboot or BIOS file to be downloaded) based on prompts and press **Enter**.

(6) Wait until the system displays a message indicating that the operation is complete.

2. Upgrading Rboot

This function downloads an Rboot file to the flash memory to update Rboot of the system.

(1) Start the TFTP server on the PC or supervisor module.

(2) Be sure to put the Rboot upgrade image file to be downloaded in the TFTP server directory of the PC or supervisor module.

(3) Connect the device to the PC through an Ethernet cable.

(4) On the menu interface, select **Upgrade rboot program**.

(5) Enter **Local IP** (IP address of the switch), **Remote IP** (IP address of the PC), and **Filename** (name of the Rboot file to be downloaded) based on prompts and press **Enter**.

3. Upgrading the Main Program

The function is used to parse a main program package and upgrade the main program. If the main program package contains Uboot or Rboot, Uboot or Rboot is upgraded depending on the version.

(1) Start the TFTP server on the PC or supervisor module.

(2) Be sure to put the upgrade image file of the main program to be downloaded in the TFTP server directory of the PC or supervisor module.

(3) Connect the device to the PC through an Ethernet cable.

(4) On the menu interface, select **Upgrade main program**.

(5) Enter **Local IP** (IP address of the switch), **Remote IP** (IP address of the PC), and **Filename** (name of the main program file to be downloaded) based on prompts and press **Enter**.

(6) Wait until the system displays a message indicating that the operation is complete.

4. Upgrade the Software Package

This function is used to parse a software package, retrieve the main program from the software package, and upgrade the device by using the main program according to the upgrade procedure of the main program.

(1) Start the TFTP server on the PC or supervisor module.

(2) Be sure to put the upgrade image file of the software package to be downloaded in the TFTP server directory of the PC or supervisor module.

(3) Connect the device to the PC through an Ethernet cable.

(4) On the menu interface, select **Upgrade the entire device by distribute package**.

(5) Enter **Local IP** (IP address of the switch), **Remote IP** (IP address of the PC), and **Filename** (name of the program file to be downloaded) based on prompts and press **Enter**.

(6) Wait until the system displays a message indicating that the operation is complete.

5. Upgrading the Flash ROM File

This function is used to refresh the ROM files (including the slave Uboot, master Uboot, and Rboot) in the flash memory to burn such files into the flash memory again. After upgrade, the baud rate is changed to **9600** and **SetMac** needs to be set again.

(1) Start the TFTP server on the PC or supervisor module.

(2) Be sure to put the ROM upgrade image file to be downloaded in the TFTP server directory of the PC or supervisor module.

(3) Connect the device to the PC through an Ethernet cable.

(4) On the menu interface, select **Burn the total FlashROM by this downloaded file**.

(5) Enter **Local IP** (IP address of the switch), **Remote IP** (IP address of the PC), and **Filename** (name of the program file to be downloaded) based on prompts and press **Enter**.

(6) Wait until the system displays a message indicating that the operation is complete.

1.1.4 Downloading X/Y/ZModem

This is a submenu. After you access the submenu, the following information is displayed:

```
====== BootLoader Menu("Ctrl+Z" to upper level) ======
```

```
   XModem utilities.
***********************************************
   X/Y/ZModem utilities.
***********************************************
   0. XModem utilities.
   1. YModem utilities.
   2. ZModem utilities.
   3. Local utilities.
***********************************************
Press a key to run the command:
```

1. Upgrading XModem

This function is used to download Uboot, BIOS, Rboot, main program, software package, or ROM through XMODEM and install it on the device.

(1) On the menu interface, select **XModem utilities**.

(2) The device displays the following submenus:

```
====== Rboot Menu (Ctrl+Z to upper level) ======
   XModem utilities.
***********************************************
   0. Upgrade uboot/bios program.
   1. Upgrade rboot program.
   2. Upgrade main program.
   3. Upgrade the entire device by distribute package.
   4. Burn the total FlashROM by this downloaded file.
***********************************************
Press a key to run the command:
```

(3) Select a required upgrade type.

(4) Select **Transfer** > **Send File** in HyperTerminal, select **XMODEM** for the protocol, and select a file to be downloaded by the upgrade type.

(5) Click **Send**.

(6) Wait until the system displays a message indicating that the operation is complete.

2. Upgrading YModem

This function is used to download Uboot, BIOS, Rboot, main program, software package, or ROM through YMODEM and install it on the device.

(1) On the menu interface, select **YModem utilities**.

(2) The device displays the following submenus:

```
====== Rboot Menu (Ctrl+Z to upper level) ======
   YModem utilities.
***********************************************
   0. Upgrade uboot/bios program.
   1. Upgrade rboot program.
   2. Upgrade main program.
```

```
   3. Upgrade the entire device by distribute package.
   4. Burn the total FlashROM by this downloaded file.
***********************************************
Press a key to run the command:
```

(3) Select a required upgrade type.

Note

This menu is similar to the TFTP menu. For details, see the TFTP menu.

(4) Select **Transfer** > **Send File** in HyperTerminal, select **YMODEM** for the protocol, and select a file to be downloaded by upgrade type.

(5) Click **Send**.

(6) Wait until the system displays a message indicating that the operation is complete.

3. Upgrading ZModem

This function is used to download Uboot, BIOS, Rboot, main program, software package, or ROM through ZMODEM and install them on the device.

(1) On the menu interface, select **ZModem utilities**.

(2) The device displays the following submenus:

```
====== Rboot Menu (Ctrl+Z to upper level) ======
   ZModem utilities.
***********************************************
   0. Upgrade uboot/bios program.
   1. Upgrade rboot program.
   2. Upgrade main program.
   3. Upgrade the entire device by distribute package.
   4. Burn the total FlashROM by this downloaded file.
***********************************************
Press a key to run the command:
```

(3) Select a required upgrade type.

(4) Select **Transfer** > **Send File** in HyperTerminal, select **ZMODEM** for the protocol, and select a file to be downloaded by upgrade type.

(5) Click **Send**.

(6) Wait until the system displays a message indicating that the operation is complete.

4. Upgrading Local Utilities

This function is used to download the Uboot, BIOS, Rboot, main program, software package, and ROM to a USB flash drive or flash memory partition and install them on the device.

(1) On the menu interface, select **Local utilities**.

(2) The device displays the following submenus:

```
====== Rboot Menu (Ctrl+Z to upper level) ======
   Local utilities.
```

```
***********************************************
   0. Upgrade uboot/bios program.
   1. Upgrade rboot program.
   2. Upgrade main program.
   3. Upgrade the entire device by distribute package.
   4. Burn the total FlashROM by this downloaded file.
***********************************************
Press a key to run the command:
```

(3) Select a required upgrade type.

(4) Based on the prompt, enter a file path.

a If a USB flash drive is used, the file path is the location of the **usb0:** file. If there are multiple USB flash drives or partitions, the file paths are usb1: file location, usb2: file location, and so on.

b If a flash memory partition is used, the file path is the location of the **flash:** file.

(5) Wait until the system displays a message indicating that the operation is complete.

1.1.5 Running the Main Program

On the menu interface, enter **3**. The program is booted to access the main program.

1.1.6 Querying and Setting Other Functions

This is a submenu. After you access the submenu, the following information is displayed:

```
====== Rboot Menu(Ctrl+Z to upper level) ======
   Scattered utilities.
***********************************************
   0. Show Version.
   1. Reload System.
   2. Set Baudrate.
   3. Format Flash.
   4. Exit menu.
   5. Set debug mode.
   6. Run main without enable password.
   7. Set Download Gateway.
***********************************************
Press a key to run the command:
```

Note

Options in the submenu increases with the update of the Rboot version but some Rboot items of some earlier products may not be listed.

1. Displaying the Boot Version

This function is used to display the versions of Uboot/BIOS and Rboot on all flash memories.

(1) On the menu interface, select **Show Version**.

(2) The system displays versions of Uboot/BIOS and Rboot.

Example:

```
The First  MasterBoot Version: 1.3.13
The First  SlaveBoot  Version: 1.3.13
The First  Rboot     Version: 1.0.5
The Second MasterBoot Version: 1.3.13
The Second SlaveBoot  Version: 1.3.13
The Second Rboot     Version: 1.0.5
```

Note

Some devices may not display all the six boot programs above and NA is displayed for the inexistent boot programs.

2. Reloading the System

On the menu interface, select **Reload System**. The system reboots automatically.

3. Setting the Baud Rate

This is a submenu. After you access the submenu, the following information is displayed:

```
====== BootLoader Menu("Ctrl+Z" to upper level) ======
   Set baudrate.
***********************************************
   0. Change baudrate to 9600
   1. Change baudrate to 57600
   2. Change baudrate to 115200
***********************************************
Press a key to run the command:
```

- On the menu interface, select **Change baudrate to 9600**. The system changes the baud rate to **9600**.
- On the menu interface, select **Change baudrate to 57600**. The system changes the baud rate to **57600**.
- On the menu interface, select **Change baudrate to 115200**. The system changes the baud rate to **115200**.

Note

The configuration applies to the boot program. In the main program, the baud rate of the boot program may change with the configuration of the main program.

4. Formatting the Main Storage Partition

Warning

If this function is used, the main program and all configurations of the device and all files in the flash memory partition are lost. Therefore, do not use this function unless necessary.

On the menu interface, select **Format Flash**. The main partition is formatted and a partition table is recreated.

5. Setting the Debugging Mode

This is a submenu. After you access the submenu, the following information is displayed:

```
====== Rboot Menu (Ctrl+Z to upper level) ======
   Set debug mode.
***********************************************
   0. Debug switch On.
   1. Debug switch Off.
***********************************************
Press a key to run the command:
```

Select **Debug switch On** to enable the debugging mode or select **Debug switch Off** to disable the debugging mode.

The main program outputs more logs in debugging mode than those in normal mode.

6. Running the Main Program Without Enabling Password

On the menu interface, select **Run main without enable password**. Click **OK**. The main program is started. In the main program, you can enable the device without a password. This function is used when you forget the password. This function is effective for only the current operation. After reboot, the password is still required.

Some devices do not support startup without a password under Rboot (but supports startup without a password under Uboot). In this case, the following information is displayed:

```
   Not supported in Rboot.
   Please reload, press Ctrl+B to enter Uboot,
   and select the same item in Uboot menu.
```

For such devices, access Uboot during startup and select the **Run main without enable password** menu.

7. Downloading TFTP Across Gateways

This function is used to configure a gateway and a mask so that TFTP can be downloaded across gateways.

On the menu interface, select **Set Download Gateway**. The following information is displayed:

```
Plz enter the Local GatewayIP [<NULL>]:
```

Enter the IP address of a gateway in the format of X.Y.Z.W. The following message is displayed:

```
Plz enter the IP Netmask [<NULL>]:
```

Enter a subnet mask in the format of X.Y.Z.W. The following message is displayed:

```
   Set Local GatewayIP to <set IP address of the gateway>
Set IP Netmask to <set subnet mask>
```

Then return to the main menu and select items in **Tftp utilities**. The gateway and subnet mask are displayed during downloading and TFTP items are downloaded across gateways.

```
   TFTP: Detect Gateway <set IP address of the gateway> ...
   TFTP: Detect Netmask <set subnet mask> ...
```

The gateway configuration is not retained. After you leave Rboot, the configuration is lost.

To clear the gateway configuration in Rboot, enter a null address in **Set Download Gateway**.

```
Plz enter the Local GatewayIP [<NULL>]:
Plz enter the IP Netmask [<NULL>]:
   Clear Local GatewayIP config.
   Clear IP Netmask config.
```

1 Configuring Uboot

1.1 Introduction

1.1.1 Overview

The Uboot menu includes all functions supported by the universal boot loader (Uboot), including booting the main program, booting Rboot, and updating Uboot or Rboot.

1.1.2 Accessing the Uboot Menu

1. Connecting to the Client

Connect the COM port of a PC to the serial port of the device through a serial port cable, start the HyperTerminal, and configure the following settings:

- Protocol type for connection: Serial
- Port for connection: COM
- Bits per second: 9600
- Data bit: 8
- Parity check: N/A
- Stop bit: 1
- Data flow control: N/A

2. Starting the Device

After the device is started, the following information is displayed:

```
Press Ctrl+B to enter Boot Menu, Press Ctrl+C to enter Rboot
```

Press **Ctrl+B**.

3. Accessing the Uboot Menu Interface

The interface is displayed as follows:

```
====== BootLoader Menu("Ctrl+Z" to upper level) ======
   TOP menu items.
**********************************************
   0. XModem utilities.
   1. Run main.
   2. Run rboot.
   3. Scattered utilities.
**********************************************
Press a key to run the command:
```

After the device displays the menu interface, select a menu item to select the corresponding function.

Press the first character of the menu item to perform the function of the menu item. If the menu item is a submenu, the submenu is accessed. The device displays the interface of the submenu.

Press **Ctrl+Z** to exit the current submenu and return to the previous-level menu.

1.1.3 Downloading XModem

On the menu interface, select **Upgrade bootloader**.

This is a submenu. After you access the submenu, the following information is displayed:

```
====== BootLoader Menu("Ctrl+Z" to upper level) ======
   XModem utilities.
*********************************************
   0. Upgrade bootloader.
   1. Upgrade rboot.
*********************************************
Press a key to run the command:
```

1. Upgrading bootloader

This function downloads a Uboot file to the flash memory to update the master Uboot of the system.

(1) On the menu interface, select **Upgrade bootloader**.

(2) Click **Send File** under **Transfer** in HyperTerminal and select a Uboot image file to be downloaded (for example, **UBOOT.BIN**).

(3) Click **Send**.

(4) Wait until the system displays a message indicating that the operation is complete.

2. Upgrading rboot

This function downloads an Rboot file to the flash memory to update Rboot of the system.

(1) On the menu interface, select **Upgrade rboot**.

(2) Click **Send File** under **Transfer** in HyperTerminal and select an Rboot image file to be downloaded (for example, **RBOOT.BIN**).

(3) Click **Send**.

(4) Wait until the system displays a message indicating that the operation is complete.

1.1.4 Running the Main Program

On the menu interface, select **Run main**. The program automatically skips to the main program from Uboot.

1.1.5 Running the Rboot Program

On the menu interface, select **Run rboot**. The program automatically skips to Rboot from Uboot.

1.1.6 Querying and Setting Other Functions

On the menu interface, select **Scattered utilities**.

This is a submenu. After you access the submenu, the following information is displayed:

```
====== BootLoader Menu("Ctrl+Z" to upper level) ======
   Scattered utilities.
*********************************************
   0. Show the bootloader version.
```

```
   1. Reload system.
   2. Set baudrate.
   3. Set default environment.
   4. Set debug mode.
5. Run main without enable password.
*********************************************
Press a key to run the command:
```

1. Showing the bootloader Version

This function is used to display the version of the boot program on the current flash memory.

(1) On the menu interface, select **Show the bootloader version**.

(2) The version of Uboot is displayed.

Information similar to the following is displayed:

```
'master_bootloader' program information:
  Version:     1.3.13
'slave_bootloader' program information:
  Version:     1.3.13
```

2. Reloading the System

On the menu interface, select **Reload system**. The system reboots automatically.

3. Setting the Baudrate

This is a submenu. In the submenu, select **Set baudrate**. The following information is displayed:

```
====== BootLoader Menu("Ctrl+Z" to upper level) ======
   Set baudrate.
*********************************************
   0. Change baudrate to 9600
   1. Change baudrate to 57600
   2. Change baudrate to 115200
*********************************************
Press a key to run the command:
```

- On the menu interface, select **Change baudrate to 9600**. The system changes the baud rate to **9600**.
- On the menu interface, select **Change baudrate to 57600**. The system changes the baud rate to **57600**.
- On the menu interface, select **Change baudrate to 115200**. The system changes the baud rate to **115200**.

4. Setting the Default Environmental Variable

This function is used to replace the environmental variable stored on the flash memory with the default environmental variable.

On the menu interface, select **Set default environment**. The following information is displayed:

```
Warning: The environment information maybe lose, Are you sure to continue? [yes/No]:
```

Enter **yes** or **no**. If you do not enter any character, **no** is used by default. When this menu is used to set the default environmental variable, the baud rate is not restored to the default value. The baud rate currently saved on the flash memory is still used.

5. Setting the Debugging Mode

This is a submenu. After you access the submenu, the following information is displayed:

```
====== BootLoader Menu("Ctrl+Z" to upper level) ======
   Set debug mode.
*********************************************
   0. Debug switch On.
   1. Debug switch Off.
*********************************************
Press a key to run the command:
```

Select **Debug switch On** to enable the debugging mode or select **Debug switch Off** to disable the debugging mode.

The main program and Rboot output more boot logs in debugging mode than those in normal mode.

6. Starting the Main Program without Enabling Password

On the menu interface, select **Run main without enable password**. Click **OK**. The main program is started. In the main program, you can enable the device without a password. This function is used when you forget the password. This function is effective for only the current operation. After reboot, the password is still required.

2 Configuring the SIMPLE CLI

2.1 Introduction

2.1.1 Overview

The SIMPLE command line interface (CLI) includes some functions supported by Uboot, which are implemented through command lines, including booting the main program, booting Rboot, and updating Uboot or Rboot.

2.1.2 Accessing the SIMPLE CLI Operation Interface

On the Uboot menu interface, press **Ctrl+Q** to access the SIMPLE CLI operation interface.

```
====== BootLoader Menu("Ctrl+Z" to upper level) ======
   TOP menu items.
*********************************************
   0. XModem utilities.
   1. Run main.
   2. Run rboot.
   3. Scattered utilities.
*********************************************
Press a key to run the command:
```

Enter **help**. The functions of commands are displayed as follows:

```
bootloader# help
Total commands:
```

```
help           Dump command list OR show a command's details
xmdown         Download programs through XModem.
runrboot       Run rboot program.
runmain        Run main program.
setbaud        Set BOOT/BOOTLOADER baudrate tools.
reload         Reload tools.
version        Show current version information.
quit           Quit from CLI command line.
```

2.1.3 Downloading Xmdown

You can run this command to upgrade the main Uboot program and Rboot program on the flash memory.

Enter **help xmdown**. The usage details of the **xmdown** command are displayed.

```
bootloader# help xmdown
Syntax: xmdown (-boot | -rboot)
Usage Details:
   -boot:     Upgrade BootLoader.
   -rboot:   Upgrade Rboot.
Examples:
   xmdown -boot
   xmdown -rboot
```

1. xmdown -boot

This command is used to upgrade the main Uboot program on the flash memory.

(1) Enter **xmdown –boot** and press **Enter**.

(2) Click **Send File** under **Transfer** in HyperTerminal and select a Uboot image file to be downloaded (for example, **UBOOT.BIN**).

(3) Click **Send**.

(4) Wait until the system displays a message indicating that the operation is complete.

2. xmdown -rboot

This command is used to upgrade the Rboot program on the flash memory.

(1) Enter **xmdown –rboot** and press **Enter**.

(2) Click **Send File** under **Transfer** in HyperTerminal and select an Rboot image file to be downloaded (for example, **RBOOT.BIN**).

(3) Click **Send**.

(4) Wait until the system displays a message indicating that the operation is complete.

2.1.4 Running the Rboot Program

Enter the **runrboot** command. The program automatically skips to Rboot from Uboot.

2.1.5 Running the Main Program

Enter the **runmain** command. The program automatically skips to the main program from Uboot.

2.1.6 Setting the Baud Rate

After the **setbaud** command is run, the baud rate of the current device is changed and the changed baud rate is saved to the environmental variable partition of the flash memory.

Enter the **help setbaud** command. The usage details of the **setbaud** command are displayed:

```
ruijie#help setbaud
Syntax: setbaud (-h | -m | -l)
Usage Details:
   -h:         Set to 115200
   -m:         Set to 57600
   -l:         Set to 9600
Examples:
   setbaud -l
   setbaud -m
setbaud –h
```

- setbaud -l: The baud rate of the current device is changed into **9600** and the changed baud rate is saved to the environmental variable partition of the flash memory.
- setbaud -m: The baud rate of the current device is changed into **57600** and the changed baud rate is saved to the environmental variable partition of the flash memory.
- setbaud -h: The baud rate of the current device is changed into **115200** and the changed baud rate is saved to the environmental variable partition of the flash memory.

2.1.7 Reloading the System

Enter the **reload** command and press **Enter**. The system reboots automatically.

2.1.8 Displaying the Version

Enter the **version** command and press **Enter**. The system displays the versions of the master Uboot and slave Uboot. For example:

```
bootloader# version
'master_bootloader' program information:
  Version:     1.3.13
'slave_bootloader' program information:
  Version:     1.3.13
```

2.1.9 Skipping to the Menu Interface

Enter the **quit** command and press **Enter**. The system returns to the menu interface.

1.4 Monitoring 7

1 Configuring License Management

1.1 Introduction

1.1.1 License Management Overview

A user needs to install a correct license file to use some extension functions of a device. A user can use the general and extension functions of the Ruijie General Operating System (RGOS) only after obtaining a license.

Note

Generally, all features of the RGOS are pre-installed in the factory. For feature licenses and license types, see their configuration guides. RGOS features or basic functions that are not expressly specified can be used directly without licenses.

1.1.2 Principles

1. Basic Concepts

- Software to be licensed

  A software function used by only a licensed user.

- Feature license

  As a license for a special feature, it is obtained through a license file, hardware entity, or legal contract. This license specifies the maximum number of supported users, the maximum number of supported instances, and valid period.

- Product authorization key (PAK)

  It is a manner of granting a license to a user by providing a license code.

- Purchase voucher

  A voucher of purchasing a license. The voucher contains the PAK and license download address. The legitimate owner of the purchase voucher logs in to the license download address, and uses the PAK to sign up. The license file is downloaded from the displayed link or is directly sent to the registered email.

- Host ID

  A unique serial number for identifying each device.

Specification

A license matches the host ID of any device added to a VSU. When the device is removed from the VSU, the feature enabled by the license becomes invalid.

Licensing for modular devices takes effect on a single device basis. In a VSU environment, the entire VSU system is licensed to use a feature only after all devices obtain the license for that feature. Licensing or delicensing takes effect only after the devices are restarted.

- License file

A file that controls the features of a licensed software. A license file is generated by using a special tool based on contract information, and each license file contains a digital signature to prevent tampering. The license file serves a product. That is, one license file is used on only one device and matches the device's host ID. License is not transferred. Licensed functions are available when the license file is installed.

- Temporary license

  A temporary license becomes invalid after the valid period expires.

- Evaluation license

  An evaluation license is temporary, and has been installed on the device before delivery. It is used to provide users with features for trial use. This type of license is independent of the host ID.

- Permanent license

  This license has no time limit and is permanently effective upon purchase by the user.

- License stacking

  Different licenses can be used on one device. For example, if a device provides both the FCoE and TRILL functions, users can purchase the licenses of the two functions and use them on the same device.

- Single-Instance license

  Only one license can be installed for one feature at a time.

- Multi-instance license

  Multiple license files can be installed for the same feature on a device.

- Grace period warning

  A grace period warning is generated in forms of log and trap messages 180 days before a license expires. Setting a grace period warning prevents licensed software from being affected when an aging license suddenly stops working upon expiration.

2. License Acquisition and Use

- Use of License

  A license must be obtained from Ruijie's official website or marketing channel. It is device-specific. You log in to the website specified in the purchase voucher and provide the PAK and host ID to obtain the license file, which is directly downloaded or given through an email. After acquisition, you need to install the license file. Afterwards, you can use the features of the license.

  RGOS licenses include permanent license and temporary license. When a user first enables a temporary license to use a feature, the valid period of the license starts, and after the period ends, the feature will be disabled. To continue using this feature, this user can purchase another license (permanent or temporary) from Ruijie's official website or marketing channel.

- License check

  After a device starts to run, the license for each feature needs to be checked. If the corresponding license is properly installed, this feature is ready for application. Otherwise, this feature becomes invalid and cannot be used.

Note

Checking the licenses for various features occurs at different times. The licenses for some features are checked during startup, and the licenses for other features are checked in real time.

- Loss of License File

  License files are stored in the **/data** directory of a device and is not lost after software upgrade.

  If the memory or file system is damaged during product use but the license file has been backed up, you can install the backup license file again after system recovery. If the license file is not backed up, you can visit Ruijie's website to obtain the license file again. This process is the same as the previous acquisition process (you do not need to purchase the license again).

  Licensing is device-based. After a license is provided for a specified device, the license file is verified only on this device. Upon maintenance or replacement of a device, the host ID may change and the obtained license file may not be identified. In this case, contact Ruijie after-sales personnel.

3. Backup, Update, and Uninstallation of a License File

- License File Backup

  When a fault such as damage of file system storage media occurs on a device, the license file on this device may be lost after you troubleshoot this fault. Therefore, you need to back up the license file in advance to reinstall it after you troubleshoot the fault.

- License File Update

  If the existing license of the system fails to meet the feature requirements, you can visit Ruijie's website to purchase a desired license and then update the license file locally.

- License File Uninstallation

  If you do not need a feature, you can uninstall the license for this feature to improve the utilization of resources like the memory. To reuse this feature, reinstall the license. It is recommended that license files be kept properly.

1.2 Configuration Task Summary

Configuration of license management includes the following tasks:

(1) Installing License File

(2) Backing Up License File

(3) (Optional) Grace Period Warning

(4) (Optional) Updating License File

(5) (Optional) Uninstalling License

(6) (Optional) Unbinding License

1.3 Configuring License Management

1.3.1 Overview

This section describes how to enable or disable a feature by installing or uninstalling a license file.

1.3.2 Installing License File

1. Overview

This section describes how to install a license file to enable a licensed feature.

2. Restrictions and Guidelines

- Ruijie provides a paper purchase voucher that contains a PAK when you purchase a license.
- Log in to Ruijie's website and obtain a license file as prompted.
- If you use a feature without being licensed, the CLI window displays a prompt, indicating that the feature is not licensed and is unavailable, and provides a website to download a license file.
- After downloading a license file from the specified website, upload this license file to the device (or store it in a USB flash drive) for installation. You can install the license file offline. Copy the license file to the file system of the device. Use conventional file system operation commands. For example, download the license file through Trivial File Transfer Protocol (TFTP) or copy the license file to a USB flash drive.
- After a license file is installed on a device, this license file is automatically backed up in the **/data** directory of the system (the license file is suffixed with **.lic**). The backup license file is deleted when the installed license is uninstalled.
- Install the license file.
  - If you run the **license install** command in the VSU environment, the license file is installed only on the local device or supervisor module.
  - If you run the **license auto-install** command in the VSU environment, the license file is automatically installed on the matched device.
  - In a VSU environment, you can run the **license auto-install** command to automatically match the device for installing the license file. In a non-VSU environment, the **license auto-install** command has the same function as the **license install** commands.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Obtain **host-id** of the device.

show license hostid

The name of a license file cannot be modified.

This command can be executed without permission.

(3) (Optional) Install the license file. Perform either of the following operations as required.

- Install a license in the system.

  license install { **flash:** | **usb0:** } *filename*

- Automatically install a license on the matched device in the VSU system.

  license auto-install { **flash:** | **usb0:** } *filename*

1.3.3 Backing Up License File

1. Overview

This section describes how to back up the license files of one or all features in the system.

2. Restrictions and Guidelines

- Evaluation license files cannot be backed up.
- Sufficient storage space is required to store backup license files. Generally, one license file is 4 KB to 10 KB.
- Backup license files are normal files.
- When all license files in the system are backed up, a .tar file is generated.
- You can run the **dir** command to save the license files to other storage devices, for example, a USB flash drive.
- After backing up license files, you can run the **dir** command to confirm the generated license files, and compare them with the license file names displayed in the **installed license** fields of permanently licensed features in the command output of the **show license all-license** or **show license file** command, to check whether licenses are correctly backed up.
- The **installed license** field displayed in the **show license all-license** command and **show license file** command is available only for multi-instance licenses. The name of a file internally backed up in the multi-instance license system is determined by the ID of the multi-instance license. One single-instance license file exists at most in the system at a time. Therefore, the internally backed up single-instance license file is named after the feature.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Back up the license files in the system.

- Back up all perpetual license files in the system.

  license copy-all { **flash:** | **usb0:** } [*target-filename*]

- Back up a license file or the license file specified by the feature name.

  license copy-file *filename* { **flash:** | **usb0:** } [*target-filename*]

No license file is backed up by default.

1.3.4 Configuring Grace Period Warning

1. Overview

This section describes how to evaluate the expiration date of a license and how to provide early warnings in form of log messages to remind users of taking actions in advance.

2. Restrictions and Guidelines

- Each licensed feature is separately configured.
- The grace period warning is affected by the device time.
- A permanent license file needs no grace period warning.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Set the grace period for reminding the user of the expiration of a license.

license grace-period *filename time*

The grace period before the expiration of a license is 180 days by default.

1.3.5 Updating License File

1. Overview

This section describes how to update the license file for a feature of the system. Generally, this function is performed to update an evaluation license file into a temporary license file.

2. Restrictions and Guidelines

- A formal permanent license file does not need to be updated.
- A later license version cannot be updated into an earlier one.
- A license file contains a generation time field. The value of this field is the time when the license file is generated on the website. When the value is closer to the current time, the license file has a later version.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Update the license file.

license update { **flash:** | **usb0:** } *filename*

1.3.6 Uninstalling License

1. Overview

This section describes how to uninstall one or all feature licenses in the system when the features are not needed.

Note

This function becomes invalid when the corresponding license is uninstalled.

2. Restrictions and Guidelines

- If the licensed feature is running, the uninstallation does not take effect immediately, but takes effect after the feature is enabled or the device is restarted next time.
- You are advised to back up a license file before uninstallation to reinstall an uninstalled license when needed.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Uninstall a license in the system.

- Uninstall a license in the system.

  license uninstall *license* [*filename*]

- Uninstall a license from a specified device in a VSU.

  license auto-uninstall *device-id license* [*filename*]

This command can be executed without permission.

1.3.7 Unbinding License

1. Overview

If you want to unbind a license from a device on the license website, unbind the license on the device first.

2. Restrictions and Guidelines

- Upon unbinding a license, you obtain a verification code, which is used to unbind the license on the license website.
- After the license is unbound, the corresponding license file cannot be reinstalled.
- The function of the **license auto-unbind** command in a non-VSU environment is the same as that of the **license unbind** command.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Unbind a license from the system. Perform either of the following operations as required.

- Unbind a license from the system.
  license unbind *pak*
- Unbind a license from a specified device in the VSU system.
  license auto-unbind *device-id pak*

This command can be executed without permission.

1.4 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
show license all-license	Displays the list of all installed license files on the device.
show license file *file-license*	Displays the information about a specified license file on the device.
show license dev-license	Displays license configurations of all devices.
show license usage	Displays licenses in use.

Command	Purpose
show license hostid	Displays the device SN used for licensing.
show license dev-hostid	Displays the device SN of each device
show license unbind-code	Displays the verification code of a license unbound from the device.
show license dev-unbind-code	Displays the verification code of a license unbound from each device in the environment.

Device Management Configuration

1. Configuring NTP
2. Configuring SNTP
3. Configuring Time Range
4. Configuring UFT Mode Management

1 Configuring NTP

1.1 Introduction

1.1.1 Overview

Network Time Protocol (NTP) is an application-layer protocol that enables network devices to synchronize time. NTP enables network devices to synchronize time with their servers or clock sources and provides high-precision time correction (the difference from the standard time is smaller than one millisecond in a LAN and smaller than decades of milliseconds in a WAN). In addition, NTP can prevent attacks by using encrypted acknowledgment. NTP is implemented based on the transport protocol, User Datagram Protocol (UDP), and the UDP port used is 123.

Currently, Ruijie devices can be used both as NTP clients and NTP servers. In other words, a Ruijie device can synchronize time with a time server, or act as a time server to provide time synchronization for other devices. When a device is used as a server, it supports only the unicast server mode. It also supports the peer mode and broadcast mode.

1.1.2 Principles

1. Basic Concepts

- NTP server

  A device uses a local clock as the reference clock source to provide time synchronization for other devices in the network.

- NTP client

  A device synchronizes time with an NTP server in the network.

- Active peer

  The active peer periodically sends a synchronization packet in which **Mode** is set to **1** to the passive peer, without considering reachability and stratum of its peer. The host running in this mode can either provide synchronization information to the peer, or synchronize the local clock based on the peer's time information.

- Passive peer

  The passive peer receives a synchronization packet from the active peer, and responds with a packet in which **Mode** is set to **2**. The host running in the passive peer mode can either provide synchronization information to the peer, or synchronize the local clock based on the peer's time information.

- Broadcast server

  In broadcast mode, the server periodically sends a clock synchronization packet in which **Mode** is set to **5** to the broadcast address 255.255.255.255, without considering reachability and stratum of its peer. The host running in broadcast mode is usually a time server running high-speed broadcast media in the network. It provides synchronization information to all peers, but does not modify its own clock.

- Broadcast client

The client listens to the clock synchronization packet from the server. After the client receives the first clock synchronization packet, it exchanges an NTP packet in which **Mode** is **3** (client mode) or **4** (server mode) with the server. That is, the client enables server/client mode for a short period of time to exchange messages with the remote server to obtain the network delay between the client and the server. The client then resumes the broadcast mode, continues to listen to the arrival of the clock synchronization packet, and synchronizes the local clock again based on the incoming clock synchronization packet.

- **Stratum**

  In NTP, "stratum" is used to describe the hops from a device to an authority clock source. An NTP server whose stratum is 1 has a directly connected atomic clock or radio controlled clock; an NTP server whose stratum is 2 obtains time from the server whose stratum is 1; an NTP server whose stratum is 3 obtains time from the server whose stratum is 2; and so on. Therefore, clock sources with lower stratum have higher clock precision.

- Hardware Clock

  A hardware clock operates based on the frequency of the quartz crystal resonator on a device and is powered by the device battery. After the device is shut down, the hardware clock continues running. After the device is started, the device obtains time information from the hardware clock as the software time of the device.

2. NTP Principles

As shown in Figure 1-1, a client exchanges NTP packets with a server to implement time synchronization.

(1) The client sends a time synchronization request packet to all servers every 64 seconds.

(2) After receiving response packets from the servers, the client filters these response packets, and synchronizes time with an optimum server.

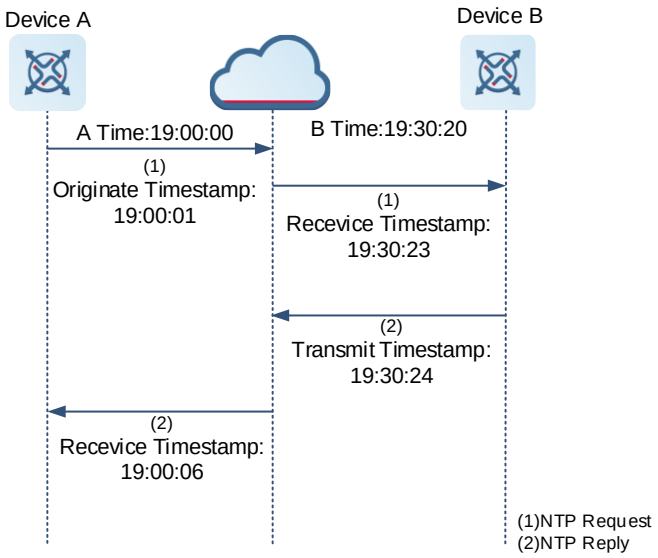
3. NTP Working Process

As shown in Figure 1-1, device B (B for short) acts as an NTP reference clock source, and device A (A for short) acts as an NTP client that synchronizes time with B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

(1) A sends an NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in **Originate Timestamp**.

(1) After a network delay of 2s, the local time (T1) when B receives the request packet is 19:30:23 and is filled in **Receive Timestamp**.

(2) B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in **Transmit Timestamp**.



(3) After a network delay of 2s, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

a A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula ((T1-T0)+(T2-T3))/2.

b A obtains the packet round-trip delay of 4 seconds between A and B by using the formula (T3-T0)-(T2-T1).

Figure 1-1 NTP Principles

- NTP working mode
  - External clock reference mode: In this mode, a device acts as both a server and a client. If receiving time synchronization requests from other clients, the device must synchronize time with the specified server, and then provide the time synchronization service for the clients only after successful synchronization with the specified server.
  - Local clock reference mode: In this mode, a device uses the default local clock as the reliable clock source and provides the time synchronization service directly for other clients.
- Peer mode
  - The peer mode runs at a lower stratum in the synchronization subnet. In this mode, the active peer and passive peer can synchronize time with each other. The passive peer needs to run the **ntp passive enable** command to enable the function of receiving packets in peer mode to eventually implement time synchronization.
  - In peer mode, a peer with a higher stratum provides time synchronization for a peer with a lower stratum.
- Broadcast mode
  - When the IP address of the server or peer cannot be determined, or too many devices in the network need time synchronization, the broadcast mode can be used to achieve time synchronization.
  - You need to configure related commands on both the server and the client. Only the client can synchronize time with the server.

4. NTP Security Mechanism

To prevent malicious damage to the time server and improve the security of time synchronization, NTP provides security authentication and access control functions.

- Security authentication

NTP uses the authentication mechanism to check whether the time synchronization information really comes from the announced server and check the information return path to provide an anti-interference protection mechanism.

An NTP client and an NTP server are configured with the same key. When sending request and response packets, a device calculates the hash values of the packets by using the MD5 algorithm based on the specified key and NTP packet content, and fills the hash values into the packet authentication information. The receiving device checks whether the packets are sent by a trusted device or modified based on the authentication information.

- NTP access control using the kiss-o-death (KoD) packet

  NTP provides a minimum security measure by using an ACL. Normally, the denial-of-service packets are discarded, and there is no operation other than incrementing the statistics counter. Sometimes a more proactive response is required. For example, the client is explicitly requested to stop sending packets to the server and to leave a message for the system operator. Therefore, open-source NTP proposes a KoD packet, which can be used to respond to special processing of the client when access control is configured on the server.

  The format of a KoD packet is the same as that of a common NTP packet, except that the **Leap Indicator** field is set to **clock unsynchronized**, the **Stratum** field is set to **0**, and the **Reference ID** field is set to a 4-byte ASCII code. The code is "RATE" if the limited flag is set and the rate threshold is exceeded. After the NTP client receives the KoD packet with the code "RATE", it limits the rate according to the minimum interval specified in the packet.

1.1.3 Protocols and Standards

- RFC 1305: Network Time Protocol (Version 3)
- RFC 5905: Network Time Protocol (Version 4)

1.2 Restrictions and Guidelines

- You cannot configure both the NTP and SNTP functions on the same device.
- Only Layer 3 Ethernet interfaces or link aggregations support NTP.
- To ensure accuracy of time synchronization, avoid configuring two or more clock sources whenever possible to prevent clock flapping.
- You can run the **ntp service disable** command to disable the NTP server function so that the device acts only as a client. This command cannot be configured together with **ntp master**.

1.3 Configuration Task Summary

NTP configuration includes the following tasks:

(1) (Optional) Configuring NTP Security Authentication

(2) Configuring Basic Functions of NTP

  a Configuring NTP in Client/Server Mode

  b (Optional) Configuring NTP in Peer Mode

  c (Optional) Configuring NTP in Broadcast Mode

(3) (Optional) Configuring NTP-Related Parameters

(4) (Optional) Configuring NTP Access Control

1.4 Configuring NTP Security Authentication

1.4.1 Overview

- Synchronizing time from a trusted reference clock source: Use a device as a client to synchronize time only from a trusted external reference clock source to the local clock.
- Providing time synchronization for a trusted device: Use the local clock of a device as the NTP reference clock source to provide time synchronization for only a trusted device.

1.4.2 Restrictions and Guidelines

- The authentication keys of the client and server must be the same.
- To provide time synchronization for a trusted device, you must specify a trusted authentication key by using the key ID. Only one trusted key can be configured. The specified authentication key must be consistent with that of the trusted device.
- To synchronize time with a trusted reference clock source, you must specify a trusted authentication key by using the key ID. Each trusted reference clock source is mapped to an authentication key. The authentication keys must be consistent with the keys of trusted reference clock sources.
- By default, a client does not use a global security authentication mechanism. If no security authentication mechanism is used, communication will not be encrypted. A global security indicator is not enough to imply that the communication between the client and server is implemented in an encrypted manner. Other global keys and an encryption key for the server must also be configured for initiating encrypted communication between the client and server.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a global security authentication mechanism for NTP.

ntp authenticate

(4) Configure a global authentication key for NTP.

ntp authentication-key *authentication-key-id* **md5** *authentication-key-string* [**0** | **7**]

The NTP global authentication mechanism is disabled by default.

(5) (Optional) Configure a globally trusted key ID for NTP.

ntp trusted-key *trusted-key-id*

(6) (Optional) Configure an authentication key ID for an external reference clock source.

ntp server [**oob** | **vrf** *vrf-name*] { *ipv4-address* | *server-name* | *ipv6-address* | **ip** *domain* | **ipv6** *domain* } [**key** *keyid* | **port** *port-number* | **prefer** | **source** *interface-type interface-number* | **version** *version*] * [**via mgmt** *interface-number*]

By default, no authentication key ID is configured for an external reference clock source.

1.5 Configuring Basic Functions of NTP

1.5.1 Restrictions and Guidelines

- When configuring the NTP server, you must specify at least one external reference clock source. A maximum of 20 different external reference clock sources can be configured.
- If it is necessary to configure an NTP key, you must configure NTP security authentication before configuring the NTP server. A device that acts as a client supports interaction with up to 20 NTP servers. You can configure an authentication key for each server (after configuring global authentication and the related key) to initiate encrypted communication with the servers.
- The default version of NTP for communicating with a server is NTP version 4. In addition, you can configure the source interface for transmitting NTP packets and specify that the NTP packets from a corresponding server can be received only on the transmitting interface.
- After a local clock is configured as the master clock (especially when a clock with a lower stratum is specified), the system does not synchronize with a clock source with a higher stratum, and therefore a real effective clock source may be overwritten. If this function is used for multiple devices in a network, the clock difference between the devices may cause unstable time synchronization of the network.
- Before a local clock is configured as the master clock, if the system never synchronizes time with an external clock source, you may need to manually calibrate the system clock to ensure that there is no excessive difference. For details about how to manually calibrate the system clock, refer to the basic management section in the Basic Configuration Commands.
- By default, if NTP works in client/server mode, after the NTP device synchronizes time from an external reliable clock source, the device acts as the time server to provide the time synchronization service for other devices. If you configure an NTP device only as a client, run the **ntp service disable** command to disable the external time synchronization service provided by NTP. After this command is configured, an external device cannot synchronize time from this NTP device.
- If you specify the **oob** mode when configuring the NTP server, you must specify the outbound interface of packets in **oob** mode as the management interface by using the parameter **via**.

1.5.2 Configuration Tasks

(1) Configuring NTP in Client/Server Mode

(2) (Optional) Configuring NTP in Peer Mode

(3) (Optional) Configuring NTP in Broadcast Mode

1.5.3 Configuring NTP in Client/Server Mode

1. Overview

This section describes how to configure a device as a client to synchronize time from an external reference clock source to the local clock. After successful time synchronization, the device can act as a time synchronization server to provide the time synchronization service.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an NTP server.

ntp server [**oob** | **vrf** *vrf-name*] { *ipv4-address* | *ipv6-address* | *server-hostname* | **ip** *domain* | **ipv6** *domain* } [**key** *keyid* | **port** *port-number* | **prefer** | **source** *interface-type interface-number* | **version** *version*] * [**via mgmt** *interface-number*]

1.5.4 Configuring NTP in Peer Mode

1. Overview

This section describes how to configure NTP in peer mode. Assume that device A has synchronized time with the server, and device B has not synchronized time with the server. If device A acts as the active peer of device B, device B synchronizes time with device A. Alternatively, if device B acts as the active peer of device A, device B synchronizes time with device B.

2. Restrictions and Guidelines

- When configuring the peer mode, you must configure the **ntp passive enable** command on the passive peer to enable the function of receiving packets in peer mode.
- A client can concurrently interact with up to 20 peers.
- If you need to configure an authentication key, configure NTP security authentication before you can configure an authentication key for each peer to initiate encrypted communication with the peer.

  NTP version 4 supports communication with peers. You can also configure the source interface for transmitting NTP packets and specify that the NTP packets from a peer can be received only on the transmitting interface.
- At least one of the clocks of the active peer and the passive peer must be in synchronized state. Otherwise, they cannot synchronize time.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the NTP peer mode. Configure at least one of the following tasks.

- Configure the NTP peer mode.

  ntp peer [**oob** | **vrf** *vrf-name*] { *ipv4-address* | *peer-name* | *ipv6-address* | **ip** *domain* | **ipv6** *domain* } [**key** *keyid* | **prefer** | **source** *interface-type interface-number* | **version** *version*]* [**via mgmt** *interface-number*]

  No NTP peer mode is configured by default.
- Configure the NTP passive peer.

  ntp passive enable

  No NTP passive peer is configured by default.

1.5.5 Configuring NTP in Broadcast Mode

1. Overview

This section describes how to configure NTP in broadcast mode. After the broadcast server and broadcast client are enabled, the server periodically sends broadcast packets to 255.255.255.255, and the broadcast client receives the broadcast packets and synchronizes time accordingly.

2. Restrictions and Guidelines

- If the broadcast client mode is disabled on the device, time synchronization is not performed.
- The packet sending period is the maximum polling time. Plus the algorithm selection, the first synchronization time is longer.

3. Prerequisites

Before configuring NTP in broadcast mode, you need to configure a clock reference source for the broadcast server so that the server's clock is in synchronized state. Otherwise, the broadcast client cannot synchronize time from the broadcast server.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure NTP in broadcast mode. Configure at least one of the following tasks.

- Configure an NTP broadcast server.

  ntp broadcast-server [**key** *key-id*] [**version** *version*]

  The broadcast server is disabled on an interface by default.

- Configure an NTP broadcast client.

  ntp broadcast-client

  The broadcast client is disabled on an interface by default.

1.6 Configuring NTP-Related Parameters

1.6.1 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the interval for time synchronization with the external server.

ntp interval *synchronization-interval-time*

By default, the NTP synchronization interval is 64s.

(4) (Optional) Configure automatic update of the hardware clock.

ntp update-calendar

Automatic update of the hardware clock is not configured by default.

(5) (Optional) Configure the NTP master clock.

ntp master [*stratum*]

The NTP master clock is disabled by default.

stratum: specifies the stratum of a local clock, ranging from 1 to 15. The default value is 8.

(6) (Optional) Disable the NTP time synchronization service provided for other devices.

ntp service disable

The NTP time synchronization service is enabled by default.

(7) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

(8) (Optional) Disable receiving of NTP packets on an interface.

ntp disable

The function of receiving NTP packets on an interface is enabled by default.

1.7 Configuring NTP Access Control

1.7.1 Overview

NTP access control provides a minimum security measure. A more secure method is to use the NTP authentication mechanism.

1.7.2 Restrictions and Guidelines

- If no access control rule is configured, all NTP services can be accessed. If access control rules are configured, only NTP services that comply with the access control rules can be accessed.
- The system currently does not support the access control query function.
- If the packet request interval of the NTP client is smaller than that allowed by the server, the NTP server discards the packets. This function takes effect only after the **ntp access-group limited** { *acl-name* | *acl-number* } [**kod**] command is configured. When the KoD-enabled NTP device acts as a client, it reduces the rate after receiving a KoD packet. A KoD-disabled device does not reduce the rate. Note that KoD cannot be triggered by specifying the interval in the **ntp interval** command.
- You can run the **ntp discard** command to configure the packet request interval allowed by the server. If the

packet request interval of the NTP client is smaller than that allowed by the server, the NTP server discards the packets. This function takes effect only after the **ntp access-group limited** { *acl-name* | *acl-number* } [**kod**] command is configured.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the NTP access control rights.

ntp access-group { **limited** | **peer** | **query-only** | **serve** | **serve-only** } { *acl-name* | *acl-number* } [**kod**]

No NTP access control rule is configured by default.

(4) (Optional) Configure the minimum packet interval allowed by NTP.

ntp discard min-spacing *discard-min-spacing-interval* **avg-spacing** *avg-spacing-interval*

By default, the minimum packet request interval allowed by NTP is 2s, and the average packet request interval is 8s.

1.8 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

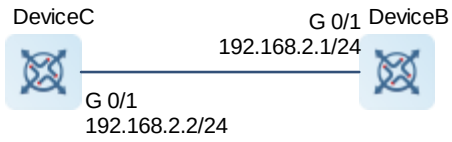
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 NTP Monitoring

Command	Purpose
show ntp status	Displays the current NTP information.
show ntp packets	Displays the sent and received NTP packets.
show ntp server	Displays the NTP server information.
show ntp peer	Displays the NTP peer list.
show ntp broadcast-server	Displays the NTP broadcast server list.
debug ntp	Debugs the DNS function.
no debug ntp	Disables the debugging function.

1.9 Configuration Examples



1.9.1 Configuring the Local Clock Reference Mode of NTP

1. Requirements

Use the local clock of a device as the NTP reference clock source to provide time synchronization.

2. Topology

Figure 1-2 Local Clock Reference Mode of NTP

3. Notes

- Configure the local clock of device B as the NTP reference clock source.
- Device C synchronizes time from device B.

4. Procedure

Set the IP address of GigabitEthernet 0/1 on device B to 192.168.2.1/24.

```
DeviceB> enble
DeviceB# configure terminal
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on device C to 192.168.2.2/24.

```
DeviceC> enble
DeviceC# configure terminal
DeviceC(config)# interface gigabitethernet 0/1
DeviceC(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceC(config-if-GigabitEthernet 0/1)# exit
```

Configure device B as the NTP server.

```
DeviceB(config)# ntp master
```

Enable the NTP function on device C.

```
DeviceC> enble
DeviceC# configure terminal
DeviceC(config)# ntp server 192.168.2.1
DeviceC(config)# ntp enable
```

5. Verification

Run the **ping** command to verify L3 reachability between device B and device C.

```
DeviceB# ping 192.168.2.2
```

```
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **clock set** command to modify the time on device B.

```
DeviceB# clock set 11:00:00
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **show clock** command on device C to check whether time synchronization is successful.

```
DeviceC# show clock
11:00:01 UTC Fri, Feb 26, 2021
```

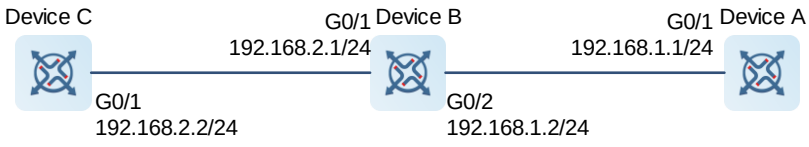
6. Configuration Files

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 ip address 192.168.2.1 255.255.255.0
ntp master
!
end
```

- Device C configuration file

```
hostname DeviceC
!
ntp server 192.168.2.1
!
interface GigabitEthernet 0/1
 ip address 192.168.2.2 255.255.255.0
!
end
```



1.9.2 Configuring the External Clock Reference Mode of NTP

1. Requirements

Use a device as a client to synchronize time from an external reference clock source to the local clock. After successful time synchronization, the device can act as a time synchronization server to provide the time synchronization service.

2. Topology

Figure 1-3 Topology for the External Clock Reference Mode of NTP

3. Notes

- Configure the NTP external clock reference mode on device B.
- Configure device A as the reference clock source of device B.
- Device C synchronizes time from device B.

4. Procedure

Set the IP address of GigabitEthernet 0/1 on device A to 192.168.1.1/24.

```
DeviceA> enble
DeviceA# configure terminal
DeviceA(config)# interface gigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on device B to 192.168.2.1/24, and the IP address of GigabitEthernet 0/2 to 192.168.1.2/24.

```
DeviceB> enble
DeviceB# configure terminal
DeviceB(config)# interface gigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
DeviceB(config)# interface gigabitEthernet 0/2
DeviceB(config-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on device C to 192.168.2.2/24.

```
DeviceC> enble
DeviceC# configure terminal
DeviceC(config)# interface gigabitEthernet 0/1
DeviceC(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceC(config-if-GigabitEthernet 0/1)# exit
```

Configure device A as the reference clock source of device B.

```
DeviceA(config)# ntp master
```

Configure the NTP external clock reference mode on device B.

```
DeviceB(config)# ntp server 192.168.1.1
```

Enable device C to synchronize time from device B.

```
DeviceC(config)# ntp server 192.168.2.1
```

5. Verification

Run the **ping** command to verify L3 reachability between device B and device A.

```
DeviceB# ping 192.168.1.1
Sending 5, 100-byte ICMP Echoes to 192.168.1.1, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **ping** command to verify L3 reachability between device B and device C.

```
DeviceB# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **show ntp status** command to display the NTP configuration.

```
DeviceB# sh ntp status
Clock is synchronized, stratum 9, reference is 192.168.1.1
nominal freq is 250.000 Hz, actual freq is 250.000 Hz, precision is 2**18
reference time is E352747.D5254A29 (14:03:51.000 UTC Sun, Nov 8, 2020)
clock offset is -0.00012 sec, root delay is 0.00282 sec
root dispersion is 0.01153 msec, peer dispersion is 0.00025 msec
system poll interval is 64, last update was 43 sec ago
system time(GMT) is E352773.740AB522 (14:04:35.000 GMT Sun, Nov 8, 2020)
```

Run the **clock set** command to modify the time on device A.

```
DeviceA# clock set 11:00:00
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **show clock** command on device B to check whether time synchronization is successful.

```
DeviceB# show clock
11:00:01 UTC Fri, Feb 26, 2021
```

Run the **show clock** command on device C to check whether time synchronization is successful.

```
DeviceC# show clock
11:00:01 UTC Fri, Feb 26, 2021
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 ip address 192.168.1.1 255.255.255.0
ntp master
!
end
```

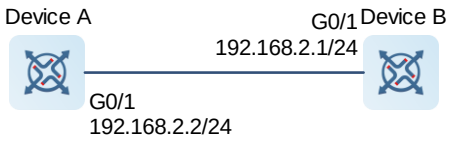
- Device B configuration file

```
hostname Device B
!
ntp server 192.168.1.1
!
interface GigabitEthernet 0/1
 ip address 192.168.2.2 255.255.255.0
!
interface GigabitEthernet 0/2
```

```
 ip address 192.168.1.2 255.255.255.0
!
end
```

- Device C configuration file

```
hostname DeviceC
!
ntp server 192.168.2.1
!
interface GigabitEthernet 0/1
 ip address 192.168.2.2 255.255.255.0
!
end
```



1.9.3 Configuring NTP Security Authentication

1. Requirements

Use a device as a client to synchronize time only from a trusted external reference clock source to the local clock. Use the local clock of a device as the NTP reference clock source to provide time synchronization for only a trusted device.

2. Topology

Figure 1-4 Topology for NTP Security Authentication

3. Notes

- Configure device A as the reference clock source of device B, enable device A to provide device B with the NTP service that requires security authentication, and set the authentication key to "abcd".

4. Procedure

Set the IP address of GigabitEthernet 0/1 on device A to 192.168.2.2/24.

```
DeviceA> enble
DeviceA# configure terminal
DeviceA(config)# interface gigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Configure device A as the reference clock source of device B, enable device A to provide device B with the NTP service that requires security authentication, and set the authentication key to "abcd".

```
Device A(config)# ntp master
Device A(config)# ntp authenticate
Device A(config)# ntp authentication-key 1 md5 abcd
```

```
Device A(config)# ntp trusted-key 1
```

Set the IP address of GigabitEthernet 0/1 on device B to 192.168.2.1/24.

```
DeviceB> enble
DeviceB# configure terminal
DeviceB(config)# interface gigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Configure device A as the reference clock source of device B, enable device A to provide device B with the NTP service that requires security authentication, and set the authentication key to "abcd".

```
DeviceB(config)# ntp authenticate
DeviceB(config)# ntp authentication-key 1 md5 abcd
DeviceB(config)# ntp trusted-key 1
DeviceB(config)# ntp server 192.168.2.2 key 1
```

5. Verification

Run the **ping** command to verify L3 reachability between device B and device A.

```
DeviceB# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **clock set** command to modify the time on device A.

```
DeviceA# clock set 11:00:00
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **show clock** command on device B to check whether time synchronization is successful.

```
DeviceB# show clock
11:00:01 UTC Fri, Feb 26, 2021
```

6. Configuration Files

- Device A configuration file

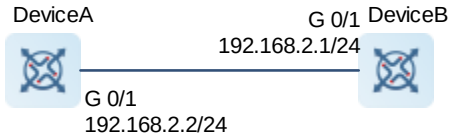
```
hostname DeviceA
!
interface GigabitEthernet 0/1
 ip address 192.168.2.2 255.255.255.0
ntp master
ntp authentication-key 1 md5 abcd
ntp authenticate
ntp trusted-key 1
!
end
```

- Device B configuration file

```
hostname DeviceB
!
```

```
ntp authentication-key 1 md5 abcd
ntp authenticate
ntp trusted-key 1
ntp server 192.168.2.2 key 1
!
interface GigabitEthernet 0/1
 ip address 192.168.2.1 255.255.255.0
!
end
```

1.9.4 Configuring NTP Access Control Rights



1. Requirements

Configure the access control function to prevent malicious damage to the time server and improve the security of time synchronization.

Use a device as a client to synchronize time only from the specified external reference clock source to the local clock.

2. Topology

Figure 1-5 Topology for Implementing NTP Access Control Rights

3. Procedure

Set the IP address of GigabitEthernet 0/1 on device A to 192.168.2.2/24.

```
DeviceA> enble
DeviceA# configure terminal
DeviceA(config)# interface gigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on device B to 192.168.2.1/24.

```
DeviceB> enble
DeviceB# configure terminal
DeviceB(config)# interface gigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Configure device A as the reference clock source of device B. Allow only the device with the IP address of 192.168.2.2 to send a time synchronization request to the local device.

```
DeviceB(config)# ntp server 192.168.2.2
DeviceB(config)# access-list 1 permit host 192.168.2.2
DeviceB(config)# ntp access-group serve-only 1
```

Configure device A as the NTP server, limit the request packet interval of the client, and send KoD packets.

```
DeviceA(config)# ip access-list standard limited1
DeviceA(config-std-nacl)# 10 permit any
DeviceA(config)# exit
DeviceA(config)# ntp access-group limited limited1 kod
DeviceA(config)# ntp discard min-spacing 5 avg-spacing 5
DeviceA(config)# ntp master
```

4. Verification

Run the **ping** command to verify L3 reachability between device B and device A.

```
DeviceB# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **clock set** command to modify the time on device A.

```
DeviceA# clock set 11:00:00
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **show clock** command on device B to check whether time synchronization is successful.

```
DeviceB# show clock
11:00:01 UTC Fri, Feb 26, 2021
```

5. Configuration Files

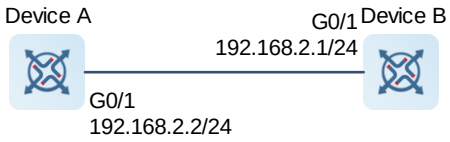
- Device A configuration file

```
hostname DeviceA
!
ip access-list standard limited1
 10 permit any
!
interface GigabitEthernet 0/1
 ip address 192.168.2.2 255.255.255.0
ntp master
ntp access-group limited limited1 kod
!
end
```

- Device B configuration file

```
hostname DeviceB
!
ip access-list standard 1
 10 permit 192.168.2.2
!
ntp server 192.168.2.2
ntp access-group serve-only 1
!
```

```
interface GigabitEthernet 0/1
 ip address 192.168.2.1 255.255.255.0
!
end
```



1.9.5 Configuring the NTP Broadcast Mode

1. Requirements

Use device A as the broadcast server to provide the time synchronization service for device B.

2. Topology

Figure 1-6 Topology for NTP Broadcast Mode

3. Notes

- Configure the local clock of Device A as the NTP reference source, and Device A as the NTP broadcast server.
- Configure device B as the NTP broadcast client to synchronize time from Device A.

4. Procedure

Set the IP address of GigabitEthernet 0/1 on device A to 192.168.2.2/24.

```
DeviceA> enble
DeviceA# configure terminal
DeviceA(config)# interface gigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on device B to 192.168.2.1/24.

```
DeviceB> enble
DeviceB# configure terminal
DeviceB(config)# interface gigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
```

Configure the local clock of device A as the NTP reference clock source.

```
DevcieA(config)# ntp master
```

Configure device A as the NTP broadcast server.

```
DevcieA(config)# interface gigabitEthernet 0/1
DevcieA(config-if-GigabitEthernet 0/1)# ntp broadcast-server
```

Configure device B as the NTP broadcast client.

```
DevcieB(config-if-GigabitEthernet 0/1)# ntp broadcast-client
```

5. Verification

Run the **ping** command to verify L3 reachability between device B and device A.

```
DeviceB# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **clock set** command to modify the time on device A.

```
DeviceA# clock set 11:00:00
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **show clock** command on device B to check whether time synchronization is successful.

```
DeviceB# show clock
11:00:01 UTC Fri, Feb 26, 2021
```

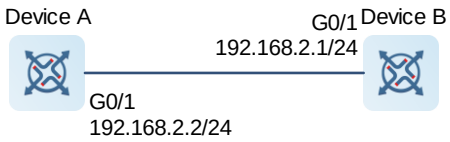
6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 ntp broadcast-server
 ip address 192.168.2.2 255.255.255.0
!
ntp master
!
end
```

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 ntp broadcast-client
 ip address 192.168.2.1 255.255.255.0
!
end
```



1.9.6 Configuring the NTP Peer Mode

1. Requirements

A time server, device A, exists in the network, and device B needs to synchronize time from device A. Configure device A as the passive peer and device B as the active peer.

2. Topology

Figure 1-7 Topology for NTP Peer Mode

3. Notes

- Configure device A as the passive peer.
- Configure device B as the active peer.

4. Procedure

Set the IP address of GigabitEthernet 0/1 on device A to 192.168.2.2/24.

```
DeviceA> enble
DeviceA# configure terminal
DeviceA(config)# interface gigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on device B to 192.168.2.1/24.

```
DeviceB> enble
DeviceB# configure terminal
DeviceB(config)# interface gigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Configure the local clock of device A as the NTP reference clock source.

```
DeviceA(config)# ntp master
```

Configure device A as the passive peer.

```
DeviceA(config)# ntp passive enable
```

Configure device B as the active peer to synchronize time from device A.

```
DeviceB(config)# ntp peer 192.168.2.2
```

5. Verification

Run the **ping** command to verify L3 reachability between device B and device A.

```
DeviceB# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **clock set** command to modify the time on device A.

```
DeviceA# clock set 11:00:00
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **show clock** command on device B to check whether time synchronization is successful.

```
DeviceB# show clock
11:00:01 UTC Fri, Feb 26, 2021
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface GigabitEthernet 0/1
 ntp broadcast-server
 ip address 192.168.2.2 255.255.255.0
!
ntp passive enable
ntp master
!
end
```

- Device B configuration file

```
hostname DeviceB
!
interface GigabitEthernet 0/1
 ntp broadcast-client
 ip address 192.168.2.1 255.255.255.0
!
ntp peer 192.168.2.2
!
end
```

1 Configuring SNTP

1.1 Introduction

1.1.1 Overview

NTP uses a complex algorithm for time synchronization, and raises high requirements for the system. As a simplified version of NTP, Simple Network Time Protocol (SNTP), inherits the protocol specification and implementation process of NTP, and adopts the same packet format and interaction mode as NTP. By setting some fields in the packet to predetermined values, SNTP simplifies the time synchronization algorithm and lowers the requirements for system performance. Although the precision of SNTP time synchronization is compromised while the algorithm is simplified, SNTP can generally achieve a precision of about 1s. Therefore, when the time precision requirements are not very high, you can choose to use SNTP. SNTP packets are the same as NTP packets, and therefore the SNTP client is fully compatible with the NTP server.

1.1.2 Principles

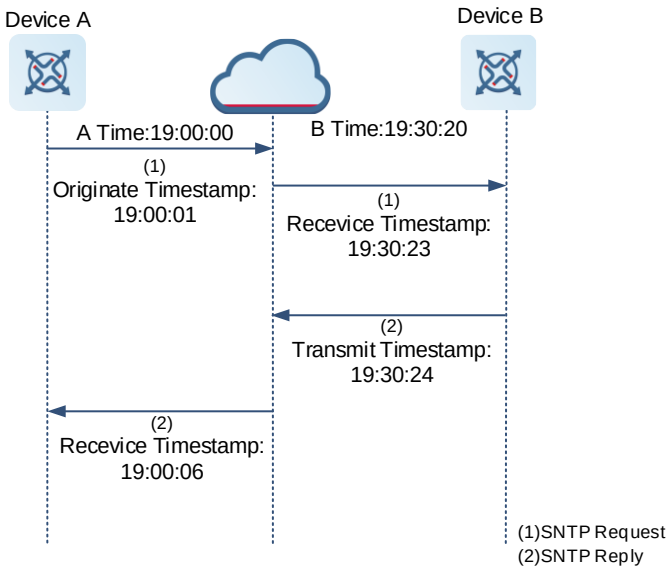
Like NTP, SNTP also uses the client/server mode for SNTP/NTP message interaction. The client sends a time synchronization packet to the server at a certain interval (half an hour by default). After receiving a response packet from the server, the client synchronizes time.

As shown in Figure 1-1, Device B (B for short) acts as an NTP reference clock source, Device A (A for short) acts as an SNTP client that synchronizes time with B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

(1) A sends an SNTP/NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in Originate Timestamp.

(2) After a network delay of 2s, the local time (T1) when B receives the request packet is 19:30:23 and is filled in Receive Timestamp.

(3) B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in Transmit Timestamp.



(4) After a network delay of 2s, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

a A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula ((T1-T0)+(T2-T3))/2.

b A obtains the packet round-trip delay of 4 seconds between A and B by using the formula (T3-T0)-(T2-T1).

Figure 1-1 SNTP Principles

1.1.3 Protocols and Standards

- RFC 2030: Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI

1.2 Restrictions and Guidelines

You cannot configure both the NTP and SNTP functions on the same device.

1.3 Configuring SNTP

1.3.1 Overview

An SNTP client accesses an NTP server regularly to calibrate the clock.

1.3.2 Restrictions and Guidelines

All time obtained through SNTP communication is Greenwich Mean Time (GMT). To obtain precise local time, you need to set the local time zone for alignment with GMT.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable SNTP.

sntp enable

The SNTP function is disabled by default.

(4) Configure the IP address of an SNTP server.

sntp server [**oob**] { *ipv4-address* | *domain* } [**via** *mgmt-name*] [**source** *source-ipv4-address*]

No SNTP server is configured by default.

(5) (Optional) Configure the SNTP time synchronization interval.

sntp interval *synchronization-interval-time*

The default interval for clock synchronization between an SNTP client and SNTP/NTP server is 1800s.

1.4 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

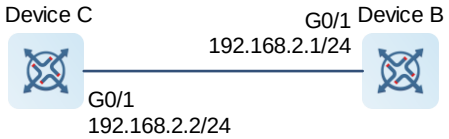
Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 SNTP Monitoring

Command	Purpose
show sntp	Displays SNTP-related parameters.
debug sntp	Debugs the DNS function.

1.5 Configuration Examples



1.5.1 Configuring Basic Functions of SNTP

1. Requirements

- Use the local clock of Device B as the NTP reference clock source to provide time synchronization for Device C.
- Use Device C as an SNTP client to synchronize time from Device B.

2. Topology

Figure 1-2 Topology for Basic SNTP Functions

3. Notes

- Configure Device B as the SNTP server of Device C.

- Enable the SNTP function on Device C.

4. Procedure

Set the IP address of GigabitEthernet 0/1 on Device B to 192.168.2.1/24.

```
DeviceB> enble
DeviceB# configure terminal
DeviceB(config)# interface gigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Set the IP address of GigabitEthernet 0/1 on Device C to 192.168.2.2/24.

```
DeviceC> enble
DeviceC# configure terminal
DeviceC(config)# interface gigabitEthernet 0/1
DeviceC(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0
DeviceC(config-if-GigabitEthernet 0/1)# exit
```

Configure Device B as the NTP server.

```
DeviceB(config)# ntp master
```

Enable the SNTP function on Device C.

```
DeviceC(config)# sntp server 192.168.2.1
DeviceC(config)# sntp enable
```

5. Verification

On Device B, run the **ping** command to verify L3 reachability between Device B and Device C.

```
DeviceB# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

On Device C, run the **show sntp** command to display the SNTP status and check whether the server is successfully configured.

```
DeviceC# show sntp
 SNTP state          : Enable
 SNTP oob mode        : Enable
 SNTP server         : 192.168.2.1
 SNTP sync interval    : 1800
 Time zone           : -0
```

Run the **clock set** command to modify the time on Device B.

```
DeviceB# clock set 11:00:00
Set system clock: 11:00:00 UTC Fri, Feb 26, 2021
```

Run the **show clock** command on Device C to check whether time synchronization is successful.

```
DeviceC# show clock
11:00:01 UTC Fri, Feb 26, 2021
```

6. Configuration Files

- Device B configuration file

```
DeviceB# show running-config
hostname DeviceB
!
interface GigabitEthernet 0/1
 ip address 192.168.2.1 255.255.255.0
ntp master
!
end
```

- Device C configuration file

```
DeviceC# show running-config
hostname DeviceC
!
sntp server 192.168.2.2
sntp enable
!
interface GigabitEthernet 0/1
 ip address 192.168.2.2 255.255.255.0
!
end
```

1 Configuring Time Range

1.1 Introduction

1.1.1 Overview

Time range is a time control service. Users can create a time range and reference the time range in a service to control the time of the service. For example, to make an access control list (ACL) take effect in a time range within a week, configure a time range and associate the ACL with the time range. In this case, the ACL is effective only in the specified time range.

1.1.2 Principles

1. Basic Concepts

A time range is defined in the following modes:

- Absolute time range

  An absolute time range indicates the time range from the specified start time to the end time, for example, from 12:00:00 on January 1, 2000 to 12:00:00 on January 1, 2001.

- Period

  A period indicates a periodic time range, for example, from 8:00 Monday to 17:00 Friday.

2. Using an Absolute Time Range

When a function is enabled in a service that references a time range, the service determines whether the current time of the system is in an absolute time range. If yes, the function can be enabled or disabled in the current time.

3. Using a Period

When a function is enabled in an application based on a time range, the application determines whether the current time of the system is in a period. If yes, the function can be enabled or disabled in the current time.

1.2 Configuring Basic Features

1.2.1 Overview

This section describes how to create a time range and configure an absolute time range or a period.

1.2.2 Restrictions and Guidelines

- Before modifying an absolute time range or a period for a service, you are advised to disassociate the time range. After the absolute time range or period is modified, associate the time range again.
- In a time range, you can configure multiple effective periods.
- If an absolute time range and a period are configured in a time range, the effective time range is a period in the absolute time range. If multiple periods are configured, the effective time is the multiple periods configured in the absolute time range.

1.2.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a time range.

time-range *time-range-name*

(4) (Optional) Configure effective time of the time range. Configure at least one of the following tasks.

- Configure an absolute time range.

  absolute { **start** *hh:mm DD/MM/YY* | **end** *hh:mm DD/MM/YY* }*

  No absolute time range is configured. The maximum time range is used by default.

- Configure a period.

  periodic *day-of-the-week time* **to** [*day-of-the-week*] *time*

  No period is configured by default. The current time is considered to be within a period.

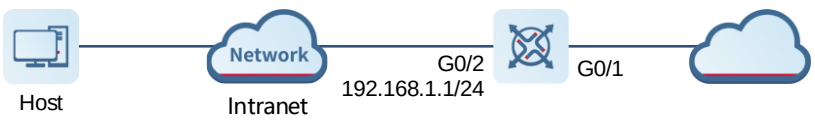
1.3 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Time Range Monitoring

Command	Purpose
show time-range [*time-range-name*]	Displays a time range.

1.4 Configuration Examples



1.4.1 Configuring Basic Features of Time Range

1. Requirements

In the traffic control, an enterprise needs to control the traffic type and traffic in a specific period. For example, an enterprise prohibits employees from accessing the Internet during work and allows them to do so after work. In this case, an ACL can be configured to associate with a time range. During the working hours (9:00 to 12:00 and 14:00 to 18:00), PCs in the Intranet are prohibited from accessing the Internet. In other time ranges, the PCs are allowed to access the Internet. The PCs can access one another at any time.

2. Topology

Figure 1-1 Topology for Configuring the Basic Features of Time Range

3. Notes

- First configure system time for the device. The effective time of an ACL is based on the system time of the device.
- A time range cannot cross 0:00, that is, to create a time range from 22:00 to 7:00 the next day, create two time ranges.

4. Procedure

(1) Configure system time in the following format: hh:mm:ss MMDDYY.

```
Hostname> enable
Hostname # clock set 10:00:00 12 1 2012
```

Set the time zone of the device to GMT+8.

```
Hostname# configure terminal
Hostname(config)# clock timezone beijing 8
```

Create a time range named **time1**, which is effective from 9:00 to 12:00 and from 14:00 to 18:00 every day.

```
Hostname(config)# time-range time1
Hostname(config-time-range)# periodic daily 9:00 to 12:00
Hostname(config-time-range)# periodic daily 14:00 to 18:00
Hostname(config-time-range)# exit
```

(2) Configure an ACL to be associated with the time range.

In the time range **time1**, configure the ACL to reject any traffic from the Intranet PCs in the network segment 192.168.1.0/24 to the Internet.

```
Hostname(config)# ip access-list extended 100
Hostname(config-ext-nacl)# 10 deny ip 192.168.1.0 0.0.0.255 any time-range
time1
```

(3) Configure the ACL to allow the Intranet PCs in the network segment 192.168.1.0/24 to access the Internet in non-working hours.

```
Hostname(config-ext-nacl)# 20 permit ip any any
Hostname(config-ext-nacl)# exit
```

Apply the ACL to interface GigabitEthernet 0/2.

```
Hostname(config)# interface GigabitEthernet 0/2
Hostname(config-if-GigabitEthernet 0/2)# ip access-group 100 in
```

5. Verification

Run the **show clock** command to display the time of the device.

```
Hostname# show clock
10:14:01 beijing Sat, Dec 1, 2012
```

Run the **show time-range** command to display the time range configurations.

```
Hostname# show time-range time1

time-range entry: time1 (active)
```

```
 periodic Daily 9:00 to 12:00
 periodic Daily 14:00 to 18:00
```

Run the **show access-lists** command to display the ACL configurations. When the time of the device is in the time range **time1**, the displayed status of the ACL is active; when the time of the device is not in the effective time of ACL, the displayed status of the ACL is inactive.

```
Hostname# show access-lists
ip access-list extended 100
10 deny ip 192.168.1.0 0.0.0.255 any time-range time1 (active)
20 permit ip any any
```

Run the **show ip access-group** command to display the calling of the ACL on the interface.

```
Hostname# show ip access-group
ip access-group 100 in
Applied On interface GigabitEthernet 0/2.
```

Set the system time to working hours so that PCs in the Intranet cannot ping the Internet during working hours.

```
Hostname# show clock
14:52:26 beijing Tue, Dec 15, 2020
Hostname# ping 14.215.177.38
Sending 5, 100-byte ICMP Echoes to 14.215.177.38, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5).
```

6. Configuration Files

```
hostname Device
!
ip access-list extended 100
 10 permit ip host 10.10.10.20 any
 20 permit ip any any
!
time-range time1
 periodic Daily 9:00 to 12:00
 periodic Daily 14:00 to 18:00
!
interface GigabitEthernet 0/2
 no switchport
 ip access-group 100 in
 ip address 192.168.1.1 255.255.255.0
!
End
```

1 Configuring UFT Mode Management

1.1 Introduction

1.1.1 Overview

The unified forwarding table (UFT) provides the function of dynamically allocating switch hardware forwarding entry resources so that users can select UFT modes to adapt to requirements of the scenarios.

1.1.2 Principles

1. UFT Mode

- **Default**

  Default UFT mode. In this mode, the hardware entries of a switch apply to most user scenarios, including user access to the gateway and large L2 gateway cores.

- **Gateway-IPv4**

  IPv4 gateway mode. This mode does not support IPv6 addresses, but allocates resources occupied by IPv6 addresses exclusively to IPv4 addresses to increase the IPv4 routing capacity. This mode is applicable to scenarios with many IPv4 routes.

- **Route**

  Dual-stack routing mode. This mode supports IPv4 and IPv6 dual-stack routes. It is applicable to traditional L3 core networks and the forwarding of many routes.

- **Bridge**

  L2 forwarding mode. This mode greatly reduces the Address Resolution Protocol (ARP)/Neighbor Discovery (ND) and Multiprotocol Label Switching (MPLS) capacity and allocates most capacity to MAC address table. It is applicable to scenarios of pure L2 services.

1.2 Restrictions and Guidelines

- Different devices support different UFT modes.
- After different UFT modes are configured, you need to save the configurations and restart the device to validate the mode.

1.3 Configuring a UFT Mode

1.3.1 Overview

Different UFT modes are configured to meet requirements of different networking scenarios.

1.3.2 Restrictions and Guidelines

- After configuration, you need to save the configurations and restart the device to validate them. If the configuration is not saved and the device is restarted, then the original configuration will still be running on the device. If only the line card is restarted, the line card may not work normally.

- Change the UFT mode to a non-default mode and save the configurations. If you upgrade the device, the UFT function may cause line cards to automatically restart during the first restart. If SYSLOG prompts that the UFT mode is not supported, and the actual operation mode of the device is different from the configuration mode, then you need to reconfigure or delete the configuration, and restart the device.
- If the system log shows that the UFT mode is not supported and the actual operating mode of the device differs from the configured mode, you need to reconfigure the UFT mode or delete the configurations and restart the device. If the CLI configuration mode before the restart is different from the mode in the config.text file, the device will restart automatically once after starting. The causes of inconsistent modes include but are not limited to the following:
  - The non-default UFT mode is saved before the device is upgraded.
  - The config.text file is manually deleted or modified.
  - The UFT mode modified in CLI is not saved.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Switch the UFT mode. The configuration tasks below are mutually exclusive. Configure one of them.

- In standalone mode, switch the UFT mode.

  switch-mode *mode-type* **slot** *slot-id*

  The UFT mode is the default mode by default.

- In virtual switching unit (VSU) mode, switch the UFT mode.

  switch-mode *mode-type* **switch** *switch-id* **slot** *slot-id*

  The UFT mode is the default mode by default.

- (Optional) Pre-configure the UFT mode globally.

  switch-mode *mode-type* **global**

  The UFT mode is the default mode by default.

1.4 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 UFT Monitoring

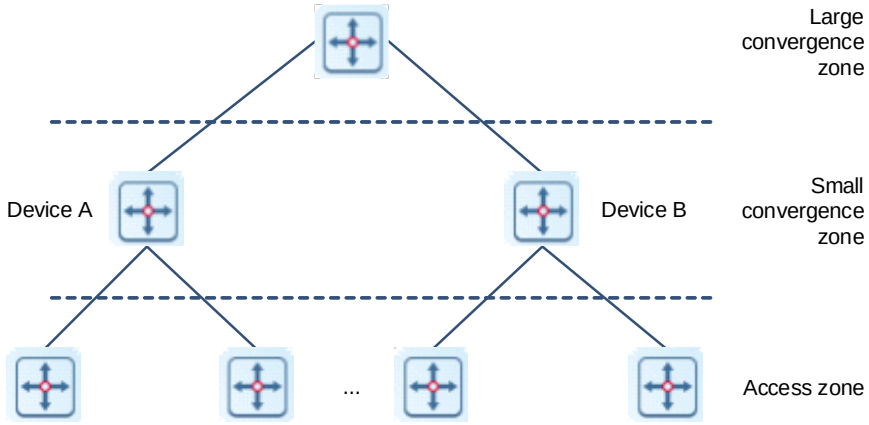
Command	Purpose
show switch-mode status	Displays information about the UFT mode of a switch.

Note

- The above monitoring command is compatible with chassis-type devices and box-type devices, as well as the standalone mode and VSU mode.

- For the stand-alone mode, the keyword **device** is invisible. For a chassis-type device, you can set **slot** to specify a line card.

1.5 Configuration Examples



1.5.1 Switching the UFT Mode of a Switch in Standalone Mode

1. Requirements

Take a common campus network as an example. Core devices may be deployed in a small convergence zone as small convergence devices of access devices. L2 functions are enabled on the devices. The small convergence zone must be supported by a large MAC address table. Therefore, you need to set the UFT mode of switches in the small convergence zone to the bridge mode and adjust the forwarding entries to support the pure L2 mode to meet the requirement for the large-capacity MAC address table.

2. Topology

Figure 1-1 Topology for UFT Mode Switching

3. Procedure

Switch the UFT mode of a line card in slot 3 of device A to the bridge mode.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# switch-mode bridge slot 3
Please save current config and restart your device!
```

4. Verification

Run the **show switch-mode status** command to display the configurations.

```
DeviceA# show switch-mode status
Slot No    Switch-Mode         Status
-------    -------------------- ------
3         bridge              ok
```

5. Configuration Files

Configuration file of device A

```
hostname DeviceA
!
switch-mode bridge slot 3
!
end
```

1 Configuring Process Restarting

1.1 Introduction

1.1.1 Overview

The command line interface (CLI) reboot process module (CMDK) provides a means of restarting a back-end process of a device on the CLI for users. Therefore, when the function of a service fails on a device, the user can restart a specified process of the member device in a specified slot on a specified device in a cluster rather than restart the device, to improve device availability.

The CMDK has the following features:

- Improve the device availability. When a process in a device becomes abnormal, users can manually restart a specified process.
- Support process restart in the virtual switching unit (VSU) environment. The CMDK can restart a specified process of the member device in a specified slot on a specified device. Therefore, users can restart a process on the master device or master supervisor module.

1.1.2 Principles

First, a process determines whether the current device is in the standalone or VSU environment. Then, the process sends a process kill message to a target node. After receiving the message, the target node restarts the whole process by running the command in the startup script.

1.2 Restrictions and Guidelines

Configuration commands are run on only the master device or master supervisor module. Other member devices do not have the permission to run the commands.

1.3 Configuration Task Summary

The RAS-CMDK configuration includes the following tasks: The following configuration tasks are optional. Configure the task as required.

- Restarting a Process of the Member Device in a Specified Slot on a Specified Device
- Starting a Process of the Member Device in a Specified Slot on a Specified Device
- Stopping a Process of the Member Device in a Specified Slot on a Specified Device
- Displaying Processes that can Be Restarted on the Member Device in a Specified Slot on a Specified Device

1.4 Restarting a Process of the Member Device in a Specified Slot on a Specified Device

1.4.1 Overview

This section describes how to restart a specified process on a specified device.

1.4.2 Restrictions and Guidelines

Only valid processes excluded from the whitelist can be restarted.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Restart a process of the member device in a specified slot on a specified device.

cmdk device *device-id* **slot** *slot-id* **module** *module-name* **restart**

1.5 Starting a Process of the Member Device in a Specified Slot on a Specified Device

1.5.1 Overview

This section describes how to start a specified process on a specified device.

1.5.2 Restrictions and Guidelines

Only valid processes can be started.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Start a process of the member device in a specified slot on a specified device.

cmdk device *device-id* **slot** *slot-id* **module** *module-name* **start**

1.6 Stopping a Process of the Member Device in a Specified Slot on a Specified Device

1.6.1 Overview

This section describes how to stop a specified process on a specified device.

1.6.2 Restrictions and Guidelines

Only valid processes excluded from the whitelist can be stopped.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Stop a process of the member device in a specified slot on a specified device.

cmdk device *device-id* **slot** *slot-id* **module** *module-name* **stop**

1.7 Displaying Processes that can Be Restarted on the Member Device in a Specified Slot on a Specified Device

1.7.1 Overview

This section describes how to display processes that can be restarted on the member device in a specified slot on a device.

1.7.2 Restrictions and Guidelines

The processes that can be restarted on the member device in a specified slot are displayed only on the master device.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Display the processes that can be restarted on the member device in a specified slot on a specified device.

cmdk device *device-id* **slot** *slot-id* **detail**

1 Configuring Supervisor Module Redundancy

1.1 Introduction

1.1.1 Overview

Redundancy (RDND) is a mechanism that improves device availability by backing up the operating status of services on the supervisor module (SM) in real time.

Principles

1. Basic Concepts

- Active/Standby SM

  On a chassis-type device with two SMs, the system elects one as the active SM for normal use purpose, and another as the standby SM for standby purpose. When the active SM fails or actively requires switchover, the standby SM becomes the new active SM. Generally, the standby SM does not participate in device management but monitors the running status of the active SM.

- Global active/standby/candidate

  If there are only two SMs in a virtual switching unit (VSU) system that consists of chassis-type devices, one is used as the active SM to manage the whole VSU system and the other is used as the standby SM of the chassis. If there are three or more SMs in a VSU system, one is selected as the active SM to manage the whole VSU system, another is used as the standby SM to back up the VSU system, and the other modules become candidate SMs. When the active and standby SMs are faulty, the candidate SMs replace them and run in the VSU system.

Note

- In most cases, the candidate SM does not participate in backup.
- A candidate SM cannot be directly promoted to an active SM. It needs to be promoted to a standby SM first.
- To differentiate the active and standby SMs inside the chassis from those in a VSU system, the active, standby, and candidate SMs in the VSU system are called global active, global standby, and global candidate SMs respectively. The redundancy mechanism is applied to the global active and global standby SMs. Therefore, the active and standby SMs mentioned in the VSU environment refer to the global active and standby SMs.

- Prerequisites for redundancy of supervisor modules

  The SM redundancy works properly only when the software and hardware of all devices in the device system are compatible.

  During startup, batch synchronization must be performed between the active device and the standby device to ensure their state consistency. Before this process, the SM redundancy does not fully play its role.

- Redundancy state of supervisor modules

  During active-standby backup, the active device has three states as follows:

- alone, namely alone state. In this state, only one device is running in the system or active/standby switchover is not completed and no redundancy is created between the new active device and the new standby device.
- batch, namely batch backup state. Redundancy is created between the active device and the standby device and batch backup is in progress.
- realtime state, namely real-time backup state. Upon batch backup, the active and standby devices are in this state. Real-time backup is performed between the active device and the standby device. Only in this state manual switchover is allowed.

2. Selection of Active and Standby Devices

- Automatic selection of active and standby devices

  Users are allowed to insert or remove SMs during running of devices. Based on the current condition of the system, a device automatically selects an engine for running, without affecting normal data exchange. The active SM makes a choice in the following circumstances:

  - If only one SM is inserted into the M1 slot or the M2 slot during startup of the device, the device selects this module as the active one.
  - If two supervisor modules are inserted during startup of the device, by default, the module in the M1 slot is selected as the active one, the module in the M2 slot as the standby one for backup purpose and a prompt is displayed.
  - If only one SM is inserted into the M1 slot or M2 slot during startup of the device and another is inserted during the running of the device, the module inserted later is used as the standby one for backup purpose and outputs prompts.
  - Assume that two SMs are inserted during startup of the device and either is removed during the running of the device (or one SM fails). If the removed or faulty module is the standby SM, the device only displays a prompt for the removal or failure of the standby SM. If the removed or faulty module is the active SM, the other module becomes the active SM and displays a prompt.
- Manual selection of the active and standby SMs

  Users can manually select the active and standby SMs based on different environments as follows:

  - In standalone mode, users can manually perform active/standby switchover, which takes effect after the SMs are reset.
  - In VSU mode, users can manually perform active/standby switchover to make the global standby SM become the global active module. If only two SMs exist in a VSU system, the original global active SM becomes the new global standby one after reset. If more than two SMs exist, one global candidate module is selected as the new global standby one and the original global active SM becomes a global candidate one after reset.

3. Information Synchronization of Supervisor Modules

- Status synchronization

  The active SM synchronizes its running status to the standby SM in real time. Thus, the standby module can take over the functions of the active module at any time, without any perceivable change.
- Configuration synchronization

During the running of the device, two system configuration files exist: **running-config**, which is dynamically generated during running and changes with the service configuration; **startup-config**, which is imported during the startup of the device. The **write** command is run to write **running-config** into **startup-config** or the **copy** command is run to copy the configuration files.

For some functions that are not directly related to uninterrupted forwarding, the synchronization of system configuration files ensures the consistency of user configurations during switchover.

In the case of the redundancy of dual SMs, the active module periodically synchronizes the **startup-config** and **running-config** files to the standby module and all candidate modules. Configurations are synchronized in the following operations:

- When a user switches from the global configuration mode to privileged EXEC mode, the **running-config** file is synchronized.
- When a user runs the **write** or **copy** command to save configurations, the **startup-config** file is synchronized.

Note

The configuration delivered through SNMP cannot be automatically synchronized to the startup-config file. You can run the **write** or **copy** command to implement synchronization of the running-config file.

- For configurations issued over SNMP, the startup-config file is not automatically synchronized and the running-config file must be synchronized via CLI configuration.

1.2 Restrictions and Guidelines

- For chassis-type devices, the system provides the active-standby backup mechanism. The system supports plug-and-play if the active and standby SMs meet redundancy conditions.
- For box-type devices, each device is equivalent to a SM and a line card. The VSU system of multiple box-type devices also provides the active-standby backup mechanism.

Caution

For box-type devices, box-type stacked VSUs are used to express the redundancy mechanism.

1.3 Configuration Task Summary

RDND configuration includes the following tasks:

All of the following configuration tasks are optional. Select the task as required.

- Configuring Manual Active/Standby Switchover
- Configuring an Automatic Synchronization Period
- Resetting Devices
- Disabling Active/Standby Switchover
- Configuring Automatic Synchronization Mode
- Configuring an Active/Standby Switchover Timeout Period

1.4 Configuring RDND

1.4.1 Overview

- The device automatically selects the active and standby SMs based on the current system, or users do so manually.
- In the SM redundancy environment, the active SM synchronizes status information and configuration files to the standby SM in real time.

1.4.2 Configuring Manual Active/Standby Switchover

1. Overview

If more than two SMs exist in the system, you can manually perform active/standby switchover to change the standby SM into the active SM and select a new standby SM from candidate SMs (the original active SM becomes a candidate SM after reset).

2. Restrictions and Guidelines

- To ensure smooth data forwarding during switchover, perform batch synchronization performed between the active supervisor module and the standby supervisor module so that the two modules are in the same state. That is, manual switchover is allowed only when the redundancy of SMs is in the real-time backup state. In addition, manual active/standby switchover is temporarily disabled by service modules during synchronization to ensure that configuration files are completely synchronized. Therefore, the following conditions must be met for the manual switchover:
  - The operation is performed on the active SM and a standby SM exists.
  - All the hot backup in the system is in the real-time state.
  - All the active/standby switchover in the system is not temporarily disabled by service modules.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Perform an active/standby switchover.

redundancy forceswitch

1.4.3 Configuring an Automatic Synchronization Period

1. Overview

By configuring the automatic synchronization period, you can adjust the synchronization period of the configuration files (**startup-config** and **running-config**) for the active SM or device.

Restrictions and Guidelines

It is recommended that a short synchronization period be configured so that the active device can frequently synchronize configurations to other member devices when configurations are modified. In this way, the configurations are not lost when services and data are forcibly switched to the standby device due to the failure of the active device.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the redundancy configuration mode.

redundancy

(4) Configure a period for automatically synchronizing configuration files.

auto-sync time-period *synchronization-interval-time*

The default period for automatically synchronizing configuration files is 1 hour.

1.4.4 Resetting Devices

1. Overview

Resetting only the standby SM does not affect data forwarding. During the resetting of the standby SM, forwarding is not interrupted or user session information is not lost.

You can run the **redundancy reload shelf** command in standalone mode to reset the entire device. In VSU mode, the device with the specified ID is reset. If the global active device is specified to be reset with two or more devices in the system, the system performs an active/standby switchover.

2. Restrictions and Guidelines

In VSU mode, if the SMs of the system are not in the real-time backup state, resetting the device where the global active SM resides will cause the whole VSU system to reset.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Reset a device.

redundancy reload { **peer** | **shelf** [*switch-id*] }

1.4.5 Disabling Active/Standby Switchover

1. Overview

This section describes how to disable forcible active/standby switchover.

2. Restrictions and Guidelines

After the configuration takes effect, the function of the **redundancy forceswitch** command is disabled.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the redundancy configuration mode.

redundancy

(4) Disable forcible active/standby switchover.

switch-disable

Forcible active/standby switchover is enabled by default.

1.5 Configuring Automatic Synchronization Mode

1.5.1 Overview

By configuring the hot standby automatic synchronization mode, you can specify the configuration files to be synchronized by the active SM. The configuration files include the running-config and startup-config files.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the redundancy configuration mode.

redundancy

(4) Configure the automatic synchronization mode of hot standby.

auto-sync { **running-coinfig** | **standard** | **startup-config** }

The automatic synchronous mode is standard by default.

1.6 Configuring an Active/Standby Switchover Timeout Period

1.6.1 Overview

You can modify the active/standby switchover timeout period through configuration.

1.6.2 Restrictions and Guidelines

- You are advised to use the default value unless otherwise specified.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the redundancy configuration mode.

redundancy

(4) Configure the active/standby switchover timeout period.

switchover timeout *timeout-value*

The timeout period for active/standby switchover is 4,000 ms by default.

1.7 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
show rdnd { **clients** | **dbinfo** | **disable** | **elements** | **inter-connection** | **keyentity** | **logs** | **netconf-state** | **pairs** | **problems** | **status** [**details**] | **switchover** | **sync** }	Debugs the hot standby information.
show redundancy auto-sync	Displays the automatic synchronization mode of hot standby.
show redundancy states	Displays the current redundancy status of device
show redundancy switchtimeout	Displays the timeout period for the active/backup switchover of hot standby.

1.8.1 Clearing the Configuration of an Offline Module 5

1 Configuring Module Hot Swapping

1.1 Introduction

1.1.1 Overview

Module hot swapping is a maintenance function provided by chassis devices. With this function, users can insert or remove a module when a device is operating.

The module hot swapping function supports automatic installation, unloading, reset, and information query of various hot-swappable modules (including the supervisor module, line cards, switch fabric modules, and multi-service card) on chassis devices.

1.1.2 Working Principle

1. Automatic Installation of an Inserted Module

Users can insert or remove a module (in hot swapping mode) when a device is operating. The operation of other modules is not affected. After a module is inserted into a slot, the management software of the device tries to install the driver of the module automatically. The configuration of a removed module is retained for future configuration. If a removed module is inserted again, the module is automatically started and its configuration becomes effective.

Note

Modules here refer to supervisor modules, line cards, switch fabric modules, and multi-service cards. Supervisor modules can be inserted into only the supervisor module slot (M1 or M2), line cards and multi-service cards can be inserted into line card slots, and switch fabric modules can be inserted into only switch fabric module slots.

2. Card Pre-installation

The card pre-installation is supported. That is, after the installed card is removed, if you save the configuration and restart the device, the configuration of the card is not lost.

3. Resetting an Online Module

The management software of a device provides the online module reset function so that users can reset an online module to rectify software failures occurring on the module.

Caution

Resetting an online module may interrupt some services on the device.

4. Application Level of a Device

In global configuration mode, run the **device-level** command to set the application level for a device, which can be the core layer, convergence layer, or access layer. By default, a device obtains its application level from the xml file that describes the device. When the **show running-config** command is run under the default

configuration, the application level of the device is not displayed. The **show device-level** command can be run to displaythe application level of the current device. When no configuration exists, "unknown" is displayed.

1.2 Configuration Task Summary

The module hot swapping configuration includes the following tasks:

- Clearing and Modifying Module/Device Configurations
- Setting the Application Level of a Device
- Setting a Module to Go Offline

1.3 Clearing and Modifying Module/Device Configurations

1.3.1 Overview

In different circumstances, different configurations need to be cleared. The specific application scenarios are described as follows:

- Clearing the configurations of a module; Auser inserts a board card into a slot on a device. Later, the user removes the board card and deletes the configurations of the board card and its port because the board card is no longer used.
- Clearing the configuration of a VSU member device: A user uses a member device in a VSU. Later, the user removes the device from the VSU and deletes the configurations of the member device in the VSU.
- Deleting the MAC address retained in the configuration file: Auser hopes to change the MAC address of the system and uses the new MAC address elected by the system. Generally, the MAC address used by the system is stored in the Supervisor Engine or flash memory of the chassis. In VSU mode, however, the system automatically stores the used MAC address in the configuration file to avoid interruption caused by the change of the MAC address. If a valid MAC address exists in the configuration file after restart of the device, the MAC address is used in preference.

1.3.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Clear the configurations of a module.

remove configuration module *slot-number*

This command is applicable to only chassis devices.

Warning

Do not run the command on online line cards. Otherwise, network loops maybe caused after the anti-loop configurations of the online line cards are deleted.

(4) (Optional) Clear the configuration of a VSU member device.

remove configuration device *device-id*

(5) (Optional) Modify the MAC address retained in the configuration file.

sysmac *mac-address*

No MAC address is specified for the system by default.

1.4 Setting the Application Level of a Device

1.4.1 Overview

This section describes how to set the application level for a device so that the administrator can intuitively learn the network layer to which the device belongs. Configurable application levels include the core layer, convergence layer, and access layer.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Set the application level of the device.

device-level { **core** | **collect** | **access** }

The application level of a device is obtained from the XML file by default.

1.5 Setting a Module to Go Offline

1.5.1 Overview

You can manually set abnormal modules to go offline to avoid their impact on the network.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Set a module to go offline.

module-offline *slot-number*

1.6 Resetting the Module

1.6.1 Overview

You can try to reset an exceptional module.

1.6.2 Restrictions and Guidelines

- If you run the **reset module** command during device operation, services may be interrupted due to module reset.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Reset a module.

- Standalone mode

reset module *slot-number*

- VSU mode

reset module *device-id/slot-number*

1.7 Monitoring

This section describes the **show** commands used for checking the running status of a configured function to verify the configuration effect.

Table 1-1 Monitoring

Command	Purpose
show version devices	Displays the device information.
show version module detail [*slot-number*] **show version module detail** [*slot-number/sslot-number*](modular device that supports base card and subcards) **show version module detail** [*device-id/slot-number*] (in VSU mode)	Displays the details of a module.
show version slots [*slot-number*] **show version slots**[*slot-number/sslot-number*](modular device that supports base card and subcards) **show version slots** [*device-id/slot-number*] (in VSU mode)	Displays the online status of a module.
show cpld-fpga version	Displays the hardware version number of the module.
show manuinfo	Displays the asset information of all independent components in the current system.
show sysmac	Displays the current MAC address of the system.
show alarm	Displays system-level alarms.
show device-level	Displays the application level of the current device.
show vsd-summary	Displays the VSD summary.

Command	Purpose
show web-api custom_info	Displays customization information provided for the web.
show web-api version	Displays the version information provided for the web.

1.8 Configuration Examples

1.8.1 Clearing the Configuration of an Offline Module

1. Requirements

A user inserted a board card into slot 1 before. The board card is no longer used because the network topology is changed. The user hopes to delete the port configuration of the board card so that the configuration file of the device can become concise.

2. Notes

Run the module configuration clearing command to delete the configuration of the board card.

3. Procedure

```
Device# enable
Device# configure terminal
Device(config)# remove configuration module 1
```

4. Verification

Run the **show version slots** command to verify that the configuration of the board card in slot 1 is removed.

```
Device# show version slots
Dev  Slot  Port Configured Module   Online Module    Software Status
---  ----  ---- -----------------   -----           --------------
1    1     0    none               none              none
1    2     24   M8606-24SFP/12GT   M8606-24SFP/12GT    none
1    3     2    M8606-2XFP         M8606-2XFP         cannot startup
1    4     24   M8606-24GT/12SFP   M8606-24GT/12SFP    ok
1    M1    0    N/A                M8606-CM          master
1    M2    0    N/A                none               none
```

1.7.1 Configuring Backplane Interface Exception Alarms and Automatic Isolation 7

1 Configuring Backplane Interface Monitoring

1.1 Introduction

1.1.1 Overview

This function supports status query, alarm reporting, automatic isolation, and manual restoration of backplane interfaces on box-type devices. When a backplane interface on a board card is abnormal (for example, incorrect frames due to chip pin damage, abnormal disabling and jitter of a backplane interface), backplane interface monitoring notifies users of the abnormal backplane interface and automatically isolates the interface according to the configured isolation detection rules to prevent packet loss or other errors. Isolation detection rules are configured by default before delivery, and users can change some configurations. Backplane interface monitoring also allows users to query the physical status of backplane interfaces.

1.1.2 Principles

1. Basic Concepts

- Backplane

  A backplane is a framework that is connected with different board cards of a box-type device.

- Backplane interface

  A backplane interface is used by a board card to be connected with another board card through the backplane.

- Polling period

  Backplane interface monitoring checks errors and jitters of a backplane interface in polling mode to determine the backplane interface status. If an exception of a backplane interface reaches the preset threshold within a polling period, an alarm is generated. The maximum number of alarm logs configured by users or configured by default before delivery takes effect only within one polling period. Users can change the default configuration.

- Polling periods for automatic isolation

  When the automatic isolation function is enabled, backplane interface monitoring isolates a backplane interface only when the number of accumulated exceptions on the backplane interface exceeds the specified number of exceptions in specified number of polling periods. This prevents a normal backplane interface from being isolated due to misjudgment. Users are allowed to configure the polling threshold. Generally, a greater polling threshold indicates a smaller misjudgment probability.

2. Exception Alarm

During normal system running, backplane interface monitoring monitors the status of all backplane interfaces. If an exception is found, an alarm syslog is printed.

This function checks the backplane interface status and statistics in polling mode periodically. If a cyclic redundancy check (CRC) error, jitter, abnormal disabling is found, an alarm syslog is printed.

Alarm syslogs for backplane interface exceptions start with "%FABRIC-4".

3. Automatic Isolation of Abnormal Backplane Interfaces

When the automatic isolation function of backplane interfaces is enabled, backplane interface monitoring actively isolates abnormal backplane interfaces to prevent them from affecting the service traffic.

Backplane interface monitoring isolates and disables backplane interfaces with consecutive CRC errors or jitters to prevent traffic from being forwarded through such interfaces. To prevent misjudgment, a backplane interface is isolated only when the backplane interface is abnormal in *N* consecutive polling periods.

4. Restoration of Isolated Backplane Interfaces

Backplane interface monitoring automatically isolates backplane interfaces with consecutive CRC errors or jitters. Users can restore the isolated backplane interfaces. A restored backplane interface is deleted from the isolation list, and continues to undergo exception detection. To restore an isolated backplane interface, you can disable the exception detection function, power off the board card to which the backplane interface belongs or the peer board card, or configure the isolated backplane interface restoration.

1.2 Configuration Task Summary

All of the following tasks are optional. Select them based on your actual requirements.

- Configuring Backplane Interface Exception Alarm
  - Configuring the Maximum Number of Exception Alarm Syslogs
  - Configuring Polling Periods
  - Configuring Alarms for CRC Errors
  - Configuring Alarms for Backplane Interface Jitters
  - Configuring Alarms for Abnormal Backplane Interface Disabling
- Configuring Automatic Isolation of Backplane Interfaces
  - Configuring Automatic Isolation
  - Configuring the Number of Polling Periods for Triggering Isolation
- Configuring Isolated Backplane Interface Restoration
  - Disabling Automatic Isolation
  - Restoring an Isolated Backplane Interface

1.3 Configuring Backplane Interface Exception Alarm

1.3.1 Overview

During normal system running, backplane interface monitoring monitors the status of all backplane interfaces at any time. If an exception is found, an alarm syslog is printed. Users can configure the function of backplane interface exception alarm to:

- Change the maximum number of alarm syslogs that are printed in a polling period.
- Change the enabling\disabling status of different types of alarm syslogs. Supported exception alarm types include CRC errors, jitters, and abnormal disabling of backplane interfaces.
- Configure the polling period for checking backplane interface exceptions.

1.3.2 Restrictions and Guidelines

The configured detection rules for backplane interface exception alarm are effective for all board cards in a cluster.

1.3.3 Configuration Tasks

All of the following tasks are optional. Select them based on your actual requirements.

- Configuring the Maximum Number of Exception Alarm Syslogs
- Configuring Polling Periods
- Configuring Alarms for CRC Errors
- Configuring Alarms for Backplane Interface Jitters
- Configuring Alarms for Abnormal Backplane Interface Disabling

1.3.4 Configuring the Maximum Number of Exception Alarm Syslogs

1. Overview

By configuring the maximum number of exception alarm syslogs, users can, according to their actual requirements, adjust the maximum number of backplane interface exception alarm syslogs that are displayed in a polling period.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the maximum number of exception alarm syslogs.

fabric-interface warning limit *limit-number*

The maximum number of alarm logs for backplane interface exceptions that are displayed is 30 by default.

1.3.5 Configuring Polling Periods

1. Overview

By configuring the polling period for checking backplane interface exceptions, users can control the time for automatic isolation of abnormal backplane interfaces.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the time of a polling period.

fabric-interface polling-period *interval*

The polling period for backplane interface detection is 60 seconds by default.

1.3.6 Configuring Alarms for CRC Errors

1. Overview

When a CRC error occurs, an alarm is generated.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the alarm switch for CRC errors.

fabric-interface warning crc-error { **on** | **off** }

The alarm function for backplane interface CRC errors is enabled by default.

1.3.7 Configuring Alarms for Backplane Interface Jitters

1. Overview

When backplane interface jitter occurs, an alarm is generated.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure alarms for backplane interface jitters.

fabric-interface warning jitter { **on** | **off** }

The alarm function for backplane interface jitters is enabled by default.

1.3.8 Configuring Alarms for Abnormal Backplane Interface Disabling

1. Overview

When a backplane interface is disabled abnormally, an alarm is generated.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure alarms for abnormal backplane interface disabling.

fabric-interface warning abnormal-down { **on** | **off** }

The alarm function for abnormal backplane interface disabling is enabled by default.

1.4 Configuring Automatic Isolation of Backplane Interfaces

1.4.1 Overview

When the automatic isolation function of backplane interfaces is enabled, backplane interface monitoring actively isolates abnormal backplane interfaces to prevent them from affecting the service traffic. The automatic isolation function of abnormal backplane interfaces allows users to control enabling and disabling of automatic backplane interface isolation and change the polling period threshold for triggering automatic isolation.

1.4.2 Restrictions and Guidelines

After the function of automatic backplane interface isolation is configured, the isolation rules are effective for all chassis in a cluster.

1.4.3 Configuration Tasks

All of the following tasks are optional. Select them based on your actual requirements.

- Configuring Automatic Isolation
- Configuring the Number of Polling Periods for Triggering Isolation

1.4.4 Configuring Automatic Isolation

1. Overview

This section describes how to configure the automatic isolation function.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the automatic isolation function.

fabric-interface isolate { **on** | **off** }

The automatic isolation function of abnormal backplane interfaces is disabled by default.

1.4.5 Configuring the Number of Polling Periods for Triggering Isolation

1. Overview

This section describes how to configure the polling period threshold for triggering automatic isolation of a backplane interface.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the number of polling periods for triggering isolation.

fabric-interface isolate polling-cnt *count-number*

The number of polling periods for triggering isolation conditions of backplane interfaces is 3 by default.

1.5 Configuring Isolated Backplane Interface Restoration

1.5.1 Overview

Backplane interface monitoring automatically isolates backplane interfaces with consecutive CRC errors or jitters. The function of isolated backplane interface restoration allows users to delete an isolated backplane interface from the isolation list. This backplane interface is restored to normal, and continues to undergone exception detection.

1.5.2 Restrictions and Guidelines

To restore an isolated backplane interface, you can disable the exception detection function, power off the board card to which the backplane interface belongs or the peer board card, or configure isolated backplane interface restoration.

1.5.3 Configuration Tasks

All of the following tasks are optional. Select them based on your actual requirements.

- Disabling Automatic Isolation
- Restoring an Isolated Backplane Interface

1.5.4 Disabling Automatic Isolation

1. Overview

This section describes how to disable the automatic isolation function.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable the automatic isolation function.

fabric-interface isolate off

The automatic isolation function of backplane interface is disabled by default.

1.5.5 Restoring an Isolated Backplane Interface

1. Overview

This section describes how to configure the number of polling periods for restoring an isolated backplane interface.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Restore an isolated backplane interface.

- Standalone device

fabric-interface isolate recovery slot *slot-id* **port** *port-id*

- Virtual Switching Unit (VSU) device

fabric-interface isolate recovery device *device-id* **slot** *slot-id* **port** *port-id*

1.6 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

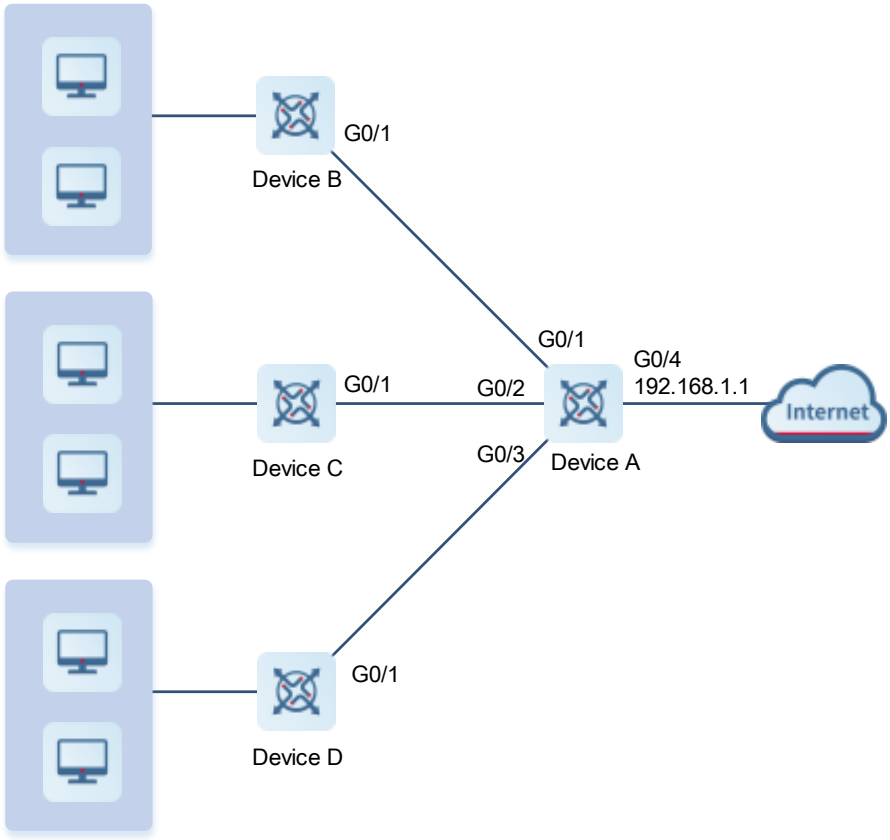
Table 1-1 Monitoring

Command	Purpose
VSU mode: **show fabric-interface connectivity** [**device** *device-id* [**slot** *slot-id* [**port** *port-id*]]] Standalone mode: **show fabric-interface connectivity** [**slot** *slot-id* [**port** *port-id*]]	Displays the backplane interface connection topology.
show fabric-interface isolate info	Displays the isolated backplane interfaces.
show fabric-interface monitor plan	Displays the current monitoring configurations.
VSU mode: **show fabric-interface status** [**device** *device-id* [**slot** *slot-id* [**port** *port-id*]]] Standalone mode: **show fabric-interface status** [**slot** *slot-id* [**port** *port-id*]]	Displays the physical and isolation status information of the backplane interface.
VSU mode: **show fabric-interface** status link-**history** [**device** *device-id* [**slot** *slot-id* [**port** *port-id*]]] Standalone mode: **show fabric-interface status link-history** [**slot** *slot-id* [**port** *port-id*]]	Displays the last 10 changes of the physical status of the backplane interface.

1.7 Configuration Examples

1.7.1 Configuring Backplane Interface Exception Alarms and Automatic Isolation

1. Requirements



As shown in Figure 1-1, Device A is a core device. If its backplane interface is faulty, traffic of the entire network may be abnormal. To prevent the backplane interface fault on Device A from affecting intranet traffic forwarding, you need to configure the backplane interface exception alarm and automatic isolation on Device A.

- Set the polling period for backplane interface detection to **30** seconds.

- Set the maximum number of syslogs that are printed in each polling period to **10**.
- Enable the function of the backplane interface exception alarm.
- Automatically isolate the backplane interfaces that are detected abnormal in four detection periods.

2. Topology

Figure 1-1 Topology of Configuring Backplane Interface Exception Alarms and Automatic Isolation

3. Notes

- On Device A, configure the function of the backplane interface exception alarm.
- On device A, configure the automatic isolation function.

4. Procedure

Configure the function of the backplane interface exception alarm.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# fabric-interface polling-period 30
DeviceA(config)# fabric-interface warning limit 10
DeviceA(config)# fabric-interface warning crc-error on
DeviceA(config)# fabric-interface warning jitter on
DeviceA(config)# fabric-interface warning abnormal-down
```

Configure the automatic isolation function.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# fabric-interface isolate on
DeviceA(config)# fabric-interface isolate polling-cnt 4
```

5. Verification

Upon the preceding configurations, run the **show fabric-interface monitor plan** command to check the backplane interface exception alarm and automatic isolation for configuration.

```
DeviceA> enable
DeviceA# show fabric-interface monitor plan
         FABRIC-INTERFACE MONITOR-PLAN RELATIVE CONFIGURATIONS
------------------------------------------------------------------------------
Isolate-switch: ON
------------------------------------------------------------------------------
Polling-cnt: 4
Polling-period: 30
------------------------------------------------------------------------------
Warning-limit: 10
CRC-warning switch: ON
Jitter-warning switch: ON
Abnormal_down-warning switch: ON
```

6. Configuration Files

Device A configuration file

```
!
fabric-interface warning limit 10
fabric-interface polling-period 30
fabric-interface isolate on
fabric-interface isolate polling-cnt 4
!
```

1 Configuring Intelligent Monitoring

1.1 Introduction

1.1.1 Overview

Intelligent monitoring is an intelligent hardware management function of devices, including intelligent power management, intelligent fan speed adjustment, and intelligent temperature monitoring. The intelligent monitoring function monitors the power supply of the chassis, processes card power-on/off and monitors its power, automatically adjusts fan speed based on the change of the ambient temperature, and monitors temperature change of the cards in real time in order to give notifications to users.

By default, the intelligent monitoring function is enabled after the device is powered on. Users can use this function without need of any configuration. Apart from the default configuration, the system provides a variety of configuration methods so that you can change the default configuration of the system as necessary.

1.1.2 Principles

1. Basic Concepts

- Operating mode of power supply

  The power supply can operate in one of the following two modes: non-redundancy mode and N+M redundancy mode.

  - Non-redundancy mode: It is also called the superposition mode. The power supply operates in non-redundancy mode by default. In this mode, the total power of the system is the sum of power of all power modules.
  - N+M redundancy mode: The system has N+M power modules in total, where M indicates the number of configured redundant power modules and N indicates the number of available power modules of the system. The total power of the system is the sum of output power of the N power modules.

- Power supply priority

  The power supply priorities of cards refer to the power-on/off priorities of the cards. A card with a higher power supply priority is powered on earlier, and powered off later. When the system power is insufficient and thus some line cards need to be powered off, a line card with the lowest priority is powered off first. The default power supply priorities of the cards are as follows: supervisor module > FE card > VSL card > line card. If the cards are of the same type, a card with a smaller slot ID has a higher priority. You can change the power supply priorities of the line cards only. The power supply priority of a line card ranges from 1 to 16, where 1 indicates the lowest priority and 16 the highest priority.

- Operating modes of fans

  A fan tray on a chassis device normally operates in one of the following three modes:

  - Normal mode: It is the default operating mode. The fans initially run at intermediate speed. As the ambient temperature changes, the rotating speed of the fans automatically decreases or increases to achieve the best heat dissipation effect.
  - Quiet mode: The fans initially run at relatively low speed. As the ambient temperature changes, the

rotating speed of the fans automatically decreases or increases. In this mode, the rotating speed of the fans is lower than that of a fan in normal mode. Therefore, in quiet mode, fans' noise is further reduced.

- User-defined mode: In this mode, users define the rotating speed of the fans and the rotating speed of all the fan trays is the same (user-defined value). The rotating speed of the fans can be set to seven levels.

Note

In Virtual Switching Unit (VSU) mode, the fans in two chassis operate in the same working mode.

- Temperature threshold

  During temperature monitoring, if the temperature reaches a certain threshold, the system takes a corresponding action. For example, if the temperature reaches an alarm threshold, the system generates a Syslog alarm. If the temperature reaches a hazard threshold, the corresponding card is powered off.

2. Power Monitoring

A device supports multiple power modules. However, different types of power modules cannot be mixed. When a power supply is inserted, the system identifies this power supply and checks whether it conflicts with the original power supply type. If yes, a power supply with a lower power is selected. The alarm indicator turns yellow and a log alarm is generated. After the power supply is removed, the abnormality is cleared and the system restores to normal.

3. Power Redundancy

You can implement redundancy of power supplies in the chassis by configuring power redundancy. As the standby power supply, the redundant power supplies are not involved in system power allocation to avoid in-service power supply failures. When setting the power supply to the redundancy mode, you need to specify the number of redundant power supplies.

After the N+M redundancy mode is configured, the system automatically monitors the redundant power supplies. As the system continuously operates or a card or power supply is removed or inserted, the remaining system power changes. The redundancy mode configured by you may fail to meet the normal power supply needs of the system. In redundancy mode, when the remaining system power is insufficient, the system alarm indicator turns yellow. In this case, you need to modify power redundancy configuration.

Caution

- When the power modules are mixed, they cannot work in redundancy mode.
- When the specified number of redundant power modules is equal to or greater than the number of available power modules, the redundancy configuration fails.
- The maximum number of redundant power modules is the remaining system power divided by the power of a single power supply. If the system determines that redundancy will result in insufficient remaining system power (exceeding the maximum allowed value), the redundancy configuration fails.

4. Manual Power-on/off of Cards

You can manually power off/on a specified card by running a power command.

- When a card is in power-on status, you can run the **power off** command to power off the card.
- When a card is in power-off status, you can run the **power on** command to power on the card.

Caution

- The device hardware boasts the power-on protection function. When the temperature of a card exceeds 50°C, the card cannot be powered on and a notification indicates card power-on failure.
- The active supervisor module of the chassis cannot be manually powered off. If you attempt to specify a card as the active supervisor module of the chassis, a notification is displayed. In VSU mode, the local active supervisor modules in two chassis cannot be manually powered off.
- When the supervisor module of a chassis is reset, the cards that are powered off by running the **power off** command can be powered on again.

5. Intelligent Speed Adjustment of Fans

When the fans work in normal or quiet or energy-saving mode, the rotating speed is automatically adjusted as the temperature changes.

The system automatically specifies a default start rotating speed for the fans based on the current operating mode of the fans. As the ambient temperature rises or drops, the fans automatically raise or reduce their rotating speed to dissipate heat and ensure that the noise is low.

The system provides a user-defined mode to ensure that all the fans operate at a user-specified rotating speed. In user-defined mode, the rotating speed of fans is fixed and not adjusted as the ambient temperature changes. Therefore, the normal mode or quiet mode is recommended so that the rotating speed of fans will automatically change as the temperature changes to best protect the device from a fault due to over-temperature.

6. Intelligent Temperature Monitoring

The active supervisor module monitors the temperature of all cards and notifies users of temperature change when the CA system runs normally.

The system defines three types of temperature, including supervisor module temperature, CPU temperature and media access controller (MAC) temperature, and two temperature thresholds, namely, alarm threshold and hazard threshold. Only hazard thresholds are defined for the CPU temperature and MAC temperature. In intelligent monitoring mode, the system monitors the temperature of all cards every two minutes. When the system discovers that the temperature of a card reaches or exceeds the alarm threshold, the active supervisor module generates a Syslog message and the alarm indicator on the panel turns yellow. If the temperature of a card reaches or exceeds the hazard threshold, the active supervisor module generates a Syslog message. The alarm indicator on the panel turns red.

Warning

The active supervisor module of the chassis or the global active supervisor module in VSU mode generates a Syslog message when discovering that its temperature exceeds the hazard threshold. At the same time, the alarm indicator on the panel turns red. However, the active supervisor module or global active supervisor module will not be automatically powered off. In this case, you need to take effective actions to cool the active supervisor module or manually remove it for cooling.

1.2 Configuration Task Summary

The intelligent monitoring configuration includes the following tasks: All the configuration tasks below are optional. Select the configuration tasks as required.

- Configuring the Operating Mode of Power Supply
- Configuring Power-on/off of Line Cards
- Configuring the Operating Mode of Fans
- Configuring Temperature Thresholds

1.3 Configuring the Operating Mode of Power Supply

1.3.1 Overview

This function can be used to configure power redundancy mode and specify the number of redundant power modules. The energy-saving mode can be enabled for a power supply to reduce power consumption and save energy.

1.3.2 Restrictions and Guidelines

- When power supplies are mixed, power redundancy cannot be configured.
- When the system power is insufficient, power redundancy configuration fails.
- In VSU mode, power redundancy cannot be configured when the chassis is not added to a stack.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure power redundancy.

VSU mode:

power redundancy [**switch** *device-id*] *power-redunancy* **enable**

Standalone mode:

power redundancy *power-redunancy* **enable**

The power redundancy mode is not enabled by default.

1.4 Configuring Power-on/off of Line Cards

1.4.1 Overview

This function can be used to power on/off a specified card.

1.4.2 Restrictions and Guidelines

Users cannot specify the active supervisor module of a chassis to power it off, including local active supervisor modules of two chassis in VSU mode.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Power on or off the specified card.

power { **on** | **off** } [**switch** *device-id*] **slot** *slot-id*

(3) Enter the global configuration mode.

configure terminal

(4) Configure the power supply priority of a line card.

power priority [**switch** *device-id*] { **save** | **slot** *slot-id priority* }

The default power-on/off priorities of the cards are as follows: supervisor module > FE card > VSL card > line card. For the line cards and FE cards, a card with a smaller slot ID has a higher priority.

(5) Specify a card to power it on/off.

power { **on** | **off** } [**switch** *device-id*] **slot** *slot-id*

1.5 Configuring the Operating Mode of Fans

1.5.1 Overview

This function can be used to adjust operating mode of fans based on needs.

1.5.2 Restrictions and Guidelines

The fans switch to energy-saving mode automatically after it is enabled. The energy-saving mode must be disabled before the fans are switched back to other operating modes, including normal, quiet and user-defined modes.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the operating mode of fans.

fan mode { **normal** | **quiet** | **defined** [**speed-level** *level*] }

The fans work in normal mode by default.

1.6 Configuring Temperature Thresholds

1.6.1 Overview

This function can be used to modify the default alarm thresholds and hazard thresholds of temperature.

1.6.2 Restrictions and Guidelines

- Temperature thresholds are set based on chassis configuration. All line cards of a chassis share the same set of thresholds.
- When the set temperature thresholds exceed the allowed values, the threshold settings are invalid.

- When the set alarm thresholds are excessively low, the system frequently generates alarm logs.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure temperature thresholds of cards.

threshold set temperature [**switch** *device-id*] { **board** *temperature* | **board shutdown** *temperature* | **cpu shutdown** *temperature* | **mac shutdown** *temperature* }

By default, the alarm threshold of the supervisor module is 56℃ and the hazard threshold is 80℃. No alarm thresholds are defined for the CPU and MAC, but the hazard thresholds are 100°C.

1.7 Monitoring

Run the **show** command to display the configuration.

Run the **clear** command to clear information.

Caution

During device operation, running the **clear** command may cause service interruption due to key information loss.

Table 1-1 Monitoring

Command	Purpose
show card voltage	Displays the voltage and voltage thresholds of cards.
show fan [[[*device-id*] *fan-id*] **detail** | **version**]	Displays fan information.
show temperature	Displays line card information such as current temperature and temperature thresholds.
show power [**priority** | **version**]	Displays power information about line cards and respective power supply priorities.
show power fault	Displays information about power module failures.
show power temperature	Displays the temperature of cards.
show power voltage	Displays the voltage of the power module.
show temperature	Displays the card temperature and thresholds.
show temperature history	Displays historical temperature information about cards.

Command	Purpose
clear temperature-history	Clears historical temperature records of cards.

1 Configuring Intelligent Component Monitoring

1.1 Introduction

1.1.1 Overview

Hardware Diagnostics Function (HDF) is used to monitor status of hardware components on the device in real time. Network devices are made up of various semiconductor chips and components. After the devices run for a long period, components may experience functional failures due to factors such as the environment, external forces, and aging, which affects normal services. You can configure HDF to query the status of hardware components on the device in real time and automatically reports faults by using alarm notifications, Trap messages, and Syslog records.

1.1.2 Principles

Based on the idea of logical diagnostic nodes, HDF adopts unified logical diagnostic nodes for anomaly detection on hardware components, implementing various functions such as node management, detection mechanism, diagnostic analysis, self-healing actions, and log alarms.

The master nodes classified based on hardware component types include the CPU, storage, electromechanical module, logic module, Double Data Rate (DDR) Synchronous Dynamic Random Access Memory (SDRAM), interface optical module, and MAC switching chip. HDF supports splitting diagnostic items by using subnodes and provides management capabilities for diagnostic objects in three levels.

The functions provided by HDF are as follows:

- Enabling diagnostics/configuring the diagnostic period: You can enable HDF and configure the diagnostic period based on your service diagnostics requirements.
- Displaying the status of diagnostic objects: You can view the device hardware status, faulty component status, hardware status of specified slots, and diagnostic subnodes and items of slots.
- Single execution of all diagnostic nodes and items: HDF supports a single real-time execution of all enabled diagnostic nodes and items based on specific scenario requirements.

1.2 Restrictions and Guidelines

- The running environment of HDF includes a supervisor module, a line card, and a switch fabric module. When you configure HDF, ensure that the related components run properly.
- A diagnostic node dynamically registers for a card in the system. In this case, the information of some diagnostic nodes may fail to be queried instantly.

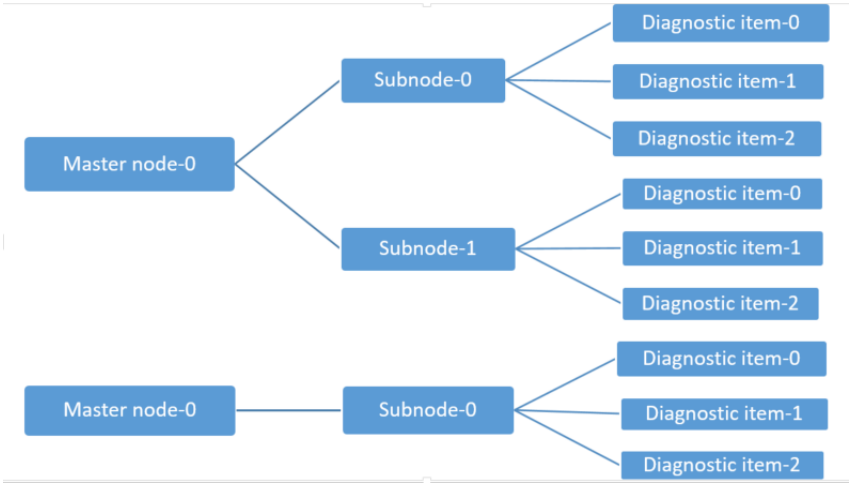
1.3 Configuration Task Summary

HDF configuration includes the following tasks:

(1) Configuring Basic Functions

(2) Configuring Single Real-time Diagnostics

(3) (Optional) Configuring the HDF Alarm Function



(4) (Optional) Configuring HDF Diagnostic Period

1.4 Configuring Basic Functions

1.4.1 Overview

You can perform management using HDF by configuring the diagnostic function on logical diagnostic nodes. Figure 1-1 shows the node management logic of HDF:

Figure 1-1 HDF Node Management

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the HDF function. All the following configuration steps are optional. Perform the configuration steps as needed.

- Enable the HDF function for a card.

  hdf enable { **all** | **slot** *slot-id* }

  The HDF function is enabled for a single card by default.

- Enable the HDF function for the master node of a card.

  hdf enable slot *slot-id* **main-node** *name*

  The HDF function is enabled for the master node by default.

- Enable the HDF function for the subnode of a card.

  hdf enable slot *slot-id* **main-node** *name* **child-node** *name*

  The HDF function is enabled for the subnode by default.

- Enable the HDF function for specific diagnostic items of a card.

hdf enable slot *slot-id* [**main-node** *name* [**child-node** *name* [**item** *item-id*]]]

The HDF function is enabled for node diagnostic items by default.

1.5 Configuring Single Real-time Diagnostics

1.5.1 Overview

The diagnostics period of different components of a card vary. By default, a round-robin HDF diagnostics is performed for each item periodically. You can configure single real-time diagnostics in special scenarios. For example, you require that the status of a device and all diagnostic items are checked in real-time for troubleshooting the device during initial setup.

1.5.2 Restrictions and Guidelines

After you configure the single real-time diagnostics function, real-time diagnostics is performed for all enabled diagnostic nodes and diagnostic items of a card. You must enable diagnostic nodes and diagnostic items through commands before you perform real-time diagnostics.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Configure single real-time diagnostics for a card.

hdf once-run slot *slot-id*

After you configure this function, real-time diagnostics is performed for all enabled diagnostic nodes and diagnostic items of the card. You can run the **show hdf** command to display the diagnostic result.

1.6 Configuring the HDF Alarm Function

1.6.1 Overview

You can configure the HDF alarm function so that alarm logs are displayed when faults are detected by specific diagnostic items of a card.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the HDF alarm function for a card.

hdf alarm enable slot *slot-id* **main-node** *name* **child-node** *name* **item** *item-id*

The HDF alarm function is enabled for diagnostic items by default.

1.7 Configuring HDF Diagnostic Period

1.7.1 Overview

You can dynamically adjust the diagnostic period of diagnostic subnodes using Command Line Interface (CLI), which helps meet service diagnostics requirements.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the period of a node diagnostic item.

hdf set cycle slot *slot-id* **main-node** *name* **child-node** *name* **time** *cycle-number*

The default periods of node diagnostic items are the initialization values in service code.

1.8 Monitoring

Run the **show** command to check the information about the device hardware status.

Table 1-1 Monitoring

Command	Purpose
show hdf all	Displays the status of the hardware components of the device.
show hdf fault	Displays the status of the faulty hardware components of the device.
show hdf slot *slot-id* [**fault**]	Displays the status of the hardware components of a specific slot.
show hdf detail-info slot *slot-id* **main-node** *name* **child-node** *name* [**item** *item-id*]	Displays the status information about the diagnostic subnodes or diagnostic items of a slot.

1 Configuring Storage Resource Monitoring

1.1 Description

1.1.1 Overview

Resource monitoring (RESMON) is a service that monitors storage system resources in network communication devices.

By monitoring the storage system resources, the device can generate an alarm when a storage system resource exception occurs, which can prevent system down due to exceptions.

The following five types of storage system resource information is monitored:

- Lifetime of the storage system
- Capacity of storage system partitions
- Read-only information of storage system partitions
- I/O rate of the storage system, including the storage media I/O rate and process I/O rate
- I/O write volume information of the storage system

1.1.2 Principles

The RESMON module detects storage system information periodically and determines whether the configured threshold is exceeded. If so, the RESMON module sends an alarm.

1. Monitoring the Lifetime of the Storage System

The main sources of the lifetime information of the storage system are as follows:

- The statistics are collected when the kernel calls the media to perform erase and write operations on the interface information.
- The register of the storage medium stores the status information of the medium, including the number of erase and write operations and the lifetime information.
- The device samples and analyzes the data at the specified interval to obtain the device lifetime information.

2. Monitoring the Capacity Information of Storage System Partitions

In each sampling interval, the partition capacity information is calculated based on the usage of each partition in the partition list.

3. Monitoring the Read-only Status Information of the File System in the Storage Partition

In each sampling period, the device uses the writing and reading detection method to detect information about the reading and writing status of each partition in the partition list, including the reading and writing status of the partition and whether the status is normal.

4. Monitoring I/O Rates of the Storage System

I/O information monitoring is divided into storage medium I/O information monitoring and process I/O information monitoring of the storage system.

In the sampling interval, the system parses the /proc/diskstats file to obtain disk I/O information, and then obtains process I/O information from the kernel through NETLINK.

5. Monitoring the I/O Write Volume of the Storage System

The I/O data collected by the kernel can be obtained, filtered, and counted to calculate the write volume information. Then, the monitoring threshold for a unit period can be calculated based on the expected lifetime, the number of erase and write operations performed by the storage medium, and the capacity of the storage medium.

1.2 Configuration Task Summary

Resource monitoring configuration includes the following tasks. All the tasks are optional. Select the tasks as needed.

- Configuring the Device to Monitor Storage System Lifetime
- Configuring the Device to Monitor the Capacity of Storage System Partitions
- Configuring the Device to Monitor the Reading and Writing Status of Storage System Partitions
- Configuring the Device to Monitor I/O Rates of the Storage System
- Configuring the Device to Monitor the I/O Write Volume of the Storage System
- Configuring the Resource Monitoring Alarm Function
- Configuring Periodic Monitoring of I/O Information of Normal Processes

1.3 Configuring the Device to Monitor Storage System Lifetime

1.3.1 Overview

This technology monitors the lifetime of the storage system.

1.3.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the sampling interval and upper threshold for monitoring the storage system lifetime for all in-service devices in a cluster.

storage lifetime set { **interval** *interval-value* [**threshold** *threshold-value*] | **threshold** *threshold-value* }

By default, the sampling interval is 60 seconds, and the upper threshold is 5%.

1.4 Configuring the Device to Monitor the Capacity of Storage System Partitions

1.4.1 Overview

This technology monitors the capacity of storage system partitions.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the sampling frequency and threshold for monitoring the partition capacity of the storage system on the in-position member device in a CSS.

storage capacity set { **interval** *interval-value* [**threshold** *threshold-value*] | **threshold** *threshold-value* }

By default, the sampling interval of storage system partition capacity monitoring is 30 seconds, and the usage threshold is 80%.

1.5 Configuring the Device to Monitor the Reading and Writing Status of Storage System Partitions

1.5.1 Overview

This technology monitors the reading and writing status of storage system partitions.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the sampling interval for monitoring the reading and writing information of the storage system partitions for all the in-service member devices in a cluster.

storage ro set interval *interval-value*

By default, the sampling interval for monitoring the reading and writing information of the storage system partition is 30 seconds.

1.6 Configuring the Device to Monitor I/O Rates of the Storage System

1.6.1 Overview

This technology monitors I/O rates of the storage system.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the sampling interval and alarm upper threshold for monitoring I/O information of the storage systems on the in-service member devices in a cluster.

storage io set { **interval** *interval-value* [threshold *threshold-value*] | **threshold** *threshold-value* }

By default, the sampling interval for monitoring I/O information of the storage system is 10 seconds, and the upper threshold is 50%.

1.7 Configuring the Device to Monitor the I/O Write Volume of the Storage System

1.7.1 Overview

You can configure the device to monitor the I/O write volume of the storage system processes.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the sampling interval and the threshold for monitoring the I/O write volume of the storage system of the in-position member device in a CSS.

storage period set { **interval** *interval-value* [**threshold** *threshold-value*] | **threshold** *threshold-value* }

By default, the sampling intervals are 1 hour, 1 day, and 1 week, and the upper threshold is dynamically calculated based on the storage memory.

1.8 Configuring the Resource Monitoring Alarm Function

1.8.1 Overview

You can enable or disable the resource monitoring alarm function.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configuring the resource monitoring alarm function for in-service member devices in a cluster.

storage alarm set mode *switch*

By default, the resource monitoring alarm function is disabled.

1.9 Configuring Periodic Monitoring of I/O Information of Normal Processes

1.9.1 Overview

You can enable or disable the function of periodically monitoring I/O information of a normal process.

1.9.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the function of periodically monitoring I/O information of normal processes in the storage system for in-service member devices in a cluster.

storage process set mode *switch*

By default, the function of periodically monitoring I/O information of normal processes in the storage system is disabled.

1.10 Monitoring

Run the **show** command to check the configuration.

Run the **debug** command to output debugging information.

Caution

Debugging occupies system resources, so disable it immediately if not required.

Table 1-1 Monitoring

Command	Purpose
show storage all-info	Displays the information about the storage system on all in-service devices in a cluster.
show storage capacity	Displays the partition capacity information of the storage system on all in-service devices in a cluster.
show storage capacity set	Displays the configuration of the partition capacity monitoring of the storage system on all in-service devices in a cluster.
show storage io	Displays the I/O information of the storage system on all in-service devices in a cluster.
show storage io set	Displays the I/O monitoring configuration of the storage system on all in-service devices in a cluster.

Command	Purpose
show storage lifetime	Displays the lifetime information of the storage system on all in-service devices in a cluster.
show storage lifetime set	Displays the lifetime monitoring configuration of the storage system on all in-service devices in a cluster.
show storage period set	Displays the configuration of the I/O write volume monitoring for the storage system on all in-service devices in a cluster.
show storage process set	Displays the periodic monitoring configuration of I/O information of all normal processes of the storage system on all in-service devices in a cluster.
show storage ro	Displays the reading and writing status information of the system storage partitions of all in-service devices in a cluster.
show storage ro set	Displays the configuration of the partition I/O status monitoring of the storage system on all in-service devices in a cluster.

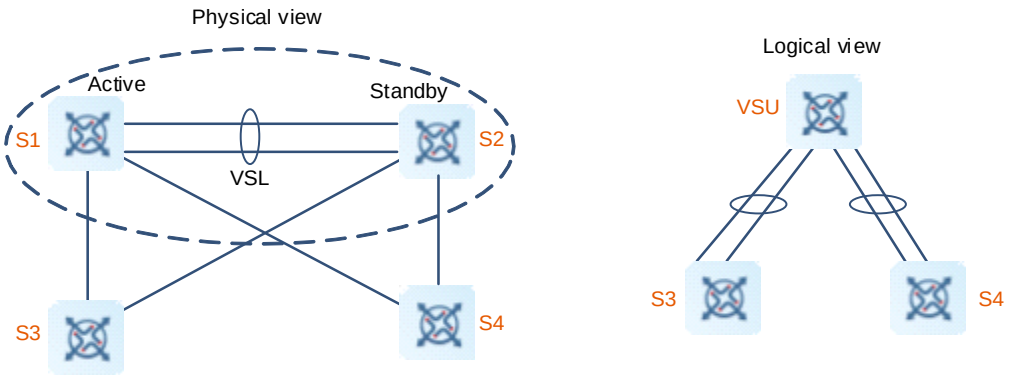
1 Configuring VSU



1.1 Introduction

Virtual Switching Unit (VSU) is an N:1 network device technology independently developed by Ruijie. It simplifies the device operation & maintenance (O&M) and network topology by virtualizing multiple network devices into a single logical device for management and use. In addition, the VSU technology connects peripherals to different member devices in the VSU through aggregated links to achieve cross-device link redundancy and improve reliability and scalability of networks.

1.1.1 Basic Concepts

As shown in Figure 1-1, the left part shows the physical view of devices that form a VSU, which is equivalent to one logical device.

Figure 1-1 Schematic Diagram of VSU

1. VSU

The VSU is a single logic entity composed of multiple redundant devices in a conventional network structure. The devices on the access layer, the distribution layer, and the core layer can form the VSU.

2. Domain ID

A domain ID is the unique identifier of a VSU and distinguishes different VSUs. Only two devices that share the same domain ID can compose a VSU.

3. Device ID

Each device in a VSU is called a member device, and each member device has a unique device ID, i.e. switch ID. This device ID is used to manage the member device and configure interfaces on the member device. When adding the device to a VSU, you need to configure an ID for a device and ensure that the ID is unique in the same VSU. If device IDs of member devices conflict in a VSU, only one device is retained according to rules.

4. Device priority

Priority is an attribute of a member device, and is used to elect a role. A higher priority indicates a higher probability of being elected as the active device. To elect a device as the active device, increase its priority. Member devices have two types of priorities.

- Configuration priority: priority stored in the configuration file, which is changed at any time, and takes effect after the configurations are saved and the VSU is restarted.
- Running priority: configuration priority stored in the configuration file at the startup, which does not change during VSU running.

5. Device role

Member devices are assigned with three roles based on their functions:

- Active device: Manages and controls the entire VSU. Only one active device exists in a VSU domain.
- Standby device: Serves as a backup of the active device and participates in data forwarding only. All received data packets are forwarded to the global active device for processing. When the active device is faulty, the standby device automatically switches to the active mode and takes over functions of the original active device.
- Candidate device: Serves as a backup of the standby device and participates in data forwarding only. When the standby device is faulty, the system automatically elects a new standby device from candidate devices to take over functions of the original standby device. When the active device is faulty and the standby device switches to the active mode, the system automatically elects a new standby device from candidate devices.

6. Role election

A VSU is composed of at least the active device and standby device. When it is composed of more than two devices, the other devices are candidate devices. Role election applies to the following scenarios:

- VSU setup
- Device fault or exit from a VSU
- VSU splitting
- VSU combination

Roles are elected based on the following rules:

- The active device is elected by priority. The device priorities are ranked as follows:

  Current active device (no active device exists upon startup) > Device with a higher priority > Device with a smaller ID > Device with a smaller MAC address
- A device directly connected to the active device is preferentially elected as the standby device to avoid dual active devices. The device priorities are ranked as follows:

  Device directly connected to the active device > Device with a higher priority > Device with a smaller MAC address

Note

- When a device joins an existing VSU in hot mode, the system does not switch between the active and standby roles, even if the device has a higher priority than the active and standby devices in the running VSU.
- The startup sequence of member devices may affect the election of the active device. A member device may not join the VSU in time due to slow startup (the current VSU directly converges if it does not discover

a neighbor within 5 minutes). In this case, the member device joins the VSU in hot mode, and the system does not switch active/standby role even if the member device has a higher priority than the active device in the current VSU.

- A candidate device is elected as a standby device only.

---

7. Virtual switching link

The VSU is a network entity of multiple devices that need to share control information and data flows. Virtual Switching Link (VSL) is a special link used to transmit control information and data flows between the devices in the VSU. Figure 1-1 shows the locations of VSLs in the VSU.

A VSL usually exists in the form of aggregation port group, and a data flow transmitted by the VSL is load-balanced among the aggregation port members based on a traffic balancing algorithm.

- VSL traffic

Control flows transmitted by the VSL between devices are classified into the following two types:

- Protocol packets received by a member device, which are forwarded through the VSL to the global active device for processing.
- Protocol packets processed by the global active device, which are forwarded through the VSL to the interfaces of other member devices and then sent to the peer devices by these interfaces.

The data flows transmitted through the VSL between devices include:

- Flooding data flows in a VLAN
- Data flows that need to be forwarded across devices and transmitted through the VSL

A VSL also transmits internal management packets of the VSU, for example, protocol information of hot backup devices, and packets that carry configurations to be delivered from the active device to other member devices.

- CRC error detection of VSL port

When a VSL port has many consecutive Cyclic Redundancy Check (CRC) errors, disable this port and switch to another VSL port. CRC errors are handled according to the following rules:

- The VSL port is checked for CRC errors every 5 seconds by default. If the number of CRC errors incremented between one check and the latest check is greater than the threshold of CRC errors (the *error-number* parameter), one CRC error occurrence is counted.
- When the number of consecutive CRC errors exceeds the configured number (the *time-number* parameter), the port is abnormal.
- If there are multiple VSLs and CRC errors occur in only one link, VSL is switched. If there are multiple VSL links and CRC errors occur in the last normal VSL, the link is not switched to prevent topology splitting.
- The values of *error-number* and *time-number* vary with the scenario. The default values of *error-number* and *time-number* are **3** and **10** respectively. In scenarios with high tolerance for CRC errors, reduce the two recommended parameter values; otherwise, increase them.

- VSL recovery

By default, a device automatically restarts and joins the VSU again after a VSL fault is rectified. If the automatic restart function is disabled, you must enable this function or directly restart the device after the VSL fault is rectified to rebuild the VSU.

1.1.2 VSU Application

Compared with conventional networks, VSU has the following advantages:

- Low cost: lightweight and dynamic network capacity expansion for protecting the equipment investment in the existing network, and reducing the construction cost.
- Simple O&M: reduced management workload, simplified networking, and lowered O&M difficulty.
- High reliability: device and link redundancy mechanisms for improved network reliability.

1. Flexible expansion

Capacity expansion applies to the following scenarios:

- Port expansion: The port density of the existing access device cannot meet the requirement of increasing access users, as shown in Figure 1-2.
- Forwarding capacity expansion: The forwarding capacity of the existing core switch cannot meet the requirement of increasing services, as shown in Figure 1-3.
- Bandwidth expansion: The uplink bandwidth cannot meet the demand in peak hours, as shown in Figure 1-4.

The above problems are solved by adding a device to form a VSU with the original device. Physically, the two devices seem to be one, and the original device backs up and sends the current configurations in batches to the new device. Therefore, this change has little impact on network planning and configuration. The VSU features the following:

- Higher port density: The VSU forwards data as a whole, and the new device is equivalent to a port expansion card of the original device to increase port density.
- Higher forwarding capacity: If one device has a forwarding capacity of 14,400 Mpps, the entire VSU has a forwarding capacity of 28800 Mpps after one device is added.
- Larger bandwidth: If a 1000 M device needs to perform 10 G uplink connection but provides only two 10G ports, up to 20 Gbps uplink bandwidth is supported. By adding one switch of the same type to set up a VSU, you can configure four 10 G ports into one aggregation group to increase the uplink bandwidth to 40 Gbps.

Figure 1-2 Port Expansion over VSU

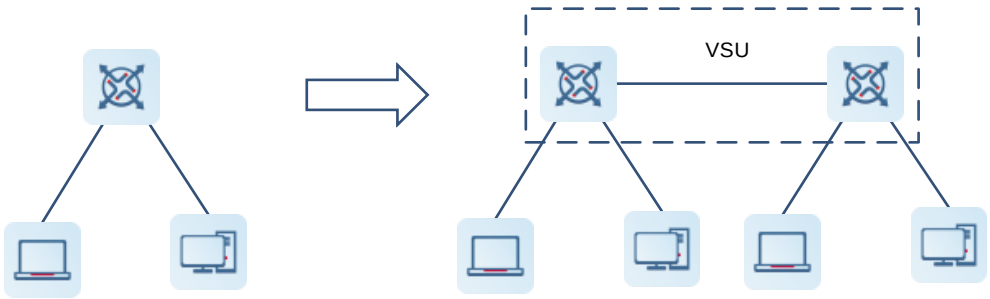


Figure 1-3 Forwarding Capacity Expansion over VSU

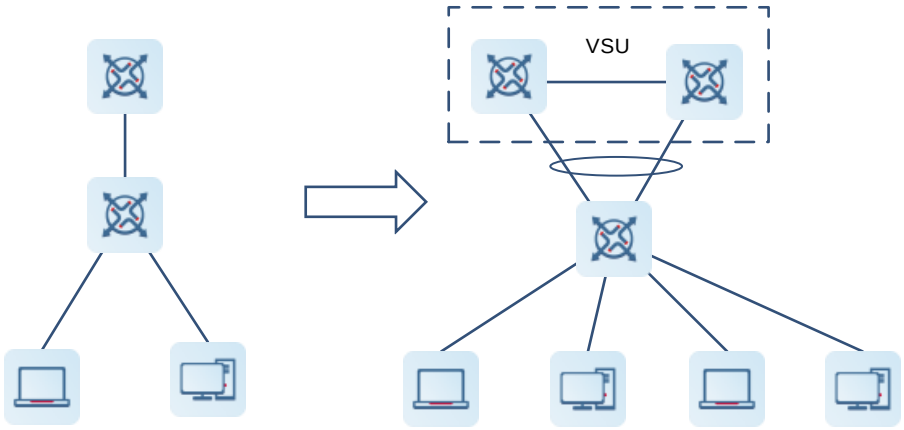

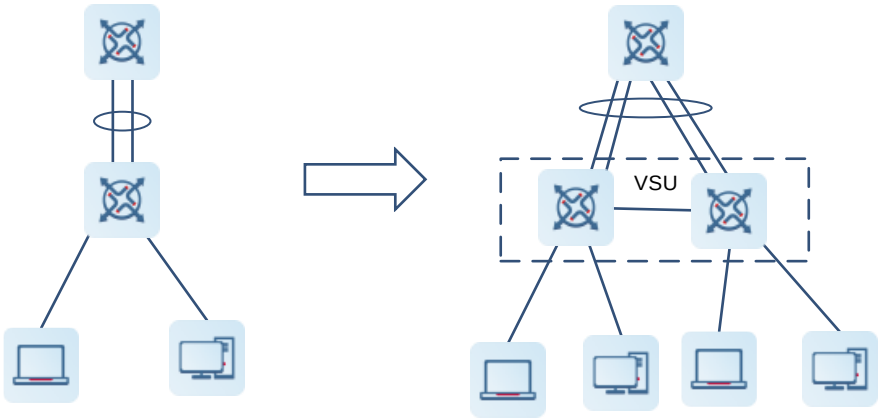

Figure 1-4 Bandwidth Expansion over VSU

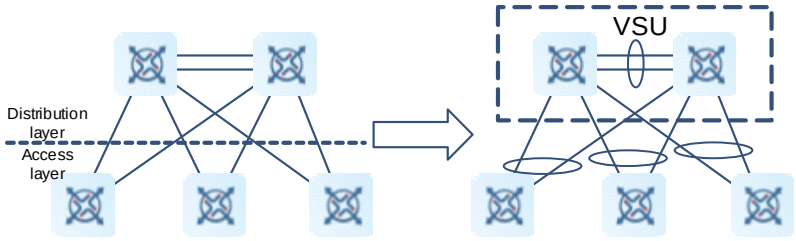


2. Simplified management

Simplified management is reflected in the following aspects:

- Device: After multiple devices form a VSU, an administrator can manage them together, without connecting to them for separate configuration and management. If a VSU is deployed between two floors/buildings, only one distribution device is needed between the floors/buildings, and this reduces the management and O&M costs.
- Networking: Figure 1-5 shows a common networking mode. Typically, each access device is connected to two distribution devices to improve network reliability. The entire network topology is complex and has a loop. You also have to enable protocols such as Multiple Spanning Tree Protocol (MSTP) and Virtual Router Redundancy Protocol (VRRP) to eliminate the loop and support gateway backup. To meet the traffic balancing requirement, multi-loop network technologies such as Ethernet ring protection switching (ERPS) also need to be enabled. As a result, the configuration is complex, and the maintenance is difficult and prone to errors. After a VSU is formed, MSTP, VRRP, and ERPS are not required. Only the common link aggregation function can balance traffic, eliminate loops, and provide cross-device link redundancy, thus simplifying the topology and making deployment easier.

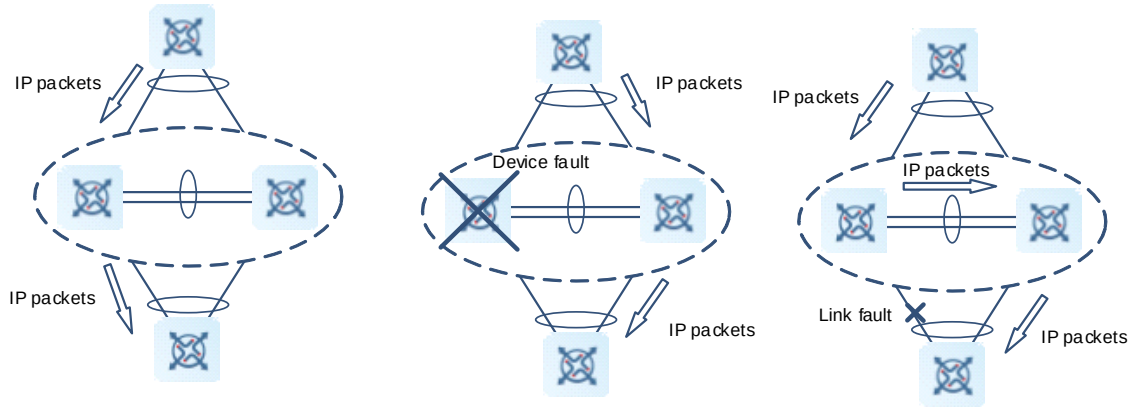
Figure 1-5 Simplified Networking over VSU

3. Hot backup

As shown in Figure 1-6, two devices form a VSU to provide the following redundancy to adapt to high reliability scenarios:

- Device redundancy: redundancy between member devices in the VSU. Failure of the standby device does not affect the entire system, but failure of the active device makes the system switch to the standby device. This switching is similar to the dual-engine switching of a standalone device. Such switching is completed within milliseconds, without interrupting services (TCP flows rely on the retransmission mechanism to ensure service continuity).
- Link redundancy: A switch connects to surrounding devices through aggregated links, which provides cross-device link redundancy, implements load balancing, and fully utilizes all bandwidth. If one member link fails, the system switches to another member link within milliseconds.

Figure 1-6 Hot Backup over VSU



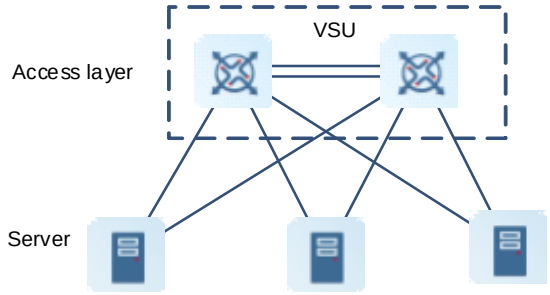


Figure 1-7 shows the typical application scenarios. Access servers with high availability requirements are connected with devices on the access layer by binding multiple network interface cards of a single server into an aggregation port. As the aggregation port allows access to only one access device, the risk of failure of the single device increases. In this case, setting up a VSU enables the server to connect to member devices in the VSU over the aggregation port. This deployment prevents network interruption caused by the single point of failure of the access device or the failure of a single link, and improves network reliability of services carried by the server.

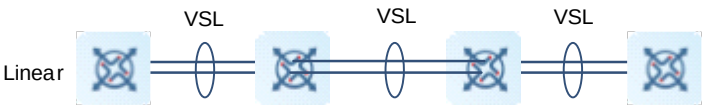
Figure 1-7 Server Access Link Redundancy



1.1.3 VSU Topology

A VSU supports linear topology and ring topology.

1. Linear topology

As shown in Figure 1-8, devices are connected through a VSL to form a line, and this topology is therefore called linear topology. The linear topology is simple. It uses a few ports and cables. Two devices are connected with a communication link only. Therefore, the VSL is less reliable.

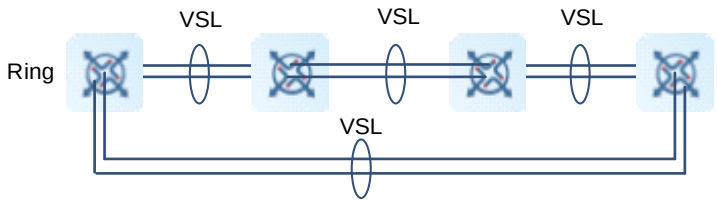


Figure 1-8 Linear Topology

2. Ring topology

In the ring topology shown in Figure 1-9, the two communication links backed up by each other form link redundancy, which improves the reliability of the VSU.

Figure 1-9 Ring Topology

Note

- The ring topology is recommended for the VSU, to ensure that the failure of any single device or any single VSL link does not affect the normal operation of the entire VSU.
- Besides, you are advised to configure multiple VSLs to improve reliability. You are advised to configure at least two VSLs, and to deploy VSLs across line cards for chassis devices

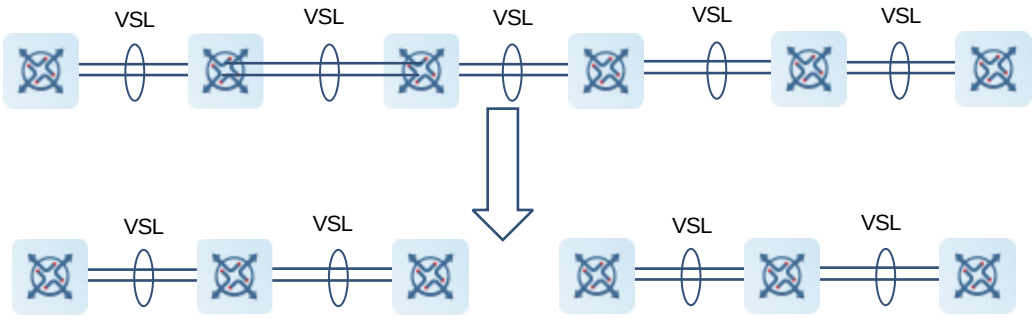
3. Topology convergence

During setup of the VSU, the management scope is determined through topology convergence. The process is as follows:

(1) The member devices discover their neighbors through a topology discovery protocol to determine the list of devices included in the VSU.

(2) The global active device is elected to manage the entire VSU.

(3) The global standby device is elected as the backup for the active device.



Note

The startup time varies with a device, and the first topology convergence time is different accordingly.

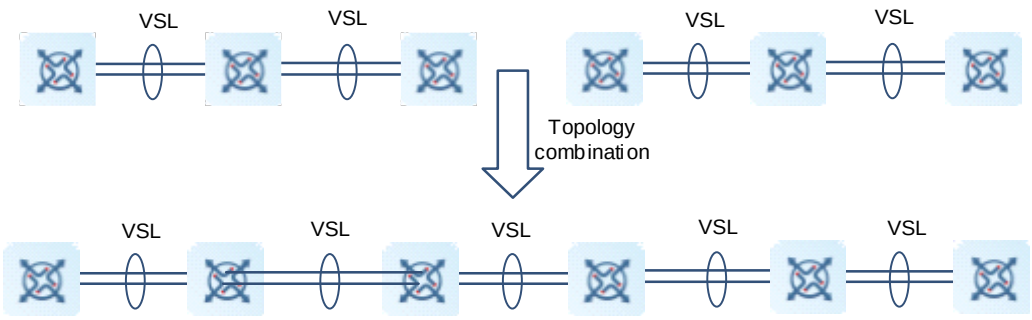
4. Topology splitting

The linear topology is split if the Virtual Switching Link-aggregation port (VSL-AP) link is disconnected. As shown in Figure 1-10, the VSU is split into two groups. In this case, there are two devices with the same configurations on the network, causing the network to malfunction. This topology splitting is resolved by deploying the dual-active detection (DAD) function (see section 1.1.4 DAD).

Figure 1-10 Topology Splitting

5. Topology combination

Topologies are combined when two VSUs with the same VSU domain ID are connected through a VSL-AP link. During topology combination, one of the VSUs automatically restarts in an attempt to join the other VSU, as shown in Figure 1-11.



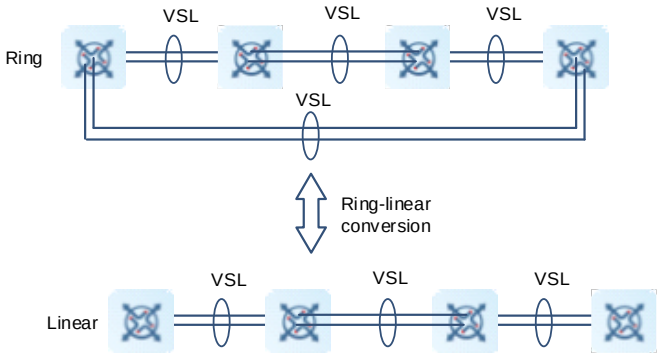
Topologies are combined based on the principle of minimizing the service impact caused by topology combination. The topology combination rules are as follows (topology combination starts from the first rule; if the optimal topology is not selected according to the first rule, the system goes on with the next rule for judgment):

(1) The user configurations are superior to other configurations. A VSU member device with the highest priority prevails.

(2) If the active device cannot be determined according to the preceding rule, a device with a smaller device ID prevails (in a case with two global active devices).

(3) If the active device cannot be determined according to the preceding rule, a device with a smaller MAC address prevails (in a case with two global active devices).

Figure 1-11 Topology Combination



Note

During topology combination of two VSUs, they must be elected. The VSU that fails the election automatically restarts and joins the other VSU in hot mode.

6. Topology conversion

As shown in Figure 1-12, when one VSL-AP link is disconnected, the ring topology is converted into a linear one. The whole VSU can still run normally without network disconnection. However, to avoid the failure of other VSL-AP links or nodes, troubleshoot the VSL fault in time for VSL recovery. After the VSL-AP link is recovered, the linear topology is converted back into a ring one.

Figure 1-12 Topology of Ring-Linear Conversion

1.1.4 DAD

When the VSL is disconnected, the standby device becomes the active device. If the original active device is still running, two active devices are main roles and an IP address conflict and other problems occur in the LAN due to their same configurations. In this case, the VSU must detect dual device devices, and take recovery measures. The VSU supports DAD in two ways:

- Bidirectional forwarding detection-based (BFD-based) DAD
- AP-based DAD

1. Detection rules

Determine the desired active device according to the following rules one by one:

(1) The healthier device prevails. (A greater sum of bandwidths of up physical ports excluding the administration port and VSL port indicates a healthier device).

(2) The global active device with a higher priority prevails.

(3) The global active device in the VSU with more physical devices prevails.

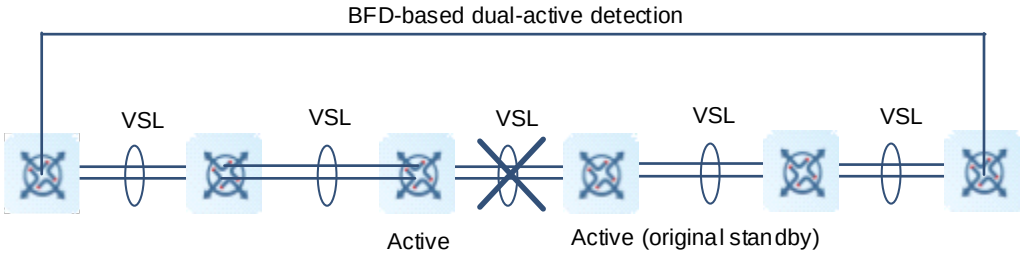
(4) The global active device with the smaller ID prevails.

(5) The global active device with the smaller MAC address prevails.

(6) The global active device with the longer startup time prevails.

Caution

If DAD is not configured, the network is interrupted after the topology is split.



2. Keepalive Timer

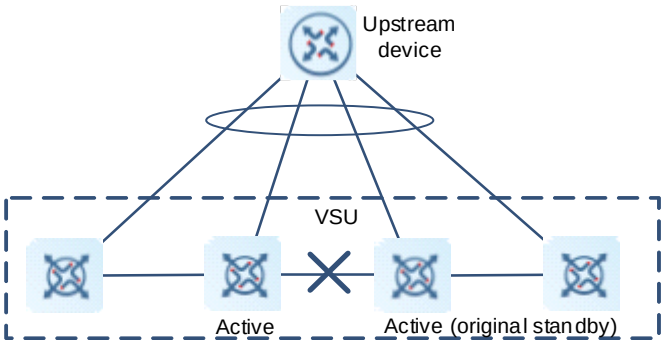
To detect the link status of dual hosts, you can configure the Keepalive Timer. When it is detected that the link is deactivated and exceeds the keepalive interval, the dual host detection protocol will become invalid and dual host detection cannot be performed.

3. BFD-based DAD

The VSU supports the BFD-based DAD function. Figure 1-13 shows the connection topology. A dedicated link for DAD is added between two edge devices. When the VSL between the global active and standby devices is disconnected, two active devices coexist. If the BFD-based DAD function is configured, the two active devices send BFD-based DAD packets to each other through the BFD link, and find two identical active devices. Finally, the VSU including one of the active devices is shut down based on rules (see "Topology combination" for details) to enter the Recovery mode to avoid network exceptions.

Figure 1-13 BFD-based DAD

Caution



- When there is only one pair of BFD links, you are advised to deploy them at both ends of the topology.
- Extended BFD is used for the BFD-based detection, and the DAD ports cannot be configured by the existing BFD configurations and display commands.

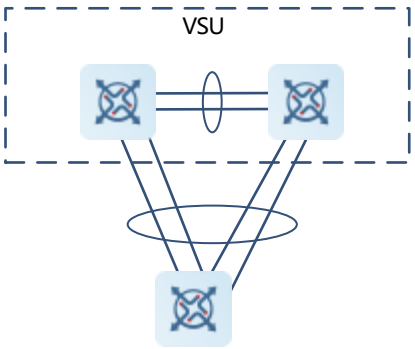
4. AP-based DAD

The VSU also supports the AP-based DAD mechanism. Figure 1-14 shows the connection topology. The VSU and the upstream device must support the AP-based DAD function. When the VSL port is disconnected, dual

active devices coexist and send detection packets to each AP member port. The upstream device forwards the detection packets from one active device to the other. The AP is composed of four member ports, which are connected to different devices in the VSU. When the topology is split, the four member ports all send and receive detection packets, and find two identical active devices. Finally, the VSU including one of the active devices is shut down based on rules (see "Topology combination" for details) to enter the Recovery mode to avoid network exceptions.

Figure 1-14 AP-based DAD

Specification



In the preceding topology, the upstream device must be a Ruijie device and can forward detection packets.

1.1.5 Traffic Forwarding

1. Cross-device Aggregation

An AP binds multiple physical links to form a logical link. The VSU supports an AP across member devices. As shown in Figure 1-15, two devices form a VSU and switch A is connected to the VSU as an AP. For switch A, the AP connections shown in the figure are equivalent to those of a common AP group.

Figure 1-15 Cross-device AP

A peripheral device is physically connected to each device in the VSU when a cross-device AP is configured. The advantages are as follows:

- Reserved bandwidth for the VSL: For cross-device AP traffic, the AP member of the same device is preferentially selected as the traffic egress, to avoid unnecessary traffic from being transmitted over the VSL.

- Improved network reliability: If a chassis fails, a member port on a normal device still works properly.

Table 1-1 lists the possible cross-device AP faults and their impact:

Table 1-1 Cross-device AP Faults and Principle Description

Fault Scenario		Principle Description
Link fault	A single link of the AP is faulty.	The cross-device AP redistributes traffic among the remaining normal links. A VSL is needed to forward traffic whose egress port is a port on the device with the faulty link.
	All links of the AP are faulty.	The AP state changes to link down just as a common AP is disconnected.
Device fault	The active device is faulty.	The original standby device is switched to the active device. Member ports on other member devices continue to work properly The cross-device AP redistributes traffic among the remaining normal links.
	The standby/candidate device is faulty.	The AP member ink connected to the member device is disconnected but other member links still work properly. The cross-device AP redistributes traffic among the remaining normal links.

2. Traffic balancing

In a VSU, traffic may have multiple egresses. The AP and Equal-cost Multi-path Routing (ECMP) have respective traffic balancing algorithms, for example, traffic is balanced based on the source and destination MAC addresses. For details, see the description about the link AP module in the interface configuration guide. In this configuration guide, packets received by the local device are preferentially forwarded by the local device. In this way, packets are forwarded to other devices not through a VSL.

1.1.6 System Management

1. Console access

The console of the VSU active device manages multiple devices in the system. The consoles of the standby and candidate devices do not support command line input. However, you can configure VSU-related commands on the active device for a specified member device, or log in to the console of the active device through the serial port of the standby device. You can also redirect to the master supervisor module of a device by running the **session** command.

2. Line card naming

For chassis-type devices in VSU mode, device ID (switch ID) is added to the ID (name) of a line card. That is, the line card ID changes from 1-dimensional to 2-dimensional. For example, line card 1/1 represents the line card in slot 1 on a member device with the ID of 1.

3. Interface naming

In VSU mode, the same slot ID may appear on multiple devices. Therefore, device ID (switch ID) is added to an interface name. For example, Tengigabitethernet 1/0/1 indicates 10G port 1 in slot 1 of a device with the ID of 1; Tengigabitethernet 2/0/2 indicates 10G port 2 in slot 1 of a device with the ID of 2.

4. Access to the file system

In VSU mode, you can access to the file systems on other member devices from the active device. The detailed access method is the same as that of the local file system. The only difference lies in URL prefixes.

5. Log management

All member devices of the VSU can display syslogs. Syslogs generated by the active device are displayed on the console of the active device, and their format is identical to that of syslogs displayed in standalone mode. Syslogs of other member devices are also displayed on the console of the active device, but their format is different from that of syslogs in standalone mode, because the device ID is added to the syslogs. For example, a syslog generated in standalone mode is "%VSU-5-DTM_TOPO_CVG: Node discovery done. Topology converged." Accordingly, a syslog generated by a member device with the device ID of 3 is "%VSU-5-DTM_TOPO_CVG:(3) Node discovery done. Topology converged."

1.1.7 System Upgrade

Usually, the main program versions of member devices in the VSU need to be consistent. But if such numerous member devices are upgraded one by one in standalone mode, this consumes much time and effort, and easily causes errors. The VSU offers a comprehensive system upgrade solution below:

- Check the main program versions of all member devices to determine whether the versions are consistent.
- If inconsistency is identified, the VSU synchronizes the main program of the active device to all member devices via Trivial File Transfer Protocol.

1.2 Restrictions and Guidelines

- VSU member devices must use the same software version.
- The port rates at both ends of a VSL must be the same.
- For a 40G/100G port, its split member ports (four 10G ports or four 25G ports) cannot be configured as VSL member ports.
- You are advised to configure the highest-rate interface on a device as the VSL interface to prevent the VSL from being disconnected due to over-high traffic.
- When the Switched Port Analyzer (SPAN) function is configured, a VSL port is used as neither the source port nor the destination port of SPAN.
- The configuration range of *switch-id* varies with product versions. If you update the device from a version with a large value range for *switch-id* to a version with a smaller value range for *switch-id*, the VSU configuration that involves the *switch-id* change may be lost. For example, originally, the value of *switch-id*

can be set to the range of 1 to 6. After the device is updated, the value of *switch-id* can be set to the range of 1 to 4. The values 5 and 6 of *switch-id* become invalid. During device update, pay attention to the value range of *switch-id*. For more information, see restriction manual of the corresponding version.

Table 1-2 VSU Setup Guide

Series	Model	Number of Ports Supporting VSL	VSL Port Rate Limit	Max. Number of VSLs	Max. Number of VSU Members	Description of Mixing Different Models in a VSU
RG-CS88 series	CS88-08	-	-	32 (VSL built on different line cards)	2	Devices of the same model: Supervisor modules of the same model support VSU.
	CS88-48GT-H line card	Not supported		-	-	-
	CM88-48SFP-H line card	Not supported				
	CM88-48XS-H line card	1~48	The VSL port must use the original rate, and cannot be configured with rate decrease or rate auto-negotiation			
	CM88-8CQ-H line card	1~8				

1.3 Configuration Task Summary

The VSU configuration includes the following tasks:

(1) Setting Up a VSU

(2) Configuring BFD-based DAD

(3) (Optional) Configuring AP-based DAD

(4) Configuring the VSL

(5) (Optional) Configuring VSU Attributes

All the following configuration tasks are optional and maybe selected as needed.

- Configuring Basic VSU Attributes
- Configuring Traffic Balancing
- Switching to Standalone Mode

- Configuring Recovery Method for Recovery Mode

(6) (Optional) Configuring the Management Interface Creation Mode

1.4 Setting Up a VSU

Caution

Switching the work mode of the device will cause the device to restart. Perform this operation after evaluating the affected service scope.

1.4.1 Overview

Devices start up in standalone mode by default. You need to configure the same domain ID on all devices used to set up a VSU, and assign a unique virtual machine ID for each device.

1.4.2 Restrictions and Guidelines

- If the current device works in VSU mode and cannot directly switch to another VSU domain, first switch to standalone mode and then to another VSU.
- The VSU configurations are applicable to a single physical device, and the configurations are stored in the special configuration file **config_vsu.dat**. Therefore, the **show running-config** command does not display the VSU configurations. You can display the current VSU configurations by running the **show switch virtual config** command only.
- In standalone mode, the VSU running information is blank. When you run the **show switch virtual**, a prompt is displayed, indicating that the device works in standalone mode and there is no VSU running information.

1.4.3 Prerequisites

The VSL between VSU devices is normal.

1.4.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the VSU domain ID and enter the VSU domain configuration mode.

switch virtual domain *domain-id*

The default domain ID is 100.

Only devices with the same domain ID can form a VSU.

(4) Configure the device ID of the VSU.

switch *switch-id*

The default device ID is 1.

(5) (Optional) Configure the device priority.

switch *switch-id* **priority** *priority-number*

The default device priority is 100. A larger value indicates a higher priority.

(6) (Optional) Configure the device alias.

switch *switch-id* **description** *device-name*

No device alias is configured by default.

(7) (Optional) Specify the manner of saving the VSU configuration file of a device.

switch cfg_mode { **normal** | **single** }

normal is selected by default. That is, the VSU configurations are separately saved in **config_vsu.dat**.

(8) Return to the global configuration mode.

exit

(9) Enter the VSL interface configuration mode.

vsl-port

(10) Add the member ports to the VSL.

port-member interface *interface-type interface-number*

No member port is configured by default.

The VSL member port is a two-dimensional port in standalone mode. The port type depends on the actual product version.

(11) Return to the privileged EXEC mode.

end

(12) Switch the device from the standalone mode to the VSU mode.

switch convert mode virtual

A device works in standalone mode by default.

1.5 Configuring BFD-based DAD

1.5.1 Overview

The BFD-based DAD is configured to prevent coexistence of two active devices.

1.5.2 Restrictions and Guidelines

- BFD detection ports must be direct physical routed ports in different devices.
- The configured port type is unlimited. DAD links are used to transmit only BFD packets and thus need less traffic. Therefore, you are advised to configure a 1000M or 100M port as the DAD port.
- After a Layer 3 (L3) port configured for DAD is switched to a Layer 2 (L2) port (by running the **switchport** command on the port), the BFD DAD configuration is automatically cleared.
- You are advised to directly connect only the active and standby devices in BFD mode.
- When the VSUs detect a dual-active conflict and one VSU enters the **Recovery** mode, you can rectify the fault by eliminating the VSL failure rather than by directly resetting the VSU in the **Recovery** mode. Otherwise, a dual-active conflict may be incurred in the network.
- Excluded ports in **Recovery** mode must be routed ports rather than VSL ports. After an excluded port is

switched from a Layer-3 port to a Layer-2 port (by running the **switchport** command on the port), the excluded port configuration associated with this port is automatically cleared.

- When dual active devices are detected, one of them must enter the **Recovery** mode. In **Recovery** mode, all service ports of the device must be disabled. To ensure normal use of certain special ports (for example, management ports for remote login to devices), you can configure excluded ports that are not disabled in Recovery mode.

1.5.3 Prerequisites

A VSU has been set up.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the Layer 2 Ethernet interface configuration mode.

interface *interface-type interface-number*

(4) Configure the BFD detection port as a Layer 3 Ethernet interface.

no switchport

A port is a Layer 2 Ethernet interface by default.

(5) Return to the global configuration mode.

exit

(6) Enter the VSU domain configuration mode.

switch virtual domain *domain-id*

(7) Enable the DAD function and specify the BFD-based detection method.

dual-active detection bfd

The DAD function is disabled by default.

(8) Configure a BFD detection port.

dual-active bfd interface *interface-type interface-number*

No BFD detection port is configured by default.

(9) (Optional) Configure the list of excluded ports for Recovery mode.

dual-active exclude interface *interface-type interface-number*

No excluded port is configured by default.

(10) (Optional) Configure the host detection link keepalive interval.

dual-active keepalive *interval*

By default, the dual-active link detection keepalive interval is 30 seconds.

1.6 Configuring AP-based DAD

1.6.1 Overview

The AP-based DAD method is configured to prevent coexistence of two active devices.

1.6.2 Restrictions and Guidelines

- When the VSUs detect a dual-active conflict and one VSU enters the **Recovery** mode, you can rectify the fault by eliminating the VSL failure rather than by directly resetting the VSU in the **Recovery** mode. Otherwise, a dual-active conflict may be incurred in the network.
- Excluded ports for the **Recovery** mode must be routed ports rather than VSL ports. After an excluded port is switched from a Layer 3 port to a Layer 2 port (by running the **switchport** command on the port), the excluded port configuration associated with this port is automatically cleared.

1.6.3 Prerequisites

A VSU has been set up.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the VSU domain configuration mode.

switch virtual domain *domain-id*

(4) Enable the DAD function and specify the AP-based detection method.

dual-active detection aggregateport

The DAD function is disabled by default.

(5) Configure an AP-based detection port.

dual-active interface *interface-type interface-number* [**vlan** *vlan-id*]

No AP-based detection port is configured by default.

When the aggregated port is a trunk port and the native VLAN is beyond the VLAN range allowed by the AP-based detection port, configure a detection VLAN for the AP-based detection port. The configured VLAN must fall in the VLAN range allowed by the trunk port, and be created on the device in advance.

(6) (Optional) Configure the list of excluded ports for Recovery mode.

dual-active exclude interface *interface-type interface-number*

No excluded port is configured by default.

When dual active devices are detected, one of them must enter the **Recovery** mode. In **Recovery** mode, all service ports of the device must be disabled. To ensure normal use of certain special ports (for example, management ports for remote login to devices), you can configure excluded ports that are not disabled in **Recovery** mode.

(7) (Optional) Configure the host detection link keepalive interval.

dual-active keepalive *interval*

By default, the dual-active link detection keepalive interval is 30 seconds.

(8) In link aggregation mode of the upstream and downstream devices, enable the function of forwarding aggregate interface-based DAD packets.

a Enter the Layer 2 aggregate interface configuration mode or Layer 3 aggregate interface configuration mode.

interface aggregateport *interface-number*

b Enable the function of forwarding aggregate interface-based DAD packets.

dad relay enable

The DAD packets are not forwarded by default.

1.7 Configuring the VSL

1.7.1 Overview

To modify a VSL member port (switch to or back from a common port, or add or delete a VSL) during setup or running of a VSU, you can log in to the VSU console through a serial port or Telnet.

1.7.2 Restrictions and Guidelines

- In practice, dynamic negotiation is used by the VSL AP to prevent link connection faults. A VSL port pool is first configured, and all VSL ports of the same member device are added to the same AP after negotiation. Ports connected to the same device are in the same AP.
- During VSU running, configured VSL member links take effect immediately. VSL ports need to be configured on all devices.
- To prevent a loop from being instantaneously generated when a VSL member port exits the VSL AP, the system automatically sets the member port to the **shutdown** state when you run the configuration command. After the VSL member port exits the VSL AP, you can reconnect the link and run the **no shutdown** command to enable the port again. When you configure the VSL port, the system runs the **shutdown** command to shut down the port first. If the configuration fails and you need to continue using the port as a common port, you can run the **no shutdown** command to enable the port again. An added member port ID must be three-dimensional.
- If a port is configured as an NLB reflex port, this port can be switched to a VSL member port only after the NLB reflex port configuration is deleted.
- If the VSU topology is split when a VSL port is switched to a common port, the VSL port must not be deleted. You can disconnect the physical port before deleting the VSL port.

1.7.3 Prerequisites

A VSU has been set up.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the VSL interface configuration mode.

vsl-port

(4) Add the member ports for the VSL.

port-member interface *interface-type interface-number*

No VSL member port is configured by default.

See Figure 1-12 VSU Setup Guide for details about the type of a VSL member port.

1.8 Configuring VSU Attributes

1.8.1 Overview

In VSU mode, you can configure enhancements to increase the reliability and usability of the VSU.

1.8.2 Configuration Tasks

The VSU attribute configuration includes the following tasks:

All the following configuration tasks are optional and may be selected as needed.

- Configuring Basic VSU Attributes
- Configuring the VSL
- Configuring Traffic Balancing
- Switching to Standalone Mode
- Configuring Recovery Method for Recovery Mode

1.8.3 Configuring Basic VSU Attributes

1. Overview

During VSU setup or running, you can log in to the console of the active or standby device of the VSU to modify some parameters.

2. Restrictions and Guidelines

All configuration commands take effect only after the device is restarted, except the device alias modification command, which takes effect immediately.

3. Prerequisites

A VSU has been set up.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the VSU domain configuration mode.

switch virtual domain *domain-id*

(4) Configure the basic VSU attributes as required.

- Modify the VSU domain ID of a specified device.

  switch *switch-id* **domain** *new-domain-id*

  The default VSU domain ID is 100.

- Modify the ID of the specified device.

  switch *switch-id* **renumber** *new-switch-id* [**force**]

  The default device ID is 1.

- Modify the priority of the specified device.

  switch *switch-id* **priority** *priority-number*

  The default device priority is 100.

- Modify the alias of the specified device.

  switch *switch-id* **description** *device-name*

  No device alias is configured by default.

- Set the CRC error parameter.

  switch crc errors *error-number* **times** *time-number*

  By default, one CRC error occurrence is recorded if the number of CRC errors incremented between two checks is 3 or more. If 10 consecutive CRC error occurrences is recorded, the port is considered abnormal.

- Specify the manner of saving the VSU configuration file of a device.

  switch cfg_mode { **normal** | **single** }

  normal is selected by default. That is, the VSU configurations are separately saved in **config_vsu.dat**.

1.8.4 Configuring Traffic Balancing

1. Overview

In the VSU, if egresses are distributed on multiple devices, traffic balancing allows forwarding traffic preferentially on the local device.

2. Restrictions and Guidelines

- By default, AP-based and ECMP-based Local Forward First (LFF) are enabled.
- In VSU mode, the cross-device AP-based LFF and ECMP-based LFF over Layer 3 ports are enabled by default. To set up a VSU with Layer 3 switches, you are advised to configure the AP-based load balancing based on IP addresses (**src-ip**, **dst-ip**, and **src-dst-ip**).

3. Prerequisites

A VSU has been set up.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the VSU domain configuration mode.

switch virtual domain *domain-id*

(4) Disable the AP-based LFF.

no switch virtual aggregateport-lff enable

In VSU mode, the aggregated port-based LFF is enabled by default.

(5) Disable the ECMP-based LFF.

no switch virtual ecmp-lff enable

In VSU mode, the ECMP-based LFF is enabled by default.

1.8.5 Switching to Standalone Mode

1. Overview

This function switches devices in a VSU to the standalone mode.

2. Restrictions and Guidelines

You can switch devices in a VSU to the standalone mode by using a saved standalone configuration file, or by clearing the VSU configuration.

3. Prerequisites

A VSU has been set up.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Switch a device to the standalone mode.

switch convert mode standalone [*switch-id*]

A device works in standalone mode by default.

switch-id is valid only in the VSU mode.

1.8.6 Configuring Recovery Method for Recovery Mode

1. Overview

This function disables the automatic restart function for the Recovery mode.

2. Restrictions and Guidelines

If the automatic restart function is disabled, you must enable this function again or manually restart the device to recover the device in recovery mode.

3. Prerequisites

A VSU has been set up.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the VSU domain configuration mode.

switch virtual domain *domain-id*

(4) Disable the automatic restart function for the **Recovery** mode.

no recovery auto-restart enable

By default, the automatic restart function is enabled for the Recovery mode after the link fault is rectified.

1.9 Configuring the Management Interface Creation Mode

1.9.1 Overview

You can configure the management interface creation mode, to create a global management interface or to create a management interface for each member device, in a VSU environment as required. The default mode is to create a management interface for each VSU member device. If the mode is configured to create a global management interface, the management interface configurations on all member devices are consistent. When the global management interface link is **Up**, it indicates that at least one physical management interface link of a member device is **Up**. When the global management interface link is **Down**, it indicates that the physical management interfaces of all member devices are **Down**.

1.9.2 Restrictions and Guidelines

- This command takes effect only after you run the **write** command to save the configuration and restart the device.
- This command is available only in VSU mode.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the management interface creation mode of VSU devices to create a global management interface.

mgmt_mode unique

The management interface creation mode of VSU devices is **normal** by default; that is, a management interface will be created for each VSU member device.

(4) Return to the privileged EXEC mode.

end

(5) Save the global configuration.

write

(6) Restart the VSU device.

reload

1.10 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-3 VSU Monitoring

Command	Purpose
show dad ap-port	Displays information about the DAD aggregate interface.
show dad bfd-port	Displays information about the BFD-enabled DAD interface.
show dad exclude-port	Displays the excluded interface for DAD.
show dad global-var	Displays variable information for DAD.
show dad relay-port	Displays information about the DAD forwarding interface.
show mgmt_mode	Displays the management interface creation mode of the VSU device.
show switch id	Displays the ID of the current device.
show switch virtual [**balance** | **config** | **role** | **topology**]	Views the topology, configurations, roles, and forwarding and balancing policies of the running VSU.
show switch virtual dual-active { **aggregateport** | **bfd** | **summary** }	Displays the information about the current DAD.
show switch virtual link [**port**]	Displays the information about the current VSL.
show vsl-dp app port *switch-id*	Displays VSL interface information.
show vsl-dp app sw *switch- id*	Displays device information of the VSL.
show web-api virtual info [**device-id** *device-id*]**show mgmt_mode**	Displays the VSU configuration provided for the web.
show web-api virtual vsl-ports [**device-id** *device-id*]	Displays the configurable VSL interface information provided for the web.

1.11 Configuration Examples

1.11.1 Setting Up a VSU

1. Requirements

As shown in **Figure 1-16**, connect Device A to Device B through two 10G cables to form a VSU with basic configurations.

2. Topology

Figure 1-16 Topology of a VSU

3. Notes

- Configure the domain ID, device ID, device priority, device name, and VSL ports for the VSU.
- Configure the VSU switching mode.

4. Procedure

(1) On Device A, set the domain ID to 100, device ID to 1, device priority to 200, VSU device name to Device A, and VSL ports to tenGigabitEthernet 0/1 and tenGigabitEthernet 0/2.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# switch virtual domain 100
DeviceA(config-vs-domain)# switch 1
DeviceA(config-vs-domain)# switch 1 priority 200
DeviceA(config-vs-domain)# switch 1 description DeviceA
DeviceA(config-vs-domain)# switch crc errors 10 times 20
DeviceA(config-vs-domain))# exit
DeviceA(config)# vsl-port
DeviceA(config-vsl-port)# port-member interface tenGigabitEthernet 0/1
DeviceA(config-vsl-port)# port-member interface tenGigabitEthernet 0/2
DeviceA(config)# exit
DeviceA# switch convert mode virtual
```

(2) On Device B, set the domain ID to 100, device ID to 2, device priority to 100, VSU device name to Device B, and VSL ports to tenGigabitEthernet 0/1 and tenGigabitEthernet 0/2.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# switch virtual domain 100
DeviceB(config-vs-domain)# switch 2
DeviceB(config-vs-domain)# switch 2 priority 100
DeviceB(config-vs-domain)# switch 2 description DeviceB
DeviceB(config-vs-domain)# switch crc errors 10 times 20
DeviceB(config-vs-domain))# exit
DeviceB(config)# vsl-port
DeviceB(config-vsl-port)# port-member interface tenGigabitEthernet 0/1
DeviceB(config-vsl-port)# port-member interface tenGigabitEthernet 0/2
DeviceB(config-vsl-port)# exit
DeviceB# switch convert mode virtual
```

5. Verification

(1) Run the **show switch virtual role** command to verify whether the role of Device A is **Active** and that of Device B is **Standby**. If yes, the VSU is setup; if not, the VSU fails to be setup.

```
DeviceA# show switch virtual role
Switch_id    Domain_id    Priority    Position    Status    Role
Description
1(1)         100(100)     200(200)    LOCAL       OK        ACTIVE       DeviceA
2(2)         100(100)     100(100)    REMOTE      OK        STANDBY      DeviceB
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
switch virtual domain 100
!
switch 1
switch 1 priority 200
switch 1 description DeviceA
switch crc errors 10 times 20
!
port-member interface TenGigabitEthernet 0/1
port-member interface TenGigabitEthernet 0/2
!
switch convert mode virtual
!
end
```

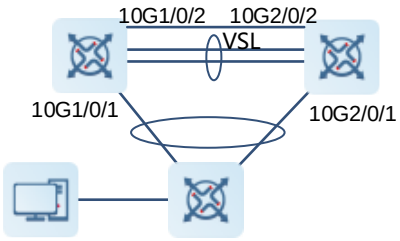
- Device B configuration file

```
hostname DeviceB
!
switch virtual domain 100
!
switch 2
switch 2 priority 100
switch 2 description DeviceB
switch crc errors 10 times 20
!
port-member interface TenGigabitEthernet 0/1
port-member interface TenGigabitEthernet 0/2
!
switch convert mode virtual
!
end
```

7. Common Errors

- Different VSU domain IDs (**domain-id**) are configured.

- The VSL ports are not up.



1.11.2 Configuring BFD-based DAD

1. Requirements

As shown in Figure 1-17, Device A and Device B form a VSU. To prevent an IP address conflict in the LAN caused by two identical active devices in case of VSL disconnection, configure the BFD-based detection mechanism to quickly detect two active devices and to actively switch one of them to the Recovery mode (the service forwarding function is disabled).

Topology

Figure 1-17 Topology for BFD-based DAD

2. Notes

- Enable the BFD-based DAD.
- Designate a BFD detection port, which must be configured as a Layer 3 port.

Note

As Device A and Device B form the VSU, the preceding configuration can be performed on either Device A or Device B. Device A is used as an example.

3. Procedure

On Device A, configure TenGigabitEthernet 1/0/2 and TenGigabitEthernet 2/0/2 as routed ports, enable the BFD-based DAD, and set the BFD-based detection ports to TenGigabitEthernet 1/0/2 and TenGigabitEthernet 2/0/2.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface TenGigabitEthernet 1/0/2
DeviceA(config-if-TenGigabitEthernet 1/0/2)# no switchport
DeviceA(config-if-TenGigabitEthernet 1/0/2)# exit
DeviceA(config)# interface TenGigabitEthernet 2/0/2
DeviceA(config-if-TenGigabitEthernet 2/0/2)# no switchport
DeviceA(config-if-TenGigabitEthernet 2/0/2)# exit
DeviceA(config)# switch virtual domain 1
DeviceA(config-vs-domain)# dual-active detection bfd
DeviceA(config-vs-domain)# dual-active bfd interface TenGigabitEthernet 1/0/2
DeviceA(config-vs-domain)# dual-active bfd interface TenGigabitEthernet 2/0/2
```

4. Verification

Disconnect all VSLs, log in to the console of Device A, and run the **show switch virtual** command to check whether **Status** is set to **OK** (Device A runs normally when dual active devices are detected).

```
DeviceA# show switch virtual
Switch_id    Domain_id    Priority    Position    Status    Role
Description
-------------------------------------------------------------------------------
---------
1(1)         1(1)         100(100)    LOCAL       OK        ACTIVE       DeviceA
```

Log in to the console of Device A, and run the **show switch virtual dual-active bfd** command to check whether the BFD enabling status is **Yes** and the status of the BFD-based detection port TenGigabitEthernet 2/0/2 of Device B is **Down**.

```
DeviceB# show switch virtual dual-active bfd
BFD dual-active detection enabled: Yes
BFD dual-active interface configured:
  TenGigabitEthernet 1/0/2: UP
  TenGigabitEthernet 2/0/2: DOWN
```

Log in to the console of Device B, and run the **show switch virtual** command to check whether the value of **Status** changes to **Recovery** and the device name is suffixed with **-RECOVERY-2**.

```
DeviceB# show switch virtual
Switch_id    Domain_id    Priority    Position    Status    Role
Description
-------------------------------------------------------------------------------
----------
2(2)         1(1)          90(90)     LOCAL       Recovery  ACTIVE       DeviceB
```

Log in to the console of Device B, and run the **show switch virtual dual-active summary** command to check whether the value of **In dual-active recovery mode** is **Yes** (Device B works in recovery mode).

```
DeviceB# show switch virtual dual-active summary
BFD dual-active detection enabled: Yes
Aggregateport dual-active detection enabled: No
Interfaces excluded from shutdown in recovery mode:
In dual-active recovery mode: Yes
```

5. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface TenGigabitEthernet 1/0/2
 no switchport
!
interface TenGigabitEthernet 2/0/2
 no switchport
!
switch virtual domain 1
```

```
dual-active detection bfd
dual-active bfd interface TenGigabitEthernet 1/0/2
dual-active bfd interface TenGigabitEthernet 2/0/2
!
switch 1
switch 1 priority 100
switch 1 description DeviceA
switch crc errors 10 times 20
!
port-member interface TenGigabitEthernet 0/1
port-member interface TenGigabitEthernet 0/2
!
switch convert mode virtual
!

end
```

- Device B configuration file

```
hostname DeviceB
!
interface TenGigabitEthernet 1/0/2
 no switchport
!
interface TenGigabitEthernet 2/0/2
 no switchport
!
switch virtual domain 1
dual-active detection bfd
dual-active bfd interface TenGigabitEthernet 1/0/2

!
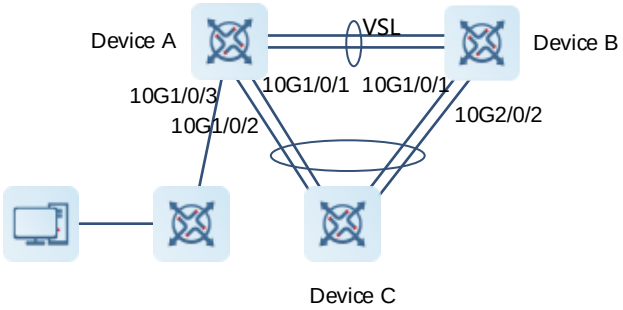
port-member interface TenGigabitEthernet 0/1
port-member interface TenGigabitEthernet 0/2
!
switch convert mode virtual
!
end
```

6. Common Errors

- The BFD-based detection port is not configured as a Layer 3 port.
- Either BFD-based or AP-based DAD is selected.



1.11.3 Configuring AP-based DAD

1. Requirements

As shown in **Figure 1-18**, Device A and Device B form a VSU, and Device C is connected to Device A and Device B separately over an AP. To prevent an IP address conflict in the LAN caused by two identical active devices in case of VSL disconnection, configure the AP-based detection mechanism to quickly detect two active devices and to actively switch one of them to the Recovery mode (the service forwarding function is disabled).

2. Topology

Figure 1-18 Topology for AP-based DAD

3. Notes

- Configure the ports connecting Device C to Device A and Device C to Device B as the same AP group.
- Enable the AP-based DAD.
- Configure the AP-based detection port.
- Configure the ports connecting Device C to Device A and Device B as the same AP group. Enable the function of forwarding AP-based DAD packets of this port group.

Note

As Device A and Device B form the VSU, the preceding configuration can be performed on either Device A or Device B. Device A is used as an example.

4. Procedure

On Device A, add TenGigabitEthernet 1/0/1, TenGigabitEthernet 1/0/2, TenGigabitEthernet 2/0/1, and TenGigabitEthernet 2/0/2 to the AP group port-group 1.

```
DeviceA> enable
DeviceA# configure
DeviceA(config)# interface range TenGigabitEthernet 1/0/1-2
DeviceA(config-if-range)# port-group 1
DeviceA(config-if-range)# exit
DeviceA(config)# interface range TenGigabitEthernet 2/0/1-2
DeviceA(config-if-range)# port-group 1
```

On Device A, enable the AP-based DAD, and set the detection port to aggregatePort 1.

```
DeviceA> enable
DeviceA# configure
DeviceA(config)# switch virtual domain 1
DeviceA(config-vs-domain)# dual-active detection aggregateport
DeviceA(config-vs-domain)# dual-active interface aggregatePort 1
```

On Device C, add TenGigabitEthernet 0/1, TenGigabitEthernet 0/2, TenGigabitEthernet 0/3 and TenGigabitEthernet 0/4 to the AP group port-group 1.

```
DeviceC> enable
DeviceC# configure
DeviceC(config)# interface range TenGigabitEthernet 0/1-4
DeviceC(config-if-range)# port-group 1
```

On Device C, configure the function of forwarding DAD packets.

```
DeviceC> enable
DeviceC# interface aggregatePort 1
DeviceC(config-if-AggregatePort 1)# dad relay enable
```

5. Verification

Run the **show switch virtual dual-active summary** and **show switch virtual dual-active aggregateport** commands to check whether the configurations are correct.

```
DeviceA# show switch virtual dual-active summary
Aggregateport dual-active detection enabled: Yes
Interfaces excluded from shutdown in recovery mode:
In dual-active recovery mode: NO
DeviceA# show switch virtual dual-active aggregateport
Aggregateport dual-active detection enabled: Yes
Aggregateport dual-active interface configured:
  AggregatePort 1: UP
    TenGigabitEthernet 1/0/1: UP
    TenGigabitEthernet 1/0/2: UP
    TenGigabitEthernet 2/0/1: UP
    TenGigabitEthernet 2/0/2: UP
```

```
DeviceB-RECOVERY-2# show switch virtual dual-active su
BFD dual-active detection enabled: No
Aggregateport dual-active detection enabled: Yes
Interfaces excluded from shutdown in recovery mode:
In dual-active recovery mode: Yes
```

```
DeviceB-RECOVERY-2# show switch virtual
Switch_id   Domain_id    Priority    Position    Status    Role       Description
------------------------------------------------------------------------------
---------
2(2)       100(100)     100(100)     LOCAL      Recovery    ACTIVE
DeviceB-RECOVERY-2
```

```
DeviceB-RECOVERY-2# show switch virtual dual-active aggregateport
Aggregateport dual-active detection enabled: Yes
Aggregateport dual-active interface configured:
  AggregatePort 7: DOWN
    TenGigabitEthernet 1/0/1: DOWN
    TenGigabitEthernet 2/0/1: DOWN
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
interface TenGigabitEthernet 1/0/1
 port-group 1
!
interface TenGigabitEthernet 1/0/2
 port-group 1
!
interface TenGigabitEthernet 2/0/1
 port-group 1
!
interface TenGigabitEthernet 2/0/2
 port-group 1
!
switch virtual domain 1
dual-active detection aggregateport
dual-active interface aggregateport 1
!
switch 1
switch 1 priority 100
switch 1 description DeviceA
switch crc errors 10 times 20
!
port-member interface TenGigabitEthernet 0/1
port-member interface TenGigabitEthernet 0/2
!
switch convert mode virtual
!

end
```

- Device B configuration file

```
hostname DeviceB
!
interface TenGigabitEthernet 1/0/1
 port-group 1
!
```

```
interface TenGigabitEthernet 1/0/2
 port-group 1
!
interface TenGigabitEthernet 2/0/1
 port-group 1
!
interface TenGigabitEthernet 2/0/2
 port-group 1
!
switch virtual domain 1
dual-active detection aggregateport
dual-active interface aggregatePort 1
!
switch 2
switch 2 priority 90
switch 2 description DeviceB
switch crc errors 10 times 20
!
port-member interface TenGigabitEthernet 0/1
port-member interface TenGigabitEthernet 0/2
!
switch convert mode virtual
!

end
```

- Device C configuration file

```
hostname DeviceC
!
interface TemGigabitEthernet 0/1
 port-group 1
!
interface TemGigabitEthernet 0/2
 port-group 1
!
interface TemGigabitEthernet 0/3
 port-group 1
!
interface TemGigabitEthernet 0/4
 port-group 1
!
interface AggregatePort 1
 dad relay enable
!

end
```

7. Common Errors

- The AP detection port must be an aggregated port
- Either AP-based or BFD-based DAD is selected.

1.12 Common Misconfigurations

- The VSL port type is not supported.
- Different domain IDs (**domain-id**) are configured.

1 Configuring Ethernet Interface

1.1 Introduction

Interfaces are important in implementing data switching on network devices. The company's devices support two types of interfaces: physical ports and logical interfaces. A physical port is a hardware port on a device, such as the 100M Ethernet interface and Gigabit Ethernet interface. A logical interface, such as the loopback interface and tunnel interface, can be associated with a physical port or independent of any physical port. For network protocols, physical ports and logical interfaces are processed in the same way.

1.1.1 Interface Classification

- Layer 2 interface

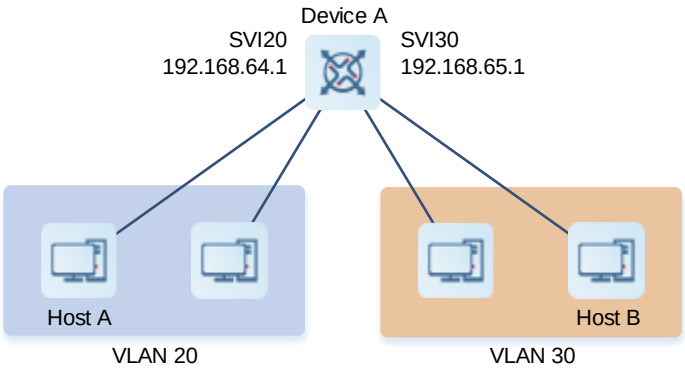
  A Layer 2 interface is a single physical port on a device and implements only the Layer 2 switching function.

- Layer 3 interface

  A physical port on a Layer 3 device can be configured as a Layer 3 interface, which functions as the gateway interface for Layer 3 switching. A Layer 3 interface does not have the Layer 2 switching function or associate with VLANs. Therefore, it can be used only as an access interface.

- Aggregate interface

  An aggregate interface is a logical link that is formed by binding multiple physical ports together. After the physical ports are bound as an aggregate interface, the bandwidths of the physical ports are added up, which expands the link bandwidth. The interfaces that are bound as an aggregate interface must be of the same type, to be specific, all of them are Layer 3 interfaces or Layer 2 interfaces. Packets that pass the aggregate interface can be distributed to the members of the aggregate interface. If a member link of the aggregate interface becomes invalid, the aggregate interface automatically transfers the traffic on this faulty link to other valid member links, improving reliability of connections.



- Switch virtual interface (SVI)

  An SVI acts as a management port of al device, through which the administrator can manage the device. You can also create an SVI as a gateway interface, which is mapped to the virtual interface of a specific virtual local area network (VLAN) to implement routing across VLANs among Layer 3 devices.

  Run the **interface vlan** command to create an SVI and assign an IP address to this interface to set up a route between VLANs.

  As shown in Figure 1-1, the hosts in VLAN 20 can directly communicate with each other without participation of Layer 3 devices. If Host A in VLAN 20 wants to communicate with Host B in VLAN 30, SVI 20 of VLAN 20 and SVI 30 of VLAN 30 must be used.

Figure 1-1 Schematic Diagram of SVI

- Loopback interface

  The loopback interface is a local Layer 3 logical interface simulated by software. The loopback interface is a virtual Ethernet interface that is always in the up state. Packets sent to the loopback interface are processed on the device locally, including the route information. The IP address of the loopback interface can be used as a device ID of the Open Shortest Path First (OSPF) routing protocol, an IP address for access to a telnet server, or a source IP address for access by a telnet client.

- Tunnel interface

  A tunnel interface is a virtual interface of a device and implements the tunnel function. Over a tunnel interface, transmission protocols (such as IP) can be used to transmit packets of any protocol. Instead of specifying any transmission protocol or load protocol, a tunnel interface provides a standard point-to-point (P2P) transmission mode. Therefore, a tunnel interface must be configured for every single link.

- Management port

  A management (MGMT) port is a physical port used to manage a device remotely. It is similar to the management method of using a serial port to log in to a device. A management port does not support the communication forwarding function.

  For the internal structure of a device, the management port is separated from the internal forwarding plane of the device. Therefore the management port does not work for the forwarding plane and the control plane of the device, which means that the communication of the management port is independent from the communication of the services running on the device, thus achieving out-of-band communication. For network communication, a MGMT port equals to any other interface by nature. Therefore, by configuring port attributes, a MGMT port also supports network communication like common ports, but the MGMT port does not support the forwarding function.

  The networks used for management and services can be separated through a MGMT port. Therefore, service network traffic and communication status will not affect device management, thus improving the reliability of device management. Even if the service network fails, the device can be managed through the management network, which is an incomparable advantage over the in-band management method of the service network. In addition, compared with a console port, a MGMT port has a higher bandwidth. In a management network with a log server, a device send logs to the log server through the MGMT port. Therefore, the communication status of the service network will not affect the sending and saving of logs.

1.1.2 Interface Numbering Rules

Table 1-1 shows the numbering rules of physical ports on the devices supporting or not supporting daughter cards in the standalone mode or virtual switch unit (VSU) mode.

Table 1-1 The Numbering Rules of Physical Ports

Daughter Cards	Stand-alone mode	VSU mode
Not Support	A physical port number consists of the slot number and port number on the slot. For example, if the slot number of the port is 2, and the port number on the slot is 3, the port ID is 2/3.	A physical port number consists of the device number, slot number and port number on the slot. For example, if the device number is 1, slot number is 2, and port number on the slot is 3, the port ID is 1/2/3.
Support	A physical port number consists of the slot number, card number and port number on the slot. For example, if the slot number of the port is 2, the card number is 1 and the port number on the slot is 3, the port ID is 2/1/3.	A physical port number consists of the device number, slot number, card number and port number on the slot. For example, if the device number is 1, the slot number of the port is 2, the card number is 1 and the port number on the slot is 3, the port ID is 1/2/1/3.

The numbering rules of the preceding devices, slots, daughter cards, and ports on slots or cards are as follows:

- The device ID ranges from 1 to the maximum number of member devices supported.
- The slot number rules are as follows: The static slot ID is 0, whereas the ID of a dynamic slot (pluggable module or line card) ranges from 1 to the number of slots. Assume that you are facing the device panel. Dynamic slots are numbered from 1 sequentially from front to rear, from left to right, and from top to bottom.
- Daughter card ID: On a line card supporting daughter cards, the daughter card ID is 0. The daughter card ID of a dynamic slot (pluggable module or line card) ranges from 1 to the number of slots. Dynamic daughter card slots are numbered from 1 sequentially from left to right, and from top to bottom.
- The port ID on a slot or a daughter card ranges from 0 to the number of ports on the slot, and is numbered sequentially from left to right.

For devices can select medium type, the device ports use both optical medium and electrical medium, such ports are called combo ports. Regardless of the medium selected, the combo port uses the same port ID.

In addition to physical ports, a device also has logical interfaces. The numbering rules of logical interfaces are as follows:

- The ID of a link aggregation ranges from 1 to the number of link aggregations supported by the device.
- The ID of an SVI is the VLAN ID corresponding to this SVI.
- The ID of a sub-interface consists of the interface ID followed by "." and the sub-interface number. The sub-interface number ranges from 1 to the sub-interface configuration range supported by the device.

Note

For the numbering rule of the aggregate interfaces, see the numbering rule of the tunnel interfaces and management ports.

1.2 Configuration Task Summary

- Configuring Common Features of Ethernet Interfaces

  The following tasks are optional. Select them as need.

  - Configuring Interfaces in a Range
  - Configuring Interface Description
  - Configuring Layer 2 or Layer 3 Interfaces
  - Configuring Interface Administrative Status
  - Configuring MTU of an Interface
  - Configuring Interface Bandwidth
  - Configuring Port Rates
  - Configuring the Flow Control Mode
  - Configuring the Duplex Mode of an Interface
  - Configuring the Auto Negotiation Mode
  - Configuring Protected Ports
  - Configuring EEE
  - Configuring Interface Traffic Statistics
  - Configuring SNMP Features for Interfaces
  - Configuring the Syslog Function for Interfaces
  - Configuring Displaying the Interface Name in the Standard Trap When the Port Link Status Is Switched Up/Down
- Configuring Optical Transceiver Features

  The following tasks are optional. Select them as need.

  - Configuring Information Collection Intervals of Optical Transceivers
  - Configuring Alarm Detection for Optical Transceivers
  - Configuring Optical Transceiver Antifake Detection
- Configuring the MAC Address of an Interface
- Configuring Port Reliability Attributes

  The following tasks are optional. Select them as need.

  - Configuring the Carrier-Delay for an Interface
  - Configuring Port Flapping Protection
  - Configuring the FEC Mode of an Interface
  - Configuring Interface Diagnostics

- Configuring Port Errdisable Recovery
- Testing Connected Cable Status
- Configuring CRC Error Frame Alarm Detection for an Interface
- Configuring PRBS Detection for an Interface
- Configuring Delayed Interface Startup Function
- Configuring Encapsulation Protocols for Layer 3 Sub-interfaces

1.3 Configuring Common Features of Ethernet Interfaces

1.3.1 Configuration Task Summary

The following tasks are optional. Select them as required.

- Configuring Interfaces in a Range
- Configuring Interface Description
- Configuring Layer 2 or Layer 3 Interfaces
- Configuring Interface Administrative Status
- Configuring MTU of an Interface
- Configuring Interface Bandwidth
- Configuring Port Rates
- Configuring the Flow Control Mode
- Configuring the Duplex Mode of an Interface
- Configuring the Auto Negotiation Mode
- Configuring Protected Ports
- Configuring EEE
- Configuring Interface Traffic Statistics
- Configuring SNMP Features for Interfaces
- Configuring the Syslog Function for Interfaces
- Configuring Displaying the Interface Name in the Standard Trap When the Port Link Status Is Switched Up/Down

1.3.2 Configuring Interfaces in a Range

1. Overview

For physical ports or logical interfaces created, enter the batch configuration mode of the interfaces within a specified range. For logical interfaces have not been created, the system will create specified logical interfaces in a batch and enter the batch configuration mode of the interfaces within a specified range. When you enter the batch configuration mode to configure multiple interfaces at a time, the attributes configured apply to all interfaces in the selected range.

Run the **interface range** command to specify several range segments, and each range segment can be separated using a comma (,). The types of interfaces within all ranges specified in a command must be the same. The **macro** parameter is used to configure the macro corresponding to a range. Before using the **macro**

parameter in the **interface range** command, you must first run the **define interface-range** command in the global configuration mode to define these macros. Run the **no define interface-range macro-name** to remove the configuration.

2. Restrictions and Guidelines

- For logical interfaces, you can run the **no interface range** command to bacth delete the interfaces in a specified range. But this command cannot batch delete physical ports.
- Run the **default interface range** command to restore the default configuration of the interfaces within a specified range in the interface configuration mode.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure a macro name for the interfaces to be configured in a batch.

define interface-range *macro-name interface-type interface-range-string*

The default macro name is not configured for the interfaces to be configured in a batch.

(4) Enter the batch configuration mode.

interface range { *interface-type interface-range-string* | **macro** *macro-name* }

The default interface range is not configured.

1.3.3 Configuring Interface Description

1. Overview

Configure a name for an interface to identify the interface and help you remember the functions of the interface.

For example, if you want to assign GigabitEthernet 0/1 for exclusive use by user A, describe the interface as "Port for User A."

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI interface configuration mode.

  interface vlan *interface-number*

- Enter the Management interface configuration mode.

  interface mgmt *interface-number*

- Enter the Tunnel interface configuration mode.

  interface tunnel *interface-number*

- Enter the Loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure the description for the interface.

description *interface-name*

The default interface name is not configured.

1.3.4 Configuring Layer 2 or Layer 3 Interfaces

1. Overview

A physical port and an aggregate interface on a Layer 3 device can be configured as Layer 3 interfaces and function as the gateway interfaces for Layer 3 switching. A Layer 3 interface cannot be used for Layer 2 switching. You can run the **no switchport** command to change a Layer 2 interface to a Layer 3 interface and assign an IP address to this interface to set up a route. You can run the **switchport** command to change a Layer 3 interface to a Layer 2 interface.

2. Restrictions and Guidelines

- Running the **no switchport** command will delete all Layer 2 features of the interface.
- A Layer 2 link aggregation with member ports cannot be configured as a Layer 3 link aggregation, and vice versa.
- When a port is a member port of a Layer 2 link aggregation or an unauthenticated dot1x port, you cannot change the port type using the **switchport** command or the **no switchport** command.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(4) Configure an interface as a Layer 2 or Layer 3 Interface. Perform at least one of the following configuration tasks:

- Configure an interface as a Layer 2 interface.

  switchport

- Configure an interface as a Layer 3 interface.

  no switchport

  All the interfaces are Layer 2 interfaces by default.

  All ports are switch ports by default.

1.3.5 Configuring Interface Administrative Status

1. Overview

Enter the interface mode to disable or enable an interface. Two administrative statuses are available for an interface: **Up** and **Down**. The administrative status of an interface is **Down** when the interface is disabled, and **Up** when the interface is enabled. In some cases, you may need to disable an interface. You can directly disable an interface by setting c. If an interface is disabled, it does not receive or send any frames, and the interface loses all its corresponding functions. You can also enable a disabled interface again by setting the management status.

2. Restrictions and Guidelines

The errdisable ports can be recovered using the **shutdown** or **no shutdown** command. To prevent unwanted link flapping caused by frequently running the **shutdown** or **no shutdown** command, there should be a certain time interval, which must be greater than the carrier delay of the interface, before you run the **shutdown** or **no shutdown** command again on an interface.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI interface configuration mode.

  interface vlan *interface-number*

- Enter the Management interface configuration mode.

  interface mgmt *interface-number*

- Enter the Tunnel interface configuration mode.

  interface tunnel *interface-number*

- Enter the Loopback interface configuration mode.

  interface loopback *interface-number*

(4) Disable the interface.

shutdown

An interface is enabled by default.

1.3.6 Configuring MTU of an Interface

1. Overview

The MTU is the length of the valid data segment in a frame. It does not include the Ethernet encapsulation overhead. If an interface receives or forwards a frame with a length greater than the MTU, this frame will be discarded.

When a large amount of data is exchanged over an interface, a frame may be greater than a standard Ethernet frame in length. This type of frame is called jumbo frame. If you want a device to receive and handle Jumbo frames, configure the MTU greater than the length of a jumbo frame for the device.

2. Restrictions and Guidelines

- Configuring the system MTU will update the MTU effective values of all the Ethernet interfaces (including the link aggregations) of the system. However, if the interface is configured with an MTU, the MTU configured for the interface will take effect.
- The **mtu forwarding** command works on all the physical ports only and controls only the forwarding of Layer 2 packets. After the command is configured, the protocol MTU is inconsistent with the forwarding MTU, which may cause problems such as flow interruption and protocol exception. For example, in an IPv6 scenario, if the global Forward MTU configuration is smaller than the default interface value when the default

MTU is configured for the interface, the IPv6 packet cannot be sent and received normally. Then the network is interrupted. You are not advised to run the command except for special needs. You are advised to use the **system mtu** command instead of the **mtu forwarding** command.

- You can set an MTU for an interface to control the maximum length of frames that can be received or forwarded by the interface.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an MTU. Configure at least one of the following tasks.

a Configure the system MTU.

system mtu *mtu-value*

No default system MTU is configured.

b Configure the MTU for a forwarding panel.

mtu forwarding *mtu-value*

The default MTU for a forwarding panel is 1500.

c Enter the interface configuration mode.

interface *interface-type interface-number*

- Enter the Layer 2 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 2 aggregate interface configuration mode.
  interface aggregateport *interface-number*
- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI interface configuration mode.
  interface vlan *interface-number*
- Enter the Tunnel interface configuration mode.
  interface tunnel *interface-number*

d Configure the MTU of an interface.

mtu *mtu-value*

The default MTU is subject to the product version.

The MTU values configured for virtual interfaces (including SVI interfaces and tunnel interfaces) and the MTU values configured by the **ip mtu** command must be smaller than or equal to the MTU values configured for the actual physical interfaces. If the MTU values are not properly configured, the packets whose lengths exceed the MTU values of physical interfaces will be discarded.

1.3.7 Configuring Interface Bandwidth

1. Overview

This command can be configured so that some routing protocols (for example, OSPF) can calculate the route metric and the Resource Reservation Protocol (RSVP) can calculate the reserved bandwidth.

2. Restrictions and Guidelines

The **bandwidth** command is a routing parameter, and does not affect the bandwidth of a physical link.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI interface configuration mode.

  interface vlan *interface-number*

- Enter the Tunnel interface configuration mode.

  interface tunnel *interface-number*

- Enter the Loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure the bandwidth for an interface.

bandwidth *bandwidth-value*

No default interface bandwidth is configured.

1.3.8 Configuring Port Rates

1. Overview

Generally, the rate of an Ethernet physical port is determined through auto negotiation with the peer device. The negotiated rate can be any rate within the interface capability. You can also configure any rate within the interface capability for the Ethernet physical port.

If the interface rate is set to the **auto** mode, the interface rate can be automatically adjusted based on the type of the inserted module. Currently supported modules include small form-factor pluggable (SFP) and enhanced SFP (SFP+) modules. If an SFP module is inserted, the interface works in Gigabit mode. If an SFP+ module is inserted, the interface works in 10 Gigabit mode. This function takes effect only when the interface rate is set to the **auto** mode.

2. Restrictions and Guidelines

- If an interface is a member port of a link aggregation, the rate of this interface depends on the rate of the link aggregation. After an interface exits a link aggregation, it will use its own rate.
- The **default interface** command will not restore the default **port speed-mode** configuration of a 25 GE port.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Management interface configuration mode.

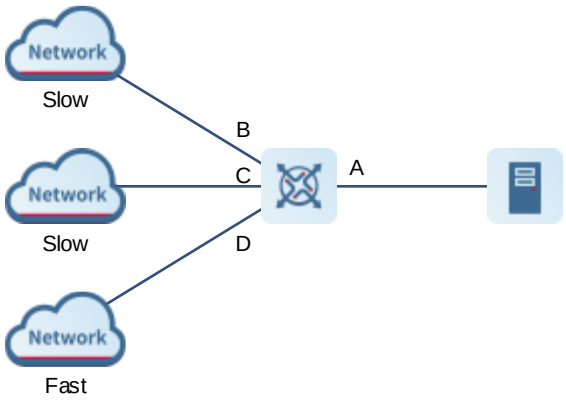
  interface mgmt *interface-number*

(4) Configure the port rate.

speed { **10** | **100** | **1000** | **10G** | **40G** | **100G** | **auto** }

The interface rate is set to auto by default.

1.3.9 Configuring the Flow Control Mode



1. Overview

There are two flow control modes of an interface:

- Symmetric flow control mode: Generally, after flow control is enabled on an interface, the interface processes the received flow control frames, and sends the flow control frames when congestion occurs on the interface.
- Asymmetric flow control mode: When an interface works in the asymmetric flow control mode, the interface processes the received flow control frames but does not forward flow control frames.
- The flow control mode of a link aggregation takes effect on all member links.

As shown in Figure 1-2, Port A of the device is an uplink port, and Ports B, C and D are downlink ports. Port B and Port C are connected to different slow networks. Port A is enabled with the functions of sending and receiving flow control frames. As Port B and Port C are connected to different slow networks, if a large amount of data is sent on Port B, Port B and Port C will be congested. Then congestion occurs in the inbound direction of Port A. Therefore, Port A sends flow control frames. When the uplink device responds to the flow control frames, it reduces the data flow sent to Port A, which indirectly slows down the network speed on Port D. In this case, disable the function of sending flow control frames on Port A to ensure the bandwidth usage of the entire network.

Figure 1-2 Interface Flow Control Diagram

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Configure the flow control mode of an interface.

flowcontrol { **auto** | **off** | **on** }

The flow control mode is disabled by default.

1.3.10 Configuring the Duplex Mode of an Interface

1. Overview

The duplex mode of an interface can be configured based on the duplex mode of a peer interface. You can specify one of the following work modes for the interface:

- Full duplex: the interface can receive packets while sending packets.
- Half duplex: the interface can receive or send packets at a time.
- Auto negotiation: the duplex mode of the interface is determined through auto negotiation between the local interface and peer interface.

2. Restrictions and Guidelines

When you configure the duplex mode of a link aggregation, the configuration takes effect on all of its member ports.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Management interface configuration mode.

  interface mgmt *interface-number*

(4) Configure the duplex mode.

duplex { **auto** | **full** | **half** }

An interface is in auto-negotiation mode by default.

1.3.11 Configuring the Auto Negotiation Mode

Specification

The RG-CS88-series CM88-48XS-H and CM88-8CQ-H line cards do not support this command.

1. Overview

- The auto negotiation mode of an interface can be **on** or **off**. The auto negotiation state of an interface is not completely equivalent to the auto negotiation mode. The auto negotiation state of an interface is jointly determined by the interface rate, duplex mode, flow control mode, and auto negotiation mode.
- Generally, if one of the interface rate, duplex mode, and flow control mode is set to **auto**, or the auto negotiation mode of an interface is **on**, the auto negotiation state of the interface is **on**, that is, the auto negotiation function of the interface is enabled. If none of the interface rate, duplex mode, and flow control mode is set to **auto**, and the auto negotiation mode of an interface is **off**, the auto negotiation function of the interface is disabled.

2. Restrictions and Guidelines

- When you configure the auto-negotiation mode for an aggregate interface, the configuration takes effect on all of its member interfaces.
- For a 100 M fiber port, the auto negotiation function is always disabled. For a Gigabit copper port, the auto negotiation function is always enabled, that is, the auto negotiation state is **on**.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Configure the auto negotiation mode for the interface.

negotiation mode { **off** | **on** }

The auto negotiation mode of an interface is disabled by default.

1.3.12 Configuring Protected Ports

1. Overview

In some application environments, it is required that communication be disabled between some ports on the device. For this purpose, you can configure some ports as protected ports. You can also disable routing between protected ports. After ports are configured as protected ports, the protected ports cannot communicate with each other, but can communicate with non-protected ports. Protected ports work in either of the two modes.

2. Restrictions and Guidelines

Two protected ports cannot communicate with each other. But when they are configured as a pair of mirroring ports, frames sent or received by the source port can be mirrored to the destination port. Currently, only an

Ethernet physical port or link aggregation can be configured as a protected port. When a link aggregation is configured as a protected port, all of its member ports are configured as protected ports. By default, the Layer 3 routing between protected ports is not blocked. In this case, you can run the **protected-ports route-deny** command to block the routing between protected ports.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Block Layer 3 routing between protected ports.

protected-ports route-deny

Layer 3 routing is not blocked between protected ports by default.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(5) Configure a protected port.

switchport protected

No interface is configured as a protected port by default.

1.3.13 Configuring EEE

Specification

The RG-CS88-series CM88-48XS-H and CM88-8CQ-H line cards do not support this command.

1. Overview

Energy Efficient Ethernet (EEE) is an Ethernet solution that saves energy.

According to the Ethernet standards or specifications, interfaces with a bandwidth of 100M or above have the active idle state. An interface will consume much power if it maintains connection without being affected by data transmission. Therefore, the power consumption is high no matter whether any data is transmitted on the link. Even if no data is transmitted, the port will always send the idle signals to retain the connection state of the link.

EEE enables a port of the device to enter the low power idle (LPI) mode to save energy. In LPI mode, the power consumption is low when the link is idle. The EEE technology can also quickly change the LPI state of a port to the normal state, providing high-performance data transmission.

After enabled with EEE, a port automatically enters LPI mode if the port is always up without sending or receiving any packet in a period of time. The port switches to the working mode when it needs to send or receive packets, thus saving energy. To make the EEE function take effect, the peer port must also support the EEE function.

2. Restrictions and Guidelines

- Only a copper port working in 100M or 1000M rate mode supports the EEE function.
- The EEE function takes effect only on the port enabled with auto negotiation.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Enable EEE on the interface.

eee enable

EEE is disabled on an interface by default.

1.3.14 Configuring Interface Traffic Statistics

1. Overview

By default, virtual interfaces such as sub-interfaces and SVIs do not support interface traffic statistics collection, while the Ethernet port and Ethernet AP support interface traffic statistics collection, but do not support IP traffic statistics collection. When you need to locate a network fault or monitor the network operation status, you can enable the interface traffic statistics collection function and IP traffic statistics collection function. And run the **show interface** *interface-type interface-number* command to view the packet statistics of the specified interface and IP packet statistics.

The default statistics collection interval of an Ethernet interface or Ethernet sub-interface is five seconds, that is, interface statistics are updated every five seconds. To meet high requirements for real-time statistics, prolong the collection interval.

The statistics of default sending and receiving rates of a device does not include interframe gaps. The sending and receiving rates of physical layer packets refers to the packet sending and receiving rates including the number of packet bytes and interframe gaps. If you wants to check the sending and receiving rates of physical layer packets, enable the device to calculate interframe gaps when it calculates the packet sending and receiving rates. Then the statistics will display the sending and receiving rates of physical layer packets. After the function is enabled, the interframe gap size is fixed at 20 bytes, which consists of 12-byte frame gaps and 8-byte preambles. There is deviation because the device calculates 12-byte frame gaps while the command statistics exclude frame gaps.

2. Restrictions and Guidelines

- Enabling the interface traffic statistics collection function and IP traffic statistics collection function consumes system resources. Enable the functions as required.

- A shorter collection interval consumes more system performance. Therefore, adjust the collection interval as required. You are advised to set the collection interval to more than 10 seconds if there are over 500 physical interfaces.
- After you run the **flow-statistics include-interframe enable** command, the device will clear the statistics of the packet sending and receiving rates of the interface and calculate the rates again.
- You can run the **show interfaces transceiver** command to view the optical module information that is collected periodically and the **show interface** [*interface-type interface-number*] **transceiver** command to view the real-time optical module information on the specified interface.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the collection interval for Ethernet interface statistics collection.

ethernet-port counter sample-period [*interval*]

The default collection interval of Ethernet interface statistics collection is five seconds.

(4) (Optional) Configure the collection interval for Ethernet sub-interface statistics collection.

ethernet-subport counter route-sample-period [*interval*]

The default collection interval of Ethernet sub-interface statistics collection is five seconds.

(5) Configure that the interface rate statistics include interframe gaps.

flow-statistics include-interframe enable

The interface rate statistics does not include interframe gaps by default.

(6) Enter the interface configuration mode.

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI interface configuration mode.

  interface vlan *interface-number*

- Enter the Tunnel interface configuration mode.

  interface tunnel *interface-number*

(7) Enable the traffic statistics collection function on the interface.

statistics { **enable** | **ip enable** }

The IP traffic statistics collection function is disabled on all interfaces by default.

(8) (Optional) Configure the interval of load calculation for the interface.

load-interval *interval*

The interval of load calculation for an interface is 10 seconds by default.

1.3.15 Configuring SNMP Features for Interfaces

1. Overview

The Simple Network Management Protocol (SNMP) is used for network monitoring and management. Because many manufactures support SNMP, it becomes a network management standard and is widely used in manufactures' interconnection systems. Through SNMP, a network administrator can check information, configure networks, locate faults and plan capacity for network nodes for network nodes. Our devices support following SNMP features.

- Interface index persistence

  Like the interface name, the interface index also identifies an interface. When an interface is created, the system automatically assigns a unique index to the interface. The index of an interface may change after the device is restarted. Enable the interface index persistence feature to retain the interface index after you restart the device.

- Enhanced name display for interfaces

  After enhanced name display for interfaces is enabled in a standard MIB node, the value of an interface name does not contain spaces. In addition, the ifName node displays the full name of the interface, which does not contain spaces. By default, the value of an interface name in a standard MIB node and the interface name do not contain spaces. In addition, the ifName node displays the short name of the interface.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable interface index persistence for the interface.

snmp-server if-index persist

The interface index persistence feature is disabled on an interface by default.

(4) Configure enhanced name display for interfaces.

snmp-server if-name enhance

The function is disabled by default.

After you run this command, save the configuration and restart the device to make the configuration take effect. Then the interface names obtained by SNMP will not contain spaces.

1.3.16 Configuring the Syslog Function for Interfaces

1. Overview

Use the syslog function to determine whether to display information about interface changes or exceptions.

Enable or disable the syslog function as required. By default, this function is enabled. When an exception occurs on an interface, for example, the interface status changes, or the interface receives error frames, or flapping occurs, the system displays prompts to notify users.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the syslog printing function on the interface.

logging [**error-frame** | **insert-remove** | **link-dither** | **link-updown** | **res-lack-frame**]

The syslog printing function is enabled on an interface.

(4) Enter the Ethernet interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(5) Configure interface information printing.

logging [**link-updown** | **link-state realtime**]

By default, the prompt information about the interface status change is printed, while the real-time information about the interface link status change is not printed.

1.3.17 Configuring Displaying the Interface Name in the Standard Trap When the Port Link Status Is Switched Up/Down

1. Overview

Configure the interface name to be displayed in the standard trap when the port link status changes to up/down.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the interface name to be displayed in the standard trap when the port link status changes to up/down.

snmp trap link-status enhance

By default, the function is disabled.

1.4 Configuring Optical Transceiver Features

1.4.1 Configuration Task Summary

The following tasks are optional. Select them as required.

- Configuring Interfaces in a Range

1.4.2 Configuring Information Collection Intervals of Optical Transceivers

1. Overview

If there is a high requirement for information collection timeliness, you can shorten the information collection period of the optical transceiver, so that the maintenance personnel can obtain information changes of the optical transceiver in time.

2. Restrictions and Guidelines

- A shorter collection interval consumes more system performance. Therefore, adjust the collection interval as required.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the information collection interval of optical transceivers on Ethernet interfaces.

ethernet-port fiber-info sample-period [*interval*]

The default information collection interval of optical transceivers on Ethernet interfaces is five minutes.

1.4.3 Configuring Alarm Detection for Optical Transceivers

1. Overview

After this function is configured, you can view the optical transceiver alarm information of an interface by using the management information base (MIB). When events such as insertion or removal of an optical transceiver, optical transceiver exceptions, and optical transceiver exception clearing are detected, related TRAP messages are sent. The exceptions include overhigh/overlow transmit power of the optical transceiver, overhigh/overlow receive power of the optical transceiver, inter-integrated circuit (IIC) fault of the optical transceiver, unsupported module type, and the like.

After the alarm detection function is enabled and a corresponding detection period is configured, the SNMP device periodically monitors the optical transceiver status on an interface. When any of the above events is detected, the SNMP device sends a related TRAP message. The SNMP device sends a TRAP message immediately for the optical transceiver insertion or removal, but sends a TRAP message in the next period for optical transceiver exceptions and optical transceiver exception clearing. The exception will be notified periodically, and the exception clearing event will be notified once only. You can disable the periodic notification function by using the repeated notification mode switch.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the alarm detection function for optical transceivers.

fiber alarm-detect enable

The default configuration of the command varies according to product version. Refer to the actual situation of the product.

(4) (Optional) Configure the alarm detection period for optical transceivers.

fiber alarm-detect period *minutes*

The default alarm detection period of optical transceiver exceptions is 10 minutes.

(5) (Optional) Configure the periodic repeated notification mode of optical transceiver alarms.

fiber alarm-detect repeat-mode { **on** | **off** }

The repeated notification mode of optical transceiver alarms is enabled by default.

1.4.4 Configuring Optical Transceiver Antifake Detection

1. Overview

Configure the optical transceiver antifake detection function to check whether the optical transceiver in use is supplied by our company.

If the optical transceiver is not supplied by our company, the data communication may be affected. If the optical transceiver antifake detection function is enabled, the device can automatically identify an optical transceiver that is not supplied by our company and generate an alarm when such a module is inserted to our company's device.

This function is disabled by default. You can enable this function through configuration.

Each optical transceiver supplied by our company has a unique antifake code. The device can read this antifake code to determine whether the module is supplied by our company. If not, the device will generate syslogs and send trap messages.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure optical transceiver antifake detection.

fiber antifake { **ignore** | **enable** }

The optical transceiver antifake detection function is disabled by default.

1.5 Configuring the MAC Address of an Interface

1.5.1 Overview

Each Layer 3 Ethernet interface has a globally unique MAC address. Our company's device supports modifying the MAC addresses of Ethernet interfaces. However, MAC addresses in the same LAN must be unique.

1.5.2 Restrictions and Guidelines

Configuration of MAC addresses may affect internal communication in a LAN. You are advised not to change the MAC address of the Layer 3 Ethernet interface in normal cases.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI interface configuration mode.

  interface vlan *interface-number*

(4) Configure the MAC address of an interface.

mac-address *mac-address*

The system uses factory settings by default.

1.6 Configuring Port Reliability Attributes

1.6.1 Configuration Task Summary

The following tasks are optional. Select them as required.

- Configuring the Carrier-Delay for an Interface
- Configuring Port Flapping Protection
- Configuring the FEC Mode of an Interface
- Configuring Interface Diagnostics
- Configuring Port Errdisable Recovery

- Testing Connected Cable Status
- Configuring CRC Error Frame Alarm Detection for an Interface
- Configuring PRBS Detection for an Interface
- Configuring Delayed Interface Startup Function
- Configuring Encapsulation Protocols for Layer 3 Sub-interfaces

1.6.2 Configuring the Carrier-Delay for an Interface

1. Overview

The carrier-delay refers to the delay after which the data carrier detect (DCD) signal changes from **down** to **up** or from **up** to **down**. If the DCD status changes during the delay, the system will ignore this change to avoid negotiation at the upper data link layer. If this parameter is set to a great value, nearly every DCD change is not detected. On the contrary, if the parameter is set to 0, every DCD signal change will be detected, resulting in poor stability.

2. Restrictions and Guidelines

- If the DCD carrier interruption time is long, set a smaller carrier delay so that the routing protocol learns about link state changes more quickly, thereby accelerating topology and route convergence.
- If the DCD carrier interruption time is shorter than the network topology or route summarization time, set a larger carrier delay (relative to carrier interruption time) to avoid frequent route flapping.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the SVI interface configuration mode.

  interface vlan *interface-number*

- Enter the Tunnel interface configuration mode.

  interface tunnel *interface-number*

- Enter the Loopback interface configuration mode.

interface loopback *interface-number*

(4) Configure the carrier-delay for an interface.

carrier-delay { [**milliseconds**] *delay-interval* | **up** [**milliseconds**] *up-interval* **down** [**milliseconds**] *down-interval* }

By default, the delay after which the DCD signal changes from **down** to **up** is 2s, and the delay after which the DCD signal changes from **up** to **down** is 0s.

1.6.3 Configuring Port Flapping Protection

1. Overview

When flapping occurs on a port, a lot of hardware interruptions occur, consuming a lot of CPU resources. On the other hand, frequent port flapping damages the port. You can configure the flapping protection function to protect ports.

By default, the port flapping protection function is enabled. You can disable this function as required. When flapping occurs on a port, the port detects flapping every 2s or 10s. If flapping occurs six times within 2s on a port, the device displays a prompt. If 10 prompts are displayed continuously, that is, port flapping is detected continuously within 20s, the port is shut down (the violation cause shows **Link Dither**). If flapping occurs 10 times within 10s on a port, the device displays a prompt without shutting down the port.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the port flapping protection function.

physical-port dither protect

The port flapping protection function is enabled by default.

(4) (Optional) Configure the port flapping protection parameters.

physical-port dither period *period-time* **threshold** *threshold-number* **period-times** *continuous-period*

By default, the port flapping detection interval is 2s, the threshold for triggering periodic flapping counting within an interval is 6 times, and the number of continuous periods during which flapping suppression is triggered is 10,

1.6.4 Configuring the FEC Mode of an Interface

Specification

Only the RG-CS88-series CM88-48XS-H and CM88-8CQ-H line cards support this command.

1. Overview

Forward error correction (FEC) is an error code correction method employing the following working principle: The sender adds a redundancy error-correcting code to the data for sending. The receiver performs error detection on the data based on the error-correcting code. If an error is found, the receiver corrects the error.

FEC improves signal quality but also causes signal delay. Users can enable or disable this function according to the actual situation.

There are three FEC modes: rs mode, base-r mode, and auto mode. Different types of interfaces support different FEC modes, depending on the specific products.

2. Restrictions and Guidelines

When the FEC function is enabled at one end of the link, it must be also enabled at the other end. If the QSFP28-100G-LR4 optical transceiver is used without affecting the negotiation status of the two ends, the FEC function is disabled by default and should not be enabled according to the IEEE standard protocol. If the QSFP28 optical transceivers other than the QSFP28-100G-LR4 are used, the FEC function is enabled by default. In this case, you are not advised to disable this function, which may lead to receiving incorrect packets.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Configure the FEC mode.

fec mode { **rs** | **base-r** | **none** | **auto** }

By default, the FEC mode of an interface is auto mode.

1.6.5 Configuring Interface Diagnostics

1. Overview

When an interface is faulty, you can implement interface diagnostics using a command. The diagnostics result and fault information are displayed during interface diagnostics. View the diagnostics information to quickly find the fault cause. Run the **show interface** [*interface-type interface-number*] **troubleshooting** command to display the recent diagnostic information of an interface in privileged EXEC mode.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enabling interface diagnostics.

troubleshooting interface *interface-type interface-number* [**extend loopback**]

Interface diagnostics is not enabled on an interface by default.

1.6.6 Configuring Port Errdisable Recovery

1. Overview

Some protocols support the port errdisable recovery function to ensure security and stability of the network. For example, in the port security protocol, when you enable port security and configure the maximum number of security addresses on the port, a port violation event will occur if the number of addresses learned on this port exceeds the maximum number of security addresses. Protocols, such as the Spanning Tree Protocol (STP), 802.1x, Rapid Ethernet Uplink Protection Protocol (REUP) and port flapping protection support the similar functions.

2. Restrictions and Guidelines

- When a port is disabled because it is set to the errdisable state by the REUP link state tracking group function, the port can be restored only by REUP at a scheduled time or by running the REUP errdisable recovery command in the global configuration mode. In other scenarios, run the errdisable recovery command in the global configuration mode to recover all the ports in errdisable state and enable these ports.
- You can manually recover a port, or automatically recover a port at a scheduled time. In addition, you can run the **shutdown** or **no shutdown** command to recover all the ports in the errdisable state and enable If the problem causing port errdisable is not fixed, the port will enter the errdisable state again.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Configure port errdisable recovery in the privileged EXEC mode.

errdisable recovery [**cause link-state**]

By default, the port errdisable recovery function is disabled.

(3) Enter the global configuration mode.

configure terminal

(4) Configure port errdisable recovery in the global configuration mode.

errdisable recovery [**cause link-state** | **interval** *interval*]

By default, the port errdisable recovery function is disabled.

For some specified errdisable recovery functions, **cause** *link-state* can be configured in privileged EXEC mode or global configuration mode. Choose one mode to configure it. If **cause** *link-state* has been configured in privileged EXEC mode, it does not need to be configured in global configuration mode.

(5) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

interface aggregateport *interface-number*

(6) Configure the port errdisable recovery interval.

errdisable recovery [**interval** *interval*]

By default, the port errdisable recovery interval is not configured.

1.6.7 Testing Connected Cable Status

Specification

The CM88-48XS-H and CM88-8CQ-H line cards of the CS88 series do not support this command.

1. Overview

An administrator uses cable detection commands to detect the operating status of a cable. Cable detection helps to identify the operating status of a cable when the cable is short-circuited, disconnected, or in another abnormal state.

2. Restrictions and Guidelines

- Only an electrical port supports cable detection. An optical port or a link aggregation does not support cable detection.
- Performing cable detection on a normally connected interface causes a temporary disconnection.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Test the operating status of a connected cable.

line-detect

1.6.8 Configuring CRC Error Frame Alarm Detection for an Interface

When an interface receives a CRC error frame, it indicates faults such as service packet loss occur on the link. An alarm will be triggered in the form of printing Syslog and sending the alarm TRAP on an Ethernet interface with CRC error frame alarm detection enabled if CRC error frame statistics exceeding the alarm threshold is detected for several consecutive sampling periods. Restrictions and Guidelines

In order to avoid alarm flapping, keep a gap between *alarm-threshold* and *resume-threshold*.

1. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the Ethernet interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Enable CRC error alarm detection.

port-detect crc-frame enable

CRC error alarm detection is enabled by default.

(5) (Optional) Configure the alarm threshold and recovery threshold for the number of CRC error packets.

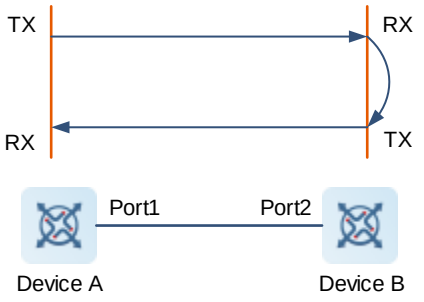
port-detect crc-frame alarm-threshold *alarm-value* **resume-threshold** *resume-value*

By default, the alarm threshold for the number of CRC error packets on the interface is 500, and the recovery threshold is 50.

(6) (Optional) Configure the number of periods for CRC error alarm detection.

port-detect crc-frame period-times *period-number*

The number of periods for CRC error alarm detection on an interface is 5 by default.



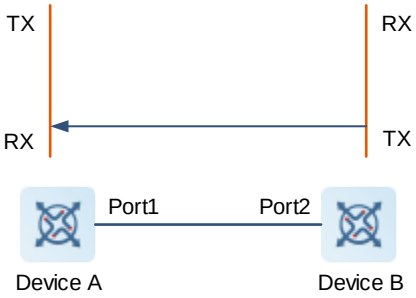
1.6.9 Configuring PRBS Detection for an Interface

Pseudo Random Binary Sequence (PRBS) is usually used for Physical Layer testing of serial buses. When an interface is faulty, you can enable PRBS detection to check whether the physical link of the interface is normal.

- PRBS Detection Scenario 1

  Figure 1-3 shows a PRBS detection scenario. When port 2 of device B (peer device) supports remote PHY loopback, enable remote PHY loopback for port 2 and then run the command for sending PRBS streams and the command for detecting PRBS on device A (local device). After the PRBS stream is transmitted to device B, the stream is looped back by device B and then received by device A. Device A compares the transmitted stream and received stream and outputs the detection result.

Figure 1-3 PRBS Detection Scenario 1



Note

The support of the PHY remote loopback function on an interface varies with different product versions.

- PRBS Detection Scenario 2

  Figure 1-4 shows another PRBS detection scenario. When port 2 of device B (peer device) does not support remote PHY loopback, enable the PRBS stream sending function for device B and then perform PRBS detection on device A (local device). Device B needs to be in the state of sending the PRBS stream during the PRBS detection process on device A to ensure the PRBS detection accuracy.

Figure 1-4 PRBS Detection Scenario 2

1. Restrictions and Guidelines

- This command can only be executed for optical interfaces.
- When an interface is faulty, you can run the command for enabling PRBS detection and the command for enabling PRBS stream sending to check whether the physical link of the interface is normal.
- You cannot run the command for enabling PRBS detection repeatedly on an interface that is already in the PRBS detection process.
- You cannot run the command for enabling PRBS stream sending repeatedly on an interface that is already in the PRBS stream sending process.
- The command for enabling PRBS stream sending and the command for enabling PRBS detection can be executed together for an interface, as long as the PRBS types in the two commands are the same.
- When an interface is in the PRBS detection process, it does not support the detection of one-key inspection loopback or PRBS loopback.
- When an interface is in the PRBS stream sending process, it does not support the detection of one-key inspection loopback or PRBS loopback.
- After the **diagnose interface prbs-abort** command is executed, the PRBS detection and PRBS stream sending functions are both terminated.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enable PRBS detection for an interface.

diagnose interface *interface-type interface-number* **prbs-detect pattern** *prbs-type* **interval** *interval-value* **repeat** *repeat-count*

(3) Enable PRBS stream sending for an interface.

diagnose interface *interface-type interface-number* **prbs-send pattern** *prbs-type* **time** *time-value*

An interface does not send PRBS streams by default.

(4) (Optional) Immediately terminate the PRBS detection and PRBS stream sending functions.

diagnose interface *interface-type interface-number* **prbs-abort**

1.6.10 Configuring Delayed Interface Startup Function

1. Overview

When the device is restarted, an interface card is replaced, or a board is reset, if the interface sends signals immediately after initialization, data loss may occur due to delayed configuration recovery or link synchronization. In this case, you can configure the interface to delay sending signals.

2. Restrictions and Guidelines

- This function is supported only by a physical interface and is not supported by a logical interface.
- When the interface is configured with the delayed interface startup function, the configuration takes effect when the interface is initialized the next time (reset, powered on/off, insertion/removal of the interface card, board reset, or device restart).

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*

(4) Configure the delayed interface startup function.

link-delay-up on-start *delay-time*

The default delay time for interface startup is 0 seconds, that is, no delay is configured.

1.7 Configuring Encapsulation Protocols for Layer 3 Sub-interfaces

1.7.1 Overview

Sub-interfaces can be used as Layer 3 access interfaces. They are configured with different stream encapsulation protocols based on services to distribute traffic based on VLAN IDs.. Layer 3 sub-interfaces are used as Layer 2 access interfaces for communication between Layer 2 devices and Layer 3 devices that belong to different VLANs.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the Layer 3 sub-interface configuration mode.

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregate sub-interface configuration mode.

  interface aggregateport *interface-number.subnumber*

(4) Configure IEEE802.1Q as the encapsulation protocol for Layer 3 sub-interfaces.

encapsulation dot1q *vlan-id*

The default Layer 3 sub-interface encapsulation protocol is IEEE802.1Q, and no VLAN is encapsulated by default.

1.8 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **clear** commands to clear information.

Caution

Services may be interrupted due to loss of vital information if you run the **clear** command during device operation.

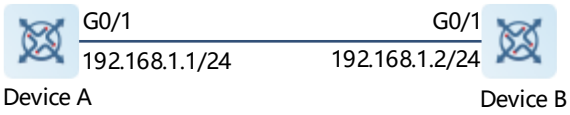
Table 1-2 Ethernet Interface Monitoring

Command	Purpose
show interfaces [*interface-type interface-number*]	Displays all the statuses and configuration information of a specified interface.
show interfaces [*interface-type interface-number*] **status**	Displays the interface status.
show interfaces [*interface-type interface-number*] **status detail**	Displays detailed interface status information.
show interfaces [*interface-type interface-number*] **status err-disabled**	Displays the interface errdisable status.
show interfaces [*interface-type interface-number*] **link-delay-up**	Displays the configuration of delayed interface startup and the interface status.

show interfaces [*interface-type interface-number*] **link-state-change statistics**	Displays the link status change time and count of a specified interface.
show interfaces [*interface-type interface-number*] **switchport** [**device** *device-id*]	Displays the status information of Layer 2 interfaces.
show interfaces [*interface-type interface-number*] **block-vlan**	Displays information about interfaces in blocking state.
show interfaces [*interface-type interface-number*] [**description**] [**up | down**]	Displays the configuration and status of an interface.
show interfaces [*interface-type interface-number*] **counters** [**up | down**]	Displays the statistics of a specified port.
show interfaces [*interface-type interface-number*] **counters increment** [**up** | **down**]	Displays the number of packets added in the previous sampling interval.
show interfaces [*interface-type interface-number*] **counters errors** [**up** | **down**] [**nozero**]	Displays the statistics about error packets.
show interfaces [*interface-type interface-number*] **counters rate** [**up | down**] [**nozero**]	Displays the packet sending/receiving rate of the interface.
show interfaces [*interface-type interface-number*] **counters rate physical-layer** [**up** | **down**] [**nozero**]	Displays the packet sending/receiving rate of an interface at the physical layer.
show interfaces [*interface-type interface-number*] **counters summary** [**up** | **down**] [**nozero**]	Displays a summary of interface packets.
show interfaces [*interface-type interface-number*] **counters drops** [**up | down**]	Displays the statistics of discarded packets of an interface.
show interfaces ethernet brief [**up** | **down**]	Displays the information about Ethernet interfaces in Up or Down state.
show interfaces *interface-type interface-number* **ethernet brief**	Displays the brief information about an Ethernet interface.
show interfaces [*interface-type interface-number*] **fault-info**	Displays the fault information about an interface.
show interfaces [*interface-type interface-number*] **line-detect**	Displays the cable status.
show interfaces [*interface-type interface-number*] **prbs-result**	Displays the PRBS detection result of an interface.

show interfaces [*interface-type interface-number*] **troubleshooting**	Displays the diagnosis information about an interface.
show interfaces usage [**up | down**] **show interfaces** *interface-type interface-number* **usage**	Displays the bandwidth usage of an interface.
show eee interface { *interface-type interface-number* | *status* } Specification The RG-CS88-series CM88-48XS-H and CM88-8CQ-H line cards do not support this command.	Displays the EEE status of an interface.
show mgmt virtual	Displays the status and statistics of the member ports of a virtual MGMT port.
show interfaces [*interface-type interface-number*] **transceiver**	Displays the basic information about the optical module on a specified interface.
show interfaces [*interface-type interface-number*] **transceiver alarm**	Displays the current fault alarms of the optical module on a specified interface.
show interfaces [*interface-type interface-number*] **transceiver diagnosis**	Displays the current measurement values of optical module diagnosis parameters of a specified interface.
show split summary	Displays the splitting and combination information of 40G/100G interfaces.
clear counters [*interface-type interface-number*]	Clears the statistics of a specified interface.
clear link-state-change statistics [*interface-type interface-number*]	Clears the statistics of link status changes of an interface.
show interfaces [*interface-type interface-number*] **troubleshooting**	Displays the diagnosis information of an interface.
show interfaces [*interface-type interface-number*] **fault-info**	Displays the fault cause and fault occurrence time of an interface.

1.9 Configuration Examples



1.9.1 Configuring Interface Attributes

1. Requirements

Interconnect two devices, and configure the basic attributes of the device interfaces.

2. Topology

Figure 1-5 Topology of Configuring Interface Attribute

3. Notes

- Connect two devices through Layer 2 interfaces.
- Configure an SVI on each of the two devices, and assign IP addresses in the same network segment to the two SVIs.
- Enable interface index persistence on the two devices.
- Enable the link trap function on the two devices.
- Configure the interface administrative status on the two devices.

4. Procedure

Configure as follows on Device A.

```
DeviceA> enable
DeviceA # configure terminal
DeviceA(config)# snmp-server if-index persist
DeviceA(config)# interface vlan 1
DeviceA(config-if-VLAN 1)# ip address 192.168.1.1 255.255.255.0
DeviceA(config-if-VLAN 1)# exit
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# snmp trap link-status
DeviceA(config-if-GigabitEthernet 0/1)# shutdown
```

Configure as follows on Device B.

```
DeviceB# configure terminal
DeviceB(config)# snmp-server if-index persist
DeviceB(config)# interface vlan 1
DeviceB(config-if-VLAN 1)# ip address 192.168.1.2 255.255.255.0
DeviceB(config-if-VLAN 1)# exit
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# snmp trap link-status
DeviceB(config-if-GigabitEthernet 0/1)# shutdown
```

5. Verification

Perform verification on Device A and Device B respectively as follows:

- Run the **shutdown** command on the interface GigabitEthernet 0/1, and check whether GigabitEthemet 0/1 and SVI 1 are in **Down** state.
- Run the **shutdown** command on the interface GigabitEthernet 0/1, and check whether a trap message indicating the **Down** state of this interface is sent.

- Restart the device, and check whether the interface index of GigabitEthernet 0/1 is the same as that before the restart.

Device A:

```
DeviceA# show interfaces gigabitEthernet 0/1
Index(dec):1 (hex):1
GigabitEthernet 0/1 is administratively down  , line protocol is DOWN

1.9.2 Configuring Interconnection Interfaces

1. Requirements

Interconnect two devices, and configure attributes of the device interfaces.

2. Topology

Figure 1-6 Interconnection Interface Configuration Topology

3. Notes

- On Device A, configure GigabitEthernet 0/1 as a Layer 2 interface in access mode, and set the default VLAN ID to 1. Configure SVI 1, assign an IP address to SVI 1, and set up a route to Switch D.
- On Device B, configure GigabitEthernet 0/1 and GigabitEthernet 0/2 as Layer 2 interfaces in trunk mode, and set the native VLAN ID to 1. Configure SVI 1, and assign an IP address to SVI 1. Configure GigabitEthernet 0/3 as a Layer 3 interface, and assign an IP address in another network segment to this interface.
- On Device C, configure GigabitEthernet 0/1 as Layer 2 interface in access mode, and set the VLAN ID to 1. Configure SVI 1, and assign an IP address to SVI 1.
- On Device D, configure GigabitEthernet 0/1 as a Layer 3 interface, assign an IP address to this interface, and set up a route to Switch A.

4. Procedure

Configure as follows on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface GigabitEthernet 0/1
```

```
DeviceA(config-if-GigabitEthernet 0/1)# switchport mode access
DeviceA(config-if-GigabitEthernet 0/1)# switchport access vlan 1
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface vlan 1
DeviceA(config-if-VLAN 1)# ip address 192.168.1.1 255.255.255.0
DeviceA(config-if-VLAN 1)# exit
DeviceA(config)# ip route 192.168.2.0 255.255.255.0 VLAN 1 192.168.1.2
```

Configure as follows on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# interface GigabitEthernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceB(config-if-GigabitEthernet 0/1)# exit

```

Configure as follows on Device D.

```
DeviceD> enable
DeviceD# configure terminal
DeviceD(config)# interface GigabitEthernet 0/1
DeviceD(config-if-GigabitEthernet 0/1)# no switchport
DeviceD(config-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
DeviceD(config-if-GigabitEthernet 0/1)# exit
DeviceD(config)# ip route 192.168.1.0 255.255.255.0  GigabitEthernet 0/1 192.168.2.2
```

5. Verification

Perform verification on Device A, Device B, Device C, and Device D respectively as follows:

- On Switch A, ping the IP addresses of interfaces of the other three devices. Verify that you can access the other two on each device.
- Verify that Device B and Device D can be pinged mutually.
- Verify that the interface status is correct.

Check the status of GigabitEthernet 0/1 on Device A.

```
DeviceA# show interfaces gigabitEthernet 0/1
Index(dec):1 (hex):1
GigabitEthernet 0/1 is UP  , line protocol is UP
Hardware is GigabitEthernet, address is 00d0.f865.de90 (bia 00d0.f865.de90)
Interface address is: no ip address
  MTU 1500 bytes, BW 100000 Kbit

1 Configuring Aggregate Interface

1.1 Introduction

An aggregate interface is used to bundle multiple physical links into one logical link to increase the link bandwidth and improve connection reliability.

1.1.1 Basic Concepts

An aggregate interface supports load balancing, that is, distributes load evenly among member links. Besides, an aggregate interface realizes link backup. When a member link of the aggregate interface is disconnected, the load carried by the link is automatically allocated to other functional member links. A member link does not forward broadcast or multicast packets to other member links.

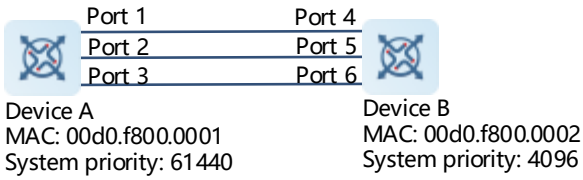
- If the link between two devices supports a maximum bandwidth of 1,000 Mbps (assuming that the devices each have a 1,000 Mbps port), when the service traffic carried by the link exceeds 1,000 Mbps, the traffic in excess will be discarded. Port aggregation can be used to solve the problem. For example, you can connect the two devices with network cables and combine multiple links to form a logical link capable of multiples of 1,000 Mbps.
- If the two devices are connected by one network cable, when the link between the two ports of the devices is disconnected, the services carried by the link will be interrupted. After the connected ports are aggregated, the services will not be affected as long as one link remains connected.

There are two kinds of link aggregation. One is the static aggregate interface mode, and the other is dynamic aggregation through Link Aggregation Control Protocol (LACP).

1. Static Aggregate Interface

The static aggregate interface mode means manually configuring physical ports and adding them to a link aggregation group. An aggregate interface in static aggregate interface mode is called a static aggregate interface, and its member ports are called member ports of a static aggregate interface. The static aggregate interface configuration is simple. You only need to run a command to add the specified physical port to the aggregate interface. After joining the aggregation group, a member port can receive and transmit data and participate in load balancing within the group.

2. Dynamic Aggregate Interface (LACP)



LACP is a protocol about dynamic link aggregation. It exchanges information with the connected device through link aggregation control protocol data units (LACPDU). An aggregate interface in LACP mode is called a dynamic aggregate interface, and its member ports are called member ports of a dynamic aggregate interface.

An LACP-enabled port sends LACPDUs to advertise its system priority, system MAC address, port priority, port number, and operation key. When receiving the LACPDU from the peer end, the device compares the system priorities of both ends based on the system ID in the packet. The end with a higher system ID priority sets the ports in the aggregation group to **Bundle** state based on the port ID priorities in a descending order, and sends an updated LACPDU. When receiving the LACPDU, the peer end sets corresponding ports to **Bundle** state so

that both ends maintain consistency when a port exits or joins the aggregation group. The physical link can forward packets only after the ports at both ends are bundled dynamically.

After link aggregation, the LACP member ports periodically exchange LACPDUs. When a port does not receive an LACPDU in the specified time, a timeout occurs and the links are unbundled. In this case, the member ports cannot forward packets. There are two timeout modes: long timeout and short timeout. In long timeout mode, a port sends a packet every 30s. If it does not receive a packet from the peer end in 90s, a timeout occurs. In short timeout mode, a port sends a packet every 1s. If it does not receive a packet from the peer end in 3s, a timeout occurs.

Figure 1-1 LACP Negotiation

As shown in Figure 1-1, Device A is connected to Device B through three ports. Set the system priority of Device A to 61440 and that of Device B to 4096. Enables LACP link aggregation on the three directly connected ports of Device A and Device B, set the aggregation mode of the three ports to the active mode, and set the port priority to the default value 32768.

When receiving an LACPDU from Device A, Device B finds that it has a higher system ID priority than Device A (a smaller value indicates a higher priority). Therefore, Device B sets Port 4, Port 5, and Port 6 to **Bundle** state based on the order of port ID priorities (or in an ascending order of port numbers if the port priorities are the same). When receiving an updated LACPDU from Device B, Device A finds that Device B has a higher system ID priority and has set Port 4, Port 5, and Port 6 to **Bundle** state. Then Device A also sets Port 1, Port 2, and Port 3 to **Bundle** state.

3. Member Port Mode

There are three aggregation modes available, namely, active, passive, and static.

Member ports in active mode initiate LACP negotiation. Member ports in passive mode only respond to received LACPDUs. Member ports in static mode do not send LACPDUs for negotiation. The following table lists the requirements for peer port mode.

Table 1-1 Requirements for Peer Port Aggregation in Aggregation Mode

Port Mode	Peer Port Mode
Active mode	Active or passive mode
Passive mode	Active mode
Static Mode	Static Mode

4. Member Port State

Static member ports can be in **Up** or **Down** state.

- When a member port is **Down**, the port cannot forward packets. The **Down** state is displayed.
- When a member port is **Up** and the link protocol is ready, the port can forward packets. The **Up** state is displayed.

LACP member ports has the following three states:

- When the link of a port is **Down**, the port cannot forward packets. The **Down** state is displayed.
- When the link of a port is **Up** and the port is added to an aggregation group (as a member of the aggregation group, the port participates in data packet forwarding of the aggregation group) after LACP negotiation, the **bndl** state is displayed.
- When the link of a port is **Up** but the port is suspended because the peer end is not enabled with LACP or the attributes of the ports are inconsistent with those of the master port, the **susp** state is displayed. (The port in **susp** state does not forward packets.)

Note

- Only full-duplex ports are capable of LACP aggregation.
- LACP aggregation can be implemented only when the rates, flow control approaches, medium types, and L2/L3 attributes of member ports are consistent.
- If you modify the preceding attributes of a member port in the aggregation group, LACP aggregation will fail.
- The ports which are prohibited from joining or exiting an aggregate interface cannot be added to or removed from a static aggregate interface or an LACP aggregate interface.

5. Capacity Mode

The maximum number of member ports is fixed, which is equal to the maximum number of aggregate interfaces multiplied by the maximum number of member ports supported by a single aggregate interface. If you want to increase the maximum number of aggregate interfaces, the maximum number of member ports supported by a single aggregate interface must be reduced, and vice versa. This concerns the aggregate interface capacity mode concept. Some devices support the configuration of the aggregate interface capacity mode. For example, if the system supports 16,384 member ports, you can select 1024 x 16, 512 x 32, and other aggregate interface capacity modes (Maximum number of aggregate interfaces multiplied by the maximum number of member ports supported by a single aggregate interface).

6. LACP System ID

By default, all the LACP interfaces on a device belong to the same LACP aggregation group.

The system is identified by a system ID and each system has a priority, which is a configurable value. The system ID consists of the LACP system priority and MAC address of the device. A lower system priority indicates a higher priority of the system ID. If the system priorities are the same, a smaller MAC address of the device indicates a higher priority of the system ID. The system with an ID of a higher priority determines the port state. The port state of a system with an ID of a lower priority keeps consistent with that of a higher priority.

The LACP system ID can be configured when LACP interfaces of multiple (a maximum of four) independent devices need to negotiate with the LACP interface of a specific device (for example, LACP interfaces of two independent ASWs need to negotiate with the LACP interface of the NC). You can set the system IDs of the LACP interfaces of independent devices to the same MAC address and configure different device IDs to implement normal negotiation.

7. LACP Device ID

The LACP device ID can be configured when LACP interfaces of multiple independent devices need to negotiate with the LACP interface of a specific device. It must be configured together with the system ID.

8. LACP Port ID

Each port has an independent LACP interface priority, which is a configurable value. The port ID consists of the LACP interface priority and port number. A smaller port priority indicates a higher priority of the port ID. If the port priorities are the same, a smaller port number indicates a higher priority of the port ID.

9. LACP Master Port

When dynamic member ports are **Up**, LACP selects one of those ports to be the master port based on the rates and duplex modes, ID priorities of the ports in the aggregation group, and the bundling state of the member ports in the **Up** state. Only the ports that have the same attributes as the master port are in **Bundle** state and participate in data forwarding. When the attributes of ports are changed, LACP reselects a master port.

10. Preferred Member Port

The preferred member port feature is used when an aggregate interface is connected to a server with two systems. An aggregate interface member port is selected as the preferred port that forwards specified packets (packets of the management VLAN) to the server. These packets will not be distributed to other member ports by load balancing. This ensures the communication with the server.

Caution

Configure the port connected to the management network interface card (NIC) of the server as the preferred member port.

Some Linux servers have two systems. For example, an HP server has a master system and remote management system. The master system is a Linux system. The remote management system with Integrated Lights-Out (iLO) provides remote management at the hardware-level. iLO can manage the server remotely even when the master system is restarted. The master system has two NICs bundled into an aggregate interface for service processing. The management system uses one of the two NICs for remote management. Because services are separated by different VLANs, the VLAN used by the management system is called a management VLAN. The port of a device connected to a server with two NICs is an aggregate interface. The packets of the management VLAN must be sent by the member port connected to the NICs of the server to ensure the communication with the remote management system. You can configure a preferred member port to send the packets of the management VLAN.

Caution

For a server with two NICs bundled through LACP, if LACP is not running when the master system is restarted, LACP negotiation fails and the aggregate interface is **Down**. In this case, the preferred member port is downgraded into a static member port and it is bound to the aggregate interface for communication with the remote management system of the server. The preferred member port will be enabled with LACP again for negotiation after the Linux system is restarted and LACP runs normally.

11. Minimum Number of Member Ports

An aggregate interface can be configured with a minimum number of member ports. When a member port exits the link aggregation group, causing the number of member ports to be smaller than the minimum number, the other member ports in the group are unbundled, and the aggregate interface is **Down**. When the member port rejoins the group, causing the number of member ports to be greater than the minimum number, the member ports in the group are automatically bundled, and the aggregate interface is **Up** again.

12. LACP Independent Ports

In normal cases, LACP independent ports are used for interworking between access switches and servers with two NICs. If the operating system (OS) is not pre-installed when a server with two NICs starts, the OS needs to be installed via the remote preboot execution environment (PXE) OS installation device. Before the OS is installed, the server with two NICs cannot perform LACP negotiation with the access device, and only one NIC can work. In this case, the port on the access device must be able to automatically change to a common Ethernet physical port to ensure normal communication between the server and the remote PXE OS installation device. After the OS is installed and both NICs can run the LACP, the port on the access device must be able to enable the LACP again for negotiation.

Caution

- LACP independent ports can work only at layer 2. After an LACP independent port is enabled through configuration, if the LACP independent port does not receive LACP packets, it automatically changes to a common Ethernet port, which automatically copies the rate, duplex mode, flow control, and VLAN configuration from the aggregate interface to ensure port forwarding capabilities.
- An LACP independent port automatically changes to a common Ethernet port only if it does not receive LACP packets within the set timeout period. After the port receives LACP packets, it changes to an LACP member port again.

1.1.2 Load Balancing

Aggregated ports segregate packet flows by using load balancing algorithms based on packet features, such as the source and destination MAC addresses, source and destination IP addresses, and L4 source and destination port numbers. The packet flow with the consistent feature is transmitted by one member link, and different packet flows are evenly distributed to member links. For example, in source MAC address-based load balancing, packets are distributed to the member links based on the source MAC addresses of the packets. Packets with different source MAC addresses are evenly distributed to member links. Packets with the identical source MAC address are forwarded by one member link.

Currently, there are several link aggregation load balancing modes as follows:

- Source MAC address or destination MAC address
- Source MAC address + destination MAC address
- Source IP address or destination IP address
- Source IP address + destination IP address
- L4 source port number or L4 destination port number
- L4 source port number + L4 destination port number
- Source IP address + L4 source port number
- Source IP address + L4 destination port number

- Destination IP address + L4 source port number
- Destination IP address + L4 destination port number
- Source IP address + L4 source port number + L4 destination port number
- Destination IP address + L4 source port number + L4 destination port number
- Source IP address + destination IP address + L4 source port number
- Source IP address + destination IP address + L4 destination port number
- Source IP address + destination IP address + L4 source port number + L4 destination port number
- Panel port for incoming packets
- Labels of Multiprotocol Label Switching (MPLS) packets
- Aggregation member port polling
- Enhanced load balancing mode

Note

- Load balancing based on IP addresses or port numbers is applicable only to L3 packets. When a device enabled with this load balancing method receives L2 packets, it automatically switches to the default load balancing method.
- All the load balancing methods use a load algorithm (hash algorithm) to calculate the member links based on the input parameters of the methods. The input parameters include the source MAC address, destination MAC address, source MAC address + destination MAC address, source IP address, destination IP address, source IP address + destination IP addresses, source IP address + destination IP address + L4 port number and so on. The algorithm ensures that packets with different input parameters are evenly distributed to member links. It does not indicate that these packets are always distributed to different member links. For example, in IP address-based load balancing, two packets with different source and destination IP addresses may be distributed to the same member link through calculation.
- Load balancing varies with product version. The actual product prevails.

1. Enhanced Load Balancing

Enhanced load balancing allows the combination of multiple fields in different types of packets. These fields include **src-mac**, **dst-mac**, **src-port** in L2 packets, **dst-ip, l4-dst-port, l4-src-port**, **protocol, src-ip, src-port** in IPv4 packets, **dst-ip, l4-dst-port, l4-src-port**, **protocol, src-ip, src-port**, **vlan** in IPv6 packets.

A device enabled with enhanced load balancing first determines the types of packets to be transmitted and performs load balancing based on the specified fields in the packets. For example, the aggregate interface performs source IP-based load balancing on the packets containing an ever-changing source IPv4 address.

Note

- All the load balancing methods are applicable to L2 and L3 aggregate interfaces. You need to configure proper load distribution methods based on different network environments to fully utilize network bandwidth.
- Perform enhanced load balancing based on the **src-mac**, **dst-mac** fields in L2 packets, and the **src-ip** field in IPv4 packets. If the incoming packet is an IPv4 packet with an ever-changing source MAC address, the enhanced balancing algorithm does not take effect, because the device performs load balancing only based on the **src-ip** field in the IPv4 packet after finding that it is an IPv4 packet.
- In enhanced load balancing, the MPLS balancing algorithm takes effect only for MPLS L3 VPN packets, but does not take effect for MPLS L2 VPN packets.

2. Hash Load Balancing Control

Hash load balancing enables users to flexibly control load balancing in different scenarios. Currently, Ruijie adopts the following hash load balancing control functions:

- Hash disturbance factor

  Traffic over aggregate interfaces is hashed for balancing. For two devices of the same type, the same path is calculated for load balancing for the same stream. When the equal-cost multi-path (ECMP) is deployed, the same stream of the two devices may be balanced to the same destination device, resulting in hash polarization. The hash disturbance factor is used to affect the load balancing algorithm. Different disturbance factors are configured for different devices to ensure that different paths are provided for the same stream.

- Symmetric hashing

  To ensure network security, a firewall cluster is deployed between the internal and external networks for traffic cleaning. This requires that both the uplink and downlink traffic of a session is transmitted to the same device in the firewall cluster for processing. The source and destination IP addresses contained in the uplink and downlink streams of a session are reversed. The uplink and downlink streams will be directed to different firewalls in the firewall cluster based on the traditional hash algorithm. Symmetric hashing ensures that uplink and downlink streams of a session be transmitted over the same path.

Figure 1-2 Differences in Packet Processing Before and After the Symmetric Hash Function Is Configured

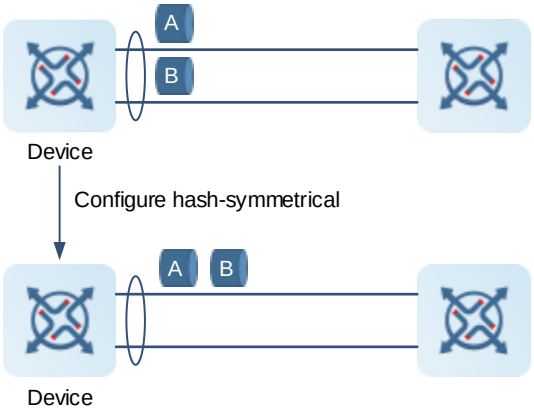


Figure 1-2 shows the differences in packet processing before and after the symmetric hash function is configured. Packets A and B are the uplink and downlink packets of a certain session respectively, and they are forwarded by an aggregate interface when passing through a device. If the device is not configured with the symmetric hash function, packets A and B may be forwarded through different physical interfaces of the aggregate interface after being hashed. If the device is configured with the symmetric hash function, packets A and B will be forwarded through the same physical interface of the aggregate interface when the device recognizes that packets A and B belong to the same session.

- Flexible hash

  In normal cases, the load balancing cluster interworks with multiple ToRs via the ECMP, and the ToRs are required to balance all packets of a session to the same scheduling server. However, when a server is faulty, all session streams will be ordered and balanced again based on the traditional load balancing mechanism of ToRs. In this case, packets of the same session may be balanced to two servers. The

flexible hash function ensures that when one link is faulty, traffic on other links is not affected and only the traffic of the faulty link is balanced to other active links. In this case, traffic of a session is balanced to the same server.

Figure 1-3 Load Balancing upon a Link Fault when the Flexible Hash Function is Not Configured

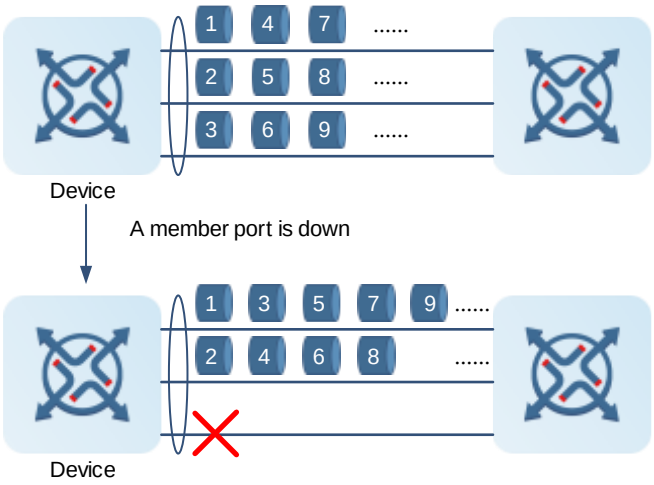

Figure 1-3 shows the load balancing upon a link fault on the condition that a device is not configured with the flexible hash function. If no fault occurs, traffic load is balanced to different links of the aggregate interface. If one of the member interfaces encounters a fault, since the flexible hash function is not configured, the traffic carried on the normal links may be affected when the aggregate interface recalculates the hash result based on the number of member interfaces.

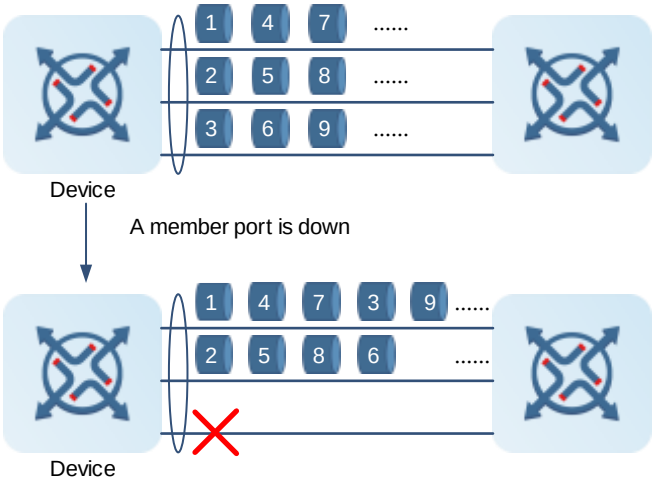
Figure 1-4 Load Balancing upon a Link Fault when the Flexible Hash Function is Configured



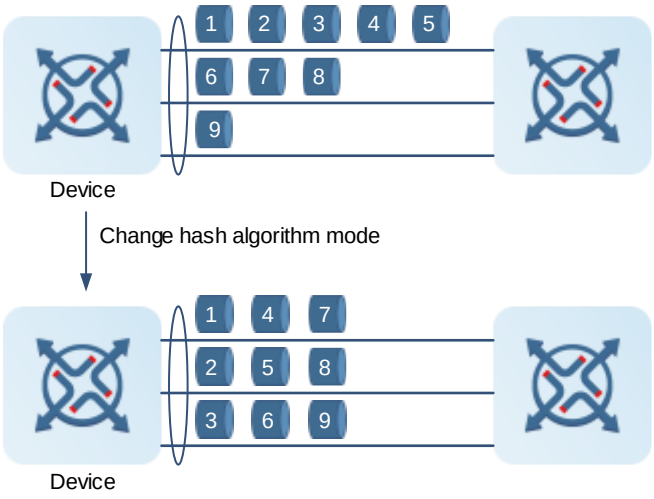


Figure 1-4 shows the load balancing upon a link fault on the condition that a device is configured with the flexible hash function. Once a member interface encounters a fault, the hash policies on the normal links will not be affected when the aggregate interface recalculates the hash result, but the traffic originally forwarded by the faulty interface will be distributed to the other member interfaces.

- Hash algorithm mode

Apply the most appropriate hash algorithm mode to different traffic models, so that when traffic changes, balance can still be kept. For example, if the source and destination MAC addresses of a stream increase by 1 at the same time, configuring the algorithm based on the source and destination MAC addresses cannot keep stream balance. In this case, a suitable hash algorithm mode needs to be applied.

Figure 1-5 Load Balancing Before and After the Hash Algorithm Mode Is Changed

1.1.3 Member Port BFD Detection

Bidirectional Forwarding Detection (BFD) is a protocol that delivers fast detection of path failures. According to RFC7130, LACP takes 3s to detect link failures even in short timeout mode. All the packets sent to the faulty link during the 3-second period will be dropped. BFD correlation delivers faster failure detection. You can configure BFD on member ports to detect link failure and switch load to other member links in case of a link failure. BFD is classified into IPv4 detection and IPv6 detection, which detect IPv4 and IPv6 paths respectively. When BFD detects that the path on a member port fails, the packets are not distributed to the member port. After BFD is enabled on an aggregate interface, BFD sessions are set up on its member ports in forwarding state independently.

1.1.4 Protocols and Standards

- IEEE 802.3ad

1.2 Configuration Task Summary

The aggregate interface configuration includes the following tasks:

(1) (Optional)Enabling the LACP Independent Port Function

(2) (Optional)Configuring VAP Pre-Switching

(3) Configuring Static Aggregate Interfaces

(4) (Optional) Configuring LACP Interfaces

(5) (Optional) Enabling LinkTrap

(6) (Optional) Configuring a Load Balancing Mode

(7) (Optional) Configuring a Capacity Mode

(8) (Optional) Enabling BFD for Member Ports

(9) (Optional) Configuring a Preferred Member Port

(10) (Optional) Configuring the Minimum Number of Member Ports

(11) (Optional)Enabling the LACP Independent Port Function

(12) (Optional)Configuring VAP Pre-Switching

1.3 Configuring Static Aggregate Interfaces

1.3.1 Overview

- Configure multiple physical ports as member ports to realize link aggregation.
- The bandwidth of the aggregation link is equal to the sum of the member link bandwidths.
- When a member link of the aggregate interface is disconnected, the load carried by the link is automatically allocated to other functional member links.

1.3.2 Restrictions and Guidelines

- Only physical ports can be added to an aggregate interface.
- Before adding an interface to a static AP, run the **shutdown** command in the interface configuration mode to avoid flapping. After the interface and its peer interface are added to the corresponding static APs, run the **no** form of the shutdown command.
- To prevent a transient loop when a member port exits, you need to set the member port to **shutdown** state before it exits the aggregate interface.
- The ports of different medium types or port modes cannot be added to the same aggregate interface.
- L2 ports can be added to only a L2 aggregate interface, and L3 ports can be added to only a L3 aggregate interface. The L2/L3 attributes of an aggregate interface that contains member ports cannot be modified.
- After a port is added to an aggregate interface, the attributes of the port are replaced by those of the aggregate interface.
- After a port is removed from an aggregate interface, the attributes of the port before the adding to the aggregate interface are restored.
- There is continuous traffic at the aggregate interface. If a member port changes from **Link Up** to **Link Down**, an error may occur in traffic statistics of the aggregate interface.
- When the aggregate interface includes a member port that supports **port speed-mode** configuration, the aggregate interface does not support speed configuration, and the original speed configuration on the aggregate interface is automatically cleared. The configured rate of the aggregate interface is switched to that of **port speed-mode** for the member port.
- You can run the **port-group** command to add a physical port to a static aggregate interface in the interface configuration mode of the specified Ethernet port. If the aggregate interface does not exist, it will be created automatically.
- You can run the **port-group mode** command to add a physical port to an LACP aggregate interface in the interface configuration mode of the specified physical port. If the aggregate interface does not exist, it will be created automatically.
- The aggregate interface feature must be configured on the devices at both ends of a link and the aggregate

interface mode must be the same (static aggregate interface or LACP aggregate interface).

- After a member port exits the aggregate interface, the default configurations of the member port may be restored. The original configurations of aggregate interface members are processed in different ways for different functions. You are advised to check and confirm the port configurations after a member port exits an aggregate interface.
- After a member port exits an aggregate interface, the port is shut down to avoid loops. After confirming that the topology is normal, you can run **no shutdown** in interface configuration mode to enable the port again.
- If the VLAN resource is in a critical state (the number of configured VLANs and the number of routed ports reach the VLAN capacity values) when a member port of L3 aggregate interface exits the aggregate interface, the port may be switched to a L2 port.
- The aggregate interface created on a L3 device that does not support L2 features is a L3 aggregate interface; otherwise the aggregate interface is a L2 aggregate interface.

Warning

- After a port is added to an aggregate interface, the attributes of the port are consistent with those of the aggregate interface. Therefore, it is generally not allowed to perform configuration on the member ports or apply configurations to a specific member port. However, some commands or functions (such as the **shutdown** and **no shutdown** commands) can be configured on the member ports. When using the member ports, you need to check whether the function that you want to configure can take effect on a specific member port, and perform the configuration properly.
- The error detection function is unavailable to static aggregation. Member ports are bound if linked up. Therefore, you needs to ensure topology accuracy and negotiated attribute consistency among the member ports.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an Ethernet aggregate interface.

interface aggregateport *ap-number*

Perform this configuration on an aggregate interface-enabled device. When an Ethernet port needs the aggregation function, create the corresponding Ethernet aggregate interface

No aggregate interface is configured by default.

(4) Enter the interface configuration mode.

interface *interface-type interface-number*

(5) Configure member ports of a static aggregate interface.

port-group *ap-number*

Perform this configuration on aggregate interface-enabled devices. To use the static aggregation function, configure the corresponding member ports of a static aggregate interface.

By default, the Ethernet physical port does not belong to any static aggregate interface or LACP aggregate interface.

(6) (Optional) Convert L2 aggregate interfaces to L3 aggregate interfaces.

no switchport

The aggregate interface is a L2 port by default.

(7) (Optional) Create a sub-interface of an Ethernet aggregate interface.

interface aggregateport *sub-ap-number*

No sub-interface of an Ethernet aggregate interface is configured by default.

1.4 Configuring LACP Interfaces

1.4.1 Overview

- Connected devices perform auto negotiation through LACP to realize dynamic link aggregation.
- The bandwidth of the aggregation link is equal to the sum of the member link bandwidths.
- When a member link of the aggregate interface is disconnected, the load carried by the link is automatically allocated to other functional member links.
- It takes 90s for LACP to detect a link failure in long timeout mode and 3s in short timeout mode.

1.4.2 Restrictions and Guidelines

- After a port exits an LACP aggregate interface, the default configurations of the port may be restored. The original configurations of LACP members are processed in different ways for different functions. You are advised to check and confirm the port configurations after a member port exits an LACP aggregate interface.
- To prevent a transient loop when a member port exits, you need to set the member port to **shutdown** state before it exits the aggregate interface.
- Changing the LACP system priority may cause LACP member ports to be disaggregated and aggregated again.
- Changing the priority of an LACP member port may cause the other member ports to be disaggregated and aggregated again.
- There is continuous traffic at the aggregate interface. If a member port changes from **Link Up** to **Link Down**, an error may occur in traffic statistics of the aggregate interface.
- When the aggregate interface includes a member port that supports **port speed-mode** configuration, the aggregate interface does not support speed configuration, and the original speed configuration on the aggregate interface is automatically cleared. The configured rate of the aggregate interface is switched to that of **port speed-mode** for the member port.
- The LACP member port configurations at both ends of a link must be consistent.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the LACP system priority.

lacp system-priority

Perform this configuration when you need to adjust the system ID priority. A smaller value indicates a higher system ID priority. The device with a higher system ID priority takes precedence in selecting an aggregate interface.

The LACP system priority of a port is 32768 by default.

(4) Configure the timeout interval of the LACP system in short timeout mode.

lacp short-timeout period *interval*

The timeout interval of the LACP system is 3 seconds in short timeout mode by default.

(5) Enter the interface configuration mode.

interface *interface-type interface-number*

(6) Configure LACP member ports.

port-group *key-number* **mode** { **active** | **passive** }

By default, the Ethernet physical port does not belong to any LACP aggregate interface.

(7) Configure the priority of an LACP member port.

lacp port-priority *port-priority*

Perform this configuration when you need to specify the port ID priority. A smaller value indicates a higher port ID priority. The port with the highest port ID priority will be selected as the master port.

The priority of the LACP member port is 32768 by default.

(8) Configure the timeout mode of LACP member ports.

lacp short-timeout

When you need to implement real-time link failure detection, configure the short timeout mode. A timeout occurs if a port does not receive a packet within 3 seconds in short timeout mode and 90 seconds in long timeout mode.

The timeout mode of an LACP member port is long timeout by default.

(9) Roll back to the global configuration mode.

exit

(10) Enter the aggregation interface configuration mode.

- Enter the Layer 2 ethernet interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface aggregateport *interface-number*

(11) (Optional) Configure the LACP system ID.

lacp system-id *system-id*

Configure the LACP system ID when LACP interfaces of multiple (a maximum of four) independent devices need to negotiate with the LACP interface of a specific device.

The LACP system ID is the system ID (MAC address) of the device by default.

(12) (Optional) Configure the LACP device ID.

lacp device *number*

Configure the LACP device ID when LACP interfaces of multiple (a maximum of four) independent devices need to negotiate with the LACP interface of a specific device.

The device ID is 0 by default.

1.5 Enabling LinkTrap

1.5.1 Overview

Enable the system with LinkTrap to send LinkTrap messages when aggregation links are changed.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the aggregate interface configuration mode.

interface Aggregateport *ap-interface-number*

(4) (Optional) Configure the LinkTrap function of an aggregate interface.

snmp trap link-status

The LinkTrap notification function of an aggregate interface is enabled by default.

(5) (Optional) Configure the LinkTrap function of member ports.

aggregateport member linktrap

The LinkTrap notification function of member ports is disabled by default.

1.6 Configuring a Load Balancing Mode

1.6.1 Overview

- The system distributes incoming packets among member links by using the specified load balancing algorithm. The packet flow with the consistent feature is transmitted by one member link, whereas different packet flows are evenly distributed to various links. A device enabled with enhanced load balancing first determines the types of packets to be transmitted and performs load balancing based on the specified fields in the packets. For example, the aggregate interface performs source IP-based load balancing on the packets containing an ever-changing source IPv4 address.
- In enhanced load balancing mode, configure the hash disturbance factor to ensure that same packets from two devices of the same type is balanced to different links.
- In enhanced load balancing mode, enable symmetric hashing to ensure that uplink and downlink packets of the same type are transmitted over the same link. For example, in load balancing based on the source and destination IP addresses, enable symmetric hashing for IPv4 packets to ensure that the uplink and downlink IPv4 packets are transmitted over the same path.

- Enable flexible hash to balance traffic of a faulty link over a member port to other active links without affecting original data streams on these active links.

1.6.2 Restrictions and Guidelines

- Different disturbance factors may lead to the same disturbance effect.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the global load balancing algorithm of an aggregate interface.

aggregateport load-balance { **dst-ip** | **dst-mac** | **enhanced profile** *profile-name* | **ip** | **src-dst-ip** | **src-dst-ip-l4port** | **src-dst-ip-src-dst-l4port** | **src-dst-mac** | **src-ip** | **src-mac** }

By default, traffic distribution for link aggregation ports is based on the enhanced template.

(4) (Optional) Enable or disable flexible hashing.

aggregateport hash-elasticity enable

Perform this operation to balance the load of a faulty link over a member port to other active links without affecting original flow on these active links.

The flexible hash balancing function is disabled by default.

(5) (Optional) Configure the global load balance algorithm mode on an aggregate interface.

aggregateport algorithm mode *algorithm-number*

Perform this operation when the traffic model changes to keep optimal load balance.

The algorithm mode varies with the product version by default. The algorithm mode is 12 by default.

(6) (Optional) Configure the balancing factor acquisition mode for a tunnel packet.

aggregateport hash-header { **inner** | **outer** }

When configuring load balancing, you can run this command to specify the balancing factor acquisition mode for a specific tunnel packet, achieving the optimal load balancing effect.

The balancing factor of a tunnel packet varies with the product version by default. The actual product prevails.

(7) (Optional) Rename the enhanced load balancing profile.

load-balance-profile *profile-name*

By default, if a device supports enhanced load balancing, the system creates a profile named **default** for enhanced load balancing. You can use this function to rename the profile or restore the default configurations.

(8) (Optional) Configure the load balancing mode of L2 packets.

l2 field { **dst-mac** | **src-mac** | **src-port** } *

When the enhanced load balancing profile configuration is used as the flow balancing mode of aggregate interface, you can perform this configuration according to the traffic feature configuration of the network to implement better load balance.

The load balancing mode of L2 packets is a combination of **src-mac**, **dst-mac**, and **vlan** by default.

(9) (Optional) Configure the load balancing mode of IPv4 packets.

ipv4 field { **dst-ip** | **l4-dst-port** | **l4-src-port** | **protocol** | **src-ip** | **src-port** | **vlan** } *

Perform this configuration to specify the load balancing mode of IPv4 packets.

The load balancing mode of IPv4 packets is a combination of **src-ip** and **dst-ip** by default.

(10) (Optional) Configure the load balancing mode of IPv6 packets.

ipv6 field { **dst-ip** | **l4-dst-port** | **l4-src-port** | **protocol** | **src-ip** | **src-port** | **vlan** } *

Perform this configuration to specify the load balancing mode of IPv6 packets.

The load balancing mode of IPv6 packets is a combination of **src-ip** and **dst-ip** by default.

(11) (Optional) Configure the load balancing mode of MPLS packets.

mpls field { **2nd-label** | **3rd-label** | **dst-ip** | **l4-dst-port** | **l4-src-port** | **protocol** | **src-ip** | **src-port** | **top-label** } *

Perform this configuration to specify the load balancing mode of MPLS packets.

The load balancing mode of MPLS packets is a combination of **src-ip dst-ip, l4-src-port, l4-dst-port, top-label** and **2nd-label** by default.

(12) (Optional) Configure a hash disturbance factor.

hash-disturb *factor-string*

Perform this operation to balance packets of the same type over the aggregate interface for devices of the same type. It is not guaranteed that either configuration affects the balancing effect. If there is no expected effect, the other values can be configured.

The load balancing hash disturbance function is disabled by default.

(13) (Optional) Enable or disable symmetric hashing.

hash-symmetrical { **ipv4** | **ipv6** }

Perform this operation to ensure that uplink and downlink streams of the same packet type are transmitted over the same path.

Symmetric hashing varies with the product version by default. The actual product prevails.

1.7 Configuring a Capacity Mode

1.7.1 Overview

- Change the maximum number of configurable aggregate interfaces and the maximum number of member ports in each aggregate interface.

1.7.2 Restrictions and Guidelines

- The system has a default aggregate interface capacity mode. You can run **show aggregateport capacity** to display the current capacity mode.

- If the current configuration (maximum number of aggregate interfaces or the number of member ports in each aggregate interface) exceeds the capacity to be configured, the capacity mode configuration will fail.
- The range of aggregate interface ID is from 1 to the total number of common aggregate interface capacity and aggregate interface expansion capacity. When the aggregate interface ID is less than or equal to the common aggregate interface capacity, the capacity resources of the common aggregate interfaces are used. When the aggregate interface ID is greater than the common aggregate interface capacity, the aggregate interface expansion capacity resources are used.
- When the aggregate interface capacity mode is switched, you need to delete the aggregate interfaces involved in resource switching first. For example, when the aggregate interface capacity mode is switched from 128*16 to 256 x 8, if aggregate interfaces 129–256 are created, you need to delete these aggregate interfaces first before switching the capacity mode configuration.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure an aggregate interface capacity mode.

aggregateport capacity mode *capacity-mode*

Perform this configuration to change the aggregate interface capacity, so as to meet the requirement imposed by changes in the number of aggregate interfaces in network deployment or the number of member ports that can be bound to each aggregate interface.

The capacity mode of an aggregate interface is 256*16.

1.8 Enabling BFD for Member Ports

1.8.1 Overview

- Enable BFD for all the member ports of a specified aggregate interface.
- After BFD is enabled for an aggregate interface, each member port performs BFD to determine whether the packets should be distributed to the member port for load balancing. When BFD detects a member port in **Down** state, the packets are not distributed to the port. When BFD detects that the member port is restored to **Up**, the packets are distributed to the port.

1.8.2 Restrictions and Guidelines

- After BFD is enabled for an aggregate interface, BFD sessions are set up. To make the sessions take effect, you need to configure BFD parameters. For details, see *Configuring BFD*.
- Enabling or disabling BFD for a single member port is not supported. You must enable or disable BFD for the entire aggregate interface group.
- Only member ports in forwarding state are enabled with BFD. If a member port is not in forwarding state because the link or LACP is **Down**, the BFD session on the member port is automatically deleted.
- If only one member port is available (that is, in forwarding state), all packets are distributed to this port. In

this case, BFD fails. When there are more than one available member port, BFD takes effect again.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 aggregate interface configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(4) (Optional) Configure BFD for member ports.

aggregate bfd-detect { **ipv4** *source-ipv4-address destination-ipv4-address* | **ipv6** *source-ipv6-address destination-ipv6-address* }

Enable BFD when you need to detect path failure on member ports in milliseconds. The flow on the faulty member port will be switched to other member port in case of link failure.

The BFD function of a member port is disabled by default.

1.9 Configuring a Preferred Member Port

1.9.1 Overview

- Configure a member port as the preferred member port.
- After the preferred member port is configured, the management VLAN packets on the aggregate interface are forwarded by this port.

1.9.2 Restrictions and Guidelines

- For details about management VLAN configuration, see *Configuring MAC VLAN*.
- Only one preferred member port can be configured for one aggregate interface.
- After an LACP member port is configured as the preferred member port, if the LACP negotiation on all member ports fails, the preferred port is automatically downgraded to a static member port.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the management VLAN of the aggregate interface.

aggregateport-admin vlan *vlan-range*

No management VLAN is configured for an aggregate interface by default.

(4) Enter the interface configuration mode.

interface *interface-type interface-number*

(5) Configure a preferred member port.

aggregateport primary-port

Perform this configuration to specify a member port dedicated to forwarding management VLAN packets. The configuration is applicable to dual-system servers. Configure the port connected to the management NIC of the server as the preferred member port.

No preferred port is configured by default.

1.10 Configuring the Minimum Number of Member Ports

1.10.1 Overview

- After the minimum number of member ports is configured, the aggregation group takes effect only when the number of active member ports is greater than the minimum number.
- You can perform this operation to ensure that the link bandwidth provided by an aggregation group is greater than or equal to the sum of bandwidth provided by member ports of aggregate interfaces.
- After an action for the minimum number of member ports is configured, for example, shutting down the aggregate interface, the action is triggered when the number of member ports in **Up** state is less than the minimum number of the member ports.

1.10.2 Restrictions and Guidelines

- If the number of member ports for an LACP interface is less than the minimum number of member ports of the aggregate interface configured, all member ports are in the unbinding state, and the peer end is also automatically unbound.
- After the minimum number of member ports of a static aggregate interface is configured, if the number of member ports of a static aggregate interface in **Up** state is less than the minimum number, the member ports of a static aggregate interface in **Up** state cannot forward data and the corresponding aggregate interface is **Down**. However, the state of the peer end is not affected. Therefore, the corresponding functions need to be configured on the peer end.
- After an action for the minimum number of member ports is configured, the action is triggered only when the number of member ports in **Up** state decreases to an insufficient number. For example, if the minimum number is set to 3, the action is triggered only when the number of member ports decreases from 3 or more to less than 3.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 aggregate interface configuration mode.

interface aggregateport *ap-number*

- Enter the Layer 3 aggregate interface configuration mode.

interface aggregateport *ap-number*

(4) (Optional) Configure the minimum number of member ports.

aggregateport member minimum *port-number*

Perform this configuration to specify the minimum number of the member ports of a link aggregation.

The minimum number of member ports of an aggregate interface is 1 by default.

(5) (Optional) Configure the action triggered when the number of member ports is smaller than the minimum value.

aggregateport member minimum action shutdown

Perform this configuration when some actions need to be triggered when the number of member ports in **Up** state is less than the minimum number of member ports.

By default, no action is configured for the minimum number of member ports in an aggregate interface.

1.11 Enabling the LACP Independent Port Function

1.11.1 Overview

- After the LACP independent port function is enabled, an LACP member port automatically changes to a common physical port if the LACP member port does not receive LACP packets within the set timeout period. The LACP member port state is changed to individual and the LACP member port can forward packets properly.
- After the LACP member port receives LACP packets, it changes to an LACP independent port again to perform LACP packet negotiation.
- The timeout period of an independent port can be adjusted by configuration.

1.11.2 Restrictions and Guidelines

- After the LACP independent port function is enabled, an LACP member port does not immediately change to a common physical port. Instead, the LACP member port changes to an independent port (a common physical port) only if it does not receive LACP packets within the set timeout period.
- The timeout period configuration of the LACP independent port only affects LACP member ports that have not changed into independent ports. After the timeout period is configured, the period calculation restarts.
- In long timeout mode, the LACP packet is sent every 30s. The timeout period should be longer than 30s so as not to affect the normal LACP negotiation. You are advised to configure the timeout period at least twice the period of LACP packet sending. In short timeout mode, the timeout period is not limited.

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the timeout period of an LACP independent port.

lacp individual-timeout period *time*

Run this command to adjust the timeout period of an LACP independent port.

The timeout period of an LACP independent port is 90s by default.

(4) Enter the interface configuration mode.

interface *interface-type interface-number*

(5) (Optional) Enable the LACP independent port function.

lacp individual-port enable

Perform this operation so that an LACP member port can forward packets normally when the LACP member port cannot perform LACP negotiation.

The LACP independent port function is disabled by default.

1.12 Configuring VAP Pre-Switching

1.12.1 Overview

In the M-LAG device upgrade scenario, you can run the **lacp force-vap-down** command to trigger the member interface of the VAP to send an LACP negotiation timeout packet. After the downlink device receives the packet, it enters the negotiation suspend state. As a result, uplink traffic of the downlink device is switched to the other M-LAG device, to reduce packet loss during device upgrade and restart. After the device upgrade is complete, run the **no lacp force-vap-down** command to cancel the pre-switching configuration and restore the uplink traffic forwarding.

By running the **lacp force-vap-down enhance** command, select a member interface as the preferred interface on the VAP, and then trigger the member interface of the VAP to send LACP negotiation timeout packets. When the LACP negotiation status of the member interface of the VAP is in the suspend state, the preferred interface takes effect to continue packet forwarding, and the VAP is always in the Up state. This ensures that services are not interrupted during pre-switching.

1.12.2 Restrictions and Guidelines

- The VAP pre-switching function is configured for M-LAG device upgrade. It takes effect only on the member interface of the VAP, and common APs are not affected. When VAP pre-switching is enabled, the member interface of the VAP is in the negotiation suspend state.
- In M-LAG scenarios, the single-homed device cannot be configured as a VAP. Otherwise, when the VAP pre-switching function is enabled, the single-homed device will experience traffic interruption.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the VAP pre-switching function.

lacp force-vap-down [**enhance**]

By default, the pre-switching function of VAP on M-LAG devices is disabled.

1.13 Monitoring

This section describes the **show** commands used for checking the running status of a configured function to verify the configuration effect.

You can run the **clear** commands to clear information.

Caution

Running the **clear** command during operation of the device may lose vital information and interrupt services.

Table 1-2 Aggregate Interface Monitoring

Command	Purpose
show aggregateport capacity	Displays the capacity mode and usage of an aggregate interface.
show aggregateport load-balance	Displays the load balancing information of an aggregate interface.
show aggregateport [*ap-number*] **summary**	Displays the summary of an aggregate interface.
show lacp capacity	Displays the LACP capability supported by the device.
show lacp counters [*key-number*]	Displays the statistics of LACP packets on LACP member ports. You can view the information of a specified LACP interface by specifying **key-number**.
show lacp counters [*key-number*]	Displays the LACP packet statistics of the member interface of the LACP link aggregation interface.
show lacp information gr	Displays LACP data synchronization information.
show lacp information ha	Displays LACP hot standby information.
show lacp information pkt-agent [**pkt_count** | **port** { *interface-index* | *interface-type interface-number* }]	Displays information about the LACP proxy.
show lacp information pkt_count	Displays packet statistics of an LACP process.
show lacp information port [*interface-index* | *interface-type interface-number* | **all**]	Displays LACP interface information.
show lacp information port-version	Checking the interface version number
show lacp summary [*key-number*]	Displays the state of an LACP interface. You can view the information of a specified LACP interface by specifying **key-number**.
show load-balance-profile [*profile-name*]	Displays the configuration of the enhanced load balancing profile.

Command	Purpose
show lacp information vap	Displays the VAP information.
clear lacp counters [*key-number*|*interface-type interface-number*]	Clears the statistics of LACP packets on an LACP member port.

1.14 Configuration Examples

1.14.1 Configuring Static Aggregate Interfaces

1. Requirements

Create aggregate interface interconnection for two devices on the IPv4 network, and configure static aggregate interfaces.

2. Topology

Figure 1-6 Topology for Configuring Static Aggregate Interfaces

3. Notes

- Add the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device A to static aggregate interface 3.
- Add the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device B to static aggregate interface 3.

4. Procedure

Create aggregate interface 3 on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface range GigabitEthernet 0/1-2
DeviceA(config-if-range)# port-group 3
```

Create aggregate interface 3 on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# interface range GigabitEthernet 0/1-2
DeviceB(config-if-range)# port-group 3
```

5. Verification

Run **show aggregateport summary** to check whether aggregate interface 3 contains member ports GigabitEthernet 0/1 and GigabitEthernet 0/2.

```
DeviceA# show aggregateport summary
```

```
AggregatePort MaxPorts SwitchPort Mode   Ports
------------- -------- ---------- ------ ----------------------------------
Ag3           8        Enabled    ACCESS Gi0/1,Gi0/2
DeviceB# show aggregateport summary
AggregatePort MaxPorts SwitchPort Mode   Ports
------------- -------- ---------- ------ ----------------------------------
Ag3           8        Enabled    ACCESS Gi0/1,Gi0/2
```

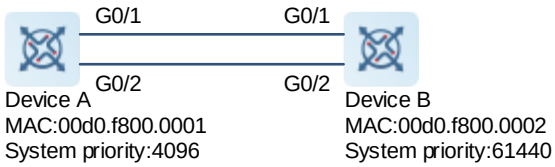
6. Configuration Files

- Device A configuration file

```
!
interface GigabitEthernet 0/1
 port-group 3
!
interface GigabitEthernet 0/2
 port-group 3
!
interface AggregatePort 3
!
```

- Device B configuration file

```
!
interface GigabitEthernet 0/1
 port-group 3
!
interface GigabitEthernet 0/2
 port-group 3
!
interface AggregatePort 3
!
```



1.14.2 Configuring LACP Interfaces

1. Requirements

Create aggregate interface interconnection for two devices on the IPv4 network, and configure dynamic aggregate interfaces.

2. Topology

Figure 1-7 Topology for Configuring LACP Ports

3. Notes

- On Device A, set the LACP system priority to 4096.
- Enable dynamic link aggregation on the GigabitEthernet0/1 and GigabitEthernet0/2 ports on Device A and add the ports to LACP interface 3.
- On Device B, set the LACP system priority to 61440.
- Enable dynamic link aggregation on the GigabitEthernet0/1 and GigabitEthernet0/2 ports on Device B and add the ports to LACP interface 3.

4. Procedure

Configure LACP Ports on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# lacp system-priority 4096
DeviceA(config)# interface range GigabitEthernet 0/1-2
DeviceA(config-if-range)# port-group 3 mode active
DeviceA(config-if-range)# end
```

Configure LACP Ports on Device B.

```
DevicB> enable
DeviceB# configure terminal
DeviceB(config)# lacp system-priority 61440
DeviceB(config)# interface range GigabitEthernet 0/1-2
DeviceB(config-if-range)# port-group 3 mode active
```

5. Verification

Run **show lacp summary 3** to check whether LACP interface 3 contains member ports GigabitEthernet0/1 and GigabitEthernet0/2.

```
DeviceA# show LACP summary 3
System Id:32768,00d0.f8fb.0001
Flags:  S - Device is requesting Slow LACPDUs
 F - Device is requesting Fast LACPDUs.
A - Device is in active mode.        P - Device is in passive mode.

```

6. Configuration Files

- Device A configuration file

```
!
lacp system-priority 4096
!
interface GigabitEthernet 0/1
 port-group 3 mode active
!
interface GigabitEthernet 0/2
 port-group 3 mode active
!
interface AggregatePort 3
!
```

- Device B configuration file

```
!
lacp system-priority 61440
!
interface GigabitEthernet 0/1
 port-group 3 mode active
!
interface GigabitEthernet 0/2
 port-group 3 mode active
!
interface AggregatePort 3
!
```

1.14.3 Enabling LinkTrap

1. Requirements

On the IPv4 network, create aggregate interface interconnection for two devices, configure static aggregate interfaces, and enable LinkTrap.

2. Topology

Figure 1-9 Topology for Enabling LinkTrap

3. Notes

- Add the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device A to static aggregate interface 3.
- Add the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device B to static aggregate interface 3.
- On Device A, disable LinkTrap for aggregate interface 3 and enable LinkTrap for its member ports.
- On Device B, disable LinkTrap for aggregate interface 3 and enable LinkTrap for its member ports.

4. Procedure

Perform the following configuration on Device A.

```
DeviceA# configure terminal
DeviceA(config)# interface range GigabitEthernet 0/1-2
DeviceA(config-if-range)# port-group 3
DeviceA(config-if-range)# exit
DeviceA(config)# aggregateport member linktrap
DeviceA(config)# interface Aggregateport 3
DeviceA(config-if-AggregatePort 3)# no snmp trap link-status
```

Perform the following configuration on Device B:

```
DeviceB# configure terminal
DeviceB(config)# interface range GigabitEthernet 0/1-2
DeviceB(config-if-range)# port-group 3
DeviceB(config-if-range)# exit
DeviceB(config)# aggregateport member linktrap
DeviceB(config)# interface Aggregateport 3
DeviceB(config-if-AggregatePort 3)# no snmp trap link-status
```

5. Verification

Run **show running** to check whether LinkTrap is enabled for aggregate interface 3 and its member ports.

```
DeviceA# show run | include AggregatePort 3
Building configuration...
Current configuration: 54 bytes
interface AggregatePort 3
```

```
 no snmp trap link-status
DeviceA# show run | include AggregatePort
aggregateport member linktrap
```

```
DeviceB# show run | include AggregatePort 3
Building configuration...
Current configuration: 54 bytes
interface AggregatePort 3
 no snmp trap link-status
DeviceB# show run | include AggregatePort
aggregateport member linktrap
```

6. Configuration Files

- Device A configuration file

```
!
interface GigabitEthernet 0/1
 port-group 3
!
interface GigabitEthernet 0/2
 port-group 3
!
interface AggregatePort 3
 no snmp trap link-status
!
aggregateport member linktrap
!
```

- Device B configuration file

```
!
interface GigabitEthernet 0/1
 port-group 3 mode active
!
interface GigabitEthernet 0/2
 port-group 3 mode active
!
interface AggregatePort 3
 no snmp trap link-status
!
aggregateport member linktrap
!
```

1.14.4 Configuring a Load Balancing Mode

1. Requirements

On the IPv4 network, create aggregate interface interconnection for two devices, configure static aggregate interfaces, and enable load balancing.

2. Topology

Figure 1-10 Topology for Configuring a Load Balancing Mode Topology

3. Notes

- Add the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device A to static aggregate interface 3.
- Add the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device B to static aggregate interface 3.
- On Device A, configure source MAC address-based load balancing for aggregate interface 3 in global configuration mode.
- On Device B, configure destination MAC address-based load balancing for aggregate interface 3 in global configuration mode.

4. Procedure

Perform the following configuration on Device A:

```
DeviceA# configure terminal
DeviceA(config)# interface range GigabitEthernet 0/1-2
DeviceA(config-if-range)# port-group 3
DeviceA(config-if-range)# exit
DeviceA(config)# aggregateport load-balance src-mac
```

Perform the following configuration on Device B:

```
DeviceB# configure terminal
DeviceB(config)# interface range GigabitEthernet 0/1-2
DeviceB(config-if-range)# port-group 3
DeviceB(config-if-range)# exit
DeviceB(config)# aggregateport load-balance dst-mac
```

5. Verification

Run **show aggregateport load-balance** to check the load balancing algorithm configuration.

```
DeviceA   # show aggregatePort load-balance
Load-balance    : Source MAC
```

```
DeviceB   # show aggregatePort load-balance
Load-balance    : Destination MAC
```

6. Configuration Files

- Device A configuration file

```
!
interface GigabitEthernet 0/1
 port-group 3
```

```
!
interface GigabitEthernet 0/2
 port-group 3
!
interface AggregatePort 3
!
aggregateport load-balance src-mac
!
```

- Device B configuration file

```
!
interface GigabitEthernet 0/1
 port-group 3
!
interface GigabitEthernet 0/2
 port-group 3
!
interface AggregatePort 3
!
aggregateport load-balance dst-mac
!
```

7. Common Errors

A user configures the factors **ipv4**, **ipv6** for enabling symmetric hashing. However, no configuration is displayed when the user runs **show running-config**. This is because symmetric hashing is enabled for some products by default. The configuration will be displayed after the user disables the function.

1.14.5 Configuring Hash Load Balancing Control

1. Requirements

Create aggregate interface interconnection for two devices on the IPv4 network.

2. Topology

Figure 1-11 Topology for Configuring Hash Load Balancing Control

3. Notes

- Add the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device A to static aggregate interface 3.
- Add the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device B to static aggregate interface 3.
- On Device A, configure the hash disturbance factor A.
- On Device B, configure the hash disturbance factor B.

- On Device A, enable flexible hash.
- On Device B, enable flexible hash.

4. Procedure

Perform the following configuration on Device A:

```
DeviceA# configure terminal
DeviceA(config)# interface range GigabitEthernet 0/1-2
DeviceA(config-if-range)# port-group 3
DeviceA(config-if-range)# exit
DeviceA(config)# load-balance-profile default
DeviceA(config-load-balance-profile)# hash-disturb A
DeviceA(config-load-balance-profile)# exit
DeviceA(config)# aggregateport hash-elasticity enable
```

Perform the following configuration on Device B:

```
DeviceB# configure terminal
DeviceB(config)# interface range GigabitEthernet 0/1-2
DeviceB(config-if-range)# port-group 3
DeviceB(config-if-range)# exit
DeviceB(config)# load-balance-profile default
DeviceA(config-load-balance-profile)# hash-disturb B
DeviceB(config-load-balance-profile)# exit
DeviceB(config)# aggregateport hash-elasticity enable
```

5. Verification

Run **show running-config** to check whether the configuration is correct.

6. Configuration Files

- Device A configuration file

```
!
load-balance-profile default
 hash-disturb A
!
interface GigabitEthernet 0/1
 port-group 3
!
interface GigabitEthernet 0/2
 port-group 3
!
interface AggregatePort 3
!
aggregateport hash-elasticity enable
!
```

- Device B configuration file

```
!
```

```
load-balance-profile default
 hash-disturb B
!
interface GigabitEthernet 0/1
 port-group 3
!
interface GigabitEthernet 0/2
 port-group 3
!
interface AggregatePort 3
!
aggregateport hash-elasticity enable
!
```

7. Common Errors

A user configures the factors **ipv4**, **ipv6** for enabling symmetric hashing. However, no configuration is displayed when the user runs **show running-config**. This is because symmetric hashing is enabled for some products by default. The configuration will be displayed after the user disables the function.

1.14.6 Configuring a Capacity Mode

1. Requirements

Create aggregate interface interconnection for two devices on the IPv4 network.

2. Topology

Figure 1-12 Configuring an Aggregate Interface Capacity Mode

3. Notes

- Add the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device A to static aggregate interface 3.
- Add the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device B to static aggregate interface 3.
- On Device A, configure the 128 x 16 capacity mode.
- On Device B, configure the 32 x 64 capacity mode.

4. Procedure

Perform the following configuration on Device A:

```
DeviceA# configure terminal
DeviceA(config)# interface range GigabitEthernet 0/1-2
DeviceA(config-if-range)# port-group 3
DeviceA(config-if-range)# exit
DeviceA(config)# aggregateport capacity mode 128*16
```

Perform the following configuration on Device B:

```
DeviceB# configure terminal
DeviceB(config)# interface range GigabitEthernet 0/1-2
DeviceB(config-if-range)# port-group 3
DeviceB(config-if-range)# exit
DeviceB(config)# aggregateport capacity mode 32*64
```

5. Verification

Run **show running-config** to check whether the configuration is correct.

Run **show aggregateport capacity** to check the aggregate interface capacity mode configuration.

```
DeviceA# show aggregatePort capacity
AggregatePort Capacity Information:
Configuration Capacity Mode: 128*16.
Effective Capacity Mode    : 128*16.
Available Capacity Mode    : 128*16.
Total Number : 128, Used: 1, Available: 127.
DeviceB   DeviceB# show aggregatePort capacity
AggregatePort Capacity Information:
Configuration Capacity Mode: 32*64.
Effective Capacity Mode    : 32*64.
Available Capacity Mode    : 32*64.
Total Number : 32, Used: 1, Available: 31.
```

6. Configuration Files

- Device A configuration file

```
!
aggregateport capacity mode 128*16
!
interface GigabitEthernet 0/1
 port-group 3
!
interface GigabitEthernet 0/2
 port-group 3
!
interface AggregatePort 3
!
aggregateport hash-elasticity enable
!
```

- Device B configuration file

```
!
aggregateport capacity mode 32*64
!
interface GigabitEthernet 0/1
 port-group 3
```

```
!
interface GigabitEthernet 0/2
 port-group 3
!
interface AggregatePort 3
!
```

1.14.7 Enabling BFD for Member Ports

1. Requirements

Create aggregate interface interconnection for two devices on the IPv4 network.

2. Topology

Figure 1-13 Topology for Enabling BFD for Member Ports

3. Notes

- Enable LACP for the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device A and add the ports to LACP interface 3.
- Enable LACP for the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device B and add the ports to LACP interface 3.
- Configure IP address 1.0.0.1 for aggregate interface 3 on Device A and enable IPv4 BFD.
- Configure IP address 1.0.0.2 for aggregate interface 3 on Device B and enable IPv4 BFD.

4. Procedure

Perform the following configuration on Device A:

```
DeviceA# configure terminal
DeviceA(config)# interface range GigabitEthernet 0/1-2
DeviceA(config-if-range)# no switchport
DeviceA(config-if-range)# port-group 3 mode active
DeviceA(config-if-range)# exit
DeviceA(config)# interface aggregateport 3
DeviceA(config-if-Aggregateport 3)# ip address 1.0.0.1 255.255.255.0
DeviceA(config-if-Aggregateport 3)# aggregate bfd-detect ipv4 1.0.0.1 1.0.0.2
DeviceA(config-if-Aggregateport 3)# bfd interval 100 min_rx 100 multiplier 3
```

Perform the following configuration on Device B:

```
DeviceB# configure terminal
DeviceB(config)# interface range GigabitEthernet 0/1-2
DeviceB(config-if-range)# no switchport
DeviceB(config-if-range)# port-group 3 mode active
DeviceB(config-if-range)# exit
```

```
DeviceB(config)# interface aggregateport 3
DeviceB(config-if-Aggregateport 3)# ip address 1.0.0.2 255.255.255.0
DeviceB(config-if-Aggregateport 3)# aggregate bfd-detect ipv4 1.0.0.2 1.0.0.1
DeviceB(config-if-Aggregateport 3)# bfd interval 100 min_rx 100 multiplier 3
```

5. Verification

Run **show running-config** to check whether the configuration is correct. to check whether the configuration is correct.

Run **show interface aggregateport** to view the BFD state of each member port.

```
DeviceA# show run | include AggregatePort 3
Building configuration…
Current configuration: 54 bytes
interface AggregatePort 3
 no switchport
 ip address 1.0.0.1 255.255.255.0
 aggregate bfd-detect ipv4 1.0.0.1 1.0.0.2
 bfd interval 100 min_rx 100 multiplier 3
DeviceA# show interface aggregateport 3
…
Aggregate Port Informations:
        Aggregate Number: 3
        Nam": "AggregatePor" 3"
        Members: (count=2)
        GigabitEthernet 0/1         Link Status: Up    Lacp Status: bndl   BFD
Status: UP
        GigabitEthernet 0/2         Link Status: Up    Lacp Status: bndl   BFD
Status: UP
```

```
DeviceB# show run | include AggregatePort 3
Building configuration...
Current configuration: 54 bytes
interface AggregatePort 3
 no switchport
 ip address 1.0.0.2 255.255.255.0
 aggregate bfd-detect ipv4 1.0.0.2 1.0.0.1
 bfd interval 100 min_rx 100 multiplier 3
DeviceB# show interface aggregateport 3
…
Aggregate Port Informations:
        Aggregate Number: 3
        Nam": "AggregatePor" 3"
        Members: (count=2)
        GigabitEthernet 0/1         Link Status: Up    Lacp Status: bndl   BFD
Status: UP
```

```
        GigabitEthernet 0/2         Link Status: Up    Lacp Status: bndl    BFD
Status: UP
```

6. Configuration Files

- Device A configuration file

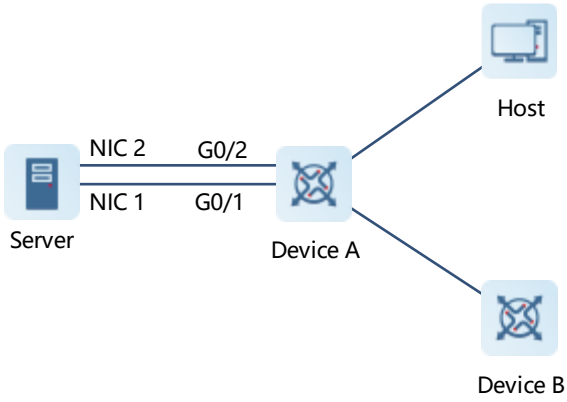
```
!
interface GigabitEthernet 0/1
 no switchport
 port-group 3 mode active
!
interface GigabitEthernet 0/2
 no switchport
 port-group 3 mode active
!
interface AggregatePort 3
 no switchport
 aggregate bfd-detect ipv4 1.0.0.1 1.0.0.2
 ip address 1.0.0.1 255.255.255.0
 bfd interval 100 min_rx 100 multiplier 3
!
```

- Device B configuration file

```
!
interface GigabitEthernet 0/1
 no switchport
 port-group 3 mode active
!
interface GigabitEthernet 0/2
 no switchport
 port-group 3 mode active
!
interface AggregatePort 3
 no switchport
 aggregate bfd-detect ipv4 1.0.0.2 1.0.0.1
 ip address 1.0.0.2 255.255.255.0
 bfd interval 100 min_rx 100 multiplier 3
!
```

7. Common Errors

- If BFD is enabled for an aggregate interface without BFD parameters, BFD does not take effect.
- After BFD is enabled for an aggregate interface, the BFD neighbor must be a directly connected aggregate interface enabled with BFD.



1.14.8 Configuring Interworking Between the Access Device and a Server with Two NICs over a Preferred LACP Port

1. Requirements

The server has two management systems: the remote management OS and server OS. The two OSs are independent of each other. When the server OS restarts, access to the remote management OS is normal. The remote management OS is used to manage the server OS and uses NIC 1 as the communication port to access the access device GigabitEthernet0/1 in Figure 1-14. It is allocated with a specific VLAN, for example, VLAN 10. The server OS is used to handle routine production services and uses NIC 1 and NIC 2 as the communication ports. LACP interface is enabled between NIC 1 and NIC 2. The server OS accesses the access device over the aggregate link. A VLAN except the management VLAN is allocated to the server OS. NIC 1 is used as the communication port for both the remote management OS and server OS. Based on the VLAN tag carried in packets, the server determines whether packets received from NIC 1 are sent to the remote management OS or server OS.

2. Topology

Figure 1-14 Topology for Configuring Interworking Between the Access Device and a Server with Two NICs over a Preferred LACP Port

3. Notes

- Enable LACP for the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on the access device and add the ports to LACP interface 3.
- Configure GigabitEthernet 0/1 on the access device as the preferred port.
- Configure VLAN 10 on the access device as the management VLAN.

4. Procedure

Create LACP interface 3 and add aggregate interface 3 to the trunk.

```
DeviceA# configure terminal
DeviceA(config)# interface range GigabitEthernet 0/1-2
DeviceA(config-if-range)# port-group 3 mode active
DeviceA(config-if-range)# exit
DeviceA(config)# interface aggregateport 3
DeviceA(config-if-Aggregateport 3)# switchport mode trunk
```

```
DeviceA(config-if-Aggregateport 3)# exit
```

Configure VLAN 10 as the management VLAN.

```
DeviceA(config)# aggregateport-admin vlan 10
```

Configure GigabitEthernet 0/1 as the preferred port.

```
DeviceA(config)# interface gigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1) aggregateport primary-port
```

5. Verification

Run **show running-config** to check whether the configuration is correct.

Run **show interface aggregateport** to query the preferred member port.

```
DeviceA# show run | include aggregateport-admin
Building configuration...
Current configuration: 54 bytes
aggregateport-admin vlan 10
DeviceA# show run | include GigabitEthernet 0/1
Building configuration...
Current configuration: 54 bytes
interface GigabitEthernet 0/1
aggregateport primary-port
 portgroup 3 mode active
DeviceA# show interface aggregateport 3
…
Aggregate Port Informations:
        Aggregate Number: 3
        Nam": "AggregatePor" 3"
        Members: (count=2)
       Primary Port: GigabitEthernet 0/1
        GigabitEthernet 0/1         Link Status: Up    Lacp Status: bndl
        GigabitEthernet 0/2         Link Status: Up    Lacp Status: bndl
  …
```

6. Configuration Files

- Device A configuration file

```
!
aggregateport-admin vlan 10
!
interface GigabitEthernet 0/1
 port-group 3 mode active
 aggregateport primary-port
!
interface GigabitEthernet 0/2
 port-group 3 mode active
!
interface AggregatePort 3
```

```
 switchport mode trunk
!
```

1.14.9 Configuring Automatic Server Deployment over a Preferred LACP Port

1. Requirements

The server has two NICs, and the two NICs connect to Switch A over the LACP interface. The server can be automatically installed over NIC 1. After the server is installed, management data streams are sent over NIC 1 and NIC 2 for mutual backup and load balancing.

2. Topology

Figure 1-15 Topology for Configuring Automatic Server Deployment over a Preferred LACP Port

3. Notes

- Enable LACP for the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device A and add the ports to LACP interface 3.
- Configure GigabitEthernet 0/1 on Device A as the preferred port.

4. Procedure

Create LACP interface 3.

```
DeviceA# configure terminal
DeviceA(config)# interface range GigabitEthernet 0/1-2
DeviceA(config-if-range)# port-group 3 mode active
DeviceA(config-if-range)# exit
```

Configure GigabitEthernet 0/1 as the preferred port.

```
DeviceA(config)# interface gigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1) aggregateport primary-port
```

5. Verification

Run **show running-config** to check whether the configuration is correct.

Run **show interface aggregateport** to query the preferred member port.

```
DeviceA# show run | include GigabitEthernet 0/1
Building configuration...
Current configuration: 54 bytes
interface GigabitEthernet 0/1
aggregateport primary-port
 portgroup 3 mode active
DeviceA# show interface aggregateport 3
…
Aggregate Port Informations:
```

```
        Aggregate Number: 3
        Nam": "AggregatePor" 3"
        Members: (count=2)
       Primary Port: GigabitEthernet 0/1
        GigabitEthernet 0/1         Link Status: Up    Lacp Status: bndl
        GigabitEthernet 0/2         Link Status: Up    Lacp Status: bndl
…
```

6. Configuration Files

- Device A configuration file

```
!
interface GigabitEthernet 0/1
 port-group 3 mode active
 aggregateport primary-port
!
interface GigabitEthernet 0/2
 port-group 3 mode active
!
interface AggregatePort 3
!
```

1.14.10 Configuring the Minimum Number of Member Ports (When the Number of Member Ports Is Less Than the Minimum Number)

1. Requirements

On the IPv4 network, create aggregate interface interconnection for two devices, and configure the number of member ports less than the minimum number of member ports.

2. Topology

Figure 1-16 Topology for Configuring the Minimum Number of Member Ports (When the Number of Member Ports Is Less Than the Minimum Number)

3. Notes

- Enable LACP for the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on Device A and add the ports to LACP interface 3.
- Enable LACP for the GigabitEthernet 0/1 and GigabitEthernet0/2 ports on Device B and add the ports to LACP interface 3.
- On Device A, set the minimum number of the member ports of aggregate interface 3 to 3.

4. Procedure

Perform the following configuration on Device A:

```
DeviceA# configure terminal
DeviceA(config)# interface range GigabitEthernet 0/1-2
DeviceA(config-if-range)# no switchport
DeviceA(config-if-range)# port-group 3 mode active
DeviceA(config-if-range)# exit
DeviceA(config)# interface aggregateport 3
DeviceA(config-if-Aggregateport 3)# aggregateport member minimum 3
```

Perform the following configuration on Device B:

```
DeviceB# configure terminal
DeviceB(config)# interface range GigabitEthernet 0/1-2
DeviceB(config-if-range)# no switchport
DeviceB(config-if-range)# port-group 3 mode active
DeviceB(config-if-range)# exit
DeviceB(config)# interface aggregateport 3
DeviceB(config-if-Aggregateport 3)# aggregateport member minimum 3
```

5. Verification

Run **show running-config** to check whether the configuration is correct.

Run **show lacp summery** to view the aggregation state of each member port.

```
DeviceA# show LACP summary 3
System Id:32768, 00d0.f8fb.0001
Flags: -S - Device is requesting Slow LACPDUs
-F - Device is requesting Fast LACPDUs.-A - Device is in active mode.       -P -
Device is in passive mode.

1.14.11 Configuring the Minimum Number of Member Ports (When the Number of Member Ports Is Not Less Than the Minimum Number)

1. Requirements

On the IPv4 network, create aggregate interface interconnection for two devices, and configure the number of member ports not less than the minimum number of member ports.

2. Topology

Figure 1-17 Topology for Configuring the Minimum Number of Member Ports (When the Number of Member Ports Is Not Less Than the Minimum Number)

3. Notes

- Enable LACP for the GigabitEthernet 0/1, GigabitEthernet 0/2, and GigabitEthernet 0/3 ports on Device A and add the ports to LACP interface 3.
- Enable LACP for the GigabitEthernet 0/1, GigabitEthernet 0/2, and GigabitEthernet 0/3 ports on Device B and add the ports to LACP interface 3.

- On Device A, set the minimum number of member ports of aggregate interface 3 to 2.

4. Procedure

Perform the following configuration on Device A:

```
DeviceA# configure terminal
DeviceA(config)# interface range GigabitEthernet 0/1-3
DeviceA(config-if-range)# no switchport
DeviceA(config-if-range)# port-group 3 mode active
DeviceA(config-if-range)# exit
DeviceA(config)# interface aggregateport 3
DeviceA(config-if-Aggregateport 3)# aggregateport member minimum 2
```

Perform the following configuration on Device B:

```
DeviceB# configure terminal
DeviceB(config)# interface range GigabitEthernet 0/1-3
DeviceB(config-if-range)# no switchport
DeviceB(config-if-range)# port-group 3 mode active
DeviceB(config-if-range)# exit
DeviceB(config)# interface aggregateport 3
DeviceB(config-if-Aggregateport 3)# aggregateport member minimum 2
```

5. Verification

Run **show running-config** to check whether the configuration is correct.

Run **show lacp summery** to view the aggregation state of each member port.

```

1.14.12 Enabling the LACP Independent Port Function

1. Requirements

The server uses NIC 1 and NIC 2 as the communication ports to get access to the GigabitEthernet0/1 and GigabitEthernet0/2 of the access device. GigabitEthernet0/1 and GigabitEthernet0/2 are added to the LACP interface, for example, aggregate interface 3. A specific VLAN, for example, VLAN 10 is allocated. The LACP independent port function is enabled for GigabitEthernet0/1 and GigabitEthernet0/2. When the OS is not installed on the server, LACP negotiation between the server and the access device fails. In this case, GigabitEthernet0/1 and GigabitEthernet0/2 of the access device change to common physical ports and are

allocated to VLAN 10 automatically. The server uses NIC 1 or NIC 2 to communicate with the remote OS installation device. After the OS is installed, the server connects to the access device in LACP mode.

2. Topology

Figure 1-18 Topology for Enabling the LACP Independent Port Function

3. Notes

- Enable LACP for the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on the access device and add the ports to LACP interface 3.
- Enable the LACP independent port function for the GigabitEthernet 0/1 and GigabitEthernet 0/2 ports on the access device.
- Allocate aggregate interface 3 on the access device to VLAN 10.

4. Procedure

Create an aggregate interface on Device A.

```
DeviceA# configure terminal
DeviceA(config)# interface range GigabitEthernet 0/1-2
DeviceA(config-if-range)# port-group 3 mode active
DeviceA(config-if-range)# lacp individual-port enable
DeviceA(config-if-range)# exit
DeviceA(config)# interface aggregateport 3
DeviceA(config-if-Aggregateport 3)# switch access vlan 10
```

5. Verification

Run **show running-config** to check whether the configuration is correct.

Run **show lacp summery** to view the aggregation state of each member port.

```
DeviceA# show LACP summary 3
System Id:32768,00d0.f8fb.0001
Flags: -S - Device is requesting Slow LACPDUs
-F - Device is requesting Fast LACPDUs.-A - Device is in active mode.       -P -
Device is in passive mode.
Aggregate port 3:

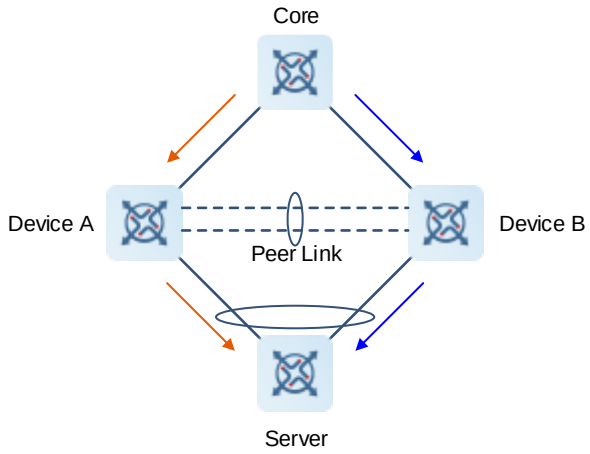
 switchport access vlan 10
!
```



1.14.13 Configuring VAP Pre-Switching

1. Requirements

In an M-LAG environment, traffic is switched to the other M-LAG device in advance during device upgrade.

2. Topology

Figure 1-19 Topology of VAP Pre- Switching

3. Notes

- Device A and Device B form an M-LAG system.
- The server is dual-homed to the M-LAG system.
- The VAP pre-switching function is configured on device A before the upgrade. Uplink traffic is switched to Device B.

4. Procedure

Configure the VAP pre-switching function on Device A.

```
DeviceA# configure terminal
DeviceA(config)# lacp force-vap-down
```

5. Verification

Run the **show run** command to check whether the configuration is correct.

Run the **show lacp summery** command to display the aggregation status of each member interface under the VAP.

```
DeviceA# show LACP summary
System Id:32768,00d0.f8fb.0001
Flags: -S - Device is requesting Slow LACPDUs
-F - Device is requesting Fast LACPDUs.-A - Device is in active mode.       -P -
Device is in passive mode.

1 Configuring MAC Address

1.1 Introduction

A Media Access Control (MAC) address is used to identify the position of a device in a network. Generally, a MAC address consists of 12 hexadecimals and contains a total of 48 bits (six bytes). The first 24 bits are applied for by vendors from The Internet Engineering Task Force (IETF) and used to identify a network device manufacturer. The last 24 bits are assigned by the vendors and used to identify network cards produced by the manufacturers.

1.1.1 MAC Address Table

A MAC address table records mappings of MAC addresses and interfaces to virtual local area networks (VLANs). A device queries the MAC address table based on the destination MAC address in a received packet. If the device finds an entry that is consistent with the destination MAC Address in the packet, the device forwards the packet through the interface corresponding to the entry in unicast mode. If the device does not find such an entry, it forwards the packet through all interfaces other than the receiving interface in broadcast mode.

Note

This section describes static, dynamic, and filtering MAC address entries. For more information about multicast MAC address entries and specific configurations, see *Configuring IGMP*.

1.1.2 Classification of MAC Address Entries

MAC address entries are classified into the following types:

- Static MAC address entries: Manually configured by the administrator. Packets whose destination MAC address matches the one in such an entry are forwarded through the correct interface. This type of entries does not age.
- Dynamic MAC address entries: Automatically generated by devices. Packets whose destination MAC address matches the one in such an entry are forwarded through the correct interface. This type of entries ages.
- Filtering MAC address entries: Manually configured by the administrator. Packets whose source or destination MAC address matches the one in such an entry are discarded. This type of entries does not age.

The priorities of these types of MAC address entries are ranked in descending order as follows: Filtering MAC address entries > Static MAC address entries > Dynamic MAC address entries. If two entries have the same MAC address and VLAN, the higher-priority entry can overwrite the lower-priority one, and entries with the same priority can overwrite each other.

1.1.3 Generation of MAC Address Entries

A MAC address entry can be automatically learned or manually configured.

1. Automatic learning

A device automatically generates a MAC address entry based on the source MAC address in a received packet. The learning procedure is as follows:

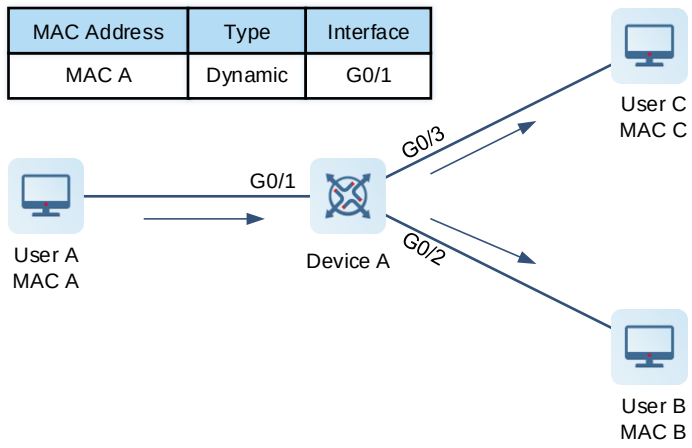
(1) Initially, the MAC address table of Device A is empty. To send a packet to User C, User A sends the packet to the interface GigabitEthernet 0/1 of Device A. Upon receiving the packet, Device A generates a MAC address entry, with the MAC address being MAC A and the interface being GigabitEthernet 0/1.

(2) As Device A does not have an entry corresponding to MAC A, it forwards the packet through all interfaces other than GigabitEthernet 0/1 in broadcast mode. In this case, other users also receive the packet that User A sends to User C.

(3) User C sends a reply packet destined for User A to Device A through the interface GigabitEthernet 0/3. Upon receiving the packet, Device A generates a MAC address entry, with the MAC address being MAC C and the interface being GigabitEthernet 0/3. Meanwhile, Device A finds an entry corresponding to MAC A and then forwards the packet to User A through GigabitEthernet 0/1 in unicast mode.

(4) After the communication between User A and User C is complete, Device A learns two MAC address entries. Later, packets are forwarded between User A and User C in unicast mode and other users do not receive packets destined for these two users.

Figure 1-1 Automatically Learning MAC Address Entry I



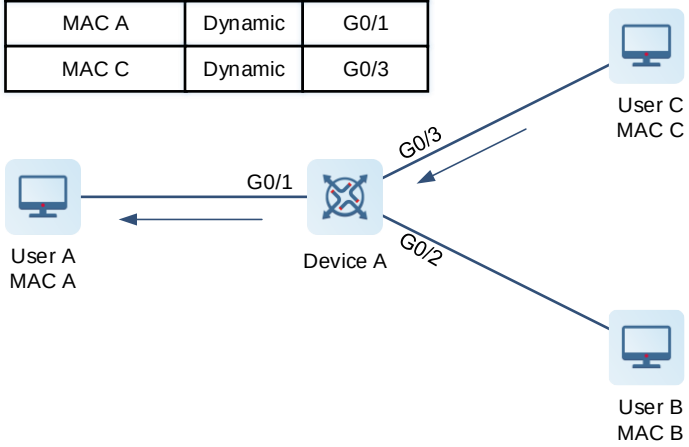


Figure 1-2 Automatically Learning MAC Address Entry II

MAC Address	Type	Interface
MAC A	Dynamic	G0/1
MAC C	Dynamic	G0/3

2. Manual configuration

If the device forwards packets based on automatically generated MAC address entries, security risks exist. For example, if an attacker forges a packet by using a MAC address of a valid user and sends the packet to another interface of the device, the device automatically updates the corresponding MAC address entry and sends subsequent packets destined for the user to the attacker. To improve network security, the network administrator can add a specified MAC address entry to bind the MAC address of the valid user to a device interface. The static MAC address entry configured in this way is not updated due to packet forwarding. If a packet whose source MAC address is the MAC address of the valid user is received from another user, the device directly discards this packet.

1.1.4 Update and Aging of MAC Address Entries

Static and filtering MAC address entries do not automatically update or age. Dynamic MAC address entries are updated and age in the following scenarios:

(1) When the device learns a new dynamic MAC address entry, the device sets the age flag bit of this entry to 1.

(2) If the source MAC address in a received packet already exists in the MAC address table, the device updates the entry and sets the age flag bit to 1.

(3) The device checks the age flag bit of a dynamic MAC address entry at the interval of the aging time. For entries whose flag bit is 1, the device sets the flag bit to 0. For entries whose flag bit is 0, the device deletes the entries.

Therefore, the actual aging time of a dynamic MAC address entry ranges between the specified age value and two times the age value.

1.1.5 Protocols and Standards

- IEEE 802.3: Carrier sense multiple access with collision detection (CSMA/CD) access method and physical layer specifications
- IEEE 802.1Q: Virtual Bridged Local Area Networks

1.2 Configuration Task Summary

All the following configuration tasks are optional and maybe selected as needed.

- Configuring Static MAC Address Entries
- Configuring Filtering MAC Address Entries
- Disabling Dynamic MAC Address Learning
  - Disabling MAC Address Learning in Global Configuration Mode
  - Disabling MAC Address Learning for an Interface
- Configuring Upper Limit of Learned MAC Addresses
  - Configuring Upper Limit of MAC Addresses Learned from a VLAN
  - Configuring Upper Limit of MAC Addresses Learned from an Interface
- Configuring Aging Time of Dynamic MAC Address Entries
- Enabling MAC Address Flapping Detection and Protection
- Configuring Reporting Interval of MAC Address Table Usage Alarms and MAC Address Table Usage Threshold
- Configuring the Function of MAC Address Entry Change Notification

1.3 Configuring Static MAC Address Entries

1.3.1 Overview

You can manually configure static MAC address entries to bind MAC addresses to device interfaces.

1.3.2 Restrictions and Guidelines

- Interfaces in the MAC address entries can be specified as L2 Ethernet interfaces or L2 aggregation ports (APs).
- If a MAC address is bound to different interfaces in the same VLAN, the last configuration prevails.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a static MAC address.

mac-address-table static *mac-address* **vlan** *vlan-id* **interface** *interface-type interface-number*

No static MAC address entryexists by default.

1.4 Configuring Filtering MAC Address Entries

1.4.1 Overview

To prohibit a user from sending and receiving packets in certain scenarios, you can add the MAC address of the user to a filtering MAC address entry. After the entry is configured, packets whose source or destination MAC address matches the MAC address in the filtering MAC address entry are directly discarded.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a filtering MAC address.

mac-address-table filtering *mac-address* **vlan** *vlan-id*

No filtering MAC address entry exists by default.

1.5 Disabling Dynamic MAC Address Learning

1.5.1 Overview

MAC address learning is enabled by default. A device automatically generates a dynamic MAC address entry based on the source MAC address in a received packet. The device queries the MAC address table to perform unicast forwarding, which reduces broadcast frequency and therefore reduces the network traffic. The device learns or updates the MAC address entry each time it receives a packet, which results in low security. An attacker may forge and send a large number of packets with different source MAC addresses to the device to use up the MAC address entry resources. Consequently, the device cannot update the MAC address entries in time. You can disable dynamic MAC address learning if required.

1.5.2 Disabling MAC Address Learning in Global Configuration Mode

1. Overview

If you disable MAC address learning in global configuration mode, the device does not learn MAC addresses.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable MAC address learning in global configuration mode.

mac-address-learning disable

MAC address learning is enabled in global configuration mode by default.

1.5.3 Disabling MAC Address Learning for an Interface

1. Overview

If MAC address learning is enabled in global configuration mode, you can disable this function for a specific interface.

2. Restrictions and Guidelines

- If 802.1X, IP Source Guard, or the port security function is configured on an interface, MAC address learning must be disabled for this interface. For more information about 802.1X, IP Source Guard, or the port security function, see *Configuring IEEE 802.1X*, *Configuring IP Source Guard*, or *Configuring Port Security*.
- This function can be enabled on L2 Ethernet interfaces and L2 APs only.

3. Procedure

(1) Enter the privileged EXEC mode.
enable

(1) Enter the global configuration mode.

configure terminal

(2) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(3) Disable MAC address learning for an interface.

no mac-address-learning

No MAC address learning is enabled for an interface by default.

1.6 Configuring Upper Limit of Learned MAC Addresses

1.6.1 Overview

The number of MAC address entries on the device is limited. Packets can be forwarded only in broadcast mode in order to prevent the device from learning a large number of dynamic MAC address entries from an interface or a VLAN (for example, when it is attacked by packets with different source addresses) and prevent MAC address learning failures on other interfaces and VLANs. In this case, you can configure the upper limit of MAC addresses learned from each interface or VLAN based on actual network plans. When the number of MAC addresses reaches the upper limit, the device stops learning MAC addresses from the corresponding interface or VLAN. You can also configure a forwarding rule to be used after the number of learned MAC addresses reaches the upper limit, to determine whether to forward packets whose source MAC address is not in the MAC address table. With this function, you can save MAC address entry resources and enhance network security.

This function is available only to dynamic MAC address entries.

1.6.2 Configuring Upper Limit of MAC Addresses Learned from a VLAN

1. Overview

You can configure the upper limit of MAC addresses learned from a VLAN and the packet forwarding rule to be used after the number of learned MAC addresses reaches the upper limit.

2. Restrictions and Guidelines

- If the number of MAC addresses learned from a VLAN is greater than the upper limit, the device stops learning MAC addresses from the VLAN, and starts learning again only after the number drops below the upper limit as aged address entries are deleted.
- This function does not limit replication of MAC address entries to a VLAN whose number of learned MAC address entries reaches the upper limit.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a VLAN and enter the VLAN configuration mode.

vlan *vlan-id*

(4) Configure the upper limit of dynamic MAC addresses learned from a VLAN.

max-dynamic-mac-count *count*

No upper limit of learned MAC addresses is configured for a VLAN by default.

(5) (Optional) Configure a forwarding rule to be used after the number of dynamic MAC addresses learned from a VLAN reaches the upper limit.

max-dynamic-mac-count exceed-action { **discard** | **forward** }

By default, after the number of MAC addresses learned from a VLAN reaches the upper limit, the device continues forwarding packets whose source MAC address is not learned.

1.6.3 Configuring Upper Limit of MAC Addresses Learned from an Interface

1. Overview

You can configure the upper limit of MAC addresses learned from an interface and the packet forwarding rule to be used after the number of learned MAC addresses reaches the upper limit.

2. Restrictions and Guidelines

If the number of MAC addresses learned from an interface is greater than the upper limit, the device stops learning MAC addresses from the interface, and starts learning again only after the number drops below the upper limit as aged MAC address entries are deleted.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure the upper limit of dynamic MAC addresses learned from an interface.

max-dynamic-mac-count *count*

No upper limit of learned MAC addresses is configured for an interface by default.

(5) (Optional) Configure a forwarding rule to be used after the number of dynamic MAC addresses learned from an interface reaches the upper limit.

max-dynamic-mac-count exceed-action { **discard** | **forward** }

By default, after the number of MAC addresses learned from an interface reaches the upper limit, the device continues forwarding packets whose source MAC address is not learned.

1.7 Configuring Aging Time of Dynamic MAC Address Entries

1. Overview

The device deletes useless dynamic MAC address entries based on the aging time to save entry resources on the device. An overly long aging time may lead to untimely deletion of useless entries, whereas an overly short aging time may lead to deletion of some valid entries and repeated learning of MAC addresses by the device, which increases the packet broadcast frequency. Therefore, you are advised to configure a proper aging time of dynamic MAC address entries as required to save device resources without affecting network stability.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the aging time of dynamic MAC addresses.

mac-address-table aging-time *time*

The aging time of dynamic MAC addresses is 300s by default.

1.8 Enabling MAC Address Flapping Detection and Protection

1.8.1 Overview

If a MAC address is learned from different interfaces in the same VLAN, MAC address flapping occurs. If MAC address flapping occurs frequently between two specific interfaces, a network loop is formed. In this case, packets with the same source MAC address are received from different interfaces, and the MAC address entry

is updated frequently. By enabling MAC address flapping detection, you can effectively monitor MAC address flapping events on the L2 network. Each time a MAC address flapping event occurs, the device reports a log alarm message. You can configure the MAC address flapping protection policy on the interfaces. When the device detects that MAC address flapping occurs between two interfaces with different priorities, the device reports an alarm message and disables the lower-priority interface.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure MAC address flapping detection.

mac-address-table flapping-logging

MAC address flapping detection is disabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(5) (Optional) Configure a MAC address flapping protection policy.

mac-address-table flapping action { **error-down** | **priority** *priority* }

No MAC address flapping protection policy is configured by default.

The MAC address flapping protection policy is available only for an interface with MAC address flapping detection enabled.

1.9 Configuring Reporting Interval of MAC Address Table Usage Alarms and MAC Address Table Usage Threshold

1.9.1 Overview

With this function, you can adjust the reporting interval of MAC address table usage alarms and MAC address table usage threshold (in percentage). When the usage of a MAC address table of a device exceeds the upper limit, the device prints an alarm message. When the usage of a MAC address table is lower than the lower limit, the device prints an alarm clearing message.

1.9.2 Restrictions and Guidelines

Each alarm clearing message corresponds to a MAC address table usage alarm message. Only when a MAC address table usage alarm message is printed, an alarm clearing message will be printed if the MAC address usage becomes lower than the lower limit. Even if the MAC address table usage alarm or alarm clearing is triggered multiple times in an alarm period, the corresponding message is printed once.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a reporting interval of the MAC address table usage alarms.

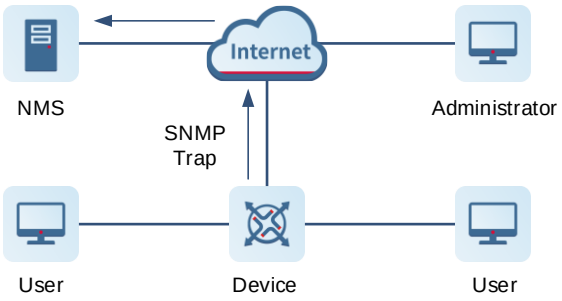
mac-address-table warning-interval *interval*

The reporting interval of the MAC address table usage alarms is 3600s by default.

If you set the interval to 0s, MAC address table usage alarm reporting is disabled.

(4) Configure the upper and lower limits of the MAC address table usage.

mac-address-table warning-threshold upper-limit *upper-limit-threshold* **lower-limit** *lower-limit-threshold*



By default, the upper and lower limits for reporting MAC address table usage alarms are 80% and 70%, respectively.

1.10 Configuring the Function of MAC Address Entry Change Notification

1.10.1 Overview

After the function of MAC address entry change notification is configured on a device, the device generates a notification message for a MAC address entry change when the device learns a new MAC address or has aged a learned MAC address. In addition, the device sends the notification message in SNMP Trap mode to a specified Network Management Station (NMS). This function helps the network administrator monitor user change of network devices.

Figure 1-3 Application Scenario of the Function of MAC Address Entry Change Notification

As shown in Figure 1-3, when the device generates a notification for an added MAC address, a new user identified by the MAC address starts to use the network. When the device generates a notification for a deleted MAC address, the corresponding user does not send packets in the address aging time. In this case, it is considered that the user stops using the network. When the device is accessed by a large number of users, the device may generate a large number of MAC address entry change notifications in a short time, and the traffic increases.

To reduce traffic, you can configure an interval for sending MAC address entry change notifications. When the configured interval arrives, the system sends all notifications in a period of time at a time. This helps reduce the network traffic. Each notification message contains information about multiple MAC address changes.

A generated notification is stored in a history table for MAC address entry change notifications. The administrator may know recent MAC address changes by checking the history table even without NMS.

1.10.2 Restrictions and Guidelines

A MAC address entry change notification is generated only for a dynamic MAC address entry.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure an NMS host address for receiving MAC address entry change notifications.

snmp-server host { *ipv4-address* | **ipv6** *ipv6-address* } **traps** [**version** { **1** | **2c** | **3** [**auth** | **noauth** | **priv**] }] *community-string*

No NMS host address is configured for receiving MAC address entry change notifications by default.

(4) Enable sending of MAC address entry change notifications in Trap messages.

snmp-server enable traps

Sending Trap messages to the NMS host is forbidden by default.

(5) Enable the function of MAC address entry change notification in global configuration mode.

mac-address-table notification

The function of MAC address entry change notification is disabled in global configuration mode by default.

(6) (Optional) Configure an interval for sending MAC address entry change notifications.

mac-address-table notification interval *interval*

The device sends MAC address entry change notifications at an interval of 1s by default.

(7) (Optional) Configure the size of a history table for MAC address entry change notifications.

mac-address-table notification history-size *size*

The size of the history table for MAC address entry change notifications is 50 by default.

(8) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(9) Enable the function of MAC address entry change notification for an interface.

snmp trap mac-notification { **added** | **removed** }

The function of MAC address entry change notification is disabled for an interface by default.

1.11 Monitoring

This section describes the **show** commands used for checking the running status of a configured function to verify the configuration effect.

You can run the **clear** commands to clear information.

Caution

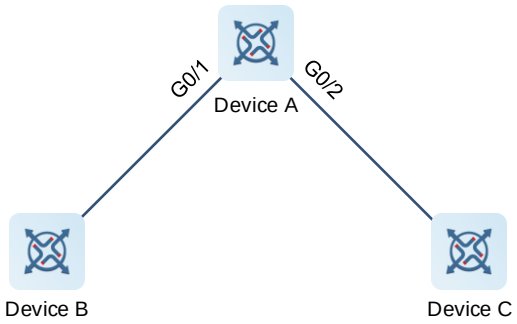
Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
clear mac-address-table dynamic [**address** *mac-address*] [**interface** *interface-type interface-number*] [**vlan** *vlan-id*]	Clears the dynamic MAC address entries.
clear mac-address-table flapping record	Clears the MAC address flapping records.
show mac-address-table dynamic [**address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*]	[**interface** *interface-type interface-number*] [**vlan** *vlan-id*]] **show mac-address-table static** [**address** *mac-address*] [**interface** *interface-type interface-number*] [**vlan** *vlan-id*] **show mac-address-table filtering** [**address** *mac-address*] [**all**] [**vlan** *vlan-id* | **vni** *vni-id* | **vsi** *vsi-id*]	Displays the MAC address table.
show mac-address-table { **evpn** | **mlag** } [**address** *mac-address*] [**all**] [**interface** *interface-type interface-number*] [**vlan** *vlan-id*] [**vni** *vni-id*] [**vsi** *vsi-id*]	Displays the EVPN or MLAG address table.
show mac-address-table [**vni** *vni-id*] [**vsi** *vsi-id*]	Displays the specific VNI or VSI address table.
show mac-address-table all	Displays all types of addresses.
show mac-address-table aging-time	Displays the aging time for dynamic MAC addresses.
show mac-address-table interface *interface-type interface-number* [**vlan** *vlan-id*] [**all**]	Displays static or dynamic MAC address entries for a specified interface
show mac-address-table max-dynamic-mac-count { **interface** *interface-type interface-number* | **vlan** [*vlan-id*] }	Displays the maximum number of dynamic MAC addresses.

show mac-address-table notification [**interface** [*interface-type interface-number*] **| history**]	Displays the configurations and history table for MAC address entry change notifications.
show mac-address-table flapping record	Displays the dynamic MAC address flapping records.

1.12 Configuration Examples



1.12.1 Configuring MAC Address Flapping Detection

1. Requirements

As shown in **Figure 1-4**, an L2 loop may occur between Device B and Device C due to misoperation. After you enable MAC address flapping detection and configure a protection policy, the device can report alarms upon loops, and disable the faulty interface based on the protection policy.

2. Topology

Figure 1-4 Topology of MAC Address Flapping Detection

3. Notes

- Enable MAC address flapping detection on Device A.
- Configure a MAC address flapping protection policy on the interfaces of Device A.
- Set the priority of GigabitEthernet 0/1 to be higher than that of GigabitEthernet 0/2 on Device A.

4. Procedure

Enable MAC address flapping detection.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# mac-address-table flapping-logging
```

Configure a protection policy to disable GigabitEthernet 0/1 upon MAC address flapping and set the priority of this interface to **5**.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# mac-address-table flapping action error-down
DeviceA(config-if-GigabitEthernet 0/1)# mac-address-table flapping action priority
5
```

```
DeviceA(config)# (config-if-GigabitEthernet 0/1)# exit
```

Configure a protection policy to disable GigabitEthernet 0/2 upon MAC address flapping and set the priority of this interface to **1**.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# mac-address-table flapping action error-down
DeviceA(config-if-GigabitEthernet 0/2)# mac-address-table flapping action priority
1
```

5. Verification

After the preceding configuration, the device generates an alarm message when MAC address flapping from GigabitEthernet 0/1 to GigabitEthernet 0/2 occurs. Run the **show mac-address-table flapping record** command to display the dynamic MAC address flapping records.

View the records on Device A after MAC address flapping is detected.

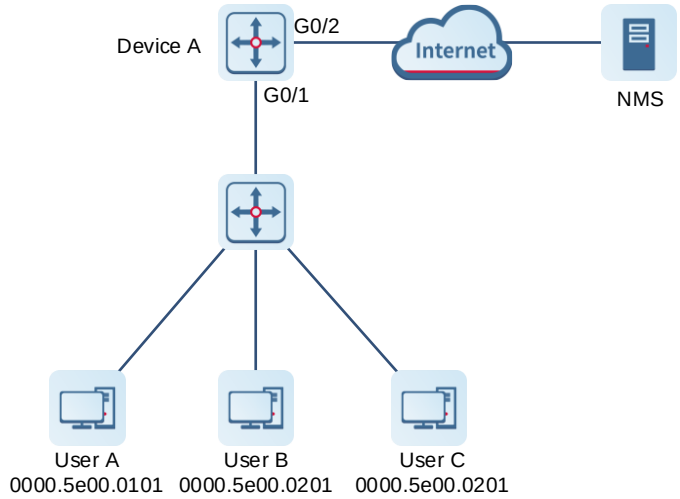
```
DeviceA# show mac-address-table flapping record
 Mac address flapping detect status      : on
 Mac address flapping detect interval    : 1s
 Mac address flapping syslog supress time : 1800s
 Mac address flapping record max count   : 300
 Mac address flapping record total count  : 2

 Move-Time          VLAN  MAC-Address    Original-Port   Move-Ports   Status
 ------------------- ----- -------------- --------------- ------------ --------
 2020.11.14 12:10:46 1     0001.1111.1111 ge0/1          ge0/2        Normal
 2020.11.14 12:10:58 1     0001.1111.1111 ge0/2          ge0/1        ERR-DOWN
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
mac-address-table flapping-logging
!
!
interface gigabitEthernet 0/1
mac-address-table flapping action error-down
mac-address-table flapping action priority 5
!
!
interface gigabitEthernet 0/2
mac-address-table flapping action error-down
mac-address-table flapping action priority 1
!
```



1.12.2 Configuring the Function of MAC Address Change Notification

1. Requirements

As shown in**Figure 1-5**, Device A is connected to devices of User A, User B, and User C, so that Device A records new MAC address entries learned from GigabitEthernet 0/1 and aged MAC address entries, sends MAC address entry change notifications to the specified NMS in SNMP Trap messages, and does not generate massive MAC address change information in a short time to prevent overusing network resources.

2. Topology

Figure 1-5 Topology of MAC Address Change Notification

3. Notes

- Enable the function of MAC address entry change notification in global configuration mode on Device A and configure an interval for sending MAC address Trap messages.
- Enable the function of MAC address entry change notification on GigabitEthernet 0/1 of Device A.
- Specify an SNMP host address and enable Trap notification of MAC address events.
- Ensure that the route between Device A and the NMS is reachable.

4. Procedure

Enable the function of MAC address entry change notification in global configuration mode on Device A and set the interval for sending MAC address Trap messages to 300s.

```
DeviceA# configure terminal
DeviceA(config)# mac-address-table notification
DeviceA(config)# mac-address-table notification interval 300
```

Enable the function of MAC address entry change notification on GigabitEthernet 0/1 and enable the function of sending Trap messages upon MAC address addition or deletion.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/2)# snmp trap mac-notification added
DeviceA(config-if-GigabitEthernet 0/2)# snmp trap mac-notification removed
```

Set the SNMP host address to 192.168.1.1, SNMP version to SNMP v1 and community string to **123** to actively send MAC address Trap messages.

```
DeviceA(config-if-GigabitEthernet 0/2)# exit
DeviceA(config)# snmp-server host 192.168.1.10 traps version 2c 123 mac-notification
```

Enable Trap notification of MAC address events.

```
DeviceA(config)# snmp-server enable traps
```

5. Verification

- View the global configuration information about the function of MAC address change notification.
- Check whether an interface is enabled with the function of MAC address change notification.
- View the MAC address table of an interface and run the **clear mac-address-table dynamic** command to simulate the aging of dynamic addresses.
- View the global configuration information about the function of MAC address change notification. View the history table of MAC address change notifications.

Run the **show mac-address-table notification** command to check whether the NMS can normally receive MAC address change notifications. The command can be executed in privileged EXEC mode, global configuration mode, and interface configuration mode. The Interval(Sec) field specifies the notification interval, Maximum History Size specifies the maximum number of entries in the history table of MAC address change notifications, and Current History Size indicates the current number of entries in the history table.

```
DeviceA# show mac-address-table notification
MAC Notification Feature : Enabled
Interval(Sec): 300
Maximum History Size : 50
Current History Size : 0
```

Run the **show mac-address-table notification** command to view the history table of MAC address change notifications.

```
DeviceA # show mac-address-table notification interface gigabitethernet 0/1
Interface             MAC Added Trap    MAC Removed Trap
-----------           --------------    --------------
GigabitEthernet 0/2   Enabled           Enabled
DeviceA # show mac-address-table interface GigabitEthernet 0/1
Vlan       MAC Address         Type    Interface
----------  ------------------- -------- ------------------
  1       00d0.3232.0001      DYNAMIC  GigabitEthernet 0/1
DeviceA # show mac-address-table notification
MAC Notification Feature : Enabled
Interval(Sec): 300
Maximum History Size : 50
Current History Size : 1
DeviceA# show mac-address-table notification history
History Index : 0
Entry Timestamp: 221683
MAC Changed Message :
```

```
Operation:ADD Vlan:1 MAC Addr: 0000.5e00.0201 GigabitEthernet 0/1
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
mac-address-table notification
mac-address-table notification interval 300
!
!
interface GigabitEthernet 0/1
 snmp trap mac-notification added
 snmp trap mac-notification removed
!
!
snmp-server host 192.168.1.10 traps version 2c 7 $10$135$2c+O$ mac-notification
snmp-server enable traps
!
```

1 Configuring MAC Loopback

1.1 Introduction

1.1.1 Overview

Media Access Control (MAC) loopback refers to a case in which packets sent from a local end are transferred internallyin the system and returned to the local end for interface self-loop.

MAC loopback can be used to determine whether an Ethernet interface is faulty. For an interface with MAC loopback enabled, if the interface runs normally, the physical status of the interface is always up even without network cable connection; and if the interface runs abnormally, the physical status of the interface is down.

MAC loopback can be applied to multi-port mirroring scenarios. One-to-many mirroring can be implemented by configuring an interface as a MAC loopback interface, and adding the mirroring destination port and expected outbound mirroring port to a remote VLAN.

1.1.2 Principles

After a MAC loopback interface is configured on a device, the chip of the device sends test packets and then receives these packets through the loopback created internally. By this, the loopback test of the interface is completed.

Caution

With MAC loopback enabled on an interface, data forwarding on this interface is abnormal. After the test, disable MAC loopback.

1.2 Restrictions and Guidelines

- MAC loopback can only enabled on a physical port instead of a logical interface.
- The function supports working on a Layer 2 or Layer 3 Ethernet interface.

1.3 Configuring Basic Features

1.3.1 Overview

This section describes how to enable MAC loopback on an interface for interface self-loop.

1.3.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Configure an interface as a loopback interface, and enable MAC loopback on the interface.

mac-loopback

MAC loopback is disabled for an interface by default.

(5) Disable MAC loopback after the test.

no mac-loopback

MAC loopback is disabled for an interface by default.

1.4 Monitoring

This section describes the **show** commands used for checking the running status of a configured function to verify the configuration effect.

Table 1-1 MAC Loopback Monitoring

Command	Purpose
show mac-loopback	Displays the interfaces enabled with MAC loopback.

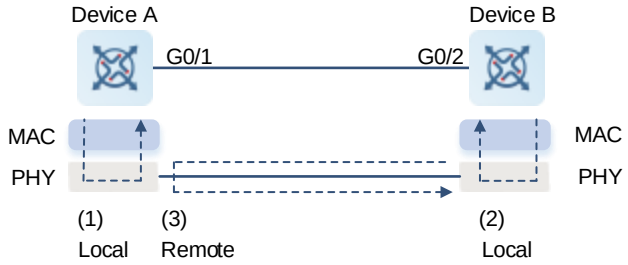
1 Configuring PHY Loopback

1.1 Introduction



1.1.1 Overview

The Physical Layer (PHY) loopback function can be used to locate the connectivity problem of the link between two interfaces. The function can be configured to local loopback.

1.1.2 Principles

If the interfaces at both ends of a link are properly configured, but the interfaces fail to enter the **Link Up** state as expected, you can use the PHY loopback function to troubleshoot link exceptions. As shown in Figure 2-1, device Aand device B are connected through GigabitEthernet 0/1 and GigabitEthernet 0/2. The PHY loopback function is used to test the connectivity between them.

Figure 1-1 PHY Loopback Test

The test steps and principles are as follows:

(1) Enable the local loopback function on GigabitEthernet 0/1. Then, the packets sent by GigabitEthernet 0/1 do not go through an external link, but are directly sent back to device Ainside the interface. If GigabitEthernet 0/1 enters the **Link Up** state on the Physical Layer, it indicates that GigabitEthernet 0/1 is normal. If GigabitEthernet 0/1 is in the **Down** state on the Physical Layer, it indicates that GigabitEthernet 0/1 is abnormal.

(2) Enable the local loopback function on GigabitEthernet 0/2. Then, the packets sent by GigabitEthernet 0/2 do not go through an external link, but are directly sent back to device B inside the interface. If GigabitEthernet 0/2 enters the **Link Up** state on the Physical Layer, it indicates that GigabitEthernet 0/2 is normal. If GigabitEthernet 0/2 is in the **Down** state on the Physical Layer, it indicates that GigabitEthernet 0/2 is abnormal.

1.2 Restrictions and Guidelines

- The PHY loopback function can be configured on physical interfaces only. Logical interfaces (including aggregate interfaces and subinterfaces) do not support PHY loopback.
- The PHY loopback function cannot be configured on a physical interface that is added to an aggregate interface.

- The PHY loopback function cannot be configured on a physical interface that is converted to a VSL interface.

1.3 Configuring Basic Features

1.3.1 Overview

Local loopback: After the **phy-loopback local** command is executed, the packets sent by the local interface do not go through an external link, but are directly sent back to the local end inside the interface.

1.3.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(4) Enable local PHY loopback.

phy-loopback local

PHY loopback is disabled for an interface by default.

(5) Disable the PHY loopback function for the interface after the test.

no phy-loopback

PHY loopback is disabled for an interface by default.

1.4 Monitoring

This section describes the **show** commands used for checking the running status of a configured function to verify the configuration effect.

Table 1-1 PHY Loopback Monitoring

Purpose	Command
Displays the interfaces enabled with PHY loopback and their configuration status.	**show phy-loopback**

1 Configuring VLAN

1.1 Introduction

1.1.1 Overview

A virtual local area network (VLAN) is a logical network created by dividing a physical network. Every VLAN has an independent broadcast domain, and different VLANs are isolated in Layer 2. Devices on different VLANs can implement communication through Layer 3 devices or Layer 3 interfaces.

1.1.2 Background and Functions

1. Background

The early local area network (LAN) adopts a bus structure, and STAs on the bus belong to the same contention domain. Bridges and L2 switches can isolate STAs onto different ports and control packet forwarding to isolate the contention domain. All ports of L2 switches belong to the same broadcast domain. When a switch receives a frame with an unknown destination address, the switch broadcasts this frame to all ports in the broadcast domain other than the source port. After receiving a reply from a port that matches the destination address, the switch learns the new MAC address based on the source address in the reply packet. This is the basic working mode of the switch. The working mode will lead to two problems:

- If the network scale is enlarged, the increasing broadcast packets waste bandwidth.
- As packets in a LAN are broadcast, each STA in the broadcast domain can receive broadcast packets in the entire LAN. If users obtain these packets using a packet capture tool, the content in the packets may be intercepted, which affects information security.

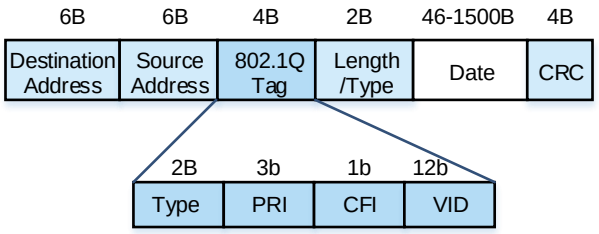
Use routers to solve the preceding two problems. Routers communicate based on Layer 3 IP addresses, and different subnets belong to different broadcast domains. This dampens the forwarding of broadcast packets. However, high forwarding performance of routers depends on central processing units (CPUs), and requires a high cost. Therefore, routers are usually used as egresses between LANs and wide area networks (WANs). In contrast, a VLAN is a solution with lower cost and solves the preceding problems by dividing the physical LAN into multiple logical LANs.

2. Functions

- Layer 2 isolation

  You can divide a physical LAN into multiple VLANs by using different division methods so as to isolate broadcast domains, which saves bandwidth and enhances LAN security. A VLAN shares the same attributes with a common physical LAN except the restriction on physical location. Every VLAN has an independent broadcast domain. If no Layer 3 interface interconnected with VLANs is configured, the VLANs are mutually isolated on L2. Users in different VLANs cannot communicate with each other. L2 unicast, broadcast and multicast frames are forwarded and transmitted in the same VLAN without entering other VLANs.

- Layer 3 interconnection



To realize Layer 3 communication between VLANs, a virtual interface is developed for an Layer 3 switch, based on the concept of router subinterfaces. The virtual interface is referred to as Switch Virtual Interface (SVI). In a Layer 3 switch, you can create an SVI and an SVI IP address for each VLAN. The SVI functions as a VLAN gateway to implement Layer 3 communication between VLANs. Therefore, an SVI is also referred to as a VLAN interface.

1.1.3 Frame Format

Based on IEEE 802.1Q, a 4-byte 802.1Q tag is inserted between the source MAC address field and protocol type field of an Ethernet frame, as shown in Figure 1-1. The VLAN ID (VID) field in the tag is used to represent the VLAN where the frame comes from. Not all devices identify tagged 802.1Q frames. Therefore, Ethernet frames can be tagged or untagged in the VLAN.

- Type: two bytes. The value **0X8100** indicates 802.1Q frames. Devices not supporting 802.1Q discard these frames upon receiving them.
- PRI: three bits. It indicates the L2 priority and corresponds to the Class of Service (CoS) priority of the Quality of Service (QoS). The value range is from 0 to 7. A larger value indicates a higher priority.
- CFI: one bit. It differentiates among Ethernet frames, Fiber Distributed Data Interface (FDDI) frames, and token ring network frames. The value **0** indicates Ethernet frames.
- VID: 12 bits. It indicates the ID of a VLAN to which packets belong. The value range of a VLAN ID is from 1 to 4094. The value **0** and **4095** are reserved and unusable.

Figure 1-1 802.1Q Frame Format

1.1.4 Port Types and Link Types

Interfaces can be classified into L2 interfaces and Layer 3 interfaces. Only L2 interfaces can be added to VLANs. Table 1-1 lists basic types of L2 interfaces. You can configure the L2 interface type of an interface to determine the allowed VLANs of the interface, and whether the packets forwarded by the interface are tagged.

Table 1-1 Basic Types of L2 Interfaces

Port Type	Function
Access	An access port carries traffic for only one VLAN. Only frames from this VLAN can pass the port. This VLAN is referred to as access VLAN, which owns attributes of a native VLAN and an allowed VLAN. The frames sent from the access port do not carry tags. When the access port receives an untagged frame from a peer device, the local device determines that the frame comes from the access VLAN and adds the access VLAN ID to the frame.

Port Type	Function
Trunk	A trunk port carries traffic for one native VLAN and multiple allowed VLANs. The frames forwarded by the trunk port from the native VLAN do not carry tags and the frames forwarded by the trunk port from allowed VLANs carry tags. Note that the trunk ports of a link must be configured with the same native VLAN.
Uplink	An uplink port carries traffic for one native VLAN and multiple allowed VLANs. Frames sent by the uplink port are tagged. In a QinQ scenario, frames sent by a Provider Edge (PE) device port connected to a public network must carry tags. Therefore, the port must be configured as an uplink port. A Customer Edge (CE) device port connected to the PE device can also be configured as an uplink port. For more information, see *Configuring QinQ*.
Hybrid	A hybrid port carries traffic for one native VLAN and multiple allowed VLANs. Allowed VLANs are classified into tagged VLANs and untagged VLANs. The frames forwarded by the hybrid port from a tagged VLAN carry tags, and the frames forwarded by the hybrid port from an untagged VLAN do not carry tags. The frames forwarded by the hybrid port from the native VLAN must not carry tags, because the native VLAN is an untagged VLAN. The MAC VLAN function applies to only untagged VLANs on the hybrid port. Therefore, the hybrid port can be used as an interface to connect to downlink clients in MAC VLAN scenarios. For more information, see *Configuring MAC VLAN*.

VLAN links include access links and trunk links.

- An access link connects STAs to a switch interface. Although some STAs can identify frames that carry VLAN tags, most STAs cannot do so. Generally, a port transmits untagged frames in the access link to ensure the compatibility of different STAs.
- A trunk link can bear data of different VLANs. You must ensure that the devices connected by the trunk link can identify the VLAN of frames transmitted on the trunk link. Untagged frames and tagged frames are transmitted based on different types of ports. Ensure that the native VLAN configuration on the peer device is consistent with that on the local device so that the trunk port transmits untagged frames from the native VLAN and tagged frames from other allowed VLANs,

Access ports can be connected by an access link only. Hybrid ports can be connected by both an access link and a trunk link. Trunk ports and uplink ports can be connected by a trunk link only.

1.1.5 VLAN Frame Processing Rules

- Frame receiving rule

  When detecting an incoming untagged frame, the port regards that the frame comes from the native VLAN of the port. If the native VLAN is an allowed VLAN of the port, the port receives the packet, and identifies the frame as one from the native VLAN. Otherwise, the port discards the packet.

  When detecting a tagged frame, the port receives the packet if the port allows the VLAN identified by the tag. Otherwise, the port discards the packet.

- Frame forwarding rule

An L2 switch can forward packets to only ports that match allowed VLANs (other than the source port).

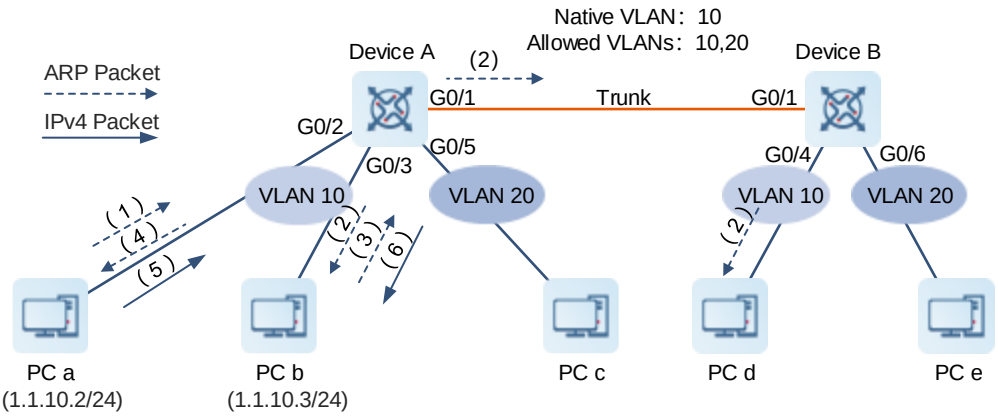
An Layer 3 switch can determine an egress VLAN by querying the routing table in software and forward packets to a port that allows the egress VLAN.

- Frame sending rule

  After packets are forwarded in the switch, the switch determines whether to add tags to the packets based on the VLAN type (tagged VLAN or untagged VLAN).

The following example displays actual application of the above rules. Table 1-2 shows the interfaces and configurations in the example.

Table 1-2 Interface Examples



Interface	Mode	Native VLAN	Allowed VLAN
GigabitEthernet 0/1	Access	10	10 (Untagged)
GigabitEthernet 0/2	Trunk	10	10 (Untagged), 20 (Tagged), and 30 (Tagged)
GigabitEthernetGi 0/3	Hybrid	20	20 (Untagged), 10 (Tagged), and 30 (Tagged)
GigabitEthernetGi 0/4	Uplink	30	30 (Tagged) and 20 (Tagged)

When GigabitEthernet 0/1 receives an untagged frame or a frame with a VLAN 10 tag, it forwards the frame to GigabitEthernet 0/2 and GigabitEthernet 0/3 that allow VLAN 10. The VLAN 10 frame sent to GigabitEthernet 0/2 is untagged, and the VLAN 10 frame sent to GigabitEthernet 0/3 is tagged. When GigabitEthernet 0/4 receives an untagged frame or a frame with a VLAN 30 tag, it forwards the frame to GigabitEthernet 0/2 and GigabitEthernet 0/3 that allow VLAN 30. The VLAN 30 frame sent to GigabitEthernet 0/2 is tagged, and the VLAN 30 frame sent to GigabitEthernet 0/3 is untagged.

1.1.6 Intra-VLAN Communication on One Device

As shown in the topology in Figure 1-2, Device A and Device B are connected through the trunk port GigabitEthernet 0/1. PC a and PC b are connected to VLAN 10 through device A. The communication between PC a and PC b is intra-VLAN communication on one device.

Figure 1-2 An Example of Intra-VLAN Communication Within One Device

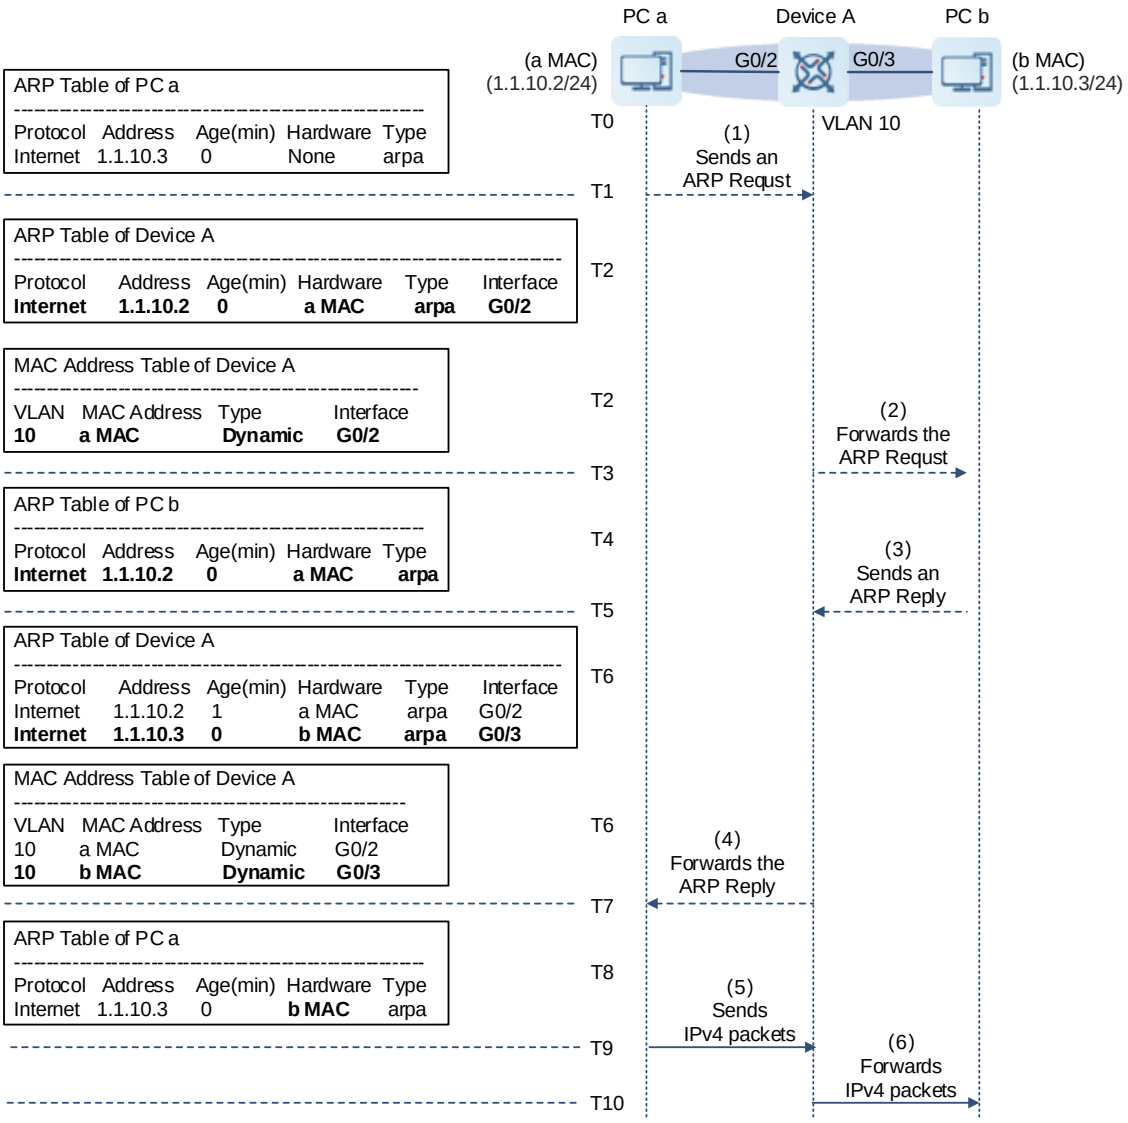
Through IP addresses, PC a (1.1.10.2/24) first determines that PC b (1.1.10.3/24) is in the same subnet as the device. The device uses the MAC address of PC b as the destination MAC address for communication. The communication steps are as follows:

If PC a does not find the MAC address of PC b, the communication goes from step (1); if PC a finds the MAC address of PC b, the communication goes from step (5).

(1) PC a does not find the MAC address of PC b in the Address Resolution Protocol (ARP) table. PC a sends a broadcast ARP request packet to request the MAC address of PC b. Device A learns the MAC address of PC a through the ARP request packet.

(2) Device A forwards the broadcast ARP request packet. PC b learns the MAC address of PC a through the ARP request packet.

(3) PC b sends a unicast ARP reply packet to PC a. Device A learns the MAC address of PC b through the ARP reply packet.



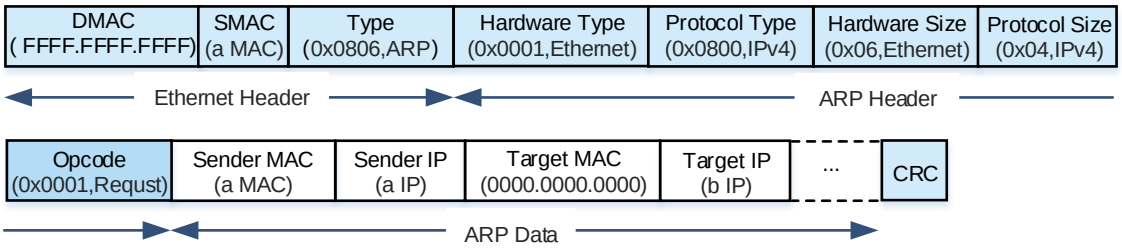
(4) Device A finds the MAC address of PC a in the ARP table and forwards the unicast ARP reply packet. PC a learns the MAC address of PC b through the ARP reply packet.

(5) PC a finds the MAC address of PC b (destination MAC address) in the ARP table and sends a unicast IPv4 packet to PC b.

(6) Device A finds the MAC address of PC b in the ARP table and forwards the unicast IPv4 packet.

Steps of intra-VLAN communication on one device are shown in Figure 1-3.

Figure 1-3 Steps of Intra-VLAN Communication



(1) PC a sends an ARP request packet to request the MAC address of PC b.

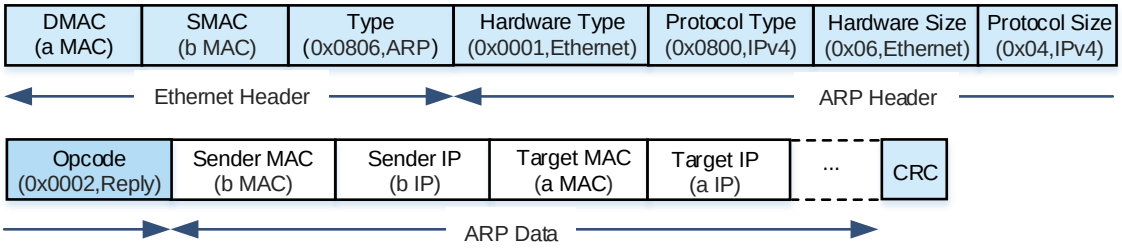
a. If PC a does not find the MAC address of PC b as shown in T0 in Figure 1-3, PC a sends an ARP request packet encapsulated in an Ethernet broadcast frame (as shown in Figure 1-4) to PC b as shown in T1 in Figure 1-3.

b. Upon receiving the ARP request packet of PC a from GigabitEthernet 0/2, if Device A finds that the packet is untagged, it determines that the packet comes from VLAN 10 and receives the packet. Device A learns the source IP address in the packet. Device A enters the mapping among the IP address, MAC address, port, and VLAN of PC a into the ARP table and enters the mapping among the VLAN, MAC address and port of PC a into the dynamic MAC address table, as shown in T2 in Figure 1-3.

Figure 1-4 The ARP Request Packet Sent by PC a for Requesting the MAC Address of PC b

(2) Device A forwards the ARP request packet.

a. Device A searches for the port that allows VLAN 10, and broadcasts the ARP request to GigabitEthernet 0/1 and GigabitEthernet 0/3 except the source port GigabitEthernet 0/2, as shown in T3 in Figure 1-3.



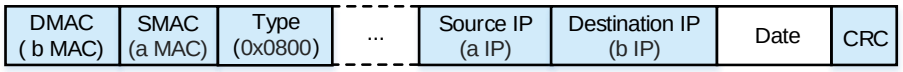
b. PC b receives the ARP request (as shown in Figure 1-4) of PC a from GigabitEthernet 0/3, learns the mapping between the IP address and MAC address of PC a, and enters the mapping into the ARP table.

(3) PC b sends a unicast ARP reply packet.

a. PC b finds that the destination IP address in the ARP request matches its own IP address, it sends a unicast ARP reply (as shown in Figure 1-5) to PC a, as shown in PC b in T5 in Figure 1-3.

b. Upon receiving the ARP reply of PC b from GigabitEthernet 0/3, Device A learns the source IP address. Device A enters the mapping among the IP address, MAC address, port, and VLAN of PC b into the ARP table and enters the mapping among the VLAN, MAC address and port of PC b into the dynamic MAC address table, as shown in T6 in Figure 1-3.

Figure 1-5 The ARP Reply Packet Sent by PC b to PC a



(4) Device A forwards the ARP reply packet.

a. Device A queries the MAC address table, matches MAC address of PC a, and forwards the ARP reply of PC b to GigabitEthernet 0/2, as shown in T7 in Figure 1-3.

b. PC a receives the ARP reply (as shown in Figure 1-5) of PC b from GigabitEthernet 0/2, learns the mapping between the IP address and MAC address of PC b, and enters the mapping into the ARP table, as shown in T8 in Figure 1-3.

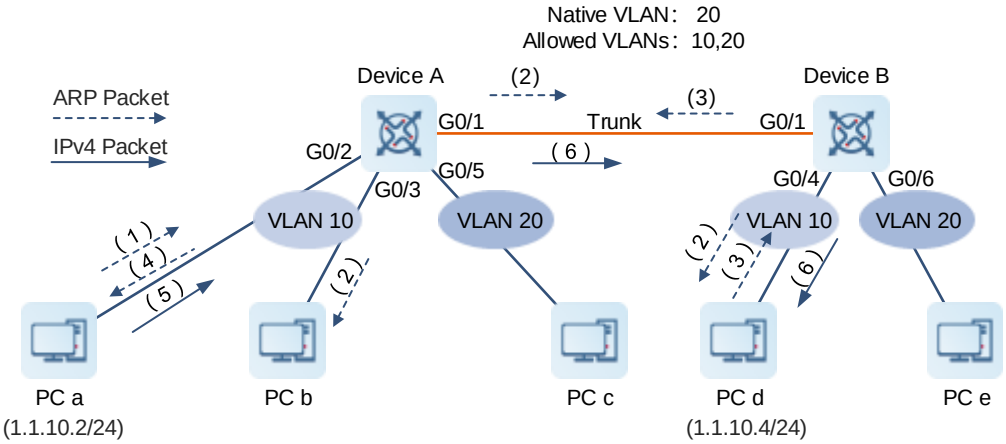
PC a sends an IPv4 packet.PC a finds the MAC address of PC b in the ARP table, generates a packet with the MAC address of PC b as the destination MAC address and the MAC address of PC a as the source MAC address, and sends the packet (as shown in Figure 1-6) to PC b, as shown in T9 in Figure 1-3 .

Figure 1-6 The IPv4 Packet Sent from PC a to PC b

(5) Device A forwards the IPv4 packet.

Upon receiving the packet from PC a, Device A refreshes the MAC address table based on the source IP address of PC a, queries the MAC address table and matches the destination MAC address of PC b, and forwards the packet (as shown in Figure 1-6) to GigabitEthernet 0/3, as shown in T10 in Figure 1-3.

1.1.7 Intra-VLAN Communication Across Devices



Ports on different devices can be assigned to the same VLAN. The procedure of intra-VLAN communication across devices is similar to the procedure of intra-VLAN communication on one device, except for the following:

- The trunk port sends a packet. If the packet comes from the native VLAN, the packet is untagged. Otherwise, the packet is tagged.
- When receiving a packet, the trunk port determines that the packet comes from the native VLAN if it is untagged. If the native VLAN is an allowed VLAN of the port, the packet is allowed to pass through the port. Otherwise, the packet is not allowed to pass through the port. If the packet is tagged, the port check whether the packet comes from an allowed VLAN. If yes, the port receives the packet and forwards it. If not, the port discards the packet.

As shown in Figure 1-9, Device A and Device B is connected through the trunk port GigabitEthernet 0/1. PC a is connected to VLAN 10 through Device A, and PC d is connected to VLAN 10 through Device B. The communication between PC a and PC d is intra-VLAN communication across devices.

To explain the process of adding and removing a tag, assume that VLAN 20 is the native VLAN of GigabitEthernet 0/1.

Figure 1-7 An Example of Intra-VLAN Communication Across Devices

PC a determines that PC d is on the same network segment as the device. PC a needs to use the MAC address of PC d as the destination MAC address for communication. The communication steps are as follows:

(1) PC a does not find the MAC address of PC d (the destination MAC address) in the ARP table. PC a sends a broadcast ARP request packet to request the MAC address of PC d. Device A learns the MAC address of PC a through the ARP request packet.

(2) Device A forwards the broadcast ARP request packet. As VLAN 10 is not the native VLAN of the trunk port GigabitEthernet 0/1, add a VLAN 10 tag to the packet and send the packet. When the GigabitEthernet 0/1 port of Device B receives the packet, the port finds that the packet carries a VLAN 10 tag and VLAN 10 is an allowed VLAN. The port allows the packet to pass through. The port removes the VLAN 10 tag from the packet and forwards the ARP request packet to the GigabitEthernet 0/4 port. Device B and PC d learn the MAC address of PC a through the ARP request packet.

(3) PC d sends a unicast ARP reply packet. The GigabitEthernet 0/1 port of Device B adds a VLAN tag to the ARP reply packet and forwards the packet. Device B and Device A learn the MAC address of PC d through the ARP reply packet.

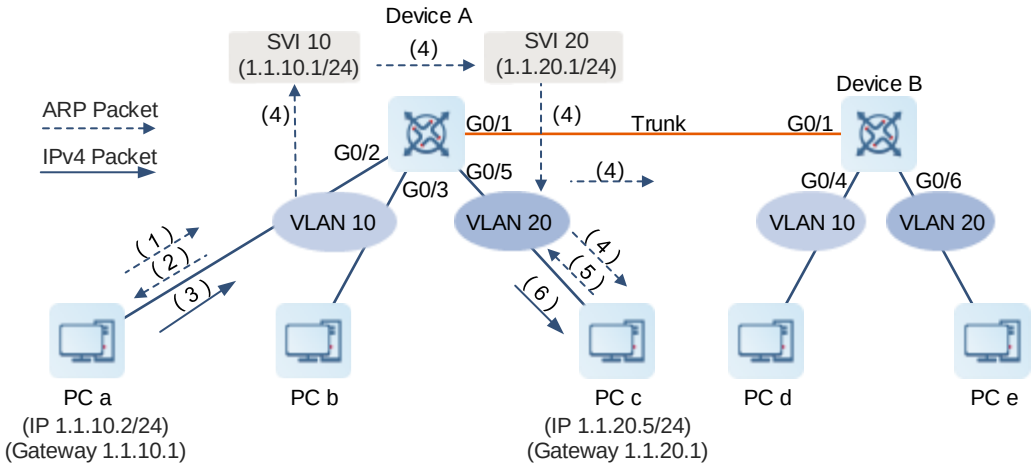
(4) When the GigabitEthernet 0/1 port of Device A receives the packet, the port finds that the packet carries a VLAN 10 tag and VLAN 10 is an allowed VLAN. The port allows the packet to pass through. Device A queries the ARP table and matches the MAC address of PC a. The port removes the VLAN 10 tag from the packet and forwards the unicast ARP request packet to the GigabitEthernet 0/2 port.

(5) PC a finds the MAC address of PC d (the destination MAC address) in the ARP table and sends a unicast IPv4 packet to PC d.

(6) Device A queries the ARP table, matches the MAC address of PC d, adds a VLAN 10 tag to the IPv4 packet and forwards the packet. When receiving the packet, .Device B queries the ARP table, matches the MAC address of PC d, removes the VLAN 10 tag from the IPv4 packet and forwards the packet.

1.1.8 Inter-VLAN Communication

In practice, devices from different VLANs may need to communicate with each other. Although VLAN broadcast domains are isolated in Layer 2, the devices from different VLANs can communicate with each other by using a Layer 3 device. But this method requires routed ports. To address this problem, a routing module can be added to a Layer 2 switch to form a Layer 3 switch.



On a Layer 3 switch, one VLAN corresponds to one SVI. The Layer 3 switch takes the SVI as an independent interface, creates an ARP entry for the interface, and records the mapping between the IP address and MAC address of the SVI.

An STA in each VLAN uses the IP address of an SVI corresponding to this VLAN as the default gateway. When the STA in the VLAN tries to communicate with an STA in another VLAN, the STA queries the MAC address of the gateway to be used as the destination MAC address, and then forwards a packet to the gateway.

When the Layer 3 switch receives the packet whose MAC address matches the SVI, the switch enables Layer 3 forwarding. If the Layer 3 switch does not know the MAC address of the destination host, the Layer 3 switch queries the routing table in the software, determines the egress VLAN of the destination host, and sends an ARP request in the egress VLAN. Upon obtaining an ARP reply from the destination host, the Layer 3 switch learns the IP address, MAC address, port, and VLAN of the destination host, updates the Layer 3 routing table, replaces the source MAC address in the packet with the MAC address of the gateway and the destination MAC address with the MAC address of the destination host, and forwards the packet to the destination host. Later, when the Layer 3 switch receives packets with the same destination MAC address, the Layer 3 switch directly queries the Layer 3 routing table, replaces the source and destination MAC addresses, and forwards the packets.

As shown in Figure 1-8, PC a belongs to VLAN 10 and PC c belongs to VLAN 20. They communicate with each other across the VLANs.

Figure 1-8 An Example of Inter-VLAN Communication

After an SVI is created, Device A generates the mappings of IP addresses to MAC addresses and a directly connected route to the Layer 3 SVI. As shown in T0 in Figure 1-9, the gateway MAC address is the MAC address of Device A.

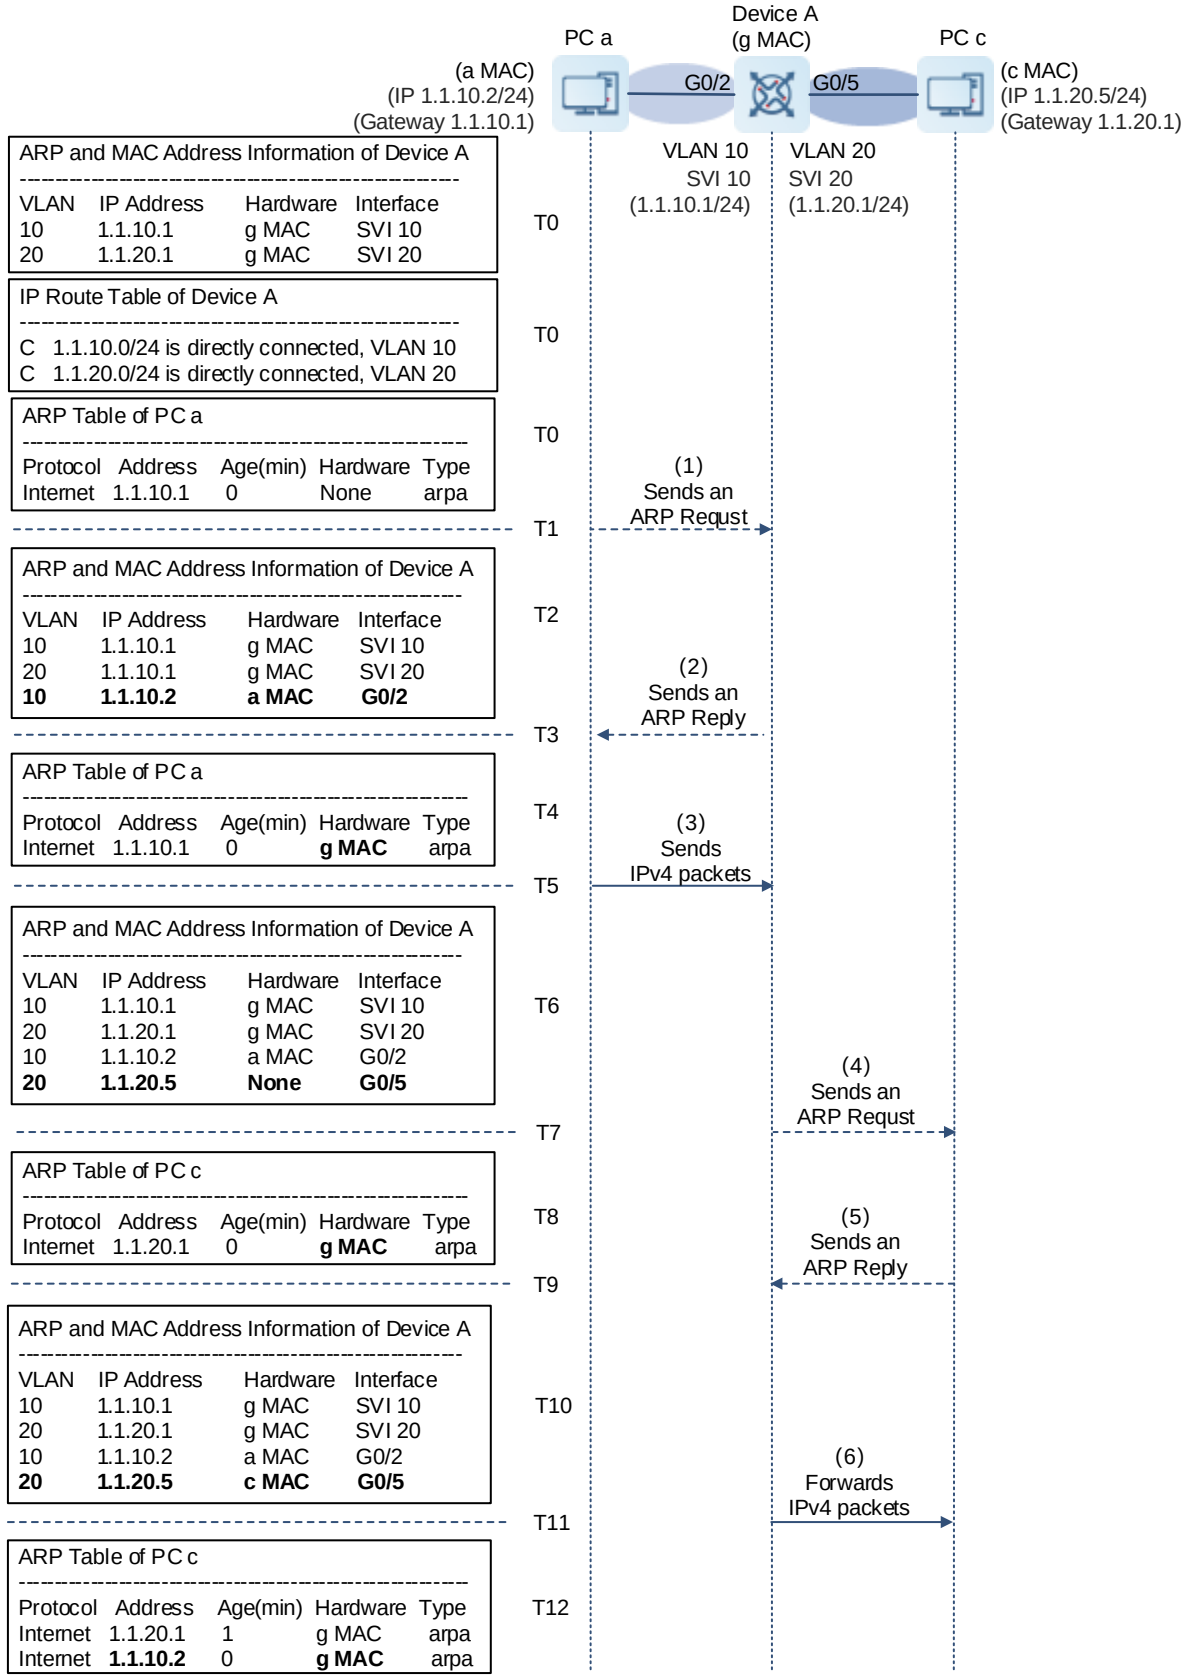
The IP address of PC a is 1.1.10.2/24 and its corresponding gateway IP address is 1.1.10.1/24. The IP address of PC c is 1.1.20.5/24 and its corresponding gateway IP address is 1.1.20.1/24. To communicate with PC c, PC a first determines that they are on different network segments. PC a takes the gateway MAC address as the destination address for communication. The communication steps are as follows:

PC a queries the ARP table for the gateway MAC address corresponding to the gateway IP address (1.1.10.1/24). If PC a does not find the MAC address of the gateway, goes from step (1). If PC a finds the MAC address of the gateway, goes from step (3).

(1) PC a does not find the MAC address of the gateway, it sends a broadcast ARP request packet to request the MAC address of the gateway. Device A learns the MAC address of PC a through the ARP request packet.

(2) Device A sends a unicast ARP reply packet. PC a learns the MAC address of the gateway through the ARP reply packet.

(3) PC a finds the MAC address of the gateway of in the ARP table, uses the gateway MAC address as the destination MAC address, and the IP address of PC c as the destination IP address, and sends a unicast IPv4 packet to PC c. When receiving the packet, if Device A does not find the MAC address of PC c, it performs step (4). If Device A finds the MAC address of PC c, it performs step (6) directly.



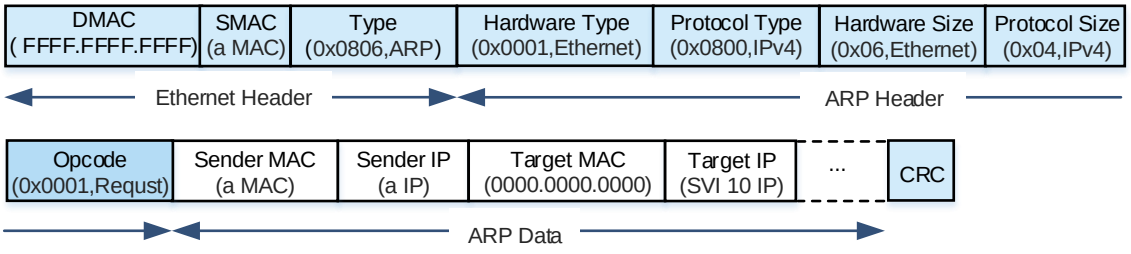
(4) Device A identifies that the destination MAC address is the MAC address of the gateway, and sends the packet to SVI 10 for forwarding. The CPU queries the software routing table, and finds that the egress VLAN corresponding to the destination IP address of PC c is VLAN 20 through the directly connected route of Layer 3 SVIs. SVI 20 in VLAN 20 sends a broadcast ARP request to request the MAC address corresponding to the IP address of PC c. PC c learns the mapping of the MAC address of the gateway and the IP address of SVI 20 through the packet.

(5) PC c sends a unicast ARP reply. Device A learns the MAC address of PC c.

(6) For the packet sent from PC a to PC c, Device A changes its source MAC address from a MAC to g MAC, and changes its destination MAC address from g MAC to c MAC, and then forwards it. PC c learns the mapping of the MAC address of the gateway and the IP address of PC a through the packet.

Steps of inter-VLAN communication are shown in Figure 1-9.

Figure 1-9 Steps of Inter-VLAN Communication

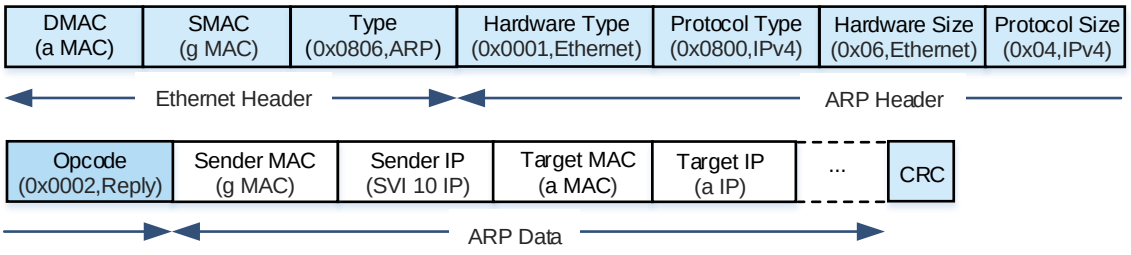


(7) PC a sends an ARP request packet to request the MAC address of the gateway.

a. If PC a does not find the MAC address of the gateway IP address (1.1.10.1) as shown in T0 in Figure 1-9, PC a sends an ARP request packet encapsulated in an Ethernet broadcast frame (as shown in Figure 1-10) to the gateway as shown in T1 in Figure 1-9. The gateway of PC a is SVI 10 whose IP address is 1.1.10.1/24. Therefore, the gateway uses the IP address of SVI 10 as a target IP address.

b. When receiving the ARP request packet of PC a from GigabitEthernet 0/2, if Device A finds that the packet is untagged, it determines that the packet comes from VLAN 10 and receives the packet. Device A learns the source IP address in the packet, and enters the mapping among the IP address, MAC address, port, and VLAN of PC a into the ARP table. Device A enters the mapping among the VLAN, MAC address, and port of PC a into the dynamic MAC address table. The ARP table and the MAC address table contain information about Layer 3 forwarding and such information is called as a Layer 3 routing table, as shown in T2 in Figure 1-9. The routing table cannot be queried but its content is reflected in the ARP table and MAC address table.

Figure 1-10 The ARP Request Packet Sent from PC a for the MAC Address of the Gateway

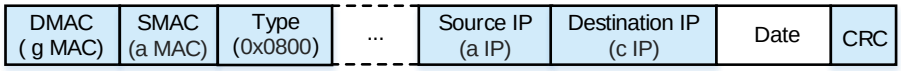


(8) Device A sends an ARP reply packet.

a. If Device A finds that the packet is an ARP packet and the destination IP address in the packet is the IP address of the SVI 10 of this device, it returns a unicast ARP reply and forwards the reply packet through GigabitEthernet 0/2, as shown in T3 in Figure 1-11Figure 1-9. The reply packet (as shown in Figure 1-11) includes the IP address and MAC address of SVI 10.

b. Upon receiving the ARP reply, PC a learns the MAC address corresponding to the gateway IP address of the SVI 10 and updates the ARP table of PC a, as shown in T4 in Figure 1-9.

Figure 1-11 ARP Reply Packet Sent by the Gateway to PC a



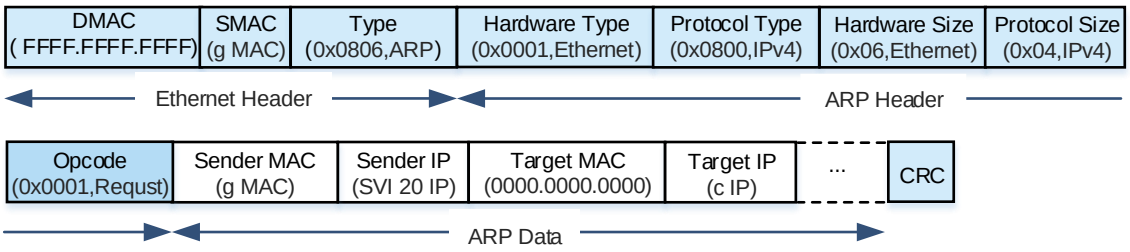
(9) PC a sends an IP packet to PC c.

a. If PC a finds the MAC address of the gateway in the ARP table, it generates a packet with the gateway MAC address as the destination MAC address and the MAC address of PC a as the source MAC

address, encapsulates the packet in an Ethernet frame (as shown in Figure 1-12), and forwards the packet to the gateway, as shown in T5 in Figure 1-11Figure 1-9.

b. Upon receiving the packet of PC a from GigabitEthernet 0/2 (as shown in Figure 1-12), Device A finds that the packet is untagged. Device A determines that the packet comes from VLAN 10 and updates the MAC address entry of PC a. The destination MAC address (gateway MAC address) is the gateway MAC address of the local device. Therefore, the packet must be forwarded at Layer 3. If Device A finds the MAC address of PC c corresponding to the IP address of PC c, the device goes to step (6).

Figure 1-12 IPv4 Packet Sent by PC a to PC c



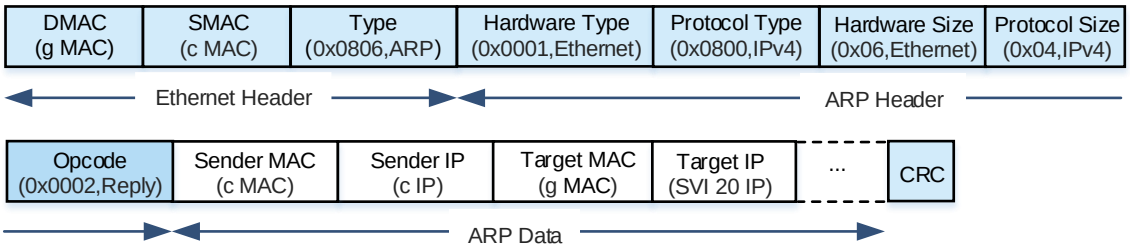
(10) The gateway sends an ARP request for the MAC address of PC c.

a. If Device A does not find the MAC address corresponding to the IP address of PC c (1.1.20.5), it sends the packet to SVI 10 to forward the packet to the CPU.

b. The CPU queries the software routing table, and finds that the IP address matches a direct route to 1.1.20.0/24 and the egress VLAN is VLAN 20. In the egress VLAN (VLAN 20), SVI 20 sends a broadcast ARP request packet for the MAC address of PC c, as shown in T7 in Figure 1-11Figure 1-9. The gateway of PC c is SVI 20. Therefore the gateway uses the IP address of SVI 20, 1.1.20.1/24, as its IP address.

c. The ARP request is sent from GigabitEthernet 0/1 and GigabitEthernet 0/5 that allow VLAN 20. PC c receives the ARP request (as shown in Figure 1-13) of Device A from GigabitEthernet 0/5, learns the mapping between the gateway IP address and gateway MAC address in VLAN 20 on Device A, and enters the mapping into the ARP table, as shown in T8 in Figure 1-11Figure 1-9.

Figure 1-13 ARP Request Packet Sent by the Gateway for Requesting MAC Address of PC c

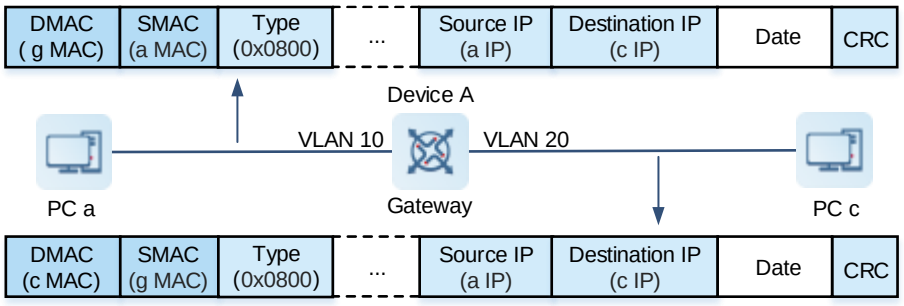


(11) PC c sends an ARP reply packet.

a. If PC c finds that the destination IP address in the ARP request matches its own IP address, it sends an ARP reply packet in unicast mode (as shown in Figure 1-14), as shown in T9 in Figure 1-11Figure 1-9.

b. Upon receiving the ARP reply (as shown in Figure 1-14) of PC c, Device A learns the mapping among the IP address, MAC address, port, and VLAN of PC c, and enters the mapping into the ARP table, as shown in T10 in Figure 1-11Figure 1-9.

Figure 1-14 ARP Reply Packet Sent by PC c to the Gateway



(12) The gateway forwards the IP packet.

a. If Device A finds the MAC address of PC c in the routing table, it replaces the MAC address of PC a with the gateway MAC address and the gateway MAC address with the MAC address of PC c, and forwards the packet of PC a to PC c (as shown in Figure 1-15), as shown in T11 in Figure 1-11Figure 1-9.

b. PC c receives this packet (as shown in Figure 1-15) from GigabitEthernet 0/5, learns the mapping between the IP address of PC a and the gateway MAC address, and enters the mapping into the ARP table, as shown in T12 in Figure 1-11Figure 1-9. Later, when PC c sends the packet to PC a, it can query the gateway MAC address corresponding to the IP address of PC a (1.1.10.2), and encapsulates the packet for PC a by using the gateway MAC address as the destination MAC address.

Figure 1-15 Packet Forwarded by the Gateway

1.1.9 VLAN Assignment Methods

1. Port-based Assignment

- Port-based VLAN

  Port-based VLAN assignment is the most basic VLAN assignment method. After the administrator configures a port with a Port Default VLAN ID (PVID), the port is assigned to a VLAN. The VLAN ID range is from 1 to 4094. In case of no VLAN assignment, all ports are assigned to VLAN 1 by default.

- Super VLAN

  Super VLAN is also referred to as VLAN aggregation, which aggregates multiple VLANs into one IP address segment. Only one IP address is assigned to a super VLAN that contains multiple sub-VLANs, and this saves address resources and facilitates network management. A VLAN accessible by an STA is subject only to an access port of the STA. That is, the STA is assigned to a VLAN based on the STA's access port. For more information, see *Super VLAN*.

- Private VLAN

  Private VLAN is a technology that can divide an L2 broadcast domain of a VLAN into multiple sub domains, and each sub domain is composed of one private VLAN pair: primary VLAN and secondary VLAN. This technology can increase the number of users that can be supported by an operator network and reduce waste of IP address resources. A VLAN accessible by an STA is subject only to an access port of the STA. That is, the STA is assigned to a VLAN based on the STA's access port. For more information, see *Private VLAN*.

2. Packet-based Assignment

- MAC-based VLAN

  MAC-based VLAN is a VLAN assignment method based on MAC addresses. When an STA is physically relocated, it can re-access the network from another device and there is no need to reconfigure a VLAN for the access port. If different STAs access the network from the same port, they can be assigned to different VLANs based on their MAC addresses. For more information, see *MAC VLAN*.

  Usually, MAC-based VLAN is used with the 802.1x VLAN delivery function to ensure secure and flexible access of 802.1x STAs.

- Voice VLAN

  A voice VLAN is a VLAN dedicated for voice data streams of users. With this technology, data streams and voice streams are transmitted in the data VLAN and the voice VLAN, respectively, to prevent mutual interference between voice calls and service packets. This function identifies voice data and assigns the voice data to the voice VLAN. This method belongs to packet content-based VLAN assignment. For more information, see *Voice VLAN*.

- Protocol-based VLAN

  Protocol-based VLAN is a VLAN assignment technology based on the protocol type or IP subnet in packets. The service types supported in a network are bound to VLANs to facilitate management and maintenance. This method belongs to packet-based VLAN assignment. For more information, see *Protocol-based VLAN*.

1.1.10 Protocols and Standards

IEEE 802.1Q: IEEE Standard for Local and Metropolitan Area Networks-Virtual Bridged Local Area Networks

1.2 Restrictions and Guidelines

- Before you configure a port type or add a port to a VLAN, ensure that the port is a Layer 2 interface.
- Run the **show interface switchport** command to show the port type. If the **Switchport** field corresponding to the port is set to **enabled**, the port is a Layer 2 interface. Otherwise, the port is a Layer 3 interface.
- Run the **switchport** command to configure a port as a Layer 2 interface. Run the **no switchport mode** command to restore the default configuration of the Layer 2 interface mode. Then run the **no switchport** command to configure the Layer 2 interface as a Layer 3 interface. When you configure a port as a Layer 2 or Layer 3 interface, all attributes of the interface are restored to the default values in the corresponding interface mode.

1.3 Configuration Task Summary

VLAN configuration includes the following tasks:

(1) Configuring VLANs

- Creating and Configuring VLANs

Caution

Deleting a static VLAN may lead to service disruption. Please proceed only after assessing the impact on the other services.

- (Optional) Configuring VLAN Names
- (Optional) Configuring SVIs

(2) Configure a port type and add ports to a VLAN. Configure at least one of the following tasks.

- Configuring Access Ports
- Configuring Trunk Ports
- Configuring Uplink Ports
- Configuring Hybrid Ports
-

1.4 Configuring VLANs

1.4.1 Overview

Create a VLAN, and enter the VLAN configuration mode.

1.4.2 Configuration Tasks

VLAN configuration includes the following tasks:

(1) Creating and Configuring VLANs

Caution

Deleting a static VLAN may lead to service disruption. Please proceed only after assessing the impact on the other services.

(2) (Optional) Configuring VLAN Names

(3) (Optional) Configuring SVIs

1.4.3 Creating and Configuring VLANs

Caution

Deleting a static VLAN may lead to service disruption. Please proceed only after assessing the impact on the other services.

1. Overview

Create a VLAN, and enter the VLAN configuration mode.

A VLAN is identified based on a VLAN ID, and the VLAN ID range is from 1 to 4094. VLAN 1 is created automatically and cannot be deleted. VLANs 2 to 4094 can be created, deleted, and edited.

2. Restrictions and Guidelines

- When you create a VLAN, the system will prompt the VLAN creation failure if hardware resource is insufficient.
- Run the **no vlan** *vlan-id* command to delete a common static VLAN. VLANs such as VLAN 1, VLANs with SVIs configured, and private VLANs cannot be deleted.
- To delete a VLAN with a created SVI, run the **no interface vlan** *vlan-id* command to delete the SVI and then the **no vlan** *vlan-id* command to delete the VLAN.
- Check created VLANs and its VLAN status. If you enter a new VLAN ID, a corresponding VLAN is created. If you enter an existing VLAN ID, the system enters the configuration mode of the corresponding VLAN, and you can modify the VLAN settings.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a VLAN and enter the VLAN configuration mode.

vlan *vlan-id*

Only VLAN 1 exists by default.

1.4.4 Configuring VLAN Names

1. Overview

Name a VLAN.

2. Restrictions and Guidelines

- You cannot rename a VLAN the same as the default name of another VLAN.
- You are advised to run the **show vlan** command to check all VLAN names in case of name duplication before you name a VLAN.
- A VLAN is named as VLAN*vlan-id*. For example, the name of VLAN 2 is VLAN0002.
- To restore the VLAN name to a default value, run the **no name** command.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the VLAN configuration mode.

vlan *vlan-id*

(4) Configure a VLAN name.

name *vlan-name*

The name of a VLAN is VLAN *vlan-id* by default.

1.4.5 Configuring SVIs

Caution

Deleting the SVI of a VLAN will cause the gateway address of the VLAN to be deleted. Proceed after evaluating the scope of the affected services.

1. Overview

You can create an SVI of a VLAN and enter the SVI configuration mode. Configure an IP address for the SVI so that devices in the VLAN can communicate at Layer 3.

2. Restrictions and Guidelines

- You cannot create SVIs for sub-VLANs of a super VLAN or secondary VLANs of a private VLAN.
- In the **interface vlan** *interface-number* command, *interface-number* indicates the SVI ID. An SVI ID must follow the ID of the corresponding VLAN, which ranges from 1 to 4,094.
- To delete a VLAN with a created SVI, run the **no interface vlan** *interface-number* command to delete the SVI and then run the **no vlan** *vlan-id* command to delete the VLAN.
- To configure an IPv4 address, see *Configuring IPv4 Basics*.
- To configure an IPv6 address, see *Configuring IPv6 Basics*.

3. Prerequisites

Create a VLAN.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an SVI of a VLAN and enter the SVI configuration mode.

interface vlan *interface-number*

No SVI is configured for a VLAN by default.

(4) (Optional) Configure an IP/IPV6 address for an SVI.

ip address { *ipv4-address mask* | *ipv4-address/mask-length* }

ipv6 address { *ipv6-address/prefix-length* | *ipv6-prefix/prefix-length* **eui-64** | *prefix-name sub-bits/prefix-length* [**eui-64**] }

No IP/IPV6 address is configured for an SVI by default.

1.5 Configuring Access Ports

1.5.1 Overview

Configure a Layer 2 interface as an access port and add the interface to a VLAN.

1.5.2 Restrictions and Guidelines

- When you run the **switchport access vlan** *vlan-id* command to add an access port to a VLAN, the command takes effect only on access ports. If you add the access port to an inexistent VLAN, the VLAN is automatically created. Run the **no switchport access vlan** command to restore the VLAN for the access port to VLAN 1.
- In the VLAN configuration mode, run the **add interface** { *interface-type interface-number* | **range** *interface-type interface-range* } command to add an access port to the current VLAN. The command takes effect only on access ports and has the same effect as that of the **switchport access vlan** *vlan-id* command. Run the **no add interface** { *interface-type interface-number* | **range** *interface-type interface-range* } command to restore the VLAN (other than VLAN 1) of a specified access port to VLAN 1.

1.5.3 Procedure (Interface Configuration Mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the Layer 2 interface as an access port.

switchport mode access

The Layer 2 interface mode is **access** by default.

(5) Add an access port to a specified VLAN. The VLAN can be automatically created.

switchport access vlan *vlan-id*

An access port belongs to VLAN 1 by default.

1.5.4 Procedure (VLAN Configuration Mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the Layer 2 interface as an access port.

switchport mode access

The Layer 2 interface mode is **access** by default.

(5) Return to the global configuration mode.

exit

(6) Create a VLAN and enter the VLAN configuration mode.

vlan *vlan-id*

Only VLAN 1 exists by default.

(7) Add an access port to a VLAN. The VLAN can be automatically created. Select a method to configure the interface or the group of interfaces.

- Add a Layer 2 Ethernet interface to a VLAN.

  add interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

  An access port belongs to VLAN 1 by default.

- Add a Layer 2 link aggregation to a VLAN.

  add interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

  An access port belongs to VLAN 1 by default.

1.6 Configuring Trunk Ports

1.6.1 Overview

A trunk link can transmit traffic of multiple VLANs. To enable a port to transmit traffic of multiple VLANs, you can configure the port as a trunk port.

You can configure a Layer 2 Ethernet interface or link aggregation as a trunk port. For more information about link aggregation, see *Configuring Aggregated Port*.

A trunk port can belong to one native VLAN and several allowed VLANs.

- Native VLAN: When the trunk port receives an untagged packet or a priority packet, the trunk port considers that the packet comes from the native VLAN of this port. A priority packet is a tagged packet, but its VLAN ID is 0 and contains only priority information. Packets of the native VLAN sent by the trunk port are untagged. When you configure a trunk link, ensure that the trunk ports of the link are bound to the same native VLAN.
- Allowed VLAN: When the trunk port receives a tagged packet, it determines whether the packet comes from an allowed VLAN of this port. If yes, the trunk port receives the packet. Otherwise, the trunk port discards the packet. Packets of an allowed VLAN sent by the trunk port are tagged.

1.6.2 Restrictions and Guidelines

- Before you configure the native VLAN and allowed VLANs for the trunk port, create these VLANs first. *When you* set the native VLAN to an inexistent VLAN, this VLAN is not created automatically.

- The native VLAN of an interface can be excluded from the allowed VLAN list for this interface. In this case, traffic of the native VLAN cannot pass through this interface.
- Run the **no switchport mode** command to restore the Layer 2 interface mode to the default configuration.

  Run the **no switchport trunk native vlan** command to restore the native VLAN of the trunk port to a default value.

  Run the **no switchport trunk allowed vlan** command to restore the allowed VLANs of the trunk port to default values.

1.6.3 Procedure

(1) Create a VLAN.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create one VLAN or a group of VLANs as the native VLAN and allowed VLANs of the trunk port.

vlan { *vlan-id* | **range** *vlan-range* }

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

(2) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(3) Configure the L2 interface as a trunk port.

switchport mode trunk

The Layer 2 interface mode is **access** by default.

(4) (Optional) Configure a native VLAN for the trunk port.

switchport trunk native vlan *vlan-id*

The native VLAN of a trunk port is VLAN 1 by default.

(5) (Optional) Configure an allowed VLAN list for the trunk port.

switchport trunk allowed vlan { **all** | **add** *vlan-list* | **remove** *vlan-list* | **except** *vlan-list* | **only** *vlan-list* }

The allowed VLANs of a trunk port are VLANs 1 to 4094 by default.

1.7 Configuring Uplink Ports

1.7.1 Overview

You can configure an interface as an uplink port to transmit only tagged frames of multiple VLANs. An uplink port can belong to one native VLAN and several allowed VLANs.

The uplink port is generally used in QinQ scenarios as an interface for a PE to connect to a public network.

- Native VLAN: When the uplink port receives an untagged packet or a priority packet, the uplink port considers that the packet comes from the native VLAN of this port. Different from the trunk port, packets of the native VLAN sent by the uplink port are tagged.
- Allowed VLAN: When the uplink port receives a tagged packet, it determines whether the packet comes from the native VLAN of this port. If yes, the uplink port receives the packet. Otherwise, the uplink port discards the packet. Packets of the allowed VLANs sent by the uplink port are tagged.

1.7.2 Restrictions and Guidelines

- Before you configure the native VLAN and allowed VLANs for the uplink port, create these VLANs first.
- Run the **no switchport mode** command to restore the Layer 2 interface mode to the default configuration.

  Run the **no switchport trunk native vlan** command to restore the native VLAN of the uplink port to a default value.

  Run the **no switchport trunk allowed vlan** command to restore the allowed VLANs of the uplink port to default values.
- Run the **show vlan** [**id** *vlan-id*] and **show interface switchport** commands to check whether the configurations take effect.

1.7.3 Procedure

(1) Create a VLAN.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create one VLAN or a group of VLANs as the native VLAN and allowed VLANs of the uplink port.

vlan { *vlan-id* | **range** *vlan-range* }

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

(2) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }
- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(3) Configure the Layer 2 interface as an uplink port.

switchport mode uplink

The Layer 2 interface mode is **access** by default.

(4) (Optional) Configure a native VLAN for the uplink port.

switchport trunk native vlan *vlan-id*

The native VLAN of an uplink port is VLAN 1 by default.

(5) (Optional) Configure an allowed VLAN list for the uplink port.

switchport trunk allowed vlan { **all** | **add** *vlan-list* | **remove** *vlan-list* | **except** *vlan-list* | **only** *vlan-list* }

The allowed VLANs of the uplink port are VLANs 1 to 4,094 by default.

1.8 Configuring Hybrid Ports

1.8.1 Overview

You can configure an interface as a hybrid port to transmit traffic of multiple VLANs. A hybrid port can belong to one native VLAN and several allowed VLANs.

- Native VLAN: When the hybrid port receives an untagged packet or a priority packet, the hybrid port considers that the packet comes from the native VLAN of this port. Packets of the native VLAN sent by the hybrid port are untagged.
- Allowed VLAN: When the hybrid port receives a tagged packet, it determines whether the packet comes from an allowed VLAN of this port. If yes, the hybrid port receives the packet. Otherwise, the hybrid port discards the packet. Different from the trunk port, the hybrid port can send tagged or untagged packets of the allowed VLANs (other than the native VLAN) based on configurations.

1.8.2 Restrictions and Guidelines

- Before you configure the native VLAN and allowed VLANs for a hybrid port, create these VLANs first.
- Run the **no switchport mode** command to restore the Layer 2 interface mode to the default configuration.

  Run the **no switchport hybrid native vlan** command to restore the native VLAN of the hybrid port to a default value.

  Run the **no switchport hybrid allowed vlan** command to restore the allowed VLANs of the hybrid port to default values.
- Run the **show vlan** [**id** *vlan-id*] and **show interface switchport** commands to check whether the configurations take effect.

1.8.3 Procedure

(1) Create a VLAN.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create one VLAN or a group of VLANs as the native VLAN and allowed VLANs of the hybrid port.

vlan { *vlan-id* | **range** *vlan-range* }

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

(2) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(3) Configure the Layer 2 interface as a hybrid port.

switchport mode hybrid

The Layer 2 interface mode is **access** by default.

(4) Configure a native VLAN for the hybrid port.

switchport hybrid native vlan *vlan-id*

The native VLAN of the hybrid port is VLAN 1 by default.

(5) Configure an allowed VLAN list for the hybrid port.

switchport hybrid allowed vlan { [**add**] **tagged** *vlan-list* | [**add**] **untagged** *vlan-list* | **only tagged** *vlan-list* | **remove** *vlan-list* }

By default, the allowed VLANs of a hybrid port are untagged VLAN 1 and tagged VLANs 2 to 4,094.

1.9 Monitoring

This section describes the **show** commands used for checking the running status of a configured function to verify the configuration effect.

This section also describes the **debug** command used for outputting debugging information.

Caution

System resources are occupied when debugging information is output. Therefore, disable the debugging function immediately after use.

You can run the **clear** commands to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-3 Monitoring

Command	Purpose
show vlan [**id** *vlan-id*]	Displays VLAN configurations.

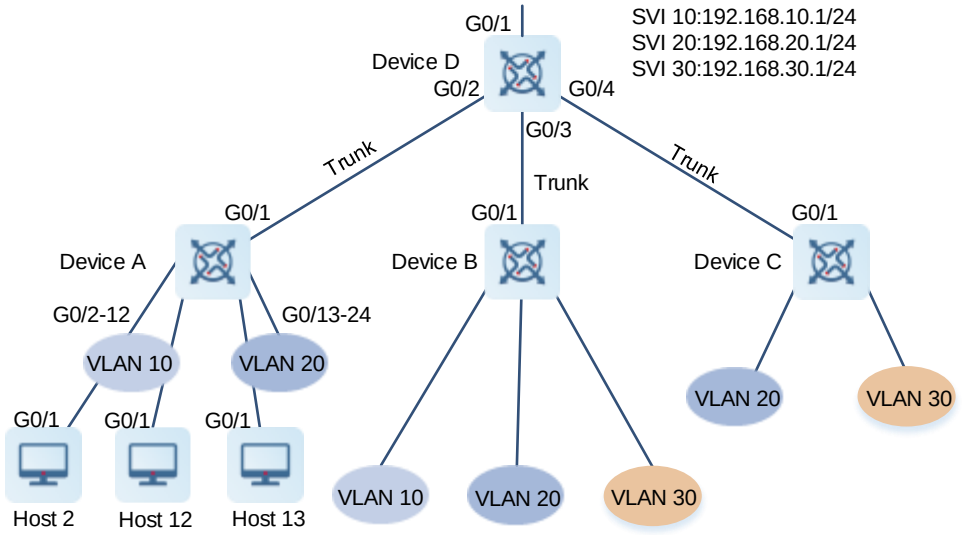
Command	Purpose
show vlan start *start-index* **end** *end-index*	Displays VLAN information in a specified VLAN ID range.
show vlan summary	Displays information about created VLANs.
show interface switchport	Displays configurations of Layer 2 interfaces.
debug bridge vlan	Enables the debug function of a VLAN.
show vlan id *vlan-id* **statistics**	Displays VLAN traffic statistics.
clear vlan statistics *vlan-id*	Clears the traffic statistics of a specified VLAN.
show bridge ability	Displays the capability value of a bridge module.
show bridge client	Displays the client information of a bridge module.
show bridge coxmng { **interface** *interface-name* **status** | **status** }	Displays the protocol exclusion information of a bridge module.
show bridge ef forward state **show bridge ef mac** **show bridge ef memory** **show bridge ef message** **show bridge ef mvlan** **show bridge ef vmap**	Displays information about the software forwarding bridge module.
show bridge interface *port-index*	Displays interface information of a bridge module.
show bridge memory	Displays memory allocation request information of a bridge module.
show bridge protocol	Displays the bridge protocol status of a bridge module.
show bridge server status	Displays the status information of the server of a bridge module.
show bridge submod	Displays information about the sub-modules of a bridge module.

1.10 Configuration Examples

1.10.1 Configuring Layer 2 Isolation and Layer 3 Interconnection of VLANs

1. Requirements

There are three departments in a user's intranet. The networks of the three departments are required to be isolated in Layer 2 and interconnected in Layer 3.



Therefore, create VLANs on the three access devices, Devices A, B, and C. The user intranet is divided into VLAN 10, VLAN 20, and VLAN 30, and they are isolated in Layer 2. Add a port to a VLAN, and all clients

connected to this port belong to the VLAN. To change the VLAN of a client, modify the VLAN configuration of the port instead of moving the client.

Configure three VLANs on the core device, Device D. Configure the ports connected to Devices A, B, and C as trunk ports, and specify the allowed VLAN lists. Configure three SVIs as the gateway interfaces of the subnets of the three VLANs. The three subnets corresponding to the VLANs are 192.168.10.0/24, 192.168.20.0/24, and 192.168.30.0/24 respectively. The subnets of the three VLANs are interconnected through IP forwarding of Layer 3 core devices.

2. Topology

Figure 1-16 Topology of Configuring Typical Scenarios

3. Notes

- On the Layer 3 core device Device D, configure the three VLANs, configure the ports for connecting Devices A, B, and C as trunk ports, and specify an allowed VLAN list to realize Layer 2 isolation.
- Configure three SVIs on Device D, which are used as the gateway interfaces of the IP subnets corresponding to the three VLANs. Configure the IP addresses for these SVIs. Configure a default gateway for hosts based on the VLANs of the hosts.
- Create the VLANs respectively on the three access devices, Devices A, B, and C, assign an access port for each VLAN, and configure the port for connecting Device D as a trunk port.

4. Procedure

(1) Create and configure VLANs.

Create VLANs on Device D and rename VLAN 10.

```
DeviceD> enable
DeviceD# configure terminal
DeviceD(config)# vlan 10
DeviceD(config-vlan)# name office
DeviceD(config-vlan)# vlan range 20,30
DeviceD(config-vlan-range)# exit
```

Create a VLAN on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan range 10,20
DeviceA(config-vlan-range)# exit
```

Create a VLAN on Devices B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# vlan range 10,20,30
DeviceB(config-vlan-range)# exit
```

Create a VLAN on Devices C.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# vlan range 20,30
DeviceC(config-vlan-range)# exit
```

(2) Configure IP addresses for the Layer 3 SVIs of the VLANs on Device D.

```
DeviceD(config)# interface vlan 10
DeviceD(config-if-VLAN 10)# ip address 192.168.10.1 255.255.255.0
DeviceD(config-if-VLAN 10)# exit
DeviceD(config)# interface vlan 20
DeviceD(config-if-VLAN 20)# ip address 192.168.20.1 255.255.255.0
DeviceD(config-if-VLAN 20)# exit
DeviceD(config)# interface vlan 30
DeviceD(config-if-VLAN 30)# ip address 192.168.30.1 255.255.255.0
DeviceD(config-if-VLAN 30)# exit
```

(3) Configure the downlink port of Device D as a trunk port and configure an allowed VLAN list for the port.

```
DeviceD(config)# interface range gigabitethernet 0/2-4
DeviceD(config-if-range)# switchport
DeviceD(config-if-range)# switchport mode trunk
DeviceD(config-if-range)# exit
DeviceD(config)# interface gigabitethernet 0/2
DeviceD(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
DeviceD(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan only 10,20
DeviceD(config-if-GigabitEthernet 0/2)# exit
DeviceD(config)# interface gigabitethernet 0/3
DeviceD(config-if-GigabitEthernet 0/3)# switchport trunk native vlan 1
DeviceD(config-if-GigabitEthernet 0/3)# switchport trunk allowed vlan only
10,20,30
DeviceD(config-if-GigabitEthernet 0/3)# exit
DeviceD(config)# interface gigabitethernet 0/4
DeviceD(config-if-GigabitEthernet 0/4)# switchport trunk native vlan 1
DeviceD(config-if-GigabitEthernet 0/4)# switchport trunk allowed vlan only 20,30
DeviceD(config-if-GigabitEthernet 0/4)# end
DeviceD# write
```

(4) Configure the uplink port of the access device as a trunk port configure an allowed VLAN list for the port. The following example configures the uplink port on Device A. The configuration on Devices B and C is similar to that on Device A.

Configure the uplink port of Device A as a trunk port and allow the traffic of all VLANs to pass through the port.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# switchport
DeviceA(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
DeviceA(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

(5) Configure the downlink port of the access device as an access port and add the port to a specified VLAN. The following example configures the downlink port on Device A. The configuration on Devices B and C is similar to that on Device A.

Configure the downlink port of Device A as an access port and add the port to different VLANs.

```
DeviceA(config)# interface range gigabitethernet 0/2-12
DeviceA(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode access
DeviceA(config-if-range)# switchport access vlan 10
DeviceA(config-if-range)# interface range gigabitethernet 0/13-24
DeviceA(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode access
DeviceA(config-if-range)# switchport access vlan 20
DeviceA(config-if-range)# end
DeviceA# write
```

5. Verification

(1) Run the **show vlan** [**id** *vlan-id*] command on Device D to display VLAN information, including the VLAN ID, name, status and ports.

```
DeviceD# show vlan
VLAN  Name      Status             Ports
---- --------  --------   -------------------------------
   1 VLAN0001   STATIC     Gi0/1, Gi0/5, Gi0/6, Gi0/7
                         Gi0/8, Gi0/9, Gi0/10, Gi0/11
                         Gi0/12, Gi0/13, Gi0/14, Gi0/15
                         Gi0/16, Gi0/17, Gi0/18, Gi0/19
                         Gi0/20, Gi0/21, Gi0/22, Gi0/23
                         Gi0/24
  10 office    STATIC     Gi0/2, Gi0/3
  20 VLAN0020  STATIC     Gi0/2, Gi0/3, Gi0/4
  30 VLAN0030  STATIC     Gi0/3, Gi0/4
```

(2) Check the port configuration and port status.

Run the **show interface switchport** command on Device D to displaythe VLAN status of ports.

```
DeviceD# show interface switchport
```

```
Interface                    Switchport Mode     Access Native Protected VLAN
lists
------------------------------ ---------- --------- ------ ------ --------- --
GigabitEthernet 0/2            enabled    TRUNK     1      Disabled  10,20
GigabitEthernet 0/3            enabled    TRUNK     1      Disabled  10,20,30
GigabitEthernet 0/4            enabled    TRUNK     1      Disabled  20,30
```

Run the **show interface description** command on Device D to check whether the port status is up.

```
DeviceD# show interface description
Interface                              Status   Administrative Description
-------------------------------------- -------- -------------- -----------
GigabitEthernet 0/2                      up       up
GigabitEthernet 0/3                      up       up
GigabitEthernet 0/4                      up       up

VLAN 10                                 up       up
VLAN 20                                 up       up
VLAN 30                                 up       up
```

(3) Run the **show ip route** command on Device D to display the direct route information of SVIs.

Packets whose destination IP address matches 192.168.10.0/24 are forwarded to VLAN 10. Packets whose destination IP address matches 192.168.20.0/24 are forwarded to VLAN 20. Packets whose destination IP address matches 192.168.30.0/24 are forwarded to VLAN 30.

```
DeviceD# show ip route
Codes:  C - Connected, L - Local, S - Static
       R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       IA - Inter area, EV - BGP EVPN, A - Arp to host
       LA - Local aggregate route
       * - candidate default

Gateway of last resort is no set
…
C    192.168.10.0/24 is directly connected, VLAN 10
C    192.168.10.1/32 is local host.
C    192.168.20.0/24 is directly connected, VLAN 20
C    192.168.20.1/32 is local host.
C    192.168.30.0/24 is directly connected, VLAN 30
C    192.168.30.1/32 is local host.
```

Ping the SVI address of a VLAN (for example, VLAN 10) on Device D.

```
DeviceD# ping 192.168.10.1
Sending 5, 100-byte ICMP Echoes to 192.168.10.1, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
```

```
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

(4) The following example describes how to ping Hosts 2, 12, and 13.

Configure the default gateway of Host 2 in VLAN 10 as 192.168.10.1, the IP address of the interface as 192.168.10.2, and the mask as 255.255.255.0.

```
Host2> enable
Host2# configure terminal
Host2(config)# ip route 0.0.0.0 0.0.0.0 192.168.10.1
Host2(config)# interface gigabitethernet 0/1
Host2(config-if-GigabitEthernet 0/1)# no switchport
Host2(config-if-GigabitEthernet 0/1)# ip address 192.168.10.2 255.255.255.0
```

Configure the default gateway of Host 12 in VLAN 10 as 192.168.10.1, the IP address of the interface as 192.168.10.12, and the mask as 255.255.255.0.

```
Host2> enable
Host2# configure terminal
Host2(config)# ip route 0.0.0.0 0.0.0.0 192.168.10.1
Host2(config)# interface gigabitethernet 0/1
Host2(config-if-GigabitEthernet 0/1)# no switchport
Host2(config-if-GigabitEthernet 0/1)# ip address 192.168.10.12 255.255.255.0
```

Configure the default gateway of Host 13 in VLAN 20 as 192.168.20.1, the IP address of the interface as 192.168.20.13, and the mask as 255.255.255.0.

```
Host13> enable
Host13# configure terminal
Host13(config)# ip route 0.0.0.0 0.0.0.0 192.168.20.1
Host13(config)# interface gigabitethernet 0/1
Host13(config-if-GigabitEthernet 0/1)# no switchport
Host13(config-if-GigabitEthernet 0/1)# ip address 192.168.20.13 255.255.255.0
```

Run the **show ip route** command on the hosts to display the default gateway. The default gateway must be configured on the transmit and receive ends. Inter-VLAN communication fails to be implemented if either end is not configured with the default gateway. Take Host 2 as an example. Due to the default route S*0.0.0.0/0 [1/0] via 192.168.10.1, a host sends a packet to the gateway 192.168.10.1 when the host tries to communicate across VLANs.

```
Host2# show ip route
Codes:  C - Connected, L - Local, S - Static
       R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       IA - Inter area, EV - BGP EVPN, A - Arp to host
       LA - Local aggregate route
       * - candidate default

Gateway of last resort is 192.168.10.1 to network 0.0.0.0
S*    0.0.0.0/0 [1/0] via 192.168.10.1
C     192.168.10.0/24 is directly connected, GigabitEthernet 0/1
```

```
C    192.168.10.2/32 is local host.
```

Ping the IP address of a host (for example, Host 2) on Device D.

```
DeviceD# ping 192.168.10.2
Sending 5, 100-byte ICMP Echoes to 192.168.10.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/3/4 ms.
```

Hosts in the same VLAN (for example, VLAN 10) can ping each other.

```
Host2# ping 192.168.10.12
Sending 5, 100-byte ICMP Echoes to 192.168.10.12, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/3 ms.
```

Hosts in different VLANs can also ping each other. If you delete the IP address of an SVI on Device D or delete the default gateway on a host, hosts in different VLANs cannot ping each other.

```
Host2# ping 192.168.20.13
Sending 5, 100-byte ICMP Echoes to 192.168.10.3, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/3 ms.
```

6. Configuration Files

- Device D configuration file

```
vlan 10
name office
vlan range 1,20,30
!
interface GigabitEthernet 0/2
switchport
switchport mode trunk
switchport trunk native vlan 1
 switchport trunk allowed vlan only 10,20
!
interface GigabitEthernet 0/3
switchport
switchport mode trunk
switchport trunk native vlan 1
 switchport trunk allowed vlan only 10,20,30
!
interface GigabitEthernet 0/4
switchport
switchport mode trunk
switchport trunk native vlan 1
 switchport trunk allowed vlan only 20,30
```

```
!
interface VLAN 10
 ip address 192.168.10.1 255.255.255.0
interface VLAN 20
 ip address 192.168.20.1 255.255.255.0
interface VLAN 30
 ip address 192.168.30.1 255.255.255.0
```

- Device A configuration file. Similar configurations of interfaces are represented by ellipsis (...). For the configuration of Devices B and C, see the Device A configuration procedure.

```
interface GigabitEthernet 0/1
 switchport mode trunk
!
interface GigabitEthernet 0/2
switchport
switchport mode access
switchport access vlan 10
…
interface GigabitEthernet 0/12
switchport
switchport mode access
switchport access vlan 10
!
interface GigabitEthernet 0/13
switchport
switchport mode access
switchport access vlan 20
…
interface GigabitEthernet 0/24
switchport
switchport mode access
switchport access vlan 20
```

7. Common Errors

- If no IP address is configured for a gateway (SVI), or no default gateway is configured for an STA, or either the transmit or receive end is not configured with the default gateway, STAs in different VLANs cannot ping each other.
- If connected trunk ports have different native VLANs, data communication may fail.
- If interfaces connected to STAs are not configured as access ports, data communication may fail.
- If only one VLAN needs to be configured for a trunk port but the default allowed VLAN of the trunk port is not deleted after the VLAN creation command is run, the configuration result is inconsistent with the configuration plan.
- The trunk port of the local device sends untagged packets of the native VLAN. If the trunk port of a device produced by another manufacture only receive tagged packets, the untagged packets sent by the local device may be discarded on the receiving end. In this case, on the local device, configure the port connected to the device of another manufacture as an uplink port so that packets sent by this port are tagged.

1 Configuring MAC VLAN

1.1 Introduction

1.1.1 Overview

The media access control (MAC) virtual local area network (VLAN) is a VLAN assignment technology based on MAC addresses. When the physical location of an STA changes and causes a change in the access port of the STA, MAC VLAN can assign the STA to a specified VLAN based on the MAC address of the STA, freeing you to reconfigure a VLAN for the STA's current access port.

1.1.2 Background and Function

1. Background

As mobile office is popularized, an STA connects to a network through different ports. It may connect to a network through port 1 at a time and then connect to the network through port 2 at another time. If VLANs are assigned based on ports and port 1 and port 2 belong to different VLANs, when the STA connects to the network in the second time through port 2, it is assigned to a different VLAN. In this case, the STA cannot use the resources in the VLAN to which port 1 belongs. If port 1 and port 2 belong to the same VLAN, when a second STA is connected through port 2, security issues may arise. To enable hosts of different VLANs to connect to a network through the same port, the MAC VLAN function is developed.

2. Function

The MAC VLAN function is to assign STAs to VLANs based on MAC addresses of the STAs. MAC VLAN is a VLAN assignment method based on users' MAC addresses.

This function is generally used in combination with the VLAN delivery function of IEEE 802.1X. After you configure or deliver MAC VLAN entries for a Layer 2 switch, VLANs can be assigned based on MAC addresses of STAs, thereby ensuring secure and flexible access of IEEE 802.1X-compliant STAs.

1.1.3 Principles

The MAC VLAN function must be configured on hybrid ports, and a MAC VLAN rule takes effect on all hybrid ports, on which the MAC VLAN function is enabled.

- The MAC VLAN function is available to untagged packets only. When a hybrid port receives an untagged packet, the port tries to match the source MAC address in the packet with the specified MAC address in the MAC VLAN rule.
  a A MAC VLAN rule has a higher priority than the voice VLAN, subnet-based VLAN, protocol-based VLAN, and port VLAN rules. If the MAC VLAN function is enabled, when receiving an untagged packet, the port matches the source MAC address in the packet with the specified MAC address in the MAC VLAN rule to check whether the packet complies with the MAC VLAN rule.
  b If they match, the port changes the VLAN in the packet to the specified VLAN in the MAC VLAN rule. Then, the subsequent processing of the packet is based on this specified VLAN. For example, after an untagged packet matches a MAC VLAN rule, the VLAN learned based on the MAC address is the one redirected according to the MAC VLAN rule.

c If they do not match, the port will match the packet against VLAN assignment rule based on packet content. The rule involves the voice VLAN, subnet-based VLAN and protocol-based VLAN. If the untagged packet matches both the MAC VLAN rule and packet content-based VLAN assignment rules, the packet is redirected to the VLAN specified in the MAC VLAN rule.

d If the port fails to match the packet with any packet content-based VLAN assignment rule, the port, according to the assignment rule of the port VLAN (common VLAN), considers that the packet belongs to the native VLAN of this port, receives the packet, and marks the packet with the native VLAN tag.

- The MAC VLAN function is unavailable to tagged packets.
- When a port receives a tagged packet, the port follows the frame receiving rules for common VLANs, and receives the packet if the port allows the packet to pass. Otherwise, the port discards the packet.
- The MAC VLAN function is unavailable to priority packets, either. In a priority packet, the VLAN ID in the VLAN tag is 0, indicating that the packet does not carry VLAN information and carries only a Class of Service (CoS) priority.

1.1.4 MAC VLAN Rule

- Configure a static MAC VLAN rule by running commands on the command line interface (CLI).

  A MAC VLAN rule reflects the mapping between a MAC address and a VLAN.

  You can configure a mapping between a MAC address and a VLAN on the CLI on a local device. Run the **show mac-vlan** command to display a MAC VLAN rule. The rule marked with "S" (static) indicates a static MAC VLAN rule.

- Configure a dynamic MAC VLAN rule by using an authentication server.

  The VLAN delivery function of IEEE 802.1X can automatically configure and deliver a mapping between a MAC address and a VLAN. Run the **show mac-vlan** command. The rule marked with "D" (dynamic) indicates a dynamic MAC VLAN rule.

  After an STA passes IEEE 802.1X authentication, the device creates a dynamic mapping between the STA's MAC address and a VLAN based on the information provided by the authentication server. After the STA goes offline, the device automatically deletes the mapping immediately.

  To use this method, configure mappings between MAC addresses and VLANs. For more information about the VLAN delivery function of IEEE 802.1X, see *Configuring IEEE 802.1X*.

- You can configure MAC VLAN rules on the local device and authentication server. If the MAC VLAN rules are consistent, they take effect concurrently. If they are inconsistent, the rule configured earlier takes effect and the rule configured later can be displayed but does not take effect. To facilitate management, you are advised to adopt one configuration method.

⚠ Caution

- If the fail VLAN function is configured in the IEEE 802.1X function, when a user fails to pass the authentication, the user packet is assigned to the fail VLAN, for example, VLAN 100. However, the static MAC VLAN rule (VLAN 200) has a higher priority. Therefore, the user packet is redirected to VLAN 200. As a result, the user cannot make communication in the fail VLAN 100. To use the fail VLAN function of the IEEE 802.1X function, do not configure a static MAC VLAN rule on the device.

1.1.5 Protocols and Standards

IEEE 802.1Q: IEEE Standard for Local and Metropolitan Area Networks-Virtual Bridged Local Area Networks

1.2 Configuring MAC VLAN

1.2.1 Overview

You can configure a static MAC VLAN entry, create a mapping between a MAC address and a VLAN, and then configure a MAC VLAN on a port so that the MAC VLAN entry takes effect on the port.

1.2.2 Restrictions and Guidelines

- The MAC VLAN function takes effect on a hybrid port only. Only an L2 interface can be configured as a hybrid port.
  - You can run the **show interface switchport** command to display the interface type. If the **Switchport** field corresponding to the interface is **enabled**, this interface is an L2 interface. If the **Switchport** field corresponding to the interface is **disabled**, this interface is an L3 interface.
  - You can run the **switchport** command to configure the interface as an L2 interface. Run the **no switchport mode** command to restore the L2 interface mode to the default mode and run the **no switchport** command to configure an L2 interface as an L3 interface. When you configure an interface as an L2 or L3 interface, all attributes of the interface are restored to the default values in this interface mode.
- Run the **mac-vlan** command to configure static MAC VLAN entries, run the **no** *mac*-**vlan** to delete static MAC VLAN entries.
- **mac-***address mac-address* indicates a MAC address. The MAC address specified in a MAC VLAN entry must be a unicast address.
- **mask** *mac-mask* indicates the mask of a MAC address. When a port with the MAC VLAN function enabled receives a packet and the packet matches a MAC VLAN entry whose mask is all F and a MAC VLAN entry whose mask is not all F, the port forwards the packet based on the latter one (indicating a larger range of MAC addresses).
  - Run the **no mac-vlan mac-address** *mac-address* [**mask** *mac-mask*] command to delete static MAC VLAN entries of a specified MAC address.
- **vlan** *vlan-id* indicates the VLAN, to which a packet is forwarded if the MAC address in the packet matches the MAC VLAN rule. Before you configure a static MAC VLAN entry or a dynamic MAC VLAN entry is generated, make sure that the specified VLAN already exists. The specified VLAN in a MAC VLAN entry cannot be a super VLAN, a remote VLAN, or a primary VLAN. However, it can be a sub VLAN or a secondary VLAN. If an untagged packet matches both a MAC VLAN rule and a voice VLAN rule, the packet is redirected to the VLAN in the MAC VLAN rule. Run the **no mac-vlan vlan** *vlan-id* command to delete the static MAC VLAN entries of a specified VLAN.
- **priority** *priority-value* indicates the 802.1p priority. The default value is **0**. When a packet matches a MAC VLAN rule, the receiving port of the packet changes the CoS priority of the packet to the value of *priority-value*. If the packet priority needs to be modified, ensure that the Quality of Service (QoS) module trusts the packet priority modified by an interface. Otherwise, the modification is invalid. If an untagged packet matches both a MAC VLAN rule and a voice VLAN rule, the packet priority is modified according to

the voice VLAN rule.

The packet trust mode of the QoS module is disabled by default. This causes the QoS module to change the priority of all packets to **0**, and overwrites the packet priority modified by the MAC VLAN function. Run the **mls qos trust** { **cos** | **ip-precedence** | **dscp** | **exp** } command in interface configuration mode, and select the **cos** parameter to enable the QoS module to trust the CoS modification, that is, the packet priority modified by the MAC VLAN function.

- Run the **no mac-vlan all** command to delete all MAC VLAN entries.
- Run the **mac-vlan enable** command to enable the MAC VLAN function on ports so that the function can take effect. Otherwise, the MAC VLAN function does not take effect even if there are global MAC VLAN entries.
- You must complete interface configuration before you enable the MAC VLAN function on a port. Otherwise, the allowed VLAN list of the port cannot be modified.

1.2.3 Procedure

(1) Create a MAC VLAN.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create a MAC VLAN.

vlan { *vlan-id* | **range** *vlan-range* }

By default, no VLAN other than VLAN 1 exists.

d Exit the VLAN configuration mode.

exit

(2) Configure a static MAC VLAN rule in global configuration mode, and specify a mapping between a MAC address and a VLAN in the rule.

mac-vlan mac-address *mac-address* [**mask** *mac-mask*] **vlan** *vlan-id* [**priority** *priority-value*]

No static MAC VLAN rule exists by default.

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the Layer 2 interface as a hybrid port.

switchport mode hybrid

The default Layer 2 interface mode is the access mode.

(5) Add the MAC VLAN to the allowed untagged VLAN list of the hybrid port.

switchport hybrid allowed vlan untagged *vlan_list*

The allowed untagged VLAN of the hybrid port is VLAN 1 by default.

(6) Configure the hybrid port to trust the CoS priority of packets.

mls qos trust cos

The default trust mode of a port is untrusted.

(7) Enable the MAC VLAN function on the port.

mac-vlan enable

The port-based MAC VLAN function is disabled by default.

1.3 Monitoring

This section describes the **show** commands used for checking the running status of a configured function to verify the configuration effect.

This section also describes the **debug** command used for outputting debugging information.

Caution

System resources are occupied when debugging information is output. Therefore, disable the debugging function immediately after use.

You can run the **clear** commands to clear information.

Caution

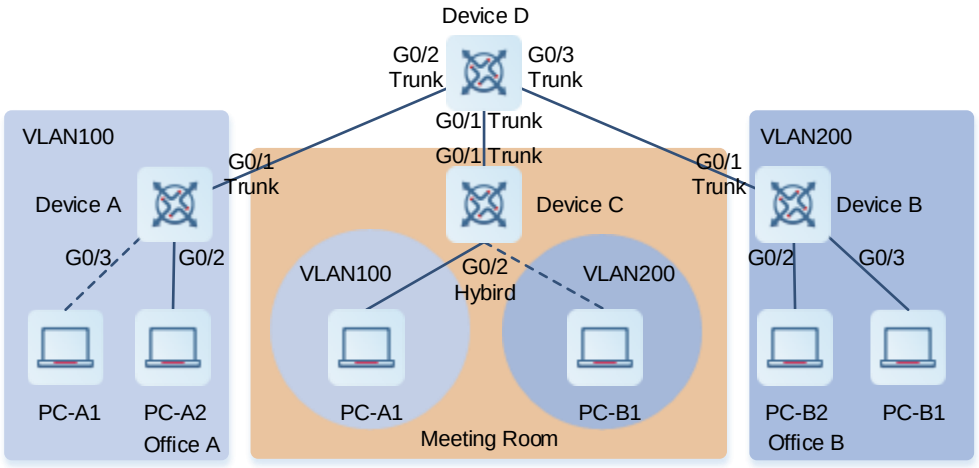
Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
show mac-vlan all	Displays all MAC VLAN entries, including static and dynamic MAC VLAN entries.
show mac-vlan dynamic	Displays dynamic MAC VLAN entries.
show mac-vlan static	Displays static MAC VLAN entries.
show mac-vlan vlan *vlan-id*	Displays MAC VLAN entries of a specified VLAN.
show mac-vlan interface	Displays ports on which the MAC VLAN function is enabled.
show mac-vlan mac-address *mac-address* [**mask** *mac-mask*]	Displays MAC VLAN entries of a specified MAC address.
debug bridge mvlan	Debugs the MAC VLAN function.

1.4 Configuration Examples

1.4.1 Configuring MAC VLAN



1. Requirements

A company provide a temporary office in a meeting room where public access ports are assigned to VLANs based on the MAC addresses of employees' portable PCs. Employee PCs connected to any port are automatically assigned to their respective department VLANs.

2. Topology

PC-A1 and PC-A2 belong to department A and they are assigned to VLAN 100. PC-B1 and PC-B2 belong to department B and they are assigned to VLAN 200. The meeting room uses public ports. PC-A1 and PC-A2 can be assigned only to VLAN 100 after access and PC-B1 and PC-B2 can be assigned only to VLAN 200.

Figure 1-1 Topology of Configuring MAC VLAN

3. Notes

- On Device D, configure the ports connecting to access devices as trunk ports.
- Create MAC VLANs on Device C and configure static MAC VLAN rules in global configuration mode.
  - Department A uses a PC with the MAC address of 54bf.6450.dd10 for access in the meeting room, and the PC is assigned to VLAN 100 with a priority of 1.
  - Department B uses multiple PCs for access in the meeting room. Their MAC addresses are in the range from 54bf.6450.dd20 to 54bf.6450.dd2F (represented with 54bf.6440.dd20 plus the mask of ffff.ffff.fff0). The PCs are assigned to VLAN 200 with a priority of 2.
- On Device C, configure the ports connecting to PCs as hybrid ports, and add the MAC VLANs to the allowed untagged VLAN list of the ports. Configure the ports to trust the CoS priority of packets. Enable the MAC VLAN function on the ports.
- Configure the uplink ports on Device A and Device B as trunk ports, and the ports connecting to PCs as access ports. Add the access ports on Device A to VLAN 100, and add the access ports on Device B to VLAN 200.

4. Procedure

(1) Create VLANs.

Configure VLAN 100 and VLAN 200 on Device D.

```
DeviceD> enable
DeviceD# configure terminal
DeviceD(config)# vlan range 100,200
DeviceD(config-vlan-range)# exit
```

Configure VLAN 100 and VLAN 200 on Device C.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# vlan rang 100,200
DeviceC(config-vlan-range)# exit
```

Configure VLAN 100 on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan 100
DeviceA(config-vlan-range)# exit
```

Configure VLAN 200 on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# vlan 200
DeviceB(config-vlan-range)# exit
```

(2) Configure trunk ports.

Configure the downlink ports GigabitEthernet 0/1–3 of Device D as trunk ports.

```
DeviceD(config)# interface range gigabitethernet 0/1-3
DeviceD(config-if-range)# switchport
DeviceD(config-if-range)# switchport mode trunk
DeviceD(config-if-range)# switchport trunk native vlan 1
DeviceD(config-if-range)# switchport trunk allowed vlan all
DeviceD(config-if-range)# end
DeviceD# write
```

Configure the uplink ports GigabitEthernet 0/1 of Devices A/B/C as trunk ports. The configurations on Devices A, B, and C are similar. The following examples takes Device A as an example.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# switchport
DeviceA(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
DeviceA(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

(3) Add user ports to static VLANs on Devices A and B.

Add the user ports GigabitEthernet 0/2–3 on Device A to VLAN 100.

```
DeviceA(config)# interface range gigabitethernet 0/2-3
DeviceA(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode access
DeviceA(config-if-range)# switchport access vlan 100
DeviceA(config-if-range)# end
DeviceA# write
```

Add the user ports GigabitEthernet 0/2–3 on Device B to VLAN 200.

```
DeviceB(config)# interface range gigabitethernet 0/2-3
DeviceB(config-if-range)# switchport
DeviceB(config-if-range)# switchport mode access
DeviceB(config-if-range)# switchport access vlan 200
DeviceB(config-if-range)# end
DeviceB# write
```

(4) Add the user port GigabitEthernet 0/2 on Device C to VLANs based on the MAC addresses of PCs.

Create a static MAC VLAN rule in global configuration mode.

```
DeviceC(config)# mac-vlan mac-address 54bf.6450.dd10 vlan 100 priority 1
DeviceC(config)# mac-vlan mac-address 54bf.6450.dd20 mask ffff.ffff.fff0 vlan 200
priority 2
```

Configure the downlink port GigabitEthernet 0/2 as a hybrid port, and add the MAC VLANs to the allowed untagged VLAN list of the port.

```
DeviceC(config)# interface gigabitethernet 0/2
DeviceC(config-if-GigabitEthernet 0/2)# switchport
DeviceC(config-if-GigabitEthernet 0/2)# switchport mode hybrid
DeviceC(config-if-GigabitEthernet 0/2)# switchport hybrid native vlan 1
DeviceC(config-if-GigabitEthernet 0/2)# switchport hybrid allowed vlan add
untagged 1,100,200
```

Configure the port to trust the CoS priority of packets.

```
DeviceC(config-if-GigabitEthernet 0/2)# mls qos trust cos
```

Enable the MAC VLAN function on the port.

```
DeviceC(config-if-GigabitEthernet 0/2)# mac-vlan enable
DeviceC(config-if-GigabitEthernet 0/2)# end
DeviceC# write
```

5. Verification

(1) Run the **show mac-vlan interface** command to display ports on which the MAC VLAN function is enabled.

```
DeviceC# show mac-vlan interface
MAC VLAN is enabled on following interface:
-------------------------------------
GigabitEthernet 0/2
```

(2) Run the **show interface** command to verify that packets sent by port GigabitEthernet 0/2 to the MAC VLAN do not carry tags.

```
DeviceC(config-if-GigabitEthernet 0/2)# show interface gigabitethernet 0/2
  Bridge attributes:
```

```
   Port-type: hybrid
Tagged vlan id: 2-99,101-199,201-4094
Tagged vlan id: None
Untagged vlan id: 1,100,200
```

(3) Check static MAC VLAN entries on Device C.

```
DeviceC# show mac-vlan static
The following MAC VLAN address exist:
S: Static   D: Dynamic
MAC ADDR          MASK           VLAN ID   PRIO   STATE
-------------------------------------------------------
54bf.6450.dd10     ffff.ffff.ffff   100      1      S
54bf.6450.dd20     ffff.ffff.fff0   200      2      S
Total MAC VLAN address count: 2
```

(4) To verify that the MAC VLAN function assigns STAs to different VLANs to implement L2 isolation, assign PC-A1, PC-A2, and PC-B2 to the same network segment and ping the STAs. Only STAs in the same VLAN can be pinged successfully.

Connect PC-A2 to the network through office A, assign PC-A2 to VLAN 100, and set its IP address and mask to 192.168.5.12/24.

```
PC-A2> enable
PC-A2# configure terminal
PC-A2(config)# interface gigabitethernet 0/1
PC-A2(config-if-GigabitEthernet 0/1)# no switchport
PC-A2(config-if-GigabitEthernet 0/1)# ip address 192.168.5.12/24
```

Connect PC-B2 to the network through office B, assign PC-B2 to VLAN 200, and set its IP address and mask to 192.168.5.22/24.

```
PC-B2> enable
PC-B2# configure terminal
PC-B2(config)# interface gigabitethernet 0/1
PC-B2(config-if-GigabitEthernet 0/1)# no switchport
PC-B2(config-if-GigabitEthernet 0/1)# ip address 192.168.5.22/24
```

Connect PC-A1 to the network through the meeting room and set its IP address and mask to 192.168.5.11/24. Verify that PC-A1 can ping PC-A2 in VLAN 100 but cannot ping PC-B2 in VLAN 200. This indicates that PC-A1 is assigned to VLAN 100 by the MAC VLAN function.

```
PC-A1> enable
PC-A1# configure terminal
PC-A1(config)# interface gigabitethernet 0/1
PC-A1(config-if-GigabitEthernet 0/1)# no switchport
PC-A1(config-if-GigabitEthernet 0/1)# ip address 192.168.5.11/24
PC-A1(config-if-GigabitEthernet 0/1)# end
PC-A1# ping 192.168.5.12
Sending 5, 100-byte ICMP Echoes to 192.168.5.12, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/22/103 ms.
```

```
PC-A1# ping 192.168.5.22
Sending 5, 100-byte ICMP Echoes to 192.168.5.22, timeout is 2 seconds:
  < press Ctrl+C to break >
....
Success rate is 0 percent (0/5).
```

6. Configuration Files

- Device C configuration file

```
vlan range 1,100,200
!
mac-vlan mac-address 54bf.645c.dd10 vlan 100 priority 1
mac-vlan mac-address 54bf.6450.dd20 mask ffff.ffff.fff0 vlan 200 priority 2
!
interface GigabitEthernet 0/1
switchport
 switchport mode trunk
switchport trunk native vlan 1
switchport trunk allowed vlan only 1-4094
!
interface GigabitEthernet 0/2
switchport
 switchport mode hybrid
switchport hybrid native vlan 1
switchport hybrid allowed vlan only tagged 2-99,101-199,201-4094
switchport hybrid allowed vlan add untagged 1,100,200

 switchport
switchport mode trunk
switchport trunk native vlan 1
switchport trunk allowed vlan only 1-4094
```

7. Common Errors

- An Ethernet interface or aggregated port is not configured as a Layer 2 interface before the MAC VLAN function is configured on the interface.
- The QoS module does not trust the packet priority modified by an interface. As a result, the MAC VLAN priority configuration does not take effect.

1 Configuring Protocol-based VLAN

1.1 Introduction

1.1.1 Overview

Protocol-based VLAN is a VLAN technology based on protocol types. When a device receives a packet without a VLAN ID from a port, the device automatically forwards the packet to a VLAN specified in a user-defined rule if the packet matches the user-defined rule.

The protocol VLAN is divided into subnet-based VLAN and protocol-based VLAN.

1.1.2 Subnet-based VLAN

VLAN assignment based on source IP address and subnet mask in a packet is referred to as subnet-based VLAN.

The subnet-based VLAN function assigns users to different VLANs based on their IP addresses. For example, in a shared office area, IP addresses of users are fixed, but the access ports are dynamic. To control user access to network resources, you can assign users to different VLANs based on their IP addresses.

Caution

Subnet-based VLANs take effect on trunk and hybrid ports, available to packets without VLAN ID only.

1.1.3 Protocol-based VLAN

VLAN assignment based on packet type and Ethernet type is referred to as protocol-based VLAN.

The protocol-based VLAN function is used to assign packets of different service types to different VLANs to facilitate management and maintenance.

Caution

Protocol-based VLANs take effect on trunk and hybrid ports. This function is available to packets without VLAN ID only.

1.1.4 Principles

When a port receives a packet, the port assigns the packet to a VLAN so that the packet belongs to this VLAN only. The procedure of determining a VLAN for a packet is as follows:

(1) If the packet carries a tag and the tag contains a VLAN ID, the packet belongs to the VLAN specified by the VLAN ID. The port receives the packet if the port allows the packet to pass. Otherwise, the port discards the packet.

(2) If the packet does not carry a VLAN ID (untagged packet or a priority packet with the VLAN ID of 0), the port tries to match the packet with VLAN assignment policies based on priority in descending order. If the packet matches a rule, the packet is assigned to the VLAN specified in the rule. If the packet matches multiple rules at the same time, the packet is forwarded based on the rule with the highest priority.

a A MAC VLAN policy has the highest priority. A packet with the MAC address matching a MAC VLAN rule is assigned to the MAC VLAN specified in the rule. The MAC VLAN policy is unavailable to priority packets.

b If a voice VLAN policy exists, a device identifies a voice packet based on the MAC address or voice organizationally unique identification (OUI) and then forwards the packet to the specified voice VLAN.

c If the IP address in a packet matches an IP address in a rule of a subnet-based VLAN policy, the packet is assigned to the subnet-based VLAN specified in the rule.

d If the packet type and Ethernet type of a packet match those configured in a rule of a protocol-based VLAN policy, the packet is assigned to the protocol-based VLAN specified in the rule.

(3) A packet is assigned to the port VLAN (access port) or native VLAN (trunk/hybrid/uplink port) in any one of the following cases: The policy-based VLAN assignment function is disabled, no policy exists, or the packet does not match any policy.

1.1.5 Protocols and Standards

- IEEE 802.1Q: IEEE Standard for Local and Metropolitan Area Networks-Virtual Bridged Local Area Networks

1.2 Restrictions and Guidelines

- The subnet-based VLAN and protocol-based VLAN function only take effect on a Layer 2 interface and the L2 interface must be a trunk or hybrid port.
- You can run the **show interface switchport** command to display the interface type. If the **Switchport** field corresponding to the interface is enabled, this interface is a Layer 2 interface. If the **Switchport** field corresponding to the interface is disabled, this interface is a Layer 3 interface.
- You can run the **switchport** command to configure the interface as a Layer 2 interface. Run the **no switchport mode** command to restore the L2 interface mode to the default mode and run the **no switchport** command to configure a Layer 2 interface as an L3 interface. When you configure an interface as a Layer 2 or Layer 3 interface, all attributes of the interface are restored to the default values in this interface mode.

1.3 Configuration Task Summary

Protocol-based VLAN configuration include the following optional tasks. Select the configuration tasks as required.

- Configuring the Subnet-based VLAN Function
- Configuring the Protocol-based VLAN Function

1.4 Configuring the Subnet-based VLAN Function

1.4.1 Overview

You can configure VLAN assignment based on IP addresses so that packets from a specified network segment or a specified IP address are forwarded to the specified VLAN.

1.4.2 Restrictions and Guidelines

- The subnet-based VLAN function takes effect on trunk or hybrid ports only. You must configure a port as a trunk or hybrid port and then run the **protocol-vlan ipv4** command to configure the subnet-based VLAN function.
- To enable the subnet-based VLAN function on a trunk or hybrid port, add all subnet-based VLANs to the allowed VLAN list of the trunk or hybrid port.
- You can enable the subnet-based VLAN function in interface configuration mode without global subnet-based VLAN configuration. However, you must enable the subnet-based VLAN function in both the global and interface configuration mode so that the subnet-based VLAN function takes effect.

1.4.3 Prerequisites

Configure a Layer 2 interface by running the **switchport** command.

1.4.4 Procedure

(1) Configure subnet-based VLAN rules in global configuration mode.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create a VLAN by configuring a policy.

vlan { *vlan-id* | **range** *vlan-range* }

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

e Configure subnet-based VLAN rules one by one in global configuration mode, and assign a specified subnet to the specified VLAN.

protocol-vlan ipv4 *ip-address* **mask** *mask* **vlan** *vlan-id*

No global subnet-based VLAN rule is configured by default.

(2) Enter the interface configuration mode and configure subnet-based VLAN.

a Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

b Enter the Layer 2 link aggregation configuration mode.

interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(3) Configure the port as a trunk or hybrid port.

switchport mode { **trunk | hybrid** }

The default Layer 2 interface mode is the access mode.

(4) Add subnet-based VLANs to the allowed VLAN list of an interface. Configure one of the following tasks.

- Configure an allowed VLAN list for the trunk port.

switchport trunk allowed vlan { **add** *vlan-list* | **all** | **except** *vlan-list* | **only** *vlan-list* | **remove** *vlan-list* }

The default allowed VLANs of the trunk port are VLANs 1 to 4094.

- Configure an allowed VLAN list for the hybrid port.

  switchport hybrid allowed vlan { [**add**] **tagged** *vlan-list* | [**add**] **untagged** *vlan-list* | **only tagged** *vlan-list* | **remove** *vlan-list* }

  The default allowed VLANs of the hybrid port are untagged VLAN 1 and tagged VLANs 2 to 4094.

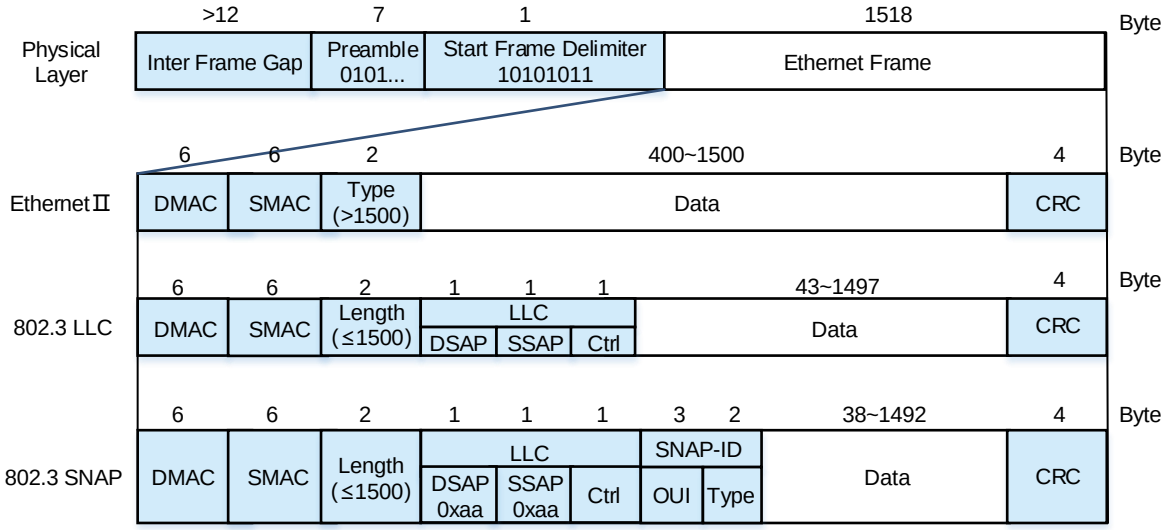
(5) Enable the subnet-based VLAN function on the interface.

protocol-vlan ipv4

The subnet-based VLAN function is disabled by default.

1.5 Configuring the Protocol-based VLAN Function

1.5.1 Overview



Protocol-based VLAN assigns packets of different service types to different VLANs to facilitate management and maintenance. Figure 1-1 shows the frame format.

This function uses **frame-type** to indicate a frame type, and supports the **EtherII**, **SNAP** and **LLC** frame types.

If the frame type is **EtherII** or **SNAP**, the **ether-type** *type* parameter is used to configure the Ethernet packet type.

If the frame type is **LLC**, the **dsap** *value* **ssap** *value* parameter is used to configure the type of a service access point (SAP).

Figure 1-1 Ethernet Frame Format

1.5.2 Restrictions and Guidelines

- The protocol-based VLAN function takes effect on trunk or hybrid ports only. You must configure an interface as a trunk or hybrid port and then run the **protocol-vlan profile vlan** command to configure the protocol-based VLAN function.

- To configure and enable the protocol-based VLAN function on a trunk or hybrid port, add all protocol-based VLANs to the allowed VLANs of the trunk or hybrid port.
- Configure the protocol-based VLAN packet type in global configuration mode, configure specified VLANs in the interface configuration mode, and enable the protocol-based VLAN function. Then the protocol-based VLAN function takes effect. When you delete the global configuration, the protocol-based VLAN configuration of all interfaces related to profile number is automatically deleted.
- **profile** *profile-number* specifies the number of a protocol-based VLAN rule (profile). The value range of this parameter
- **frame-type**: Specifies a frame type. The values include **EtherII**, **SNAP**, and **LLC**. If the frame type is **EtherII** or **SNAP**, configure the **ether-type** *type* parameter to specify the corresponding Ethernet type. When the frame type is **LLC**, configure the **dsap** *value* **ssap** *value* parameter to specify the corresponding SAP type.
- **ether-type** *type* specifies an Ethernet type of frames. The value range is from 1501 to 65535 (in decimal notation of the protocol ID). The value can also be a protocol name or the protocol ID in hexadecimal notation. The supported protocols include AARP (0x80f3), AMBER (0x6008), APPLETALK (0x809b), ARP (0x0806), CFM (0x8902), DECNET-IV (0x6003), DIAGNOSTIC (0x6005), EAPOL (0x888e), FC_ETH, HEX6000 (0x6000), HEX8042 (0x8042), IPv4 (0x0800), IPv6 (0x86DD), IPX (0x8137), LAT (0x6004), LAVC-SCA (0x6007), MAC_IN_MAC (0x88E7), MOP-CONSOLE (0x6002), MOP-DUMP (0x6001), MUMPS (0x6009), NETBIOS (0x8040), SNX-IDP (0x0600), VINES-ECHO (0x0baf), and X-25 (0x0805).
- In the **dsap** *value* **ssap** *value* parameter, **dsap** specifies a destination service access point (DSAP), and **ssap** specifies a source service access point (SSAP). The range of *value* is from 0 to 255, corresponding to 0x00 to 0xFF of one byte in hexadecimal notation. For example, if an IP packet is encapsulated into a Logical Link Control (LLC) frame, the DSAP value and SSAP value are both 0x06.
- *vlan-id* specifies a VLAN ID. The value range is from 1 to 4094.

1.5.3 Prerequisites

Configure an interface as a Layer 2 interface by running the **switchport** command.

1.5.4 Procedure

(1) Create a VLAN assigned by the protocol-based VLAN policy.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create a VLAN by configuring a policy.

vlan { *vlan-id* | **range** *vlan-range* }

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

(2) Configure protocol VLAN rules one by one in global configuration mode.

protocol-vlan profile *profile-number* **frame-type** { **etherII ether-type** *type* | **snap ether-type** *type* | **llc dsap** *value* **ssap** *value* }

No global protocol-based VLAN rule is configured by default.

(3) Enter the interface configuration mode and configure protocol-based VLAN.

a Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

b Enter the Layer 2 link aggregation configuration mode.

interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the port as a trunk or hybrid port.

switchport mode { **trunk | hybrid** }

The default Layer 2 interface mode is the access mode.

(5) Add protocol-based VLANs to the allowed VLAN list of an interface. Configure one of the following tasks.

- Configure an allowed VLAN list for the trunk port.

  switchport trunk allowed vlan { **all** | **add** *vlan-list* | **remove** *vlan-list* | **except** *vlan-list* | **only** *vlan-list* }

  The default allowed VLANs of the trunk port are VLANs 1 to 4094.

- Configure an allowed VLAN list for the hybrid port.

  switchport hybrid allowed vlan { [**add**] **tagged** *vlan-list* | [**add**] **untagged** *vlan-list* | **only tagged** *vlan-list* | **remove** *vlan-list* }

  The default allowed VLANs of the hybrid port are untagged VLAN 1 and tagged VLANs 2 to 4094.

(6) Configure protocol-based VLAN rules one by one on the interface so that packets that match the *num* rule are assigned to the VLAN specified by VLAN *vlan-id*.

protocol-vlan profile *profile-number* **vlan** *vlan-id*

The protocol-based VLAN function is disabled by default.

1.6 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

Caution

System resources are occupied when debugging information is output. Therefore, disable the debugging function immediately after use.

Run the **clear** commands to clear information.

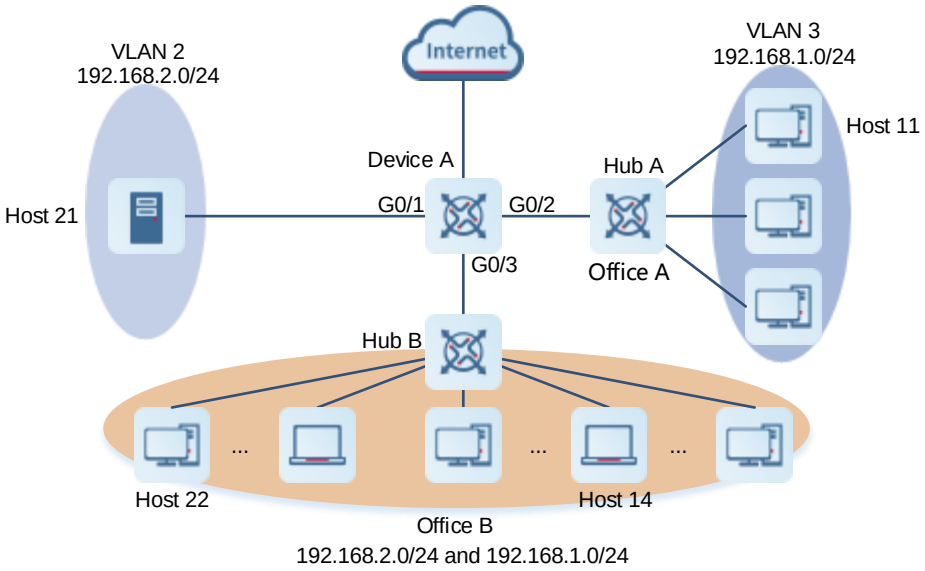
Caution

Running the **clear** command may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
show protocol-vlan	Displays configurations of all protocol-based VLANs.
show protocol-vlan profile	Displays the protocol-based VLAN configuration.
show protocol-vlan ipv4	Displays the subnet-based VLAN configuration.
debug bridge protvlan	Debugs the protocol-based VLAN function.

1.7 Configuration Examples



1.7.1 Configuring Subnet-based VLANs

1. Requirements

Office area Aand office area B are connected to Layer 3 device A through hubs. In office area A, hosts belong to a fixed network segment and are assigned to VLANs based on ports. In shared office area B, there are two network segments of hosts. Such hosts are not connected through fixed access ports and therefore they cannot be assigned to VLANs based on ports. Device Amust assign hosts in office area B to VLANs based on the IP address segments, to which user packets belong.

2. Topology

Figure 1-2 Topology of Configuring Subnet-based VLANs

3. Notes

- Configure VLAN 2 and VLAN 3 on device A.
- Configure GigabitEthernet 0/1 as an access port and assign the port to VLAN 2. Configure GigabitEthernet 0/2 as an access port and assign the port to VLAN 3.

- Configure a subnet-based VLAN rule in global configuration mode on device A and assign the IP address segment 192.168.2.0/24 to VLAN 2 and the IP address segment 192.168.1.0/24 to VLAN 3.
- Configure GigabitEthernet 0/3 as a hybrid port, add untagged VLAN 2 and VLAN 3 to the allowed VLAN list of the port, and enable the subnet-based VLAN function on GigabitEthernet 0/3.

4. Procedure

(1) Create VLANs to be assigned based on subnets. Configure a global subnet-based VLAN rule, in which packets with IP addresses in the network segment of 192.168.1.0/24 are assigned to VLAN 3 and packets with IP addresses in the network segment of 192.168.2.0/24 are assigned to VLAN 2.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan range 2-3
DeviceA(config-vlan)# exit
DeviceA(config)# protocol-vlan ipv4 192.168.1.0 mask 255.255.255.0 vlan 3
DeviceA(config)# protocol-vlan ipv4 192.168.2.0 mask 255.255.255.0 vlan 2
```

(2) Configure GigabitEthernet 0/1 and GigabitEthernet 0/2 as access ports and add them to different VLANs.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# switchport
DeviceA(config-if-GigabitEthernet 0/1)# switchport access vlan 2
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# switchport
DeviceA(config-if-GigabitEthernet 0/2)# switchport access vlan 3
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

(3) Configure GigabitEthernet 0/3 that will run the subnet-based VLAN function as a hybrid port, and allow packets from the subnet-based VLANs to pass.

```
DeviceA(config)# interface gigabitethernet 0/3
DeviceA(config-if-GigabitEthernet 0/3)# switchport
DeviceA(config-if-GigabitEthernet 0/3)# switchport mode hybrid
DeviceA(config-if-GigabitEthernet 0/3)# switchport hybrid allowed vlan untagged
2-3
```

(4) Enable the subnet-based VLAN function on GigabitEthernet 0/3 that needs to run the subnet-based VLAN function.

```
DeviceA(config-if-GigabitEthernet 0/3)# protocol-vlan ipv4
```

5. Verification

(1) Run the **show protocol-vlan ipv4** command to check whether the protocol-based VLAN configuration on the device is correct.

```
DeviceA# show protocol-vlan ipv4
ip            mask          vlan
--------------- --------------- ----
192.168.1.0    255.255.255.0   3
192.168.2.0    255.255.255.0   2
interface          ipv4 status
```

```
-------------------- -----------
Gi0/3              enable
```

(2) Take hosts 21, 22, 11, and 14 as examples to verify the subnet-based VLAN assignment effect.

Set the default gateway address of host 21 in VLAN 2 to 192.168.2.1, and the IP address to 192.168.2.21/24.

```
Host21> enable
Host21# configure terminal
Host21(config)# ip route 0.0.0.0 0.0.0.0 192.168.2.1
Host21(config)# interface gigabitethernet 0/1
Host21(config-if-GigabitEthernet 0/1)# no switchport
Host21(config-if-GigabitEthernet 0/1)# ip address 192.168.2.21/24
Host21(config-if-GigabitEthernet 0/1)# end
```

Set the default gateway address of host 22 in VLAN 2 to 192.168.2.1, and the IP address to 192.168.2.22/24.

```
Host22> enable
Host22# configure terminal
Host22(config)# ip route 0.0.0.0 0.0.0.0 192.168.2.1
Host22(config)# interface gigabitethernet 0/1
Host22(config-if-GigabitEthernet 0/1)# no switchport
Host22(config-if-GigabitEthernet 0/1)# ip address 192.168.2.22/24
Host22(config-if-GigabitEthernet 0/1)# end
```

Set the default gateway address of host 11 in VLAN 3 to 192.168.1.1, and the IP address to 192.168.1.11/24.

```
Host11> enable
Host11# configure terminal
Host11(config)# ip route 0.0.0.0 0.0.0.0 192.168.1.1
Host11(config)# interface gigabitethernet 0/1
Host11(config-if-GigabitEthernet 0/1)# no switchport
Host11(config-if-GigabitEthernet 0/1)# ip address 192.168.1.11/24
Host11(config-if-GigabitEthernet 0/1)# end
```

Set the default gateway address of host 14 in VLAN 3 to 192.168.1.1, and the IP address to 192.168.1.14/24.

```
Host14> enable
Host14# configure terminal
Host14(config)# ip route 0.0.0.0 0.0.0.0 192.168.1.1
Host14(config)# interface gigabitethernet 0/1
Host14(config-if-GigabitEthernet 0/1)# no switchport
Host14(config-if-GigabitEthernet 0/1)# ip address 192.168.1.14/24
Host14(config-if-GigabitEthernet 0/1)# end
```

Verify that host 22 is assigned to VLAN 2 by the subnet-based VLAN function, and host 22 can ping host 21 in VLAN 2 but cannot ping host 11 in VLAN 3.

```
Host22# ping 192.168.2.21
Sending 5, 100-byte ICMP Echoes to 192.168.2.21, timeout is 2 seconds:
```

```
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/4 ms.
Host22# ping 192.168.1.11
Sending 5, 100-byte ICMP Echoes to 192.168.1.11, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5).
```

Verify that host 14 is assigned to VLAN 3 by the subnet-based VLAN function, and host 14 can ping host 11 in VLAN 3 but cannot ping host 21 in VLAN 2.

```
Host14# ping 192.168.1.11
Sending 5, 100-byte ICMP Echoes to 192.168.1.11, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/4 ms.
Host14# ping 192.168.2.21
Sending 5, 100-byte ICMP Echoes to 192.168.2.21, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5).
```

Configure the IP addresses of the SVI gateways for VLAN 2 and VLAN 3 on device A to implement L3 connection between the VLANs.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface vlan 2
DeviceA(config-if-VLAN 2)# ip address 192.168.2.1/24
DeviceA(config-if-VLAN 2)# exit
DeviceA(config)# interface vlan 3
DeviceA(config-if-VLAN 3)# ip address 192.168.1.1/24
DeviceA(config-if-VLAN 2)# end
```

Verify that host 14 in VLAN 3 can ping host 21 in VLAN 2. Likewise, verify that host 22 in VLAN 3 can ping host 21 in VLAN 2.

```
Host14# ping 192.168.2.21
Sending 5, 100-byte ICMP Echoes to 192.168.2.21, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 3/19/79 ms.
```

6. Configuration Files

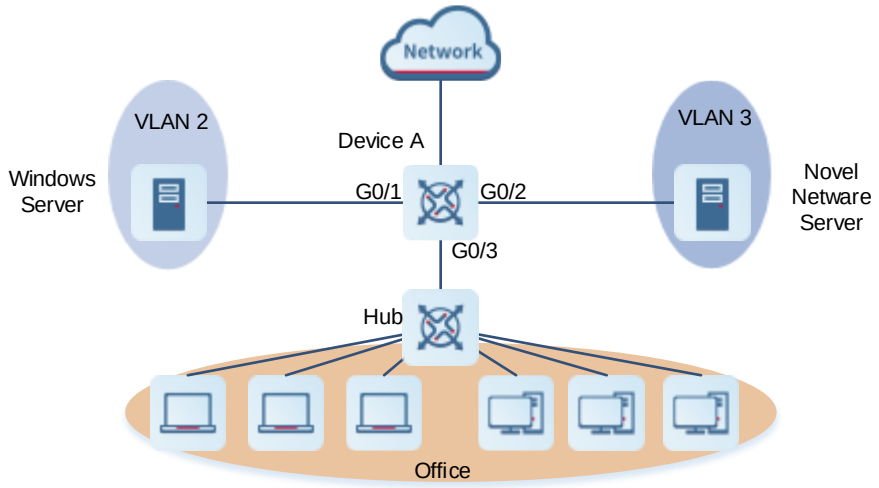
Device A configuration file

```
protocol-vlan ipv4 192.168.1.0 mask 255.255.255.0 vlan 3
protocol-vlan ipv4 192.168.2.0 mask 255.255.255.0 vlan 2
!
vlan range 2-3
```

```
!
interface GigabitEthernet 0/1
switchport
switchport mode access
switchport access vlan 2
!
interface GigabitEthernet 0/2
switchport
switchport mode access
switchport access vlan 3
!
interface GigabitEthernet 0/3
switchport
switchport mode hybrid
switchport hybrid allowed vlan only tagged 4-4094
switchport hybrid allowed vlan add untagged 1-3
protocol-vlan ipv4
```

7. Common Errors

- A port connected to the device is not a trunk or hybrid port.
- The allowed VLAN list of the port connected to the device does not contain the user communication VLANs.
- The subnet-based VLAN function is disabled on a port.
- Packets match a VLAN assignment policy with a higher priority (for example, MAC VLAN or voice VLAN) on the port, causing the failure of the subnet-based VLAN policy to take effect.



1.7.2 Configuring Protocol-based VLANs

1. Requirements

In an office area, some PCs run the Windows NT operating system (OS) and support the IP protocol, and some run the Novell Netware OS and support the Internetwork Packet Exchange (IPX) protocol. Two servers in the office network are used to isolate hosts running different OSs at L2 so that the hosts running Windows NT can access only the Windows NT server and the hosts running Novell Netware can access only the Novell Netware server. The purpose is to reduce network traffic.

2. Topology

Figure 1-3 Topology of Configuring Protocol-based VLAN

3. Notes

- Configure VLAN 2 and VLAN 3 on device A.
- Configure GigabitEthernet 0/1 as an access port and assign the port to VLAN 2. Configure GigabitEthernet 0/2 as an access port and assign the port to VLAN 3.
- Configure protocol-based VLAN rules in global configuration mode on device A so that IP packets match rule 1 and IPX packets match rule 2.
- Configure GigabitEthernet 0/3 as a hybrid port and add VLAN 2 and VLAN 3 to the allowed untagged VLAN list of the port. Enable the protocol-based VLAN function on GigabitEthernet 0/3, and associate rule 1 with VLAN 2 and rule 2 with VLAN 3.

4. Procedure

(1) Create VLAN 2 and VLAN 3 to be assigned according to protocol rules.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan range 2-3
DeviceA(config-vlan)# exit
```

(2) Configure protocol-based VLAN rules in global configuration mode.

Apply rule 1 to IP packets whose frame type is EthernetII and Ethernet type is 0x0800.

```
DeviceA(config)# protocol-vlan profile 1 frame-type ETHERII ether-type 0x0800
```

Apply rule 2 to IPX packets whose frame type is EthernetII and Ethernet type is 0x8137.

```
DeviceA(config)# protocol-vlan profile 2 frame-type ETHERII ether-type 0x8137
```

(3) Configure ports that connect to servers as access ports and add the ports to different VLANs.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# switchport
DeviceA(config-if-GigabitEthernet 0/1)# switchport access vlan 2
```

```
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# switchport
DeviceA(config-if-GigabitEthernet 0/2)# switchport access vlan 3
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

(4) Configure the port that needs to run the protocol-based VLAN function as a hybrid port, and add VLAN 2 and VLAN 3 to the allowed VLAN list of the port.

```
DeviceA(config)# interface gigabitethernet 0/3
DeviceA(config-if-GigabitEthernet 0/3)# switchport
DeviceA(config-if-GigabitEthernet 0/3)# switchport mode hybrid
DeviceA(config-if-GigabitEthernet 0/3)# switchport hybrid allowed vlan untagged
2-3
```

(5) Enable the protocol-based VLAN function on GigabitEthernet 0/3, and assign packets that match rule 1 to VLAN 2 and packets that match rule 2 to VLAN 3.

```
DeviceA(config-if-GigabitEthernet 0/3)# protocol-vlan profile 1 vlan 2
DeviceA(config-if-GigabitEthernet 0/3)# protocol-vlan profile 2 vlan 3
```

5. Verification

Run the **show protocol-vlan profile** [*profile-number*] command to check whether the protocol-based VLAN configuration on the device is correct.

```
DeviceA(config)# show protocol-vlan profile
profile frame-type      ether-type/DSAP+SSAP   interface      vlan
------- --------------- ---------------------- --------------- ----
1       ETHERII         0x0800                 Gi0/3          2
2       ETHERII         0x8137                 Gi0/3          3
```

6. Configuration Files

Device A configuration file

```
protocol-vlan profile 1 frame-type ETHERII ether-type IPV4
protocol-vlan profile 2 frame-type ETHERII ether-type IPX
!
vlan range 2-3
!
interface GigabitEthernet 0/1
switchport
switchport mode access
switchport access vlan 2
!
interface GigabitEthernet 0/2
switchport
switchport mode access
switchport access vlan 3
!
interface GigabitEthernet 0/3
switchport
```

```
switchport mode hybrid
switchport hybrid allowed vlan only tagged 4-4094
switchport hybrid allowed vlan add untagged 1-3
protocol-vlan profile 1 vlan 2
protocol-vlan profile 2 vlan 3
```

7. Common Errors

- A port connected to the device is not a trunk or hybrid port.
- The allowed VLAN list of the port connected to the device does not contain the user communication VLANs.
- The protocol-based VLAN function is disabled on a port.
- Packets match a VLAN assignment policy with a higher priority (for example, MAC VLAN, voice VLAN, or subnet-based VLAN) on the port, causing the failure of the protocol-based VLAN policy to take effect.

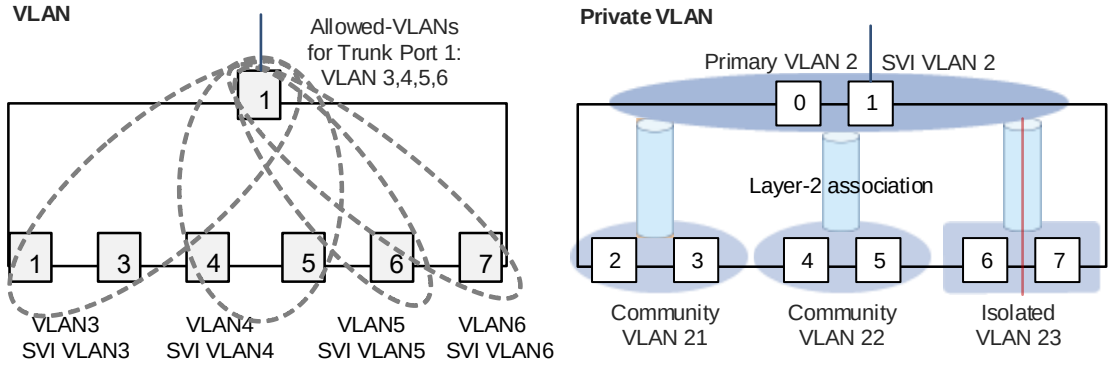
1 Configuring Private VLAN

1.1 Introduction

1.1.1 Overview

Carriers hope to isolate users to authenticate and charge each user, avoid virus attacks and broadcast storms, and strengthen user security. VLANs are isolated at Layer 2. If each user is assigned with a VLAN, the authentication, billing, and security requirements can be met. However, a device supports 4094 VLANs at most. Assigning a VLAN to each user limits the number of users supported by a device. What's more, it is infeasible for a Layer 3 device to assign one IP address to each VLAN in consideration of scarce IP addresses. To solve the problem, the private VLAN (PVLAN) technology is developed.



1.1.2 Basic Concepts

The PVLAN technology divides a Layer 2 broadcast domain of a VLAN into multiple sub-domains to form a dual-layer VLAN structure. The outer layer is referred to as primary VLAN, and the inner layer is referred to as secondary VLAN. Secondary VLANs can be further divided to community VLANs and isolated VLANs.

1. Features

- You can configure multiple PVLANs on a device. A PVLAN is a PVLAN domain.
- Each PVLAN can contain only one primary VLAN and multiple secondary VLANs. The primary VLAN corresponds to multiple secondary VLANs. The primary VLAN and one secondary VLAN form a PVLAN pair, which represents a PVLAN sub-domain. For example, VLAN 2/21 represents a PVLAN sub-domain. A PVLAN domain can have multiple PVLAN sub-domains. The secondary VLANs of different sub-domains are different, but they share the same primary VLAN.
- Both the primary VLAN and secondary VLANs can contain ports. As shown in Figure 1-1, ports 0 and 1 within the primary VLAN belong to primary VLAN 2; and ports 2 and 3 belong to community VLAN 21. After a Layer 2 association is configured between primary VLAN 2 and community VLAN 21, ports 0, 1, 2, and 3 belong to the same PVLAN sub-domain VLAN 2/21. They can make Layer 2 communication with each other.
- In a PVLAN, Layer 3 switch virtual interfaces (SVIs) can be created only in the primary VLAN, and Layer 3 SVIs cannot be created in secondary VLANs. You can make Layer 3 communication with the port in a primary VLAN through a port in the secondary VLAN only after a Layer 3 association is configured between the secondary VLAN and the primary VLAN. Otherwise, the hosts can make only Layer 2 communication.

Figure 1-1 Logic Diagram of PVLAN

2. Primary VLAN and Promiscuous Port

Ports belonging to the primary VLAN are referred to as promiscuous ports. A PVLAN can have one or more promiscuous ports.

- In a PVLAN domain, a promiscuous port can communicate with any port, including another promiscuous port, a community VLAN port, and an isolated VLAN port. A promiscuous port is used as an uplink port for connecting to an external network or a port for connecting to a shared server so that hosts in all secondary VLANs can access the network and shared server.
- Outside a PVLAN domain, a promiscuous port belongs to the primary VLAN, allows common packets with the primary VLAN ID to pass through, and discards the other common VLAN packets.

3. Community VLAN and Community Port

A PVLAN domain can have multiple community VLANs. The ports in a community VLAN are referred to as community ports.

- Community ports in a community VLAN can communicate with each other but community ports of different community VLANs cannot communicate with each other.
- Community ports can communicate with promiscuous ports.
- Community ports cannot communicate with isolated ports.

4. Isolated VLAN and Isolated Port

A PVLAN domain can have only one isolated VLAN. Ports in an isolated VLAN are referred to as isolated ports.

- Isolated ports cannot communicate with each other. You can assign required hosts to an isolated VLAN for isolation.
- Isolated ports can communicate with only promiscuous ports. Packets can be forwarded from isolated ports to the promiscuous ports and vice versa.
- Packets can be forwarded from an isolated port to a trunk port. When receiving a packet (packet from the promiscuous port) with the VLAN ID of the primary VLAN ID, the trunk port can forward the packet to the isolated port. This enables the isolated port to communicate with an external network through a promiscuous port. Hosts in an isolated VLAN cannot communicate with each other. Therefore, when receiving a packet with the VLAN ID of the isolated VLAN, the trunk port cannot forward the packet to the isolated port.

Caution

Ports in a PVLAN can be used as mirroring source ports but cannot be used as mirroring destination ports.

1.1.3 Packet Forwarding Rules

Table 1-1 lists packet forwarding rules between ports in a PVLAN and VLAN tag changes.

Table 1-1 Packet Forwarding Rules Between Different Types of Ports and VLAN Tag Changes

Input Port	Output Port	Packet Forwarding Rules and VLAN Tag Changes
Promiscuous Port	Promiscuous Port	Reachable, VLAN tag unchanged
	Community Port	Reachable, VLAN tag unchanged
	Isolated Port	Reachable, VLAN tag unchanged
	Trunk Port	Reachable, a primary VLAN tag added
Community Port	Promiscuous Port	Reachable, VLAN tag unchanged
	Community Port	● Reachable in the same community VLAN, VLAN tag unchanged ● Unreachable in different community VLANs
	Isolated Port	Unreachable
	Trunk Port	Reachable, a community VLAN tag added
Isolated Port	Promiscuous Port	Reachable, VLAN tag unchanged
	Community Port	Unreachable
	Isolated Port	Unreachable
	Trunk Port	Reachable. An isolated VLAN tag is added to an isolated VLAN packet and the packet is forwarded through isolated ports.
Trunk Port	Promiscuous Port	Reachable, VLAN tag removed
	Community Port	● Reachable in the primary VLAN, VLAN tag removed ● Reachable in the same community VLAN, VLAN tag removed ● Unreachable in different community VLANs ● Unreachable in an isolated VLAN
	Isolated Port	● Reachable in the primary VLAN, VLAN tag removed ● Unreachable in a community VLAN ● Unreachable in an isolated VLAN
	Trunk Port	Reachable, VLAN tag unchanged
Switch CPU	Promiscuous Port	Reachable, no VLAN tag

Input Port	Output Port	Packet Forwarding Rules and VLAN Tag Changes
	Community Port	Reachable, no VLAN tag
	Isolated Port	Reachable, no VLAN tag
	Trunk Port	Reachable, a primary VLAN tag added

1.2 Restrictions and Guidelines

- You can only configure a Layer 2 Ethernet interface or a Layer 2 aggregated port as an isolated, community or promiscuous port within a PLVAN and add the port to the PVLAN.
- You can run the **show interface switchport** command to display the interface type. If the **Switchport** field corresponding to the interface is **enabled**, this interface is a Layer 2 interface. If the **Switchport** field corresponding to the interface is **disabled**, this interface is a Layer 3 interface.
- You can run the **switchport** command to configure the interface as a Layer 2 interface. Run the **no switchport mode** command to restore the Layer 2 interface mode to the default mode and run the **no switchport** command to configure a Layer 2 interface as a Layer 3 interface. When you configure an interface as a Layer 2 or 3 interface, all attributes of the interface are restored to the default values in this interface mode.

1.3 Configuration Task Summary

The configuration includes the following tasks:

(1) Configure PVLAN.

a Configuring PVLAN and Layer 2 Association

b Configuring a Layer 3 Association for a PVLAN

(2) Configure port types and add the ports to PVLAN pairs.

a Configuring an Isolated Port or a Community Port

b Configuring a Promiscuous Port

1.4 Configuring PVLAN and Layer 2 Association

1.4.1 Overview

The primary VLAN and secondary VLANs of a PVLAN cannot exist separately. You must add the secondary VLANs to the primary VLAN to form a Layer 2 association and multiple PVLAN pairs, which is also called PVLAN sub-domains.

You can add isolated ports and community ports to the primary VLAN and secondary VLANs only after a Layer 2 association is configured between the secondary VLANs and the primary VLAN. If you cancel a Layer 2 association, the PVLAN pairs, to which the isolated ports and promiscuous ports are added, are canceled as well.

After a Layer 2 association is configured between the secondary VLANs and the primary VLAN, you can configure a Layer 3 association so that the multiple secondary VLANs use the same IP gateway to save IP address resources.

Use the **private-vlan association** command to configure a Layer 2 association between the primary VLAN and the secondary VLANs.

1.4.2 Restrictions and Guidelines

- The PVLAN supports only host and promiscuous ports. Before you configure a common VLAN as a PVLAN, ensure that the ports in the PVLAN are valid. Otherwise, the configuration may fail. If a trunk, hybrid or uplink port exists in a common VLAN, the common VLAN can be configured as a PVLAN, but you are advised to remove the unused port from the PVLAN. If an access or dot1q-tunnel port exists in a common VLAN, the common VLAN cannot be configured as a PVLAN.
- **primary**: Configure a common VLAN as the primary VLAN of a PVLAN. A primary VLAN specifies a PVLAN. The device support creating multiple PVLANs and configuring multiple primary VLANs.
- **community**: Configure a common VLAN as a community VLAN. A Private VLAN has one or more community VLANs. Therefore, each primary VLAN can be associated with one or more community VLANs.
- **isolated**: Configure a common VLAN as an isolated VLAN. A Private VLAN has only one isolated VLAN. Therefore, each primary VLAN can be associated with only one isolated VLAN.
- *secondary-vlan-list* indicates a list of secondary VLANs. **add** *secondary-vlan-list* is used to associate with a secondary VLAN. **remove** *secondary-vlan-list* is used to remove the association specified by *secondary-vlan-list*.
- You cannot delete a PVLAN by using the **no vlan** command. You must run the **no private-vlan** { **community** | **isolated** | **primary** } command to restore a PVLAN to a common static VLAN, and be sure to keep the original PVLAN attributes unchanged.
- Before you modify PVLAN attributes of a port, you must restore the PVLAN to a common static VLAN and then configure new PVLAN attributes for the port. When you restore a PVLAN to a common static VLAN, all the associations in the PVLAN are canceled. You need to reconfigure associations for the PVLAN and add ports to the PVLAN.

1.4.3 Procedure

(1) Configure a secondary VLAN for a PVLAN.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create a secondary VLAN and enter the VLAN configuration mode.

vlan { *vlan-id* | **range** *vlan-range* }

Only VLAN 1 exists by default.

d Configure attributes of the secondary VLAN.

private-vlan { **community** | **isolated** }

A VLAN is a common VLAN and has no PVLAN attribute by default.

e Return to the global configuration mode.

exit

(2) Configure a primary VLAN for the PVLAN.

a Create a primary VLAN and enter the VLAN configuration mode.

vlan *vlan-id*

Only VLAN 1 exists by default.

b Configure attributes of the primary VLAN.

private-vlan primary

A VLAN is a common VLAN and has no PVLAN attribute by default.

(3) Add the secondary VLAN to the primary VLAN to form a Layer 2 association.

private-vlan association { *secondary-vlan-list* | **add** *secondary-vlan-list* | **remove** *secondary-vlan-list* }

No Layer 2 association is configured between the primary VLAN and the secondary VLANs by default.

1.5 Configuring a Layer 3 Association for a PVLAN

1.5.1 Overview

To enable hosts in a secondary VLAN domain to access an external network, configure a Layer 3 SVI for the primary VLAN, configure an IP address for the SVI, and then configure a Layer 3 association between the primary VLAN and the secondary VLAN on the SVI of the primary VLAN. Then, hosts in the secondary VLAN can make Layer 3 communication through the SVI of the primary VLAN. If no Layer 3 association is configured between the primary VLAN and the secondary VLAN, the hosts in the secondary VLAN cannot make Layer 3 communication.

You can use the **private-vlan mapping** command to configure/remove a Layer 3 association between the primary VLAN and the secondary VLAN.

1.5.2 Restrictions and Guidelines

- You can create an SVI only for a primary VLAN. Run the **interface vlan** *interface-number* command to create an SVI. The value of *interface-number* must be the VID of a primary VLAN.
- To configure an IPv4 address, see *Configuring IPv4 Basics*.
- To configure an IPv6 address, see *Configuring IPv6 Basics*.

1.5.3 Prerequisites

Create a PVLAN and a Layer 2 association between a secondary VLAN and the primary VLAN.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an SVI for the primary VLAN and enter the SVI configuration mode.

interface vlan *interface-number*

No SVI exists in a VLAN by default.

(4) Configure an IP address for the SVI.

ip address { *ipv4-address mask* | *ipv4-address/mask-length* }

An SVI has no IP address by default.

(5) Configure a Layer 3 association for the PVLAN.

private-vlan mapping { *secondary-vlan-list* | **add** *secondary-vlan-list* | **remove** *secondary-vlan-list* }

No Layer 3 association is configured between the primary VLAN and the secondary VLANs by default.

1.6 Configuring an Isolated Port or a Community Port

1.6.1 Overview

After the primary VLAN and secondary VLAN as well as a Layer 2 association are configured, you need to configure ports connected to hosts. User ports are configured as host ports. If an enterprise has only one host, you can configure the user port as an isolated port and add the port to an isolated VLAN. If an enterprise has multiple hosts, you can configure the user ports as community ports and add the ports to a community VLAN. The host ports added to an isolated VLAN are isolated ports, and the host ports added to community VLANs are community ports.

1.6.2 Restrictions and Guidelines

- The Layer 2 interfaces connected to hosts must be configured as host ports before they are associated with PVLAN pairs to add the host ports to a secondary VLAN of a PVLAN.
- *primary-vlan-id* specifies the primary VLAN ID in a PVLAN pair. *secondary-vlan-id* specifies a secondary VLAN ID in a PVLAN pair. The VLANs specified by *primary-vlan-id* and *secondary-vlan-id* must be a PVLAN pair that has a Layer 2 association.
- One host port can be associated with only one PVLAN pair. To modify the association of a host port with a PVLAN pair, use the **no switchport private-vlan host-association** command to cancel the association between the host port and the PVLAN pair.

1.6.3 Prerequisites

- Configure an interface as a Layer 2 interface.

Create a PVLAN and a Layer 2 association between a secondary VLAN and the primary VLAN.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure a Layer 2 interface as a PVLAN host port.

switchport mode private-vlan host

A Layer 2 interface is an access port by default.

(5) Associate the host port with a PVLAN pair that has a Layer 2 association and add the host port to a secondary VLAN of the PLVAN.

switchport private-vlan host-association *primary-vlan-id secondary-vlan-id*

A port belongs to VLAN 1 and is not associated with a Layer 2 PVLAN pair by default.

1.7 Configuring a Promiscuous Port

1.7.1 Overview

To enable a port connected to an external network or a server to be accessible to community ports and isolated ports, configure the port as a promiscuous port so that uplink and downlink packets can be normally forwarded.

1.7.2 Restrictions and Guidelines

- You must configured a Layer 2 interface as a promiscuous port and then associate the promiscuous port with a PVLAN pair to add the port to the primary VLAN of the PLVAN.
- A promiscuous port can be associated with multiple PVLAN pairs that share the same primary VLAN. However, a host port can be associated with one PVLAN pair only.

1.7.3 Prerequisites

- Configure an interface as a Layer 2 interface.

Create a PVLAN and a Layer 2 association between a secondary VLAN and the primary VLAN.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure a Layer 2 interface as a PVLAN promiscuous port.

switchport mode private-vlan promiscuous

A Layer 2 interface is an access port by default.

(5) Associate the promiscuous port with one or more PVLAN pairs that have Layer 2 associations to add the port to the primary VLAN of the PLVAN.

switchport private-vlan mapping *primary-vlan-id* { *secondary-vlan-list* | **add** *secondary-vlan-list* | **remove** *secondary-vlan-list* }

A port belongs to VLAN 1 and is not associated with a Layer 2 PVLAN pair by default.

1.8 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Table 1-2 Monitoring

Command	Purpose
show vlan private-vlan [**community** | **primary** | **isolated**]	Displays PVLAN configuration.

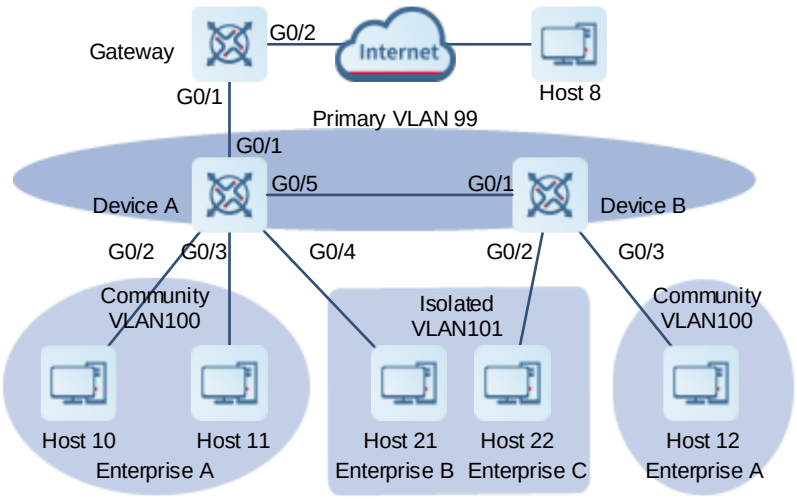
1.9 Configuration Examples

1.9.1 Configuring PVLAN Across Layer 2 Devices

1. Requirements

As shown in Figure 1-2, in the hosting service operation network, enterprise hosts are connected to the network through device A or device B. Main requirements are as follows:

- Hosts of an enterprise can communicate with each other but the host communication between enterprises is isolated. All enterprise hosts share the same gateway address and can communicate with the external network through this gateway address.



The deployment mode is as follows:

- Configure the PVLAN function on device A and device B and the interconnection ports are all trunk ports. Add all enterprise hosts to the same PVLAN (for example, primary VLAN 99).
- All the enterprise hosts communicate with an external network through a shared SVI of the primary VLAN 99. The external network perceives the primary VLAN 99 only and does not perceive secondary VLANs. Configure GigabitEthernet 0/1 of device A as a promiscuous port and connect this interface to the gateway. The promiscuous port only allows primary VLAN packets from the PVLAN to pass through and outputs untagged packets.
- GigabitEthernet 0/1 of the gateway can function as a trunk or hybrid port. Because packets forwarded by a promiscuous port are untagged, set the native VLAN of GigabitEthernet 0/1 of the gateway to the primary VLAN of the PVLAN.
- If an enterprise has multiple hosts, allocate the hosts to different community VLANs and configure the ports connected to the hosts as host ports of the community VLANs so that the hosts in the enterprise can communicate with each other but host communication between enterprises is isolated.

If an enterprise has only one host, allocate the host to an isolated VLAN and configure the port connected to the host as the host port of the isolated VLAN, to implement isolation of communication between hosts of different enterprises.

2. Topology

Figure 1-2 Topology of PVLAN Applied Across Layer 2 Devices

3. Notes

- Add all enterprise hosts to a PVLAN (primary VLAN 99). All enterprise hosts share the same SVI through this PVLAN to communicate with the external network. Enterprise A has multiple hosts. Assign the hosts to community VLAN 100 so that hosts in the enterprise can communicate with each other and the host communication between enterprises is isolated. Enterprise B and enterprise C has only one host each. Assign the hosts to isolated VLAN 101. The hosts in enterprise B and enterprise C cannot communicate with each other. Configure a PVLAN on Device A and Device B. The PVLAN contains one primary VLAN 99, one community VLAN 100, and one isolated VLAN 101.
- Configure a Layer 3 SVI for the primary VLAN on Device A, and configure a Layer 3 association between the primary VLAN and the secondary VLANs.
- Configure GigabitEthernet 0/2-0/4 of Device A as host ports. Configure GigabitEthernet 0/2 and 0/3 of Device B as host ports.
- Configure GigabitEthernet 0/1 of Device A connected to a gateway as a promiscuous port. Only packets from the primary VLAN can pass through this port. No tag is carried when the promiscuous port outputs packets from the primary VLAN.
- Because the PVLAN runs across devices, the ports connecting different devices must be configured as trunk ports. Configure GigabitEthernet 0/5 of Device A and GigabitEthernet 0/1 of Device B as trunk ports. GigabitEthernet 0/1 of the gateway can be configured as a trunk port or hybrid port. Because packets forwarded by a promiscuous port do not carry tags, the native VLAN of GigabitEthernet 0/1 must be set to the primary VLAN of the PVLAN.

4. Procedure

(1) Configure a PVLAN and Layer 2 associations.

Configure a Layer 2 association between the secondary VLANs (VLAN 100 and VLAN 101) and the primary VLAN 99 on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan 100
DeviceA(config-vlan)# private-vlan community
DeviceA(config-vlan)# exit
DeviceA(config)# vlan 101
DeviceA(config-vlan)# private-vlan isolated
DeviceA(config-vlan)# exit
DeviceA(config)# vlan 99
DeviceA(config-vlan)# private-vlan primary
DeviceA(config-vlan)# private-vlan association 100-101
DeviceA(config-vlan)# exit
```

Configure a Layer 2 association between the secondary VLANs (VLAN 100 and VLAN 101) and the primary VLAN 99 on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# vlan 100
DeviceB(config-vlan)# private-vlan community
DeviceB(config-vlan)# exit
DeviceB(config)# vlan 101
DeviceB(config-vlan)# private-vlan isolated
DeviceB(config-vlan)# exit
DeviceB(config)# vlan 99
DeviceB(config-vlan)# private-vlan primary
DeviceB(config-vlan)# private-vlan association 100-101
DeviceB(config-vlan)# exit
```

(2) Configure a Layer 3 association for the PVLAN.

Configure an IP address and a mask for the Layer 3 SVI of the primary VLAN on Device A, and configure a Layer 3 association between the primary VLAN and the secondary VLANs.

```
DeviceA(config)# interface vlan 99
DeviceA(config-vlan)# ip address 192.168.99.1 255.255.255.0
DeviceA(config-vlan)# private-vlan mapping 100,101
DeviceA(config-vlan)# exit
```

(3) Add the host ports to the secondary VLANs.

Configure the ports of Device A connected to hosts as host ports and associate the ports with PVLAN pairs to add the ports to the secondary VLANs.

```
DeviceA(config)# interface range gigabitethernet 0/2-3
DeviceA(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode private-vlan host
DeviceA(config-if-range)# switchport private-vlan host-association 99 100
DeviceA(config-if-range)# exit
DeviceA(config)# interface gigabitethernet 0/4
```

```
DeviceA(config-if-GigabitEthernet 0/4)# switchport
DeviceA(config-if-GigabitEthernet 0/4)# switchport mode private-vlan host
DeviceA(config-if-GigabitEthernet 0/4)# switchport private-vlan host-association
99 101
DeviceA(config-if-GigabitEthernet 0/4)# exit
```

Configure the ports of Device B connected to hosts as host ports and associate the ports with PVLAN pairs to add the ports to the secondary VLANs.

```
DeviceB(config)# interface gigabitethernet 0/2
DeviceB(config-if-GigabitEthernet 0/2)# switchport
DeviceB(config-if-GigabitEthernet 0/2)# switchport mode private-vlan host
DeviceB(config-if-GigabitEthernet 0/2)# switchport private-vlan host-association
99 101
DeviceB(config-if-GigabitEthernet 0/2)# exit
DeviceB(config)# interface gigabitethernet 0/3
DeviceB(config-if-GigabitEthernet 0/3)# switchport
DeviceB(config-if-GigabitEthernet 0/3)# switchport mode private-vlan host
DeviceB(config-if-GigabitEthernet 0/3)# switchport private-vlan host-association
99 100
DeviceB(config-if-GigabitEthernet 0/3)# exit
```

(4) Configure GigabitEthernet 0/1 of Device A as a promiscuous port and associate the port with the primary VLAN 99 and the secondary VLANs 100 and 101 to add the port to the primary VLAN.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# switchport
DeviceA(config-if-GigabitEthernet 0/1)# switchport mode private-vlan promiscuous
DeviceA(config-if-GigabitEthernet 0/1)# switchport private-vlan mapping 99 add
100-101
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

(5) Configure the ports connecting devices in the PVLAN as common trunk ports.

Configure GigabitEthernet 0/5 of Device A as a trunk port.

```
DeviceA(config)# interface gigabitethernet 0/5
DeviceA(config-if-GigabitEthernet 0/5)# switchport
 DeviceA(config-if-GigabitEthernet 0/5)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/5)# switchport trunk native vlan 1
DeviceA(config-if-GigabitEthernet 0/5)# switchport trunk allowed vlan all
DeviceA(config-if-GigabitEthernet 0/5)# end
DeviceA# write
```

Configure GigabitEthernet 0/1 of Device B as a trunk port.

```
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# switchport
DeviceB(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceB(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
DeviceB(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
DeviceB(config-if-GigabitEthernet 0/1)# end
DeviceB# write
```

(6) Configure the downlink port GigabitEthernet 0/1 of the gateway as a trunk port and set the native VLAN of this port to the primary VLAN.

```
GW> enable
GW# configure terminal
GW(config)# interface gigabitethernet 0/1
GW(config-if-GigabitEthernet 0/1)# switchport
GW(config-if-GigabitEthernet 0/1)# switchport mode trunk
GW(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 99
GW(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
GW(config-if-GigabitEthernet 0/1)# end
GW# write
```

5. Verification

(1) Check whether the VLAN and port configurations are correct.

Check whether the VLAN and port configurations on Device A are correct. GigabitEthernet 0/1 is a promiscuous port and belongs to primary VLAN 99. GigabitEthernet 0/2 and GigabitEthernet 0/3 are community ports and belong to community VLAN 100. GigabitEthernet 0/4 is an isolated port and belongs to isolated VLAN 101. GigabitEthernet 0/5 is a trunk port and belongs to all VLANs. A Layer 3 SVI address is configured on Device A and the routing function is enabled.

```
DeviceA# show vlan private-vlan
VLAN  Type      Status   Routed    Ports                Associated VLANs
----  ----     -------   ------    ------------------     ------------------
99    primary    active   Enabled    Gi0/1, Gi0/5          100-101
100   community  active   Enabled    Gi0/2, Gi0/3, Gi0/5    99
101   isolated   active   Enabled    Gi0/4, Gi0/5          99
```

Check whether the VLAN and port configurations on Device B are correct.

```
DeviceB# show vlan private-vlan
VLAN  Type      Status   Routed    Ports                Associated VLANs
----  ----     -------   ------    ------------------     ------------------
99    primary    active   Disabled   Gi0/1                100-101
100   community  active   Disabled   Gi0/1, Gi0/3          99
101   isolated   active   Disabled   Gi0/1, Gi0/2          99
```

Check whether the gateway configuration is correct.

```
GW# show interface gigabitethernet 0/1 switchport
Interface                    Switchport Mode     Access Native Protected VLAN
lists
------------------------------ ---------- --------- ------ ------ ---------
----------
GigabitEthernet 0/1            enabled    TRUNK     1      99     Disabled  ALL
```

(2) Configure IP addresses and masks for hosts. To facilitate verification, add the hosts to the same network segment.

Configure an IP address and a mask for host 10 in the community VLAN.

```
Host10> enable
```

```
Host10# configure terminal
Host10(config)# interface gigabitethernet 0/1
Host10(config-if-GigabitEthernet 0/1)# no switchport
Host10(config-if-GigabitEthernet 0/1)# ip address 192.168.99.10 255.255.255.0
```

Configure an IP address and a mask for host 11 in the community VLAN.

```
Host11> enable
Host11# configure terminal
Host11(config)# interface gigabitethernet 0/1
Host11(config-if-GigabitEthernet 0/1)# no switchport
Host11(config-if-GigabitEthernet 0/1)# ip address 192.168.99.11 255.255.255.0
```

Configure an IP address and a mask for host 12 in the community VLAN.

```
Host12> enable
Host12# configure terminal
Host12(config)# interface gigabitethernet 0/1
Host12(config-if-GigabitEthernet 0/1)# no switchport
Host12(config-if-GigabitEthernet 0/1)# ip address 192.168.99.12 255.255.255.0
```

Configure an IP address and a mask for host 21 in the isolated VLAN.

```
Host21> enable
Host21# configure terminal
Host21(config)# interface gigabitethernet 0/1
Host21(config-if-GigabitEthernet 0/1)# no switchport
Host21(config-if-GigabitEthernet 0/1)# ip address 192.168.99.21 255.255.255.0
```

Configure an IP address and a mask for host 22 in the isolated VLAN.

```
Host22> enable
Host22# configure terminal
Host22(config)# interface gigabitethernet 0/1
Host22(config-if-GigabitEthernet 0/1)# no switchport
Host22(config-if-GigabitEthernet 0/1)# ip address 192.168.99.22 255.255.255.0
```

To simulate external network data, connect host 8 to the gateway interface GigabitEthernet 0/2 and add GigabitEthernet 0/2 to VLAN 99.

```
GW> enable
GW# configure terminal
GW(config)# interface gigabitethernet 0/2
GW(config-if-GigabitEthernet 0/2)# switchport
GW(config-if-GigabitEthernet 0/2)# switchport access vlan 99
```

Configure an address and a mask for host 8.

```
Host8> enable
Host8# configure terminal
Host8(config)# interface gigabitethernet 0/1
Host8(config-if-GigabitEthernet 0/1)# no switchport
Host8(config-if-GigabitEthernet 0/1)# ip address 192.168.99.8 255.255.255.0
```

(3) Check whether packets from the hosts in the PVLAN are forwarded in accordance with the forwarding rules of the PVLAN ports.

Hosts in the same community VLAN can communicate with each other even if the PVLAN is configured across devices.

```
Host10# ping 192.168.99.11
Sending 5, 100-byte ICMP Echoes to 192.168.99.11, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/3 ms.
Host10# ping 192.168.99.12
Sending 5, 100-byte ICMP Echoes to 192.168.99.12, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/3 ms.
```

Hosts in an isolated VLAN cannot communicate with each other.

```
Host21# ping 192.168.99.22
Sending 5, 100-byte ICMP Echoes to 192.168.99.22, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5).
```

Hosts in a community VLAN cannot communicate with hosts in an isolated VLAN.

```
Host10# ping 192.168.99.22
Sending 5, 100-byte ICMP Echoes to 192.168.99.22, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5).
```

Hosts in a community VLAN and hosts in an isolated VLAN can communicate with an external network through the promiscuous port and gateway.

```
Host10# ping 192.168.99.8
Sending 5, 100-byte ICMP Echoes to 192.168.99.8, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/4 ms.
Host22# ping 192.168.99.8
Sending 5, 100-byte ICMP Echoes to 192.168.99.8, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/4 ms.
```

6. Configuration Files

 switchport mode trunk
switchport trunk native vlan 99
switchport trunk allowed vlan only 1-4094
```

7. Common Errors

- No Layer 2 association is configured between the primary VLAN and the secondary VLANs of a PVLAN. As a result, a VLAN list fails to be added to an isolated port, a promiscuous port, or a community port when you configure the port.
- A host has been associated with a PVLAN pair when it is associated with another PVLAN pair, which will cause a configuration error.
- No Layer 3 association is configured for a PVLAN.

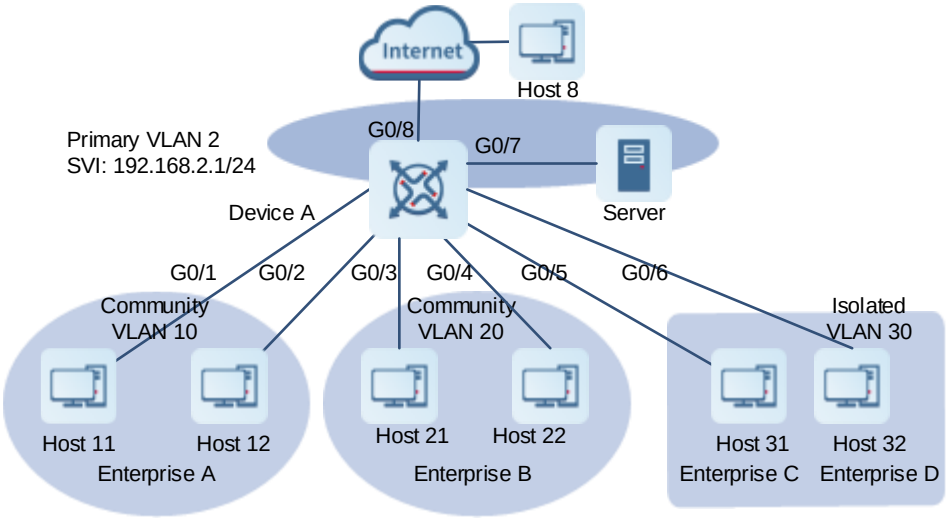
1.9.2 Configuring PVLAN on a Single Layer 3 Device

1. Requirements

As shown in Figure 1-3, in the hosting service operation network, enterprise hosts are connected to the network through the Layer 3 Device A. Main requirements are as follows:

- Hosts of an enterprise can communicate with each other but the host communication between enterprises is isolated.
- All enterprise hosts share the same gateway address and can communicate with the external network through this gateway address.
- All enterprise hosts can access the server.

The deployment mode is as follows:



- Add all enterprise hosts to the same PVLAN (for example, primary VLAN 2). Assign hosts of enterprise A to community VLAN 10, hosts of enterprise B to community VLAN 20, and hosts of enterprises C and D to

isolated VLAN 30.

- Configure the SVI gateway (for example, 192.168.2.1/24) of the PVLAN on the Layer 3 device A and configure the mappings between the primary VLAN and the secondary VLANs on the Layer 3. Then, all enterprise hosts can communicate with the external network through this gateway address.
- Configure the port directly connected to the server as a promiscuous port. All enterprise hosts can communicate with the server through the promiscuous port.

2. Topology

Figure 1-3 Topology of PVLAN Applied on a Single Layer 3 Device

3. Notes

- Configure the PVLAN function on Device A. VLAN 2 is the primary VLAN. VLAN 10, VLAN 20, and VLAN 30 are secondary VLANs.
- Configure GigabitEthernet 0/7 that is directly connected to the server as a promiscuous port. Then, all enterprise hosts can communicate with the server through the promiscuous port.
- Configure GigabitEthernet 0/8 of Device A that is connected to an external network as a promiscuous port. Set the IP address of the gateway SVI to 192.168.2.1/24 and configure a Layer 3 associations between the primary VLAN 2 and the secondary VLANs (VLAN 10, VLAN 20, and VLAN 30). All enterprise hosts can communicate with an external network based on this gateway IP address.

4. Procedure

(1) Configure a Layer 2 association between the primary VLAN and the secondary VLANs.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan 10
DeviceA(config-vlan)# private-vlan community
DeviceA(config-vlan)# exit
DeviceA(config)# vlan 20
DeviceA(config-vlan)# private-vlan community
```

```
DeviceA(config-vlan)# exit
DeviceA(config)# vlan 30
DeviceA(config-vlan)# private-vlan isolated
DeviceA(config-vlan)# exit
DeviceA(config)# vlan 2
DeviceA(config-vlan)# private-vlan primary
DeviceA(config-vlan)# private-vlan association 10,20,30
DeviceA(config-vlan)# exit
```

(2) Configure the ports connected to hosts as host ports and associate the ports with the primary VLAN and secondary VLANs to add the ports to the secondary VLANs.

```
DeviceA(config)# interface range gigabitethernet 0/1-2
DeviceA(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode private-vlan host
DeviceA(config-if-range)# switchport private-vlan host-association 2 10
DeviceA(config-if-range)# exit
DeviceA(config)# interface range gigabitethernet 0/3-4
DeviceA(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode private-vlan host
DeviceA(config-if-range)# switchport private-vlan host-association 2 20
DeviceA(config-if-range)# exit
DeviceA(config)# interface range gigabitethernet 0/5-6
DeviceA(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode private-vlan host
DeviceA(config-if-range)# switchport private-vlan host-association 2 30
DeviceA(config-if-range)# exit
```

(3) Configure GigabitEthernet 0/7 connected to the server as a promiscuous port and associate the port with the primary VLAN and the secondary VLANs to add the port to the primary VLAN.

```
DeviceA(config)# interface gigabitethernet 0/7
DeviceA(config-if-GigabitEthernet 0/7)# switchport
DeviceA(config-if-GigabitEthernet 0/7)# switchport mode private-vlan promiscuous
DeviceA(config-if-GigabitEthernet 0/7)# switchport private-vlan mapping 2
10,20,30
DeviceA(config-if-GigabitEthernet 0/7)# exit
```

(4) Configure GigabitEthernet 0/8 connected to an external network as a promiscuous port and associate the port with the primary VLAN and the secondary VLANs to add the port to the primary VLAN.

```
DeviceA(config)# interface gigabitethernet 0/8
DeviceA(config-if-GigabitEthernet 0/8)# switchport
DeviceA(config-if-GigabitEthernet 0/8)# switchport mode private-vlan promiscuous
DeviceA(config-if-GigabitEthernet 0/8)# switchport private-vlan mapping 2
10,20,30
DeviceA(config-if-GigabitEthernet 0/8)# exit
```

(5) Create an SVI for the primary VLAN, configure an SVI address, and configure a Layer 3 association for the PVLAN.

```
DeviceA(config)# interface vlan 2
```

```
DeviceA(config-if-VLAN 2)# ip address 192.168.2.1 255.255.255.0
DeviceA(config-if-VLAN 2)# private-vlan mapping 10,20,30
DeviceA(config-if-VLAN 2)# end
DeviceA# write
```

5. Verification

(1) Check whether the PVLAN and port configurations are correct.

```
DeviceA# show vlan private-vlan
VLAN   Type      Status   Routed   Ports         Associated VLANs
-----  ---------  -------  -------  ------------   -------------------
2     primary    active   Enabled  Gi0/7, Gi0/8   10,20,30
10    community  active    Enabled  Gi0/1, Gi0/2    2
20    community  active    Enabled  Gi0/3, Gi0/4    2
30    isolated   active    Enabled  Gi0/5, Gi0/6    2
```

(2) Configure IP addresses and masks for hosts.

Configure an IP address and a mask for host 11.

```
Host11> enable
Host11# configure terminal
Host11(config)# interface gigabitethernet 0/1
Host11(config-if-GigabitEthernet 0/1)# no switchport
Host11(config-if-GigabitEthernet 0/1)# ip address 192.168.2.11 255.255.255.0
```

Configure an IP address and a mask for host 12.

```
Host12> enable
Host12# configure terminal
Host12(config)# interface gigabitethernet 0/1
Host12(config-if-GigabitEthernet 0/1)# no switchport
Host12(config-if-GigabitEthernet 0/1)# ip address 192.168.2.12 255.255.255.0
```

Configure an IP address and a mask for host 21.

```
Host21> enable
Host21# configure terminal
Host21(config)# interface gigabitethernet 0/1
Host21(config-if-GigabitEthernet 0/1)# no switchport
Host21(config-if-GigabitEthernet 0/1)# ip address 192.168.2.21 255.255.255.0
```

(3) Check whether packets from the hosts in the PVLAN are forwarded in accordance with the forwarding rules of the PVLAN ports.

Hosts in the same community VLAN can communicate with each other. Hosts in different community VLANs cannot communicate with each other.

```
Host11# ping 192.168.2.12
Sending 5, 100-byte ICMP Echoes to 192.168.2.12, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/3 ms.
```

```
Host11# ping 192.168.2.21
Sending 5, 100-byte ICMP Echoes to 192.168.2.21, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5).
```

Hosts in an isolated VLAN cannot communicate with each other (the specific process is omitted).

Hosts in a community VLAN cannot communicate with hosts in an isolated VLAN (the specific process is omitted).

Hosts in a community VLAN and hosts in an isolated VLAN can communicate with an external network through the promiscuous port (the specific process is omitted).

Promiscuous ports can communicate with each other (the specific process is omitted).

6. Configuration Files

Device A configuration file

```
vlan 2
 private-vlan primary
 private-vlan association add 10,20,30
!
vlan 10
 private-vlan community
!
vlan 20

switchport
 switchport mode private-vlan host
 switchport private-vlan host-association 2 30
!
interface GigabitEthernet 0/7
switchport
 switchport mode private-vlan promiscuous
 switchport private-vlan mapping 2 add 10,20,30
!
interface GigabitEthernet 0/8
switchport
 switchport mode private-vlan promiscuous
 switchport private-vlan mapping 2 add 10,20,30
!
interface VLAN 2
private-vlan mapping add 10,20,30
ip address 192.168.2.1 255.255.255.0
```

7. Common Errors

- No Layer 2 association is configured between the primary VLAN and the secondary VLANs of a PVLAN. As a result, configuring a Layer 3 association fails.
- No Layer 3 association is configured. As a result, hosts cannot communicate with the external network.
- The ports connecting to the server and the external network are not configured as promiscuous ports. Therefore, uplink and downlink configurations are asymmetric, causing a packet forwarding failure.

1 Configuring Super-VLAN

1.1 Introduction

1.1.1 Overview

Super virtual local area network (VLAN), also referred to as VLAN aggregation, is a VLAN assignment method.

A common VLAN corresponds to a subnet and is used to complete Layer 3 communication with another VLAN based on a gateway IP address.

The super-VLAN technology allows you to configure common VLANs as sub-VLANs, aggregate them into one super-VLAN, assign only one IP address to the super-VLAN as the gateway IP address to implement inter-VLAN Layer 3 communication. This technology saves IP address resources and facilitates network management.

1.1.2 Background and Function

1. Background

A common VLAN corresponds to a logical subnet and is isolated from other VLANs at Layer 2. Each subnet must be assigned with a gateway IP address to implement inter-VLAN Layer 3 communication. In addition to the gateway IP address, each subnet also requires a subnet ID and a subnet-directed broadcast IP address as dedicated addresses. These three addresses cannot be assigned to hosts.

Suppose that a local area network (LAN) covers three departments and therefore requires three VLANs. The VLAN IDs and hosts of the three departments are as follows: VLAN 10 (31 hosts), VLAN 20 (44 hosts), and VLAN 30 (128 hosts). There are 203 hosts in total. The network segment 192.168.1.0/24 has 256 IP addresses, which are assigned to the three departments to meet network requirements. A device performs a logical "AND" operation on IP addresses and subnet masks in binary format to identify the subnet, to which the hosts belong. The VLAN assignment result is as follows:

- VLAN 10 requires 31 host addresses and 3 dedicated addresses, totaling 34 addresses. VLAN 10 needs to be assigned with 64 IP addresses (2^6) with the subnet mask of /26.

  IP address range: 192.168.1.0 to 192.168.1.63 = 11000000.10101000.00000001.(00000000 to 00111111)

  Subnet mask (/26): 255.255.255.192 = 11111111.11111111.11111111.11000000

  Network ID obtained via logical "AND" operation in binary format: 192.168.1.0 = 11000000.10101000.00000001.00000000

  Gateway IP address: 192.168.1.1 = 11000000.10101000.00000001.00000001

  Subnet-directed broadcast IP address: 192.168.1.63 = 11000000.10101000.00000001.00111111

  Host IP address: 192.168.1.2 to 192.168.1.62 (31 hosts must be assigned with 61 addresses, and therefore 30 addresses are wasted)

- VLAN 20 requires 44 host addresses and 3 dedicated addresses, totaling 47 addresses. VLAN 20 needs to be assigned with 64 addresses (2^6) with the subnet mask of /26.

  IP address range: 192.168.1.64 to 192.168.1.127 = 11000000.10101000.00000001.(01000000 to 01111111)

Subnet mask (/26): 255.255.255.192 = 11111111.11111111.11111111.11000000

Network ID obtained via logical "AND" operation in binary format: 192.168.1.64 = 11000000.10101000.00000001.01000000

Gateway IP address: 192.168.1.65 = 11000000.10101000.00000001.01000001

Subnet-directed broadcast IP address: 192.168.1.127 = 11000000.10101000.00000001.01111111

Host IP address: 192.168.1.66 to 192.168.1.126 (44 hosts must be assigned with 61 addresses, and therefore 17 addresses are wasted)

- Only 125 addresses are available to VLAN 30 that includes 128 hosts.

  IP address range: 192.168.1.128 to 192.168.1.255 = 11000000.10101000.00000001.(10000000 to 11111111)

  Subnet mask (/25): 255.255.255.128 = 11111111.11111111.11111111.10000000

  Network ID obtained via logical "AND" operation in binary format: 192.168.1.128 = 11000000.10101000.00000001.10000000

  Gateway IP address: 192.168.1.129 = 11000000.10101000.00000001.10000001

  Subnet-directed broadcast IP address: 192.168.1.255 = 11000000.10101000.00000001.11111111

  Host IP address: 192.168.1.130 to 192.168.1.254 (128 hosts are assigned with only 125 addresses)

It can be inferred from the assignment method that if each VLAN is assigned with a subnet, 9 dedicated addresses are required and 47 (30 + 17) host addresses are wasted. Though the network segment 192.168.1.0/24 contains 256 addresses, they cannot meet the IP address requirements of the 203 hosts.

This assignment method also lacks flexibility. If you add hosts to VLAN 20, exceeding the limit 64, you have to add the new hosts to another VLAN and assign IP addresses of another network segment to the new hosts unless you change the original IP address assignment policy. As a result, hosts from the same department do not belong to the same network segment.

To avoid the IP address waste and address assignment management problems, the super-VLAN technology is developed.

2. Function

The super-VLAN technology is used to aggregate multiple sub-VLANs into one super-VLAN.

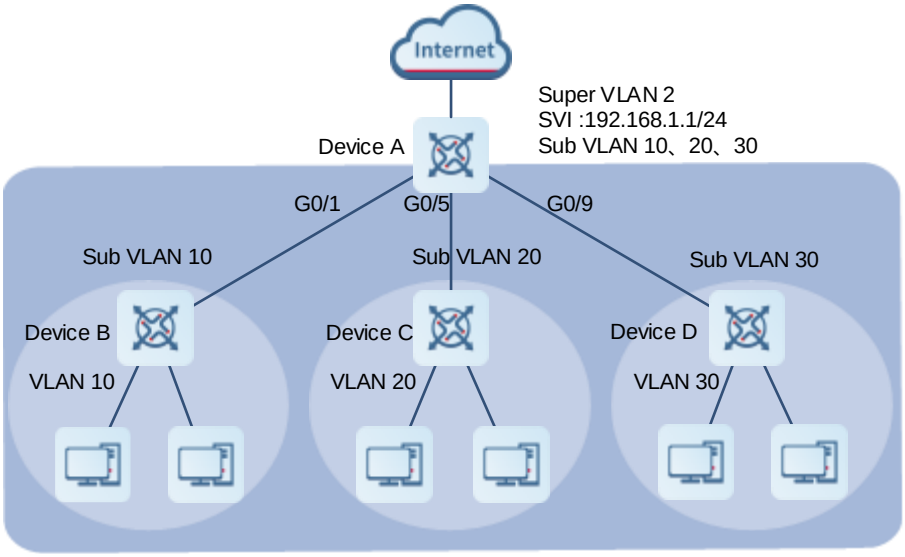
Layer 2 isolation is implemented by sub-VLANs, and Layer 3 interconnection is implemented by super-VLANs.

A super-VLAN corresponds to a logical subnet, and all sub-VLANs in the super-VLAN belong to this subnet and share the same network ID, gateway IP address, and subnet-directed broadcast IP address. This saves IP address resources and improves network management flexibility.

3. Features

- Super-VLAN

  A super-VLAN corresponds to a network segment. Switch virtual interfaces (SVIs) can be created only in super-VLANs, but no physical port can be added to the super-VLANs. Super-VLAN manages inter-VLAN communication of sub-VLANs by using the SVIs. A super-VLAN cannot be considered as an IEEE 802.1Q VLAN. A super-VLAN has only Layer 3 attributes of a common VLAN.



- Sub-VLAN

Each sub-VLAN is an independent broadcast domain, and is isolated from other sub-VLANs at Layer 2. A sub-VLAN belongs to only one super-VLAN. No SVI can be created in a sub-VLAN, which can contain only physical ports. A sub-VLAN has only Layer 2 attributes of a common VLAN. To implement Layer 3 communication across broadcast domains, sub-VLANs must use the SVIs of the super-VLAN.

4. Application

After the super-VLAN technology is applied to the case described in Background, the network segment 192.168.1.0/24 can meet the requirement for IP addresses. As shown in Figure 1-1, on Device A, VLAN 2 is configured as a super-VLAN, SVI address 192.168.1.1/24 as the gateway address, and VLAN 10, VLAN 20 and VLAN 30 as sub-VLANs. Hosts are isolated at Layer 2 through sub-VLANs and make Layer 3 communication with hosts in other network segments based on the common gateway IP address. The network segment accommodates IP addresses ranging from 192.168.1.2 to 192.168.1.254. A total of 253 IP addresses can be assigned to the 203 hosts in the sub-VLANs, and there are some idle addresses left. Devices B, C, and D are used to expand the access ports and configured with VLAN 10, VLAN 20, and VLAN 30, respectively.

Figure 1-1 Application of Super-VLAN

1.1.3 Principles

1. Communication in a Sub-VLAN

A common VLAN corresponds to a subnet, and hosts in the subnet belong to the same broadcast domain. When a host (source host) in a common VLAN sends a packet, the host determines whether the destination host is in the same subnet as the source host. If yes, the host broadcasts an Address Resolution Protocol (ARP) request to request and obtain the MAC address of the destination host, and then completes Layer 2 communication with the destination host. If not, the host broadcasts an ARP request to request and obtain the MAC address of the gateway, and then forwards the packet to the gateway for Layer 3 communication.

In a super-VLAN, when a host (source host) in a sub-VLAN sends a packet, the host determines whether the destination host is in the same subnet as the source host and whether they belong to the same sub-VLAN. If yes, the communication procedure is similar to the Layer 2 communication procedure of a common VLAN. The communication steps are as follows:

(1) The source host determines that the destination host is in the same subnet as the source host but the destination MAC address is unknown. The source host broadcasts an ARP request to request the destination MAC address.

(2) A switch learns the MAC address and forwards the ARP broadcast request to all ports except the source port in the sub-VLAN.

(3) Upon receiving the ARP request, the destination host in the sub-VLAN sends a unicast ARP reply to the source host.

(4) The switch learns the MAC address and forwards the ARP reply packet.

(5) Upon receiving the ARP reply packet, the source host obtains the destination MAC address and then can realize Layer 2 communication with the destination host.

2. Communication Between Different Sub-VLANs in a Super-VLAN

Though the sub-VLANs in a super-VLAN belong to the same subnet, they are isolated at Layer 2 and belong to different broadcast domains. When a host (source host) in a sub-VLAN tries to communicate with a host (destination host) in another sub-VLAN of the super-VLAN, the communication initially follows an Layer 2 forwarding procedure because the source host does not know it is isolated from the destination host. In this case, communication between different sub-VLANs relies on proxy ARP of a switch. The actual communication procedure is completed at Layer 3. The communication steps are as follows.

(1) The source host determines that the destination host is in the same subnet as the source host but the destination MAC address is unknown. The source host broadcasts an ARP request to request the destination MAC address.

(2) A switch learns the source MAC address and forwards the ARP request to all ports except the source port in the sub-VLAN.

(3) Hosts in other sub-VLANs cannot receive this ARP request. Therefore, no ARP reply is sent to the switch. After a specified period of time, the switch enables proxy ARP, replaces the source MAC address in the request packet with the gateway MAC address of the super-VLAN, and broadcasts the ARP request in all sub-VLANs of the super-VLAN to request the destination MAC address.

Note

- The IP addresses in sub-VLANs may be discontinuous and dynamic due to the address assignment policy of a Dynamic Host Configuration Protocol (DHCP) server or capacity expansion. This makes the super-VLAN unable to identify the sub-VLAN, to which the destination IP address belongs. Therefore, the broadcast packet is sent to all sub-VLANs in the super-VLAN by default.
- You can configure an IP address range for each sub-VLAN so that the broadcast packet can be sent to a specific sub-VLAN based on the IP address. In this case, the DHCP function must be disabled, because the IP addresses assigned by this function may fall out of the IP address range of a specific sub-VLAN. The configured static IP addresses must be within the IP address range of a specific sub-VLAN. Otherwise, communication between sub-VLANs cannot be realized.
- You can configure a sub-VLAN as a broadcast VLAN so that broadcast packets sent by the super-VLAN are destined to this sub-VLAN. However, this configuration may cause the failure of the destination host to receive the ARP broadcast request, resulting in a communication exception.

(4) Upon receiving the ARP request, the destination host in another sub-VLAN learns the mapping between the gateway MAC address and the source IP address and sends a unicast ARP reply to the gateway.

(5) The switch learns the following mapping of the destination host: "IP address – MAC address – sub-VLAN – port". The switch replaces the destination MAC address with the gateway MAC address and sends the unicast ARP reply to the source host.

(6) Upon receiving the ARP reply, the source host regards the gateway MAC address as the destination MAC address, learns the mapping between the gateway MAC address and the destination IP address, and completes Layer 3 communication through the proxy gateway.

The process in which the gateway replaces the source MAC address with the gateway MAC address to send an ARP request and the process in which the gateway replaces the destination MAC address with the gateway MAC address to send an ARP reply are referred to as proxy ARP. Communication across broadcast domains needs to rely on proxy ARP.

3. Communication Between Super-VLANs

Different super-VLANs correspond to different subnets and the destination host and source host in different super-VLANs belong to different broadcast domains. The source host can determine that the destination host is in a different broadcast domain based on the IP address network segment. The communication process is similar to the communication between different network segments of common VLANs. In this communication procedure, the gateway also performs proxy ARP. However, the gateway is an SVI of the super-VLAN rather than the SVI of a common VLAN.

4. Inter-Device Layer 2 Communication

Super-VLAN works at Layer 3. The SVI of a super-VLAN is used as a gateway only in Layer 3 communication across broadcast domains (across network segments or in the same network segment). The VLAN ID of a super-VLAN is not used in Layer 2 communication.

No physical port can be added to a super-VLAN. On a device where a super-VLAN is configured, packets with containing VLAN ID of the super-VLAN cannot pass through any port of the device.

As shown in Figure 1-1, VLAN 2 is configured as a super-VLAN on Device A. Assume that VLAN 2 is configured as a common VLAN on Device B. When Device A receives a packet from VLAN 2 on Device B, Device A discards this packet.

The communication between sub-VLAN 10 on Device A and VLAN 10 on Device B is inter-device Layer 2 communication. Their connected interfaces must allow packets of sub-VLAN 10 to pass so that the packets can be forwarded by the interface. If packets are tagged, the VLAN ID in the tags is the VLAN ID of sub-VLAN 10.

1.2 Configuration Task Summary

The configuration includes the following tasks:

(1) Configure a super-VLAN and sub-VLANs.

a Configuring Layer 2 Association for a

b Configuring Layer 3 Communication for a

c (Optional) Configuring an IP Address Range for a

d (Optional) Configuring a Broadcast VLAN

(2) Configure ports and add the ports to the sub-VLANs. For more information, see *Configuring VLAN*.

1.3 Configuring Layer 2 Association for a Super-VLAN

1.3.1 Overview

You can configure a common VLAN as a super-VLAN, configure other common VLANs as sub-VLANs, and add the sub-VLANs to the super-VLAN. A sub-VLAN is a broadcast domain, hosts in a sub-VLAN can make Layer 2 communication with each other but are Layer 2 isolated from hosts outside the sub-VLAN.

1.3.2 Restrictions and Guidelines

- Super-VLAN
  - VLAN 1 cannot be configured as a super-VLAN.
  - No physical port can be added to a super-VLAN. After a common VLAN is configured as a super-VLAN, the ports that have been added to the VLAN exit the VLAN and are added to VLAN 1.
  - A super-VLAN does not belong to any physical port. Therefore, the device configured with the super-VLAN cannot process packets that contain the super-VLAN tag.
  - A super-VLAN cannot be configured as a sub-VLAN of another super-VLAN. A sub-VLAN of a super-VLAN cannot be configured as a super-VLAN.
  - You can use the **no supervlan** command to restore a super-VLAN and all its sub-VLANs to common VLANs. You must restore a super-VLAN to a common VLAN before deleting this super-VLAN by running the **no vlan** command.
- Sub-VLAN
  - You must configure sub-VLANs for a super-VLAN so that the super-VLAN is valid.
  - VLAN 1 cannot be configured as a sub-VLAN.
  - You can configure multiple super-VLANs on a device. A sub-VLAN can be added to one super-VLAN only and the sub-VLANs in different super-VLANs must be unique.
  - Avoid configuring too many sub-VLANs. A broadcast packet of a super-VLAN is sent to all its sub-VLANs by default. The configuration of too many sub-VLANs will degrade the performance.
  - Physical ports can be added to a sub-VLAN. A common VLAN configured with an Layer 3 SVI cannot be configured as a sub-VLAN.
  - You must restore a sub-VLAN to a common VLAN by running the **no subvlan** command before deleting this sub-VLAN by running the **no vlan** command. In super-VLAN configuration mode, you can use the **no subvlan** [*vlan-id-list*] command to restore a specific sub-VLAN in the super-VLAN to a common VLAN.

1.3.3 Procedure

(1) Create a common VLAN to be configured as a sub-VLAN.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create a common VLAN to be configured as a sub-VLAN.

vlan { *vlan-id* | **range** *vlan-range* }

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

(2) Create a common VLAN to be configured as a super-VLAN and enter the VLAN configuration mode.

vlan *vlan-id*

Only VLAN 1 exists by default.

(3) Configure a common VLAN as a super-VLAN.

supervlan

No super-VLAN is configured by default.

(4) Add the common VLAN to the super-VLAN to make the common VLAN a sub-VLAN of the super-VLAN.

subvlan *vlan-id-list*

No common VLAN is added to a super-VLAN as a sub-VLAN by default.

1.4 Configuring Layer 3 Communication for a Super-VLAN

1.4.1 Overview

A super-VLAN corresponds to a logical subnet. No physical port can be added to a super-VLAN and only a Layer 3 SVI can be configured for the super-VLAN. IP addresses must be configured for Layer 3 SVIs. Sub-VLANs of a super-VLAN share the gateway address of the super-VLAN and reside in the same network segment.

Proxy ARP must be enabled on the super-VLAN and sub-VLANs so that hosts in the sub-VLANs can implement Layer 3 communication across broadcast domains through proxy ARP of the super-VLAN.

1.4.2 Restrictions and Guidelines

- An SVI and an IP address must be configured for a super-VLAN. The SVI is a virtual interface used for communication between sub-VLANs. You cannot configure an SVI for a sub-VLAN.
- In the **interface vlan** *interface-number* command, *interface-number* indicates the SVI number, which must be the ID of the VLAN to which the SVI belong. The value range is 1-4094.
- When you configure an SVI for a super-VLAN, the system assigns a Layer 3 interface invisible to hosts to each sub-VLAN in the super-VLAN. The system may restore some sub-VLANs to common VLANs due to resource deficiency. After an SVI is configured for a super-VLAN, the attempt of adding sub-VLANs may fail due to resource deficiency.
- Proxy ARP must be configured in VLAN configuration mode. Proxy ARP must be enabled on both the super-VLAN and its sub-VLANs so that Layer 3 communication can be implemented. Proxy ARP is enabled by default. To isolate communication between sub-VLANs, you can use the **no proxy-arp** command to disable proxy ARP.
- To configure an IPv4 address, see Configuring IPv4.
- To configure an IPv6 address, see Configuring IPv6.

1.4.3 Procedure

(1) Configure a gateway for a super-VLAN.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create an SVI for the super-VLAN and enter the SVI configuration mode.

interface vlan *interface-number*

No SVI exists in a VLAN by default.

d Configure an IP address and a subnet mask for the gateway of the super-VLAN.

ip address { *ipv4-address mask* | *ipv4-address/mask-length* }

No IP address is configured for an SVI by default.

e Return to the global configuration mode.

exit

(2) (Optional) Enable proxy ARP.

a Enter the VLAN configuration mode of the super-VLAN and sub-VLAN.

vlan { *vlan-id* | **range** *vlan-range* }

b Enable proxy ARP for the super-VLAN and the sub-VLAN.

proxy-arp

Proxy ARP is enabled for the super-VLAN and the sub-VLAN by default.

1.5 Configuring an IP Address Range for a Sub-VLAN

1.5.1 Overview

The gateway IP address and subnet mask of a super-VLAN jointly determine the subnet range. A super-VLAN sends a broadcast packet to all sub-VLANs in the super-VLAN by default. To limit the broadcast range, you can configure an IP address range for each sub-VLAN so that the super-VLAN can send a broadcast packet to a specific sub-VLAN based on an IP address range. The IP addresses of hosts must be within the IP address range of the local sub-VLAN. Otherwise, the hosts cannot make Layer 3 communication. Unless otherwise specified, you do not need to configure an IP address range for a sub-VLAN.

1.5.2 Restrictions and Guidelines

- The IP address range of a sub-VLAN must be within the gateway IP address range of the super-VLAN that the sub-VLAN belongs to.
- IP address ranges for different sub-VLANs of a super-VLAN cannot overlap.
- IP addresses (both static and dynamic IP addresses) of hosts in a sub-VLAN must be within the IP address range of the sub-VLAN. Otherwise, hosts in the sub-VLAN cannot make Layer 3 communication.
- The IP addresses assigned by the DHCP function may fall out of the IP address range you specify for a sub-VLAN. If the IP addresses assigned by the DHCP function fall out of the specified IP address range,

hosts in the sub-VLAN cannot communicate with an external network. Therefore, you are not advised to configure an IP address range for a sub-VLAN if DHCP is used to dynamically assign IP addresses to hosts.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the sub-VLAN configuration mode.

vlan *vlan-id*

(4) Configure the IP address range for users in the sub-VLAN.

subvlan-address-range *start-ipv4-address end-ipv4-address*

No IP address range is configured for users in the sub-VLAN by default.

1.6 Configuring a Broadcast VLAN

1.6.1 Overview

A super-VLAN sends a broadcast packet to all sub-VLANs in the super-VLAN by default. To limit the broadcast range, you can configure a sub-VLAN as a broadcast VLAN so that broadcast packets of the super-VLAN are sent in only this sub-VLAN.

1.6.2 Restrictions and Guidelines

Only a sub-VLAN of a super-VLAN can be configured as a broadcast VLAN. Only one broadcast VLAN can be configured for a super-VLAN. A later configured broadcast VLAN overwrites a previously configured broadcast VLAN.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the super-VLAN configuration mode.

vlan { *vlan-id* | **range** *vlan-range* }

(4) Configure a broadcast VLAN.

bcast vlan *sub-vlan-id*

No broadcast VLAN exists by default. A super-VLAN sends broadcast packets to all of its sub-VLANs.

1.7 Monitoring

Run the **show** commands to check the running status of a configured function and verify the configuration effect.

Run the **debug** command to output debugging information.

Caution

System resources are occupied when debugging information is output. Therefore, disable the debugging function immediately after use.

You can run the **clear** commands to clear information.

Caution

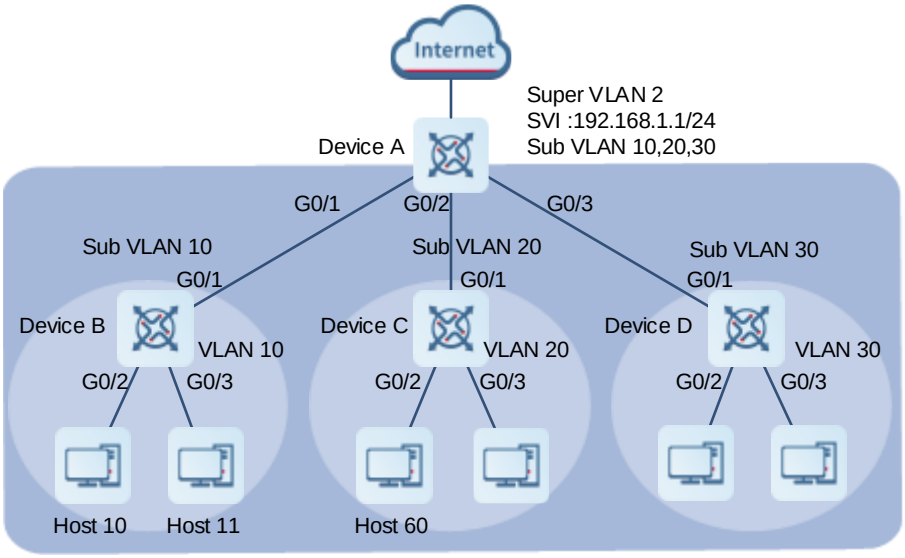
Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
show supervlan [**id** *super-vlan-id*]	Displays the configuration of super-VLAN and sub-VLAN.
debug bridge svlan	Debugs the super-VLAN function.

1.8 Configuration Examples

1.8.1 Configuring Super-VLAN



1. Requirements

A super-VLAN 2 is configured and the network segment 192.168.1.0/24 is assigned to the super-VLAN. Sub-VLANs 10, 20 and 30 are added to the super-VLAN. Hosts in the sub-VLANs are in the same network segment and share a gateway IP address 192.168.1.1/24 to save IP addresses. Hosts are assigned static IP addresses. IP address ranges are configured for the three sub-VLANs.

- Sub-VLAN 10: 192.168.1.10/24 to 192.168.1.50/24
- Sub-VLAN 20: 192.168.1.60/24 to 192.168.1.100/24
- Sub-VLAN 30: 192.168.1.110/24 to 192.168.1.150/24

2. Topology

Figure 1-2 Application of Super-VLAN

3. Notes

- Configure a super-VLAN and sub-VLANs on Device A (core device).
- Configure the common VLANs on Devices B, C, and D (access devices) that correspond to the sub-VLANs on Device A.

4. Procedure

(1) Create a common VLAN to be configured as a sub-VLAN.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan range 10,20,30
DeviceA(config-vlan-range)# exit
```

(2) Create VLAN 2, configure VLAN 2 as a super-VLAN, configure VLANs 10, 20 and 30 as sub-VLANs of the super-VLAN, and configure VLAN 10 as a broadcast VLAN of the super-VLAN.

```
DeviceA(config)# vlan 2
DeviceA(config-vlan)# supervlan
DeviceA(config-vlan)# subvlan 10,20,30
DeviceA(config-vlan)# bcast vlan 10
DeviceA(config-vlan)# exit
```

(3) Configure a gateway for the super-VLAN.

```
DeviceA(config)# interface vlan 2
DeviceA(config-if-VLAN 2)# ip address 192.168.1.1 255.255.255.0
DeviceA(config-if-VLAN 2)# exit
```

(4) Configure IP address ranges for the sub-VLANs.

```
DeviceA(config)# vlan 10
```

```
DeviceA(config-vlan)# subvlan-address-range 192.168.1.10 192.168.1.50
DeviceA(config-vlan)# exit
DeviceA(config)# vlan 20
DeviceA(config-vlan)# subvlan-address-range 192.168.1.60 192.168.1.100
DeviceA(config-vlan)# exit
DeviceA(config)# vlan 30
DeviceA(config-vlan)# subvlan-address-range 192.168.1.110 192.168.1.150
DeviceA(config-vlan)# exit
```

(5) Configure GigabitEthernet 0/1, 0/2, and 0/3 as trunk ports, and add them to the sub-VLANs.

```
DeviceA(config)# interface range gigabitethernet 0/1,0/2,0/3
DeviceA(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode trunk
DeviceA(config-if-range)# end
DeviceA(config-if-range)# switchport trunk native vlan 1
DeviceA(config-if-range)# switchport trunk allowed vlan all
DeviceA# write
```

5. Verification

(1) Check the super-VLAN configuration.

```
DeviceA(config)# show supervlan
supervlan id  supervlan arp-proxy  bcast vlan  subvlan id  subvlan arp-proxy
subvlan ip range
------------  -------------------  ----------  ----------  -----------------
----------------
2           ON                10          10        ON    192.168.1.10 -
192.168.1.50
                                          20        ON    192.168.1.60 -
192.168.1.100
                                          30        ON    192.168.1.110 -
192.168.1.150
```

(2) Check ports that are added to VLANs.

```
DeviceA(config)# show vlan
VLAN      Name                            Status    Ports
---------- -------------------------------- ---------
-----------------------------------
       2 VLAN0002                         SUPER
      10 VLAN0010                          SUB      Gi0/1, Gi0/2, Gi0/3
      20 VLAN0020                          SUB      Gi0/1, Gi0/2, Gi0/3
      30 VLAN0030                          SUB      Gi0/1, Gi0/3, Gi0/3
```

(3) Verify that hosts in a sub-VLAN can make Layer 2 communication with each other.

On host 10 in sub-VLAN 10, set the default gateway address to the gateway IP address of the super-VLAN 192.168.1.1 and the IP address in the IP address range of the sub-VLAN (that is, 192.168.1.10 to 192.168.1.50).

```
Host10> enable
```

```
Host10# configure terminal
Host10(config)# ip route 192.168.1.0 255.255.255.0 192.168.1.1
Host10(config)# interface gigabitethernet 0/1
Host10(config-if-GigabitEthernet 0/1)# no switchport
Host10(config-if-GigabitEthernet 0/1)# ip address 192.168.1.10 255.255.255.0
```

On host 11 in sub-VLAN 10, set the default gateway address to the gateway IP address of the super-VLAN 192.168.1.1 and the IP address in the IP address range of the sub-VLAN (that is, 192.168.1.10 to 192.168.1.50).

```
Host11> enable
Host11# configure terminal
Host11(config)# ip route 192.168.1.0 255.255.255.0 192.168.1.1
Host11(config)#interface gigabitethernet 0/1
Host11(config-if-GigabitEthernet 0/1)# no switchport
Host11(config-if-GigabitEthernet 0/1)# ip address 192.168.1.11 255.255.255.0
```

Verify that host 10 can ping host 11 no matter whether the gateway IP address of the super-VLAN is configured on Device A.

```
Host10# ping 192.168.1.11
Sending 5, 100-byte ICMP Echoes to 192.168.1.11, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/3 ms.
```

Set the IP address of host 11 to 192.168.1.51/24, which falls out of the IP address range of the sub-VLAN, and verify that the communication of host 11 in the sub-VLAN is not affected.

```
Host11(config-if-GigabitEthernet 0/1)# ip address 192.168.1.51 255.255.255.0
Host10# ping 192.168.1.51
Sending 5, 100-byte ICMP Echoes to 192.168.1.51, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/21/97 ms.
```

(4) Verify that hosts in different sub-VLANs can make Layer 3 communication but are isolated at Layer 2.

On host 60 in sub-VLAN 20, set the default gateway address to the gateway IP address of the super-VLAN 192.168.1.1 and the IP address in the IP address range of the sub-VLAN (that is, 192.168.1.60 to 192.168.1.100).

```
Host60> enable
Host60# configure terminal
Host60(config)# ip route 192.168.1.0 255.255.255.0 192.168.1.1
Host60(config)# interface gigabitethernet 0/1
Host60(config-if-GigabitEthernet 0/1)# no switchport
Host60(config-if-GigabitEthernet 0/1)# ip address 192.168.1.60 255.255.255.0
```

Configure an SVI and a gateway IP address for super-VLAN 2, and verify that host 60 (192.168.1.60/24) can ping host 10 (192.168.1.10/24) and that host 60 cannot ping host 11 (192.168.1.51/24) because host 11 falls out of the IP address range of the sub-VLAN.

```
Host60# ping 192.168.1.10
```

```
Sending 5, 100-byte ICMP Echoes to 192.168.1.10, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/19/95 ms.
Host60# ping 192.168.1.51
Sending 5, 100-byte ICMP Echoes to 192.168.1.51, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5).
```

Delete the gateway IP address of super-VLAN 2, and verify that host 60 (192.168.1.60/24) cannot ping host 10 (192.168.1.10/24).

```
DeviceA(config)# interface vlan 2
DeviceA(config-if-VLAN 2)# no ip address
%notice: all IPv4 addresses on this interface are removed.
Host60# ping 192.168.1.10
Sending 5, 100-byte ICMP Echoes to 192.168.1.10, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5).
```

6. Configuration Files

- Device A configuration file

```
vlan 2
 supervlan
 subvlan 10,20,30
 bcast vlan 10
!
vlan 10
 subvlan-address-range 192.168.1.10 192.168.1.50

7. Common Errors

- An SVI is configured for a common VLAN before the VLAN is configured as a sub-VLAN. As a result, the common VLAN cannot be configured as a sub-VLAN of a super-VLAN.
- No SVI and gateway IP address are configured for a super-VLAN. Consequently, communication between sub-VLANs and between sub-VLANs and other VLANs fails.
- Proxy ARP is disabled on the super-VLAN or sub-VLANs. Consequently, communication between the sub-VLANs fails.
- An IP address range is configured for a sub-VLAN. However, the static or dynamic IP addresses allocated to hosts in the sub-VLAN are not in this range. Consequently, the hosts cannot make Layer 3 communication.

1 Configuring Voice VLAN

1.1 Introduction

1.1.1 Overview

A voice virtual local area network (VLAN) is a VLAN dedicated to voice traffic of users. The voice VLAN technology constrains data traffic and voice traffic in the data VLAN and the voice VLAN, respectively, to prevent mutual interference between voice calls and data services and improve call quality.

1.1.2 Background and Function

- Background

Voice over IP (VoIP) telephones are widely used thanks to rapid development of technologies. Packet loss and latency greatly affect the quality of voice calls and users are more sensitive to the reduction of the quality of voice calls than the reduction of the quality of data or videos. Therefore, when the bandwidth is limited, it is necessary to guarantee the quality of voice data first so as to ensure the quality of voice calls.

- Functions of voice VLAN
  - a Identifies voice traffic.
  - b Supports automatic or manual adding of ports to a voice VLAN.
  - c Delivers Quality of Service (QoS) policies for voice traffic to improve the transmission priority of the voice traffic.
  - d Transmits voice data in a voice VLAN to ensure quality of voice calls.

1.1.3 Identifying Voice Traffic

Before assigning voice traffic to a voice VLAN, a switch device should be able to identify the voice traffic. Two methods can be used for the switch to identify voice data:

- Identifying voice data based on the Organizationally Unique Identifier (OUI) in the source MAC address of a packet

The source MAC address of a voice packet contains the OUI of a voice device vendor. After a voice VLAN OUI is configured, the device compares the source MAC address in a received packet with the voice VLAN OUI. If they match, the device can identify the voice packet and assign the packet to the voice VLAN.

Note

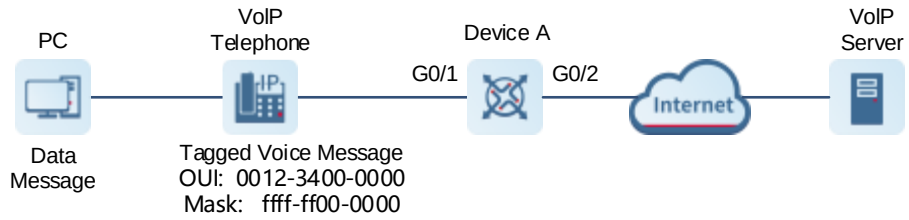
The MAC address field of an Ethernet packet is composed of 48 bits. The first 24 bits are referred to as an OUI, which is assigned by the Institute of Electrical and Electronics Engineers (IEEE) to device vendors. Each vendor assigns the last 24 bits based on this address segment to provide 48-bit MAC addresses.

- Identifying VoIP telephones based on the Link Layer Discovery Protocol (LLDP)

If there are a large number of VoIP telephones in a network, it is complex to configure OUIs of the VoIP telephones.

If a VoIP telephone supports LLDP, it automatically sends an LLDP packet when it goes online. This device can capture the LLDP packet and identify the device capability field in the packet. If the capability is "telephone", the device identifies the voice device as a VoIP telephone. Then, the device extracts the source MAC address from the packet and uses the address as the MAC address of the VoIP telephone, implementing automatic identification of the VoIP telephone.

If the policy of delivering a voice VLAN by LLDP is configured, this device can capture the LLDP packet from the VoIP telephone, fill voice VLAN information to related fields of the packet, and send the packet to the VoIP telephone. The VoIP telephone obtains the voice VLAN ID of this device. If the VoIP telephone supports tagged packets, it adds a VLAN tag to a voice packet before sending the packet. Upon receiving the tagged packet from the VoIP telephone, this device compares the VLAN tag in the packet with the voice VLAN ID. If they match, the device identifies the packet as a voice packet.



1.1.4 Work Mode of the Voice VLAN

The voice VLAN function supports manual and automatic work modes, which differ in the method of adding ports to a voice VLAN.

1. Automatic Mode

Connecting a PC and a VoIP telephone to a switch port in serial mode is the most common connection mode. The port transmits both voice data and common service data. When transmitting voice data, the port automatically forwards the voice packets to the voice VLAN. In this case, the port works in the automatic mode.

Figure 1-1 Network Topology of Voice VLAN in Automatic Mode

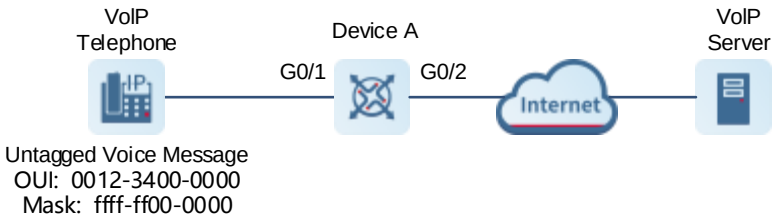
The working procedure of the voice VLAN in automatic mode is as follows.

(1) Adding a port to a voice VLAN: The device identifies the source MAC address in a packet, and compares the source MAC address with the OUI. If they match, the packet is identified as a voice packet. The voice packet can be identified based on a tag as well. The device automatically adds the input port of this voice packet to the voice VLAN and forwards the voice packet to the voice VLAN.

(2) Applying a priority policy: After the device identifies the voice packet based on the OUI, the device delivers a policy and changes the priority of the voice packet to the voice traffic priority.

(3) Removing the port from the voice VLAN after aging: The device maintains the port in the voice VLAN according to the aging mechanism. After the MAC address in the voice packet ages, if the port still fails to receive any voice packet within the aging time, the device removes this port from the voice VLAN.

Caution



- In automatic mode, ports are automatically added to and removed from a voice VLAN. You are not allowed to manually add ports to a voice VLAN. Before you enable the voice VLAN function on a port, remove the voice VLAN from the allowed static VLAN list of the port to prevent the port from staying in the voice VLAN.

- Static MAC addresses do not age. Therefore, you are not advised to configure OUIs as static MAC addresses in automatic mode.

2. Manual Mode

If only a VoIP telephone is connected to a device port, the port transmits only voice packets. The administrator can manually add the port to a voice VLAN or remove the port from the voice VLAN. In this networking mode, the port transmits voice data only, which prevents service data from affecting transmission of voice data.

Figure 1-2 Network Topology of Voice VLAN in Manual Mode

The working procedure of the voice VLAN in manual mode is as follows.

Applying a priority policy: The device identifies the source MAC address in a packet, and compares the source MAC address with the configured OUI. If they match, the device delivers a policy and changes the priority of the voice packet to the voice traffic priority.

1.1.5 Selection of the Work Mode

You can find out whether voice traffic contains tags based on the type and configuration of VoIP telephones and then select a proper work mode for the device.

1. Types of VoIP Telephones

Like any other network device, a VoIP telephone needs an IP address before it can implement communication normally in the network. VoIP telephones are categorized into two types, based on whether they automatically obtain IP addresses and voice VLAN information. One type of VoIP telephones can automatically obtain IP addresses and voice VLAN IDs. The other type of VoIP telephone requires you to configure IP addresses and voice VLAN IDs for them. Both types of VoIP telephones may send tagged and untagged voice traffic.

- VoIP telephones that can automatically obtain IP addresses and voice VLAN IDs

  The VoIP telephones can automatically obtain IP addresses via the Dynamic Host Configuration Protocol (DHCP).

  A VoIP telephone requests voice VLAN information from the DHCP server. If the DHCP server returns the required information, the VoIP telephone sends a voice packet carrying the voice VLAN tag. If the DHCP server does not return the required information, the VoIP telephone sends a voice packet that does not carry the voice VLAN tag.

- VoIP telephones in need of manual configuration of IP addresses and voice VLAN IDs

  IP addresses must be manually configured. Otherwise, the VoIP telephones cannot normally work.

If a voice VLAN ID is configured for a VoIP telephone, the VoIP telephone sends and receives only tagged voice traffic based on the configuration. If no voice VLAN ID is configured for a VoIP telephone, the VoIP telephone sends and receives only untagged voice traffic.

2. Types of Voice Traffic

- Tagged voice traffic

  When a VoIP telephone obtains voice VLAN information automatically or via manual configuration, the VoIP telephone sends tagged voice traffic.

  In this case, a port can be configured as a trunk, hybrid, or uplink port. The port sends data packets to the native VLAN, and sends tagged voice packets to a non-native VLAN that is used as a voice VLAN. A voice VLAN supports both automatic and manual modes.

  - In automatic mode, the allowed static VLAN list of a port must contain the native VLAN and exclude the voice VLAN, and the voice VLAN is automatically added to or removed from the allowed VLAN list of the port. After the voice VLAN function is enabled on the port, when the port receives a tagged voice packet, the port is added to the voice VLAN to transmit tagged voice traffic. If the port does not receive a new voice packet within the aging time after the MAC address in the packet ages, the port removes the voice VLAN from the allowed VLAN list of the port.
  - In manual mode, the native VLAN and voice VLAN must be added to the allowed static VLAN list of a port.

- Untagged voice traffic

  If a VoIP telephone automatically obtains an IP address but does not obtain voice VLAN information, or an IP address is configured for the VoIP telephone but no voice VLAN is configured, the VoIP telephone sends and receives untagged voice traffic.

  In this case, the voice VLAN of the port must work in manual mode. You must configure a native VLAN for the receive port and allow packets with the native VLAN ID to pass. The native VLAN can be configured as a voice VLAN so that untagged voice packets are transmitted over the voice VLAN.

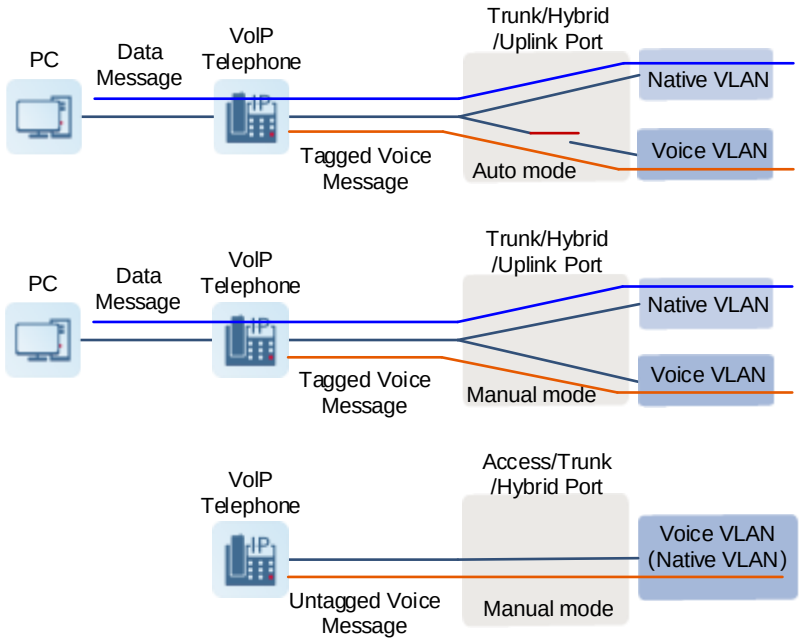
Note

VoIP telephones from different vendors may be different in the work principle, support for voice VLAN, and the process of obtaining IP addresses and voice VLAN information. For more information, see the user manual of the VoIP telephone.

3. Supported Work Modes

Table 1-1 Work Modes for Tagged Voice Traffic

Port Type	Mode	Supported Work Mode and Configuration Requirement
	Automatic	The native VLAN is added to the allowed VLAN list of a port to transmit common data. The voice VLAN is removed from the allowed VLAN list of the port and the port can join or exit the VLAN automatically. A native VLAN cannot be configured as a voice VLAN.
	Manual	Both the native VLAN and voice VLAN (tagged) are added to the allowed VLAN list of a port. A native VLAN cannot be configured as a voice VLAN.



Port Type	Mode	Supported Work Mode and Configuration Requirement
Access Promiscuous Host	N/A	The access ports, promiscuous ports of PVLAN, and host ports do not support tagged voice traffic.

Table 1-2 Work Modes for Untagged Voice Traffic

If the voice traffic is untagged, the device supports only the manual mode.

Port Type	Mode	Supported Work Mode and Configuration Requirement
Access	Manual	The voice VLAN is the VLAN to which the access port belongs.
Host	Manual	The voice VLAN is the secondary VLAN (isolated or community VLAN) of a host port.
Promiscuous	Manual	The voice VLAN is the primary VLAN of a promiscuous port.
Trunk	Manual	The voice VLAN is the native VLAN of an access port and the port allows packets with the native VLAN ID to pass through.
Hybrid	Manual	Select either of the following configuration methods: ● The voice VLAN is the native VLAN of an access port and the port allows packets with the native VLAN ID to pass through. ● The MAC VLAN function is configured to identify packets with MAC addresses matching the MAC address of a VoIP telephone as voice traffic and assign them to the voice VLAN. In this case, the voice VLAN is not necessarily configured as a native VLAN of a hybrid port.
Uplink	N/A	An uplink port does not forward untagged packets. Therefore, when the voice traffic is untagged, the port cannot be configured as an uplink port.

Figure 1-3 Work Mode Selection

1.1.6 Security Mode of Voice VLAN

When a port is added to a voice VLAN, the device no longer checks the source MAC address in the packets. Theoretically, all voice packets can be transmitted over the voice VLAN. Therefore, the device may suffer malicious packet attacks, which affects normal voice communication in the voice VLAN.

To better isolate voice traffic from data traffic during transmission, the device provides the security mode for a voice VLAN.

When the security mode is enabled, only voice traffic can be transmitted in the voice VLAN. The device checks the source MAC address in each packet. When the source MAC address in the packet matches the voice VLAN OUI, the packet can be transmitted in the voice VLAN. Otherwise, the device discards the packet.

Note

In security mode, the device checks the source MAC addresses of only untagged packets and tagged packets with the voice VLAN ID. For tagged packets with non-voice VLAN IDs, the device forwards or discards the packets according to VLAN rules, irrespective of the security/common mode of the voice VLAN.

Caution

It is not recommended that both voice data and service data be transmitted over the voice VLAN. If you want to transmit both voice data and service data over the voice VLAN, disable the voice VLAN function in security mode.

1.2 Restrictions and Guidelines

- Voice VLAN can only be enabled on Layer 2 Ethernet interfaces (Access ports, Trunk port, Hybrid port,

Uplink port, PVLAN Host port and Promiscuous port), but not on the aggregate interface or Layer 3 interface.

- You can use the **show interface switchport** command to view the interface type. If the Switchport field corresponding to the interface is "enabled", it means that the interface is a Layer 2 interface. If the Switchport field corresponding to the interface is "disabled", it means that the interface is a Layer 3 interface.
- You can run the **switchport** command to configure the interface as a Layer 2 interface. First, use the **no switchport mode** command to restore the Layer 2 interface mode to the default value, and then use the **no switchport** command to configure the Layer 2 interface as a Layer 3 interface. When the Layer 2/Layer 3 interface mode is changed, all properties of the interface is restored to the default values of the interface type.

1.3 Configuration Task Summary

The configuration includes the following tasks:

(1) Configuring a Voice VLAN

(2) (Optional) Configuring a Voice VLAN OUI

(3) (Optional) Configuring a Voice Traffic Priority for a Voice VLAN

(4) (Optional) Configuration Aging Time for a Voice VLAN

(5) (Optional) Configuring Security Mode for a Voice VLAN

(6) Add a port to a voice VLAN and enable the voice VLAN function on the port. Select at least one of the following to configure.

- Configuring the Device to Automatically Add a Port to a Voice VLAN to Transmit Tagged Voice Traffic
- Manually Adding a Port to a Voice VLAN to Transmit Tagged Voice Traffic
- Manually Adding a Port to a Voice VLAN to Transmit Untagged Voice Traffic

(7) (Optional) Configuring LLDP to Deliver a Voice VLAN Policy

1.4 Configuring a Voice VLAN

1.4.1 Overview

You can create a voice VLAN on a device used to transmit voice packets only, and enable the voice VLAN function in global configuration mode. The voice VLAN function must be enabled on the port that is connected to a VoIP telephone so that the voice VLAN function can take effect.

1.4.2 Restrictions and Guidelines

- Only one voice VLAN can be configured. You must disable the voice VLAN function before you modify the voice VLAN ID. You can use the **no voice vlan** command to disable the voice VLAN function in global configuration mode.
- You must create a VLAN before configuring a voice VLAN. VLAN IDs must meet the following requirements:
  - VLAN 1 cannot be configured as a voice VLAN. Therefore, the value range of *vlanid* is from 2 to 4094.
  - A VLAN cannot be configured as a voice VLAN and a super VLAN at the same time.
  - A protocol VLAN is valid to only untagged packets received by a trunk or hybrid port. In a voice VLAN in

automatic mode, the trunk and hybrid ports can process only tagged voice traffic. Therefore, do not configure a VLAN as a protocol VLAN and a voice VLAN at the same time.

- If the 802.1x automatic VLAN hopping function is enabled on an access port, do not configure the VLAN ID delivered by 802.1x as the voice VLAN ID to ensure that the function works properly.
- If a VoIP telephone sends tagged voice traffic and the 802.1x authentication and guest VLAN functions are enabled on the access port, configure different VLAN IDs for the voice VLAN, native VLAN, and 802.1x guest VLAN to ensure proper running of the functions.
- Do not configure a VLAN as a remote VLAN of the remote switched port analyzer (RSPAN) and a voice VLAN at the same time. Otherwise, the RSPAN and voice VLAN functions may be affected.

- If a PC and a VoIP telephone are connected to the same port in serial mode, and both the 802.1x authentication and voice VLAN functions are enabled on the port, the PC must pass 802.1X authentication to access the network. If the OUI of the VoIP telephone matches the voice VLAN OUI, the VoIP telephone can make communication via the voice VLAN without passing 802.1x authentication.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a VLAN.

vlan *voice-vlan-id*

Only VLAN 1 exists by default.

(4) Return to the global configuration mode.

exit

(5) Configure the VLAN as a voice VLAN.

voice vlan *voice-vlan-id*

No voice VLAN is configured by default.

1.5 Configuring a Voice VLAN OUI

1.5.1 Overview

After a VoIP telephone is connected to the device, you must configure the OUI of the VoIP telephone on the device so that the VoIP telephone can communicate over the network.

The device allows you to set an OUI to be identified by the voice VLAN function. For more information about the OUI, see the principle of the voice VLAN function. The device that supports the voice VLAN function identifies the source MAC address in a received packet, and compares the source MAC address with the OUI of the voice VLAN configured on the device to check whether the traffic is sent from a specified voice device. The priority of a received packet can be changed to the voice traffic priority only when the source MAC address in the packet matches the OUI of the voice VLAN.

1.5.2 Restrictions and Guidelines

- The OUI of the voice VLAN cannot be a multicast address, and the configured mask should not contain non-consecutive 1's.
- *mac-address* indicates the source MAC address in a voice packet. *oui-mask* indicates the valid length of an OUI, which is expressed by a mask. *text* indicates a descriptor of an OUI.
- You can use the **no voice vlan mac-address oui** command in global configuration mode to delete an OUI configured on a device.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a voice VLAN OUI.

voice vlan mac-address *mac-address* **mask** *oui-mask* [**description** *text*]

No OUI is configured by default.

1.6 Configuring a Voice Traffic Priority for a Voice VLAN

1.6.1 Overview

You can modify the Class of Service (CoS) and differentiated services code point (DSCP) values for voice traffic in a voice VLAN on the device to improve the priority of the voice traffic and the quality of voice calls.

- The CoS value indicates L2 priority and is represented by three bits. The value range is from 0 to 7. A larger value indicates a higher priority. The CoS value is stored in the L2 header of a packet and filled in the PRI field of an 802.1Q VLAN tag. The CoS value of a common VLAN packet is **0**, which indicates the lowest priority. The default CoS value of voice traffic in a voice VLAN is **6**, which indicates a higher priority than common VLAN packets.
- The DSCP value indicates IP priority (IP PRE) and is represented by six bits. The value range is from 0 to 63. A larger value indicates a higher priority. The DSCP value is stored in the L3 header of a packet. For an IPv4 packet, the DSCP value is filled in the first six bits (bit 0 to bit 5) of the type of service (ToS) field in the header of the packet. For an IPv6 packet, the DSCP value is filled in the first six bits in the **Traffic Class** field of the IPv6 packet header. The DSCP value of a common IP packet is **0**, which indicates the lowest priority. The default DSCP value of voice traffic in a voice VLAN is **46**, which indicates a higher priority than common IP packets.
- The packet trust mode of the QoS module is disabled by default. This causes the QoS module to change the priority of all packets to **0**, and overwrites the packet priority modified by the voice VLAN function. You must run the **mls qos trust** { **cos** | **ip-precedence** | **dscp** | **exp** } command in interface configuration mode, and select the **cos** and **dscp** parameters to enable the trust mode of the QoS module to trust the packet priority modified by the voice VLAN function.

For more information about CoS and DSCP, see *Configuring QoS*.

1.6.2 Restrictions and Guidelines

- To restore the QoS and DSCP values to default values, you can run the **no voice vlan cos** or **no voice vlan dscp** command in global configuration mode.
- *cos-value* indicates the CoS value of voice traffic in a voice VLAN. The value range is from 0 to 7, and the default value is **6**.
- *dscp-value* indicates the DSCP value of voice traffic in a voice VLAN. The value range is from 0 to 63, and the default value is **46**.

1.6.3 Prerequisites

- Configure an interface connected to an audio deice as a Layer 2 interface.

A voice VLAN has been configured. An OUI has been configured.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Specify the priority of voice packets in a voice VLAN.

voice vlan { **cos** *cos-value* | **dscp** *dscp-value* }

The default CoS and DSCP values of voice packets are **6** and **46**, respectively.

(4) Enter the Layer 2 Ethernet interface configuration mode to configure an interface connected to a voice device.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

(5) Enable the trust mode of the QoS module to trust the priority of voice packets.

mls qos trust { **cos** | **dscp** }

The trust mode of the QoS module is disabled by default.

1.7 Configuration Aging Time for a Voice VLAN

1.7.1 Overview

In automatic mode, after the MAC address in a voice packet ages, if the port does not receive any more voice packets within the aging time, the device removes this port from the voice VLAN.

The aging time is only valid in automatic mode. In manual mode, the aging time is invalid and therefore does not need to be configured.

1.7.2 Restrictions and Guidelines

- The aging time of a voice VLAN starts after the MAC address in a voice packet ages. The value range is from 5 to 10000, in minutes.
- To restore the aging time to the default value, you can run the **no voice vlan aging** command in global configuration mode.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure aging time of a voice VLAN.

voice vlan aging *age*

The default aging time of a voice VLAN is 1440 minutes.

1.8 Configuring Security Mode for a Voice VLAN

1.8.1 Overview

To guarantee quality of voice traffic during transmission and prevent malicious attacks, you can enable the security mode of a voice VLAN to allow only voice traffic to be transmitted in the voice VLAN.

1.8.2 Restrictions and Guidelines

To disable the security mode of the voice VLAN, you can run the **no voice vlan security enable** command in global configuration mode.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the security mode of the voice VLAN.

voice vlan security enable

The security mode of a voice VLAN is enabled by default.

1.9 Configuring the Device to Automatically Add a Port to a Voice VLAN to Transmit Tagged Voice Traffic

1.9.1 Overview

To use a port for VoIP telephone communication, you must add the port to a voice VLAN, configure the work mode for the voice VLAN, and enable the voice VLAN function on the port.

1.9.2 Restrictions and Guidelines

- Even if the voice VLAN function is disabled in global configuration mode, you can still enable the voice VLAN function on a port but the configuration does not take effect.
- When a port works in automatic mode, the native VLAN is used to transmit common VLAN packets. Do not configure the native VLAN of the port as a voice VLAN. If a port is automatically added to a voice VLAN after

the port identifies voice traffic, you cannot manually add the port to or delete the port from the voice VLAN by using commands.

- If a port does not transmit packet data of a voice VLAN, remove the voice VLAN from the allowed VLAN list of the port.
- When a port works in manual mode, you must manually add the port to the voice VLAN to ensure that the voice VLAN function can take effect. To configure a port to work in manual mode, you can run the **no voice vlan mode auto** command.
- After the voice VLAN function is enabled on a port, you are not allowed to switch the port between the manual mode and automatic mode and the allowed VLAN list of the port cannot be changed. To change the voice VLAN work mode or the allowed VLAN list of the port, disable the voice VLAN function on the port first. After the voice VLAN function is enabled on a port, to ensure normal operation of the function, you are not advised to change the port type (such as access, trunk, or hybrid port). To change the port type, disable the voice VLAN function on this port first. To disable the voice VLAN function of a port, you can run the **no voice vlan enable** command.
- If the voice traffic is tagged, a user port can be configured as a trunk, hybrid, or uplink port. The access port, host port of PVLAN, and promiscuous port of PVLAN do not support tagged voice traffic.
- If you want to transmit untagged common packets from a PC and tagged voice packets from a VoIP telephone over a user port, configure the user port as a trunk port and configure the device to automatically add the port to a voice VLAN. The configuration steps are as follows: The configuration steps for a hybrid or an uplink port are similar to the following configuration steps.

1.9.3 Prerequisites

Configure a voice VLAN.

1.9.4 Procedure

(1) Create a data VLAN.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create a VLAN to transmit common packets.

vlan *data-vlan-id*

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

(2) Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

(3) Configure the user port as a trunk port.

switchport mode trunk

An interface works in access mode by default.

(4) Configure the VLAN used for transmitting common packets as a native VLAN of the user port to transmit untagged common packets.

switchport trunk native vlan *data-vlan-id*

The default native VLAN of a trunk port is VLAN 1.

(5) Configure an allowed VLAN list for the user port, add the data VLAN to the list, and exclude the voice VLAN from the list.

switchport trunk allowed vlan except *voice-vlan-id*

The default allowed VLANs of a trunk port are VLANs 1 to 4094.

(6) Configure the voice VLAN to work in automatic mode so that the voice VLAN is automatically added to the allowed VLAN list of this port when the port receives voice data.

voice vlan mode auto

A voice VLAN works in automatic mode by default.

(7) Enable the voice VLAN function on the user port.

voice vlan enable

The voice VLAN function is disabled on a port by default.

1.10 Manually Adding a Port to a Voice VLAN to Transmit Tagged Voice Traffic

1.10.1 Overview

To use a port for VoIP telephone communication, you must add the port to a voice VLAN, configure the work mode for the voice VLAN, and enable the voice VLAN function on the port.

1.10.2 Restrictions and Guidelines

- If the voice traffic is tagged, a user port can be configured as a trunk, hybrid, or uplink port. The access port, host port of PVLAN, and promiscuous port of PVLAN do not support tagged voice traffic. Therefore, they cannot be added to a voice VLAN.
- If you want to transmit untagged common packets from a PC and tagged voice packets from a VoIP telephone over a user port, configure the user port as a trunk port and manually add the port to a voice VLAN. The configuration steps are as follows: The configuration steps for a hybrid or an uplink port are similar to the following configuration steps.

1.10.3 Prerequisites

Configure a voice VLAN.

1.10.4 Procedure

(1) Create a data VLAN.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create a VLAN to transmit common packets.

vlan *data-vlan-id*

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

(2) Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

(3) Configure the user port as a trunk port.

switchport mode trunk

An interface works in access mode by default.

(4) Configure the VLAN used for transmitting common packets as a native VLAN of the user port to transmit untagged common packets.

switchport trunk native vlan *data-vlan-id*

The default native VLAN of a trunk port is VLAN 1.

(5) Configure an allowed VLAN list for the user port, and add only the data VLAN and voice VLAN to the allowed VLAN list.

switchport trunk allowed vlan only *data-vlan-id*,*voice-vlan-id*

The default allowed VLANs of a trunk port are VLANs 1 to 4094.

(6) Configure the voice VLAN to work in manual mode.

no voice vlan mode auto

A voice VLAN works in automatic mode by default.

(7) Enable the voice VLAN function on the user port.

voice vlan enable

The voice VLAN function is disabled on a port by default.

1.11 Manually Adding a Port to a Voice VLAN to Transmit Untagged Voice Traffic

1.11.1 Overview

To use a port for VoIP telephone communication, you must add the port to a voice VLAN, configure the work mode for the voice VLAN, and enable the voice VLAN function on the port.

1.11.2 Restrictions and Guidelines

- When the voice traffic is untagged, you must manually add a port to a voice VLAN. The port type can be access port, trunk port, hybrid port, host port of PVLAN, or promiscuous port of PVLAN. The uplink port does not send untagged packets. Therefore, it cannot be added to a voice VLAN.
- Taking the access port as an example, if you want to transmit untagged voice packets from a VoIP telephone over a user port, configure the user port as an access port and manually add the port to a voice VLAN.

1.11.3 Prerequisites

Configure a voice VLAN.

1.11.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

(4) Configure the user port as an access port.

switchport mode access

An interface works in access mode by default.

(5) Add the access port to the voice VLAN to transmit common untagged packets.

switchport access vlan *voice-vlan-id*

An access port belongs to VLAN 1 by default.

(6) Configure the voice VLAN to work in manual mode.

no voice vlan mode auto

A voice VLAN works in automatic mode by default.

(7) Enable the voice VLAN function on the user port.

voice vlan enable

The voice VLAN function is disabled on a port by default.

1.12 Configuring LLDP to Deliver a Voice VLAN Policy

1.12.1 Overview

A VoIP telephone supporting the LLDP function automatically sends an LLDP packet when it goes online. If the LLDP Network Policy type/length/value (TLV) function is enabled on this device, the device can capture the LLDP packet sent by the VoIP telephone and deliver a voice VLAN policy to the VoIP telephone. If a voice VLAN policy requires the VoIP telephone to send tagged frames and the VoIP telephone supports tagged frames, the VoIP telephone adds a VLAN tag to voice packets before transmission according to the voice VLAN policy. If the voice VLAN policy requires the VoIP telephone to send untagged frames, the VoIP telephone sends untagged packets.

If the VoIP telephone does not support the Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED), you must manually add the MAC address of the VoIP telephone to the OUI list of the voice VLAN.

1.12.2 Restrictions and Guidelines

- You can run the **lldp network-policy profile** *profile-num* command in global configuration mode to create a policy or enter the LLDP network policy configuration mode of a policy. *profile-num* indicates the ID of an LLDP network policy. The value range is from 1 to 1024.

- After entering the LLDP network policy configuration mode, you can run the { **voice** | **voice-signaling** } **vlan** command to configure a specific network policy. You can run the **no** { **voice** | **voice-signaling** } **vlan** command to delete a voice VLAN policy.
- You can run the **no lldp network-policy profile** *profile-num* command in Layer 2 Ethernet interface configuration mode to delete an LLDP network policy.
- For more information about command description, see *Configuring LLDP*.

1.12.3 Prerequisites

- A voice VLAN has been configured.
- The trust mode of the QoS module has been enabled to trust packet priority modification.
- The port connected to a VoIP telephone has been manually added to a voice VLAN and the voice VLAN function has been enabled on the port.
  - To enable the VoIP telephone to send tagged frames, see Manually Adding a Port to a Voice VLAN to Transmit Tagged Voice Traffic.
  - To enable the VoIP telephone to send untagged voice traffic, see Manually Adding a Port to a Voice VLAN to Transmit Untagged Voice Traffic.

1.12.4 Procedure

(1) Create an LLDP network policy and enter the LLDP Network Policy configuration mode.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create an LLDP network policy and enter the LLDP Network Policy configuration mode.

lldp network-policy profile *profile-num*

No LLDP network policy is configured by default.

(2) Configure a voice VLAN policy. Select at least one of the following to configure:

- Configure a voice VLAN policy to enable the VoIP telephone to send tagged frames.

  { **voice** | **voice-signaling** } **vlan** { *voice-vlan-id* | **dot1p** } [**cos** *cos* | **dscp** *dscp*]

  No voice VLAN policy is configured by default.

- Configure a voice VLAN policy to enable the VoIP telephone to send untagged frames. In this case, you need to manually add the port to the voice VLAN.

  { **voice** | **voice-signaling** } **vlan untagged**

  No voice VLAN policy is configured by default.

(3) Configure an interface to allow advertising the Network Policy TLV.

a Return to the global configuration mode.

exit

b Enter the Layer 2 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

c Configure the interface to allow advertising the Network Policy TLV.

lldp tlv-enable med-tlv network-policy profile *profile-num*

The port is allowed to advertise the Network Policy TLV by default.

1.13 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

Caution

System resources are occupied when debugging information is output. Therefore, disable the debugging function immediately after use.

Run the **clear** commands to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

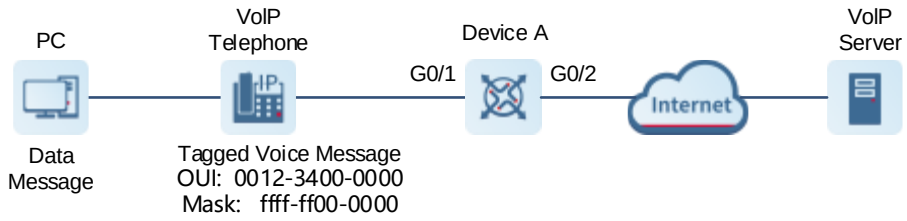
Table 1-3 Monitoring

Command	Purpose
show voice vlan	Displays the voice VLAN configuration.
show voice vlan oui	Displays the OUI configuration of the voice VLAN.
debug bridge vvlan	Debugs the voice VLAN function.

1.14 Configuration Examples

1.14.1 Configuring a Port to Transmit Tagged Voice Traffic in Automatic Mode

1. Requirements



Each office staff member is assigned an Ethernet port. This port is used for service communication of a PC and voice communication of a VoIP telephone.

The VoIP telephone can automatically obtain an IP address and voice VLAN information and send tagged voice traffic. The MAC address of the VoIP telephone is 0012.3456.7890 and the OUI is 0012.3400.0000. To ensure the quality of voice calls, voice traffic is directed to a voice VLAN. The port aging time is set to 1000 minutes, CoS value to **5**, and DSCP value to **40**. The security mode of the voice VLAN needs to be enabled to transmit only voice traffic.

The PC is connected to the network through the VoIP telephone in serial mode and the PC sends untagged data traffic. The data traffic of the PC is isolated from the voice traffic of the VoIP telephone.

2. Topology

Figure 1-4 Network Topology of Voice VLAN in Automatic Mode

3. Notes

- The link needs to carry both tagged voice traffic and untagged data traffic. Therefore, set the port connected to the VoIP telephone to work in automatic mode.
- Configure GigabitEthernet 0/1 as a trunk port so that data traffic is transmitted in native VLAN 5 and voice traffic is transmitted in voice VLAN 2 separately.
- In automatic mode, GigabitEthernet 0/1 is automatically added to the voice VLAN. You are not allowed to manually add the port to the voice VLAN. Remove voice VLAN 2 from the allowed VLAN list of GigabitEthernet 0/1 so that the port determines whether to reside in the voice VLAN based on the aging time. The aging time must be configured for the port.
- GigabitEthernet 0/1 is connected to the VoIP telephone that automatically obtains an IP address. After the VoIP telephone obtains an IP address in the voice VLAN, the VoIP telephone can be normally used.
- (Optional) If 802.1x authentication is needed for the PC, enable the 802.1x authentication function on GigabitEthernet 0/1; to enable the voice packets of the VoIP telephone to be forwarded to the voice VLAN without 802.1x authentication, configure a security channel and an ACL policy. For more information about the support of this function and specific configuration, see *Configuring IEEE 802.1X* and *Configuring ACL*.

4. Procedure

(1) Configure voice VLAN 2 to transmit voice traffic.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan 2
DeviceA(config-vlan)# exit
DeviceA(config)# voice vlan 2
```

(2) Set the OUI used for identifying voice packets to 0012.3400.0000, mask to ffff.ff00.0000, and vendor to B. The priority of a received packet can be changed only when the source MAC address in the packet matches the voice VLAN OUI.

```
DeviceA(config)# voice vlan mac-address 0012.3400.0000 mask ffff.ff00.0000
description B
```

(3) Set the CoS value to **5** and the DSCP value to **40** for voice traffic of the voice VLAN.

```
DeviceA(config)# voice vlan cos 5
DeviceA(config)# voice vlan dscp 40
```

(4) Set the aging time of the voice VLAN to 1000 minutes. This configuration is required in automatic mode only.

```
DeviceA(config)# voice vlan aging 1000
```

(5) Enable the security mode of the voice VLAN. This mode is enabled by default.

```
DeviceA(config)# voice vlan security enable
```

(6) Create VLAN 5 to transmit common data.

```
DeviceA(config)# vlan 5
DeviceA(config-vlan)# exit
```

(7) Configure GigabitEthernet 0/1 as a trunk port and data VLAN 5 as a native VLAN of the port, and remove voice VLAN 2 from the allowed VLAN list of GigabitEthernet 0/1 so that voice VLAN 2 is automatically added to the allowed VLAN list of the port.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# switchport
DeviceA(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 5
DeviceA(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan except 2
```

(8) Enable the trust mode of the QoS module to trust the packet priority modification. Configure automatic adding of the port to the voice VLAN and enable the voice VLAN function on the port. The voice VLAN works in automatic mode by default.

```
DeviceA(config-if-GigabitEthernet 0/1)# mls qos trust cos
DeviceA(config-if-GigabitEthernet 0/1)# voice vlan mode auto
DeviceA(config-if-GigabitEthernet 0/1)# voice vlan enable
```

(9) (Optional) Enable 802.1x authentication on GigabitEthernet 0/1. Configure a security channel and an ACL policy.

```
DeviceA(config-if-GigabitEthernet 0/1)# dot1x port-control auto
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# expert access-list extended safe_channel
DeviceA(config-exp-nacl)# permit etype-any 0012.3400.0000 0000.00ff.ffff any
DeviceA(config-exp-nacl)# exit
DeviceA(config)# security global access-group safe_channel
```

(10) Configure the uplink port GigabitEthernet 0/2 as a trunk port.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# switchport
DeviceA(config-if-GigabitEthernet 0/2)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
DeviceA(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan all
DeviceA(config-if-GigabitEthernet 0/2)# end
DeviceA# write
```

5. Verification

Run the **show voice vlan** command to check the current status of the voice VLAN on the device.

```
DeviceA# show voice vlan
Voice Vlan status: ENABLE
Voice Vlan ID       : 2
Voice Vlan security mode: Security
```

```
Voice Vlan aging time: 1000 minutes
Voice Vlan cos      : 5
Voice Vlan dscp     : 40
Current voice vlan enabled port mode:
PORT              MODE
------------------- ----------
Gi0/1             AUTO
```

Check the voice VLAN OUI of the device.

```
DeviceA# show voice vlan oui
Oui           Mask            Description
0012.3400.0000  ffff.ff00.0000    B
```

Check port configuration.

```
DeviceA# show interface swithport
Interface           Switchport Mode     Access Native Protected VLAN lists
-------------------- ---------- --------- ------ ------ ---------
----------------------
GigabitEthernet 0/1   enabled    TRUNK         5     Disabled  1,3-4094
GigabitEthernet 0/2   enabled    TRUNK         1     Disabled  ALL
```

6. Configuration Files

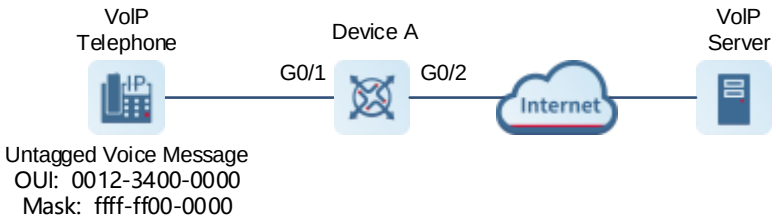
Device A configuration file

```
voice vlan 2
voice vlan cos 5
voice vlan dscp 40
voice vlan aging 1000
voice vlan mac-address 0012.3400.0000 mask ffff.ff00.0000 description "B"
!
expert access-list extended safe_channel
 10 permit etype-any 0012.3400.0000 0000.00ff.ffff any
!
security global access-group safe_channel
!
vlan range 1-2,5
!
interface GigabitEthernet 0/1
switchport
 switchport mode trunk
 switchport trunk native vlan 5
 switchport trunk allowed vlan only 1,3-4094
 voice vlan enable
dot1x port-control auto
 mls qos trust cos
!
interface GigabitEthernet 0/2
 switchport
```

```
switchport mode trunk
switchport trunk native vlan 1
switchport trunk allowed vlan only 1-4094
```

7. Common Errors

- When a voice VLAN works in automatic mode, the voice VLAN is not removed from the allowed VLAN list of the port.
- The trust mode of the QoS module is not enabled. Consequently, the packet priority modification cannot take effect, affecting voice traffic transmission.



1.14.2 Configuring a Port to Transmit Untagged Voice Traffic in Manual Mode

1. Requirements

A VoIP telephone is connected to voice VLAN 2 through GigabitEthernet 0/1 of device A. This link carries only voice traffic. This type of networking is generally used when VoIP telephones are deployed in conference rooms or when no PC is required to transmit data services. The port connected to the VoIP telephone is set to work in manual mode to send untagged voice traffic to device A. The security mode is enabled to enable the voice VLAN to transmit only voice traffic. The CoS value is changed to **5** and the DSCP value is changed to **40** for the voice VLAN.

2. Topology

Figure 1-5 Network Topology of Voice VLAN in Manual Mode

3. Notes

- GigabitEthernet 0/1 receives only untagged voice traffic from the VoIP telephone. Since the untagged voice traffic cannot be forwarded in automatic mode. Therefore, configure the voice VLAN on the port to work in manual mode.
- You can configure GigabitEthernet 0/1 as a hybrid port and voice VLAN 2 as a native VLAN, and add the voice VLAN to the allowed untagged VLAN list of the port. You can also configure GigabitEthernet 0/1 as an access port, and add the port to the voice VLAN. In the following example, GigabitEthernet 0/1 is configured as an access port.

4. Procedure

(1) Create VLAN 2, and configure this VLAN as a voice VLAN.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan 2
```

```
DeviceA(config-vlan)# exit
DeviceA(config)# voice vlan 2
```

(2) Set the CoS value to **5** and the DSCP value to **40** for voice traffic of the voice VLAN.

```
DeviceA(config)# voice vlan cos 5
DeviceA(config)# voice vlan dscp 40
```

(3) Set the OUI for identifying voice packets to 0012.3400.0000, mask to ffff.ff00.0000, and vendor to B on the device.

```
DeviceA(config)# voice vlan mac-address 0012.3400.0000 mask ffff.ff00.0000
description B
```

(4) Enable the security mode of the voice VLAN. This mode is enabled by default.

```
DeviceA(config)# voice vlan security enable
```

(5) Configure GigabitEthernet 0/1 as an access port and add the port to voice VLAN 2.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# switchport
DeviceA(config-if-GigabitEthernet 0/1)# switchport mode access
DeviceA(config-if-GigabitEthernet 0/1)# switchport access vlan 2
```

(6) Enable the trust mode of the QoS module to trust the priority of voice packets. Manually add the user port to the voice VLAN and enable the voice VLAN function on the port.

```
DeviceA(config-if-GigabitEthernet 0/1)# mls qos trust cos
DeviceA(config-if-GigabitEthernet 0/1)# no voice vlan mode auto
DeviceA(config-if-GigabitEthernet 0/1)# voice vlan enable
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

(7) Configure the uplink port GigabitEthernet 0/2 as a trunk port.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# switchport
DeviceA(config-if-GigabitEthernet 0/2)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
DeviceA(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan all
DeviceA(config-if-GigabitEthernet 0/2)# end
DeviceA# write
```

5. Verification

Run the **show voice vlan** command to check the current status of the voice VLAN on the device. GigabitEthernet 0/1 is manually added.

```
DeviceA# show voice vlan
Voice Vlan status: ENABLE
Voice Vlan ID       : 2
Voice Vlan security mode: Security
Voice Vlan aging time: 1440 minutes
Voice Vlan cos      : 5
Voice Vlan dscp     : 40
Current voice vlan enabled port mode:
PORT              MODE
```

```
-------------------- ----------
Gi0/1              MANUAL
```

Check the voice VLAN OUI of the device.

```
DeviceA# show voice vlan oui
Oui           Mask            Description
0012.3400.0000  ffff.ff00.0000    B
```

Check port configuration.

```
DeviceA# show interface switchport
Interface           Switchport Mode     Access Native Protected VLAN lists
-------------------- ---------- --------- ------ ------ ---------
----------------------
GigabitEthernet 0/1   enabled    Access    2     1     Disabled  ALL
GigabitEthernet 0/2   enabled    TRUNK          1     Disabled  ALL
```

6. Configuration Files

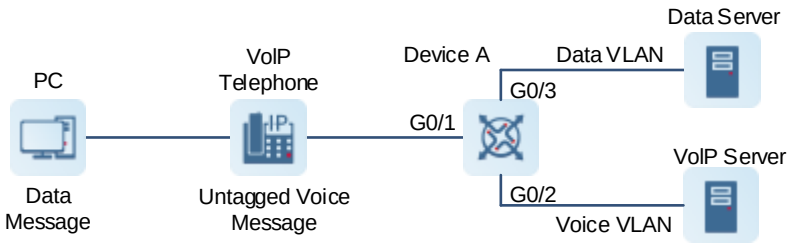
Device A configuration file

```
voice vlan 2
voice vlan cos 5
voice vlan dscp 40
voice vlan mac-address 0012.3400.0000 mask ffff.ff00.0000 description "B"
!
vlan range 1-2
!
interface GigabitEthernet 0/1
switchport
switchport mode access
 switchport access vlan 2
 no voice vlan mode auto
 voice vlan enable
mls qos trust cos
!
interface GigabitEthernet 0/2
 switchport
switchport mode trunk
switchport trunk native vlan 1
switchport trunk allowed vlan only 1-4094
```

7. Common Errors

The trust mode of the QoS module is not enabled. Consequently, the packet priority modification cannot take effect, affecting voice traffic transmission.

1.14.3 Configuring Isolation of Untagged Voice Traffic from Data Traffic



1. Requirements

A PC is connected to a VoIP telephone and the VoIP telephone is connected to device A. The VoIP telephone automatically obtains an IP address and sends untagged voice traffic. The PC sends untagged data traffic. To

ensure quality of voice calls, the voice data must be transmitted in the dedicated voice VLAN 2 and this voice VLAN cannot transmit non-voice data. Common data is transmitted in VLAN 3 separately.

2. Topology

Figure 1-6 Network Topology of Isolation of Voice VLAN from Data VLAN

3. Notes

- Configure GigabitEthernet 0/1 to forward voice traffic and data traffic separately. Packets from the VoIP telephone and PC are untagged. Therefore, configure the port as a hybrid port and enable data traffic to be forwarded in the native VLAN and voice traffic to be forwarded over the voice VLAN.
- The VoIP telephone connected to GigabitEthernet 0/1 sends untagged voice traffic. Therefore, set the voice VLAN to work in manual mode. The PC sends untagged data traffic. To isolate the data traffic from the voice traffic, enable the MAC VLAN function on GigabitEthernet 0/1 so that the port identifies the MAC address of the voice traffic and assigns the voice traffic to the voice VLAN.
- To ensure that the hybrid port receives untagged data traffic and voice traffic, add the data VLAN and voice VLAN to the allowed untagged VLAN list of the port.

4. Procedure

(1) A voice VLAN has been configured.

```
DeviceA>en
DeviceA# configure terminal
DeviceA(config)# vlan 2
DeviceA(config-vlan)# exit
DeviceA(config)# voice vlan 2
```

(2) Configure the device to identify packets with the OUI of 0012.3400.0000 and mask of ffff.ff00.0000 as voice packets and forward the packets to the voice VLAN.

```
DeviceA(config)# voice vlan mac-address 0012.3400.0000 mask ffff.ff00.0000
description B
```

(3) Configure MAC VLAN entries in global configuration mode so that voice traffic is forwarded to voice VLAN 2.

```
DeviceA(config)# mac-vlan mac-address 0012.3456.7890 mask ffff.ffff.ffff vlan 2
```

(4) Create data VLAN 3 to transmit common data.

```
DeviceA(config)# vlan 3
DeviceA(config-vlan)# exit
```

(5) Configure GigabitEthernet 0/1 as a hybrid port and data VLAN 3 as a native VLAN. In this way, the device sends untagged packets of data VLAN 3 and untagged packets of voice VLAN 2 to the user port.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# switchport
DeviceA(config-if-GigabitEthernet 0/1)# switchport mode hybrid
DeviceA(config-if-GigabitEthernet 0/1)# switchport hybrid native vlan 3
DeviceA(config-if-GigabitEthernet 0/1)# switchport hybrid allowed vlan add
untagged 2-3
```

(6) Enable the trust mode of the QoS module to trust packet priority modification. Set the voice VLAN of GigabitEthernet 0/1 to work in manual mode and enable the voice VLAN and MAC VLAN functions on the port.

```
DeviceA(config-if-GigabitEthernet 0/1)# mls qos trust cos
DeviceA(config-if-GigabitEthernet 0/1)# no voice vlan mode auto
DeviceA(config-if-GigabitEthernet 0/1)# voice vlan enable
DeviceA(config-if-GigabitEthernet 0/1)# mac-vlan enable
```

(7) Add GigabitEthernet 0/2 connected to the voice server to voice VLAN 2.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# switchport
DeviceA(config-if-GigabitEthernet 0/2)# switchport mode access
DeviceA(config-if-GigabitEthernet 0/2)# switchport access vlan 2
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

(8) Configure GigabitEthernet 0/3 connected to the data server as a trunk port, and remove voice VLAN 2 from the allowed VLAN list of the port.

```
DeviceA(config)# interface gigabitethernet 0/3
DeviceA(config-if-GigabitEthernet 0/3)# switchport
DeviceA(config-if-GigabitEthernet 0/3)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/3)# switchport trunk native vlan 1
DeviceA(config-if-GigabitEthernet 0/3)# switchport trunk allowed vlan except 2
DeviceA(config-if-GigabitEthernet 0/3)# end
DeviceA# write
```

5. Verification

Check the current status of the voice VLAN on the device.

```
DeviceA# show voice vlan
Voice Vlan status: ENABLE
Voice Vlan ID: 2
Voice Vlan security mode: Security
Voice Vlan aging time: 1440minutes
Voice Vlan cos: 6
Voice Vlan dscp: 46
Current voice vlan enabled port mode:
PORT                MODE
------------------- ----------
Gi0/1               MANUAL
```

Check the OUI of the voice device.

```
DeviceA# show voice vlan oui
```

```
OUI           Mask          Description
--------------- --------------- ------------------------------
0012.3400.0000  ffff.ff00.0000  B
```

Check the MAC VLAN entries.

```
DeviceA# show mac-vlan all
The following MAC VLAN address exist:
S: Static   D: Dynamic
MAC ADDR       MASK          VLAN ID  PRIO  STATE
-------------------------------------------------
0012.3456.7890  ffff.ffff.ffff  2       0     S
Total MAC VLAN address count: 1
```

6. Configuration Files

Device A configuration file

```
voice vlan 2
voice vlan mac-address 0012.3400.0000 mask ffff.ff00.0000 description "B"
mac-vlan mac-address 0012.3456.7890 mask ffff.ffff.ffff vlan 2
!
vlan range 1-3
!

1 Configuring GVRP

1.1 Introduction

1.1.1 Overview

Generic Attribute Registration Protocol (GARP) VLAN registration protocol (GVRP) is a protocol for dynamically configuring virtual local area network (VLAN) attributes. It propagates VLAN attributes through protocol packets, and implements automatic registration and deregistration of VLANs on an IEEE 802.1Q trunk port.

1.1.2 Background and Function

A network is huge and complex. It is impossible to learn the network topology and VLAN conditions in a short period of time, and manual configuration brings heavy workload and easily leads to errors. The GARP provides a mechanism to help the members of the same switching network to mutually distribute, propagate, and register information including VLAN and multicast address.

An application entity that complies with GARP is called a GARP application. At present, major GARP applications include GVRP and GARP Multicast Registration Protocol (GMRP). An application entity diffuses the attribute information through protocol data packets. The destination MAC address of protocol packets is the specific multicast MAC address. If a device supporting GARP receives packets of GARP application entities, it will distinguish different applications according to their destination MAC address, and then deliver the packets to different applications (GVRP or GMRP) for processing.

- GVRP is a GARP application. It can dynamically configure and diffuse VLAN attributes, and implements dynamic and automatic registration/deregistration of VLANs on an IEEE 802.1Q trunk port.
- GMRP is another GARP application. It provides a restricted multicast diffusion function similar to the IGMP probing technology.

With the VLAN automatic registration function of GVRP, you can configure the VLAN, and dynamically maintain the process of creating a VLAN and adding/deleting ports to/from a VLAN, ensuring the VLAN connectivity in the topology.

GVRP simplifies the VLAN configuration and management. It reduces the workload of manually configuring VLANs and adding ports to VLANs, and reduces the possibility of network disconnection due to inconsistent configuration.

1.1.3 Principles

1. Working Process

(1) GVRP advertising

If the GVRP function is enabled for a device and the advertising mode of the trunk port is **Normal**, the trunk port will regularly collect the VLAN information on the local port, encapsulate the information in GVRP packets and send them to the peer device, informing the peer device of the VLAN that the trunk port has joined or exited. The VLAN information type is GVRP Message Types, including Join message, Leave message, and LeaveAll message.

(2) GVRP registration (registration/deregistration)

The destination MAC address of a message packet is the specific multicast MAC address. After GVRP is enabled, the trunk port can recognize GVRP packets from other devices and obtain the VLAN registration or deregistration information by parsing the packets. If the registration mode is **Normal**, the port will create and join a VLAN dynamically, or the port will exit the VLAN and update the local VLAN registration information dynamically.

(3) GVRP advertisement diffusion

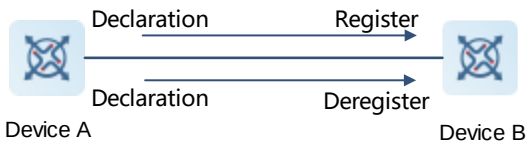
The device can also propagate the local VLAN registration information to other devices. The VLAN registration information includes the manually configured static registration information on the local device and the dynamic registration information from other devices. In this way, all devices in a VLAN maintain consistent VLAN information.

2. GVRP Advertising Modes

On a device with the GVRP function enabled, the trunk port regularly collects or does not collect VLAN information of the local port according to the advertising mode of the port (**Normal** or **Non-Applicant**).

- **Normal** mode: A device collects the VLAN information, and encapsulates it in GVRP packets, and sends the packets to the peer device to externally advertise its VLAN information, including dynamic and static VLAN information. On such a basis, the peer device determines the VLAN to be created.
- **Non-Applicant** mode: A device does not collect the VLAN information or advertise its VLAN information.

3. GVRP Registration Mode



After receiving GVRP packets from the interconnected trunk port, the peer device parses the VLAN information and decides to process or not to process the VLAN information according to the port registration mode (**Normal** or **Disabled**).

- **Normal** mode: The device processes the VLAN information, dynamically creates a new VLAN and adds the port that receives the packet to the VLAN, or removes it from the VLAN.
- **Disabled** mode: The device does not process the VLAN information in the received GVRP packet.

4. VLAN Registration and Deregistration

Figure 1-1 shows the VLAN registration and deregistration process.

Figure 1-1 VLAN Registration and Deregistration

Device A sends a registration declaration to Device B through a GVRP advertisement, and the port of Device B receives the VLAN registration declaration and joins the VLAN contained in the declaration. This process is called VLAN registration.

Device A sends a deregistration declaration to Device B through a GVRP advertisement, and the port of Device B receives the VLAN deregistration declaration and exits the VLAN contained in the declaration. This process is called VLAN deregistration.

1.1.4 Basic Concepts

1. Static and Dynamic VLANs

- A manually created or deleted VLAN is a static VLAN.
- A VLAN dynamically created or deleted through GVRP is a dynamic VLAN.

The protocol state machine controls the process that a port joins or exits a dynamic VLAN. Only the trunk port that has received a GVRP registration or deregistration declaration can join or exit the dynamic VLAN created by GVRP; other trunk ports that have not received any GVRP registration or deregistration declaration cannot join or exit a dynamic VLAN, and even manual configuration cannot add or remove such a port to/from a dynamic VLAN.

The VLAN registration information propagated by GVRP includes the manually configured static registration information on the local device and the dynamic registration information from other devices. You can switch a dynamic VLAN to a static VLAN through configuration, but not the other way around.

2. Message Types

Terminals or bridge devices are GVRP members, and each port enabled with GVRP is called a GVRP application entity. The entities exchange information by transferring three types of messages.

- Join message

  The device sends a Join message in the following cases.

  - When a GVRP application entity wants other GVRP entities to register its own attribute information, it sends a Join message.
  - When a GVRP application entity receives a Join message from another GVRP entity, it sends a Join message for diffusion.
  - When a GVRP application entity is statically configured with attributes and requires other entities to register the attributes, it sends a Join message.

  Two types of Join messages are available: JoinEmpty and JoinIn. The differences between the two are as follows.

  - JoinEmpty message: Used to declare an unregistered attribute.
  - JoinIn message: Used to declare a registered attribute.

- Leave message

  The device sends a Leave message in the following cases.

  - When a GVRP application entity wants other GVRP entities to deregister its own attribute information, it sends a Leave message.
  - When a GVRP application entity receives a Leave message from another GVRP entity, it sends a Leave message.
  - When a GVRP application entity statically deregisters VLAN attributes and requires other entities to deregister the attributes, it sends a Leave message.

  Two types of Leave messages are available: LeaveEmpty and LeaveIn. The differences between the two are as follows.

  - LeaveEmpty message: Used to deregister an unregistered attribute.

- LeaveIn message: Used to deregister a registered attribute.

- LeaveAll message

  After GVRP is enabled, each GVRP application entity will enable its own LeaveAll timer. If the LeaveAll timer of a GVRP entity times out, it will send a LeaveAll message to deregister all attributes, which will cause other GVRP entities to re-register the attribute information. If a GVRP entity receives a LeaveAll message from another entity, it will send a LeaveAll message and restart the LeaveAll timer to initiate a new cycle.

3. Timer Types

GVRP defines four timers to control GVRP message sending.

- Hold timer

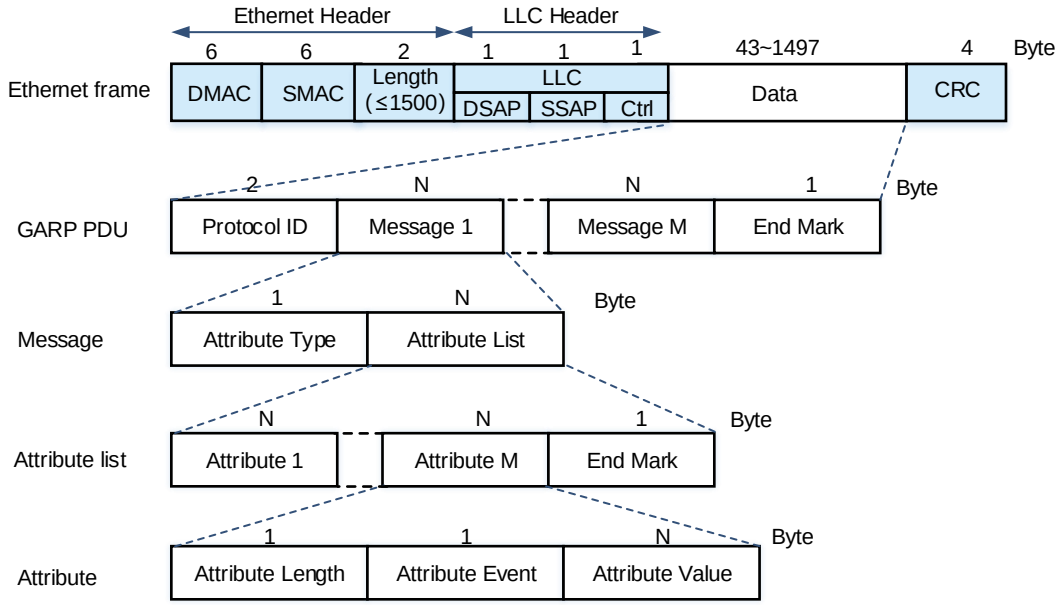
  The Hold timer defines the maximum delay interval *hold* before a port sends a Join message or Leave message. When a GVRP application entity has its attributes changed or receives a GVRP message from another entity, it enables the Hold timer. During the timeout period, the GVRP encapsulates all GVRP messages to be sent into packets as few as possible, and sends the packets when the timer times out. This reduces the quantity of sent packets and saves bandwidth resources. The interval is from 0 to *hold*.

- Join timer

  The Join timer defines the waiting time for Join message retransmission, conductive to ensuring the reliability of Join message transmission. After sending a Join message, the GVRP application entity will wait for a Join timer interval. If it receives a JoinIn message sent from another entity before the Join timer times out, it will not resend the Join message; otherwise, it will resend the Join message. Each GVRP application entity has one Join timer, and all attributes share one Join timer.

- Leave timer

  The Leave timer defines the waiting time from receiving a Leave message by the port to deleting the port from the VLAN, which helps to avoid frequent network changes. If the GVRP application entity wants other entities to deregister its VLAN attribute information, it will send a Leave message; the entity receiving the message will enable the Leave timer, and, if the port does not receive the Join message of the attribute information after the Leave timer times out, the state of the port becomes **Empty** and the port is removed from the VLAN member list; if the port receives the Join message of the attribute information before the Leave timer times out, the port will not be removed from the VLAN and the timer will time out.



- LeaveAll timer

  The LeaveAll timer defines the minimum time interval *leaveall* for the port to send a LeaveAll message. Each GVRP application entity enables its own LeaveAll timer when the entity is enabled. If the LeaveAll timer times out, the GVRP application entity will send a LeaveAll message to instruct other entities to re-register the attribute information. The interval ranges from *leaveall* to the sum of *leaveall* and *hold*. The LeaveAll message is also sent to the local port to trigger the Leave timer to start timing again and initiate a new cycle; if the port receives the LeaveAll message before the timer times out, the timer restarts timing.

1.1.5 Packet Format

The GVRP protocol packets are encapsulated in Ethernet frames. Figure 1-2 shows the packet format.

Figure 1-2 GVRP Packet Format of Ethernet Frame

The following table describes the meaning of each GVRP Ethernet frame field.

Table 1-1 Meanings of GVRP Ethernet Frame Fields

Field	Number of Bytes	Description
Protocol ID	2	Indicates the protocol ID, 0x0001.
Message	N	Indicates 1 to M (M is a positive integer) messages. Each message consists of the attribute type and attribute list.
Attribute Type	1	Indicates the attribute type, defined by the specific GARP application. 0x01: Indicates GVRP application, and **Attribute Value** is **VLAN ID**.
Attribute List	N	Indicates the attribute list, composed of 1 to M (M is a positive integer) attributes and the end mark.
Attribute	N	Indicates an attribute. Each attribute consists of the attribute length, attribute event, and attribute value.
Attribute Length	1	Indicates the attribute length. The value range is from 0x02 to 0xFF, that is, from 2 to 255.

Field	Number of Bytes	Description
Attribute Event	1	Indicates the event type described by the attribute. 0x00: LeaveAll Event 0x01: JoinEmpty Event 0x02: JoinIn Event 0x03: LeaveEmpty Event 0x04: LeaveIn Event 0x05: Empty Event
Attribute Value	N	Indicates the attribute value. The attribute value of GVRP is **VLAN ID**, but the attribute value of **LeaveAll** is invalid.
End Mark	1	Indicates the end mark of GVRP PDU, 0x00.

1.1.6 Protocols and Standards

- IEEE 802.1D: IEEE Standard for Local and metropolitan area networks: Media Access Control (MAC) Bridges
- IEEE 802.1Q: IEEE Standard for Local and Metropolitan Area Networks-Virtual Bridged Local Area Networks

1.2 Restrictions and Guidelines

- GVRP function can only be enabled on Trunk ports. Only Layer 2 Ethernet interfaces and Layer 2 aggregate interface can be configured as Trunk ports.
- You can use the **show interface switchport** command to view the interface type. if the **Switchport** field corresponding to the interface is "enabled", it means that the interface is a Layer 2 interface. If the Switchport field corresponding to the interface is "disabled", it means that the interface is a Layer 3 interface.
- You can use the **switchport** command to configure the interface as a Layer 2 interface. Use the **no switchport mode** command to restore the Layer 2 interface mode to the default value, and then use the **no switchport** command to configure the Layer 2 interface as a Layer 3 interface. When the Layer 2/Layer 3 interface mode is changed, all properties of the interface will be restored to the default values of the interface type.

1.3 Configuration Task Summary

- Configuring GVRP includes the following tasks:
- When the GVRP function is enabled, the configuration includes the following tasks:
  - a Configuring Basic Features
  - b (Optional) Configuring GVRP advertising mode
  - c (Optional) Confgiruing GVRP registration mode

d (Optional) Configuring GVRP BPDU Tunnels

- When the GVRP function is disabled, the configuration includes the following task:
  - (Optional) Configuring Transparent Transmission of GVRP BPDU

1.4 Configuring Basic Features

1.4.1 Overview

When the GVRP function is enabled, the device can send GVRP packets containing the VLAN information, dynamically create or delete VLANs and add or remove ports to/from VLANs. Devices synchronize respective VLAN information to maintain communication in the topology. This function can reduce the manual configuration workload and simplify VLAN management. When the GVRP function is disabled, the device will not send or handle GVRP packets containing the VLAN information.

Dynamic VLAN creation must be enabled. When the VLAN indicated in the packet received by the port (only JoinIn and JoinEmpty) does not exist on the local device, GVRP may create this VLAN. If this function is enabled, when the device receives the Join message from GVRP, a VLAN will be created dynamically.

1.4.2 Restrictions and Guidelines

- GVRP needs to be enabled on the two devices connected for communication. The GVRP function takes effect only on trunk ports. All the VLANs created by GVRP are tagged VLANs. GVRP information is transmitted only by trunk Links. The transmitted information contains the information on all VLANs on the current device, including dynamically learned VLANs and manually configured VLANs. The VLAN information that is dynamically learned by GVRP is saved in the memory temporarily, but not in the flash memory of the system. When the device is reset, all the information will be lost. Users cannot save the VLAN information that is dynamically learned.
- The relationship between GVRP and Spanning Tree Protocol (STP) is as follows.
  - If STP is not enabled, all available ports can participate in GVRP.
  - If STP is enabled, only ports in **Forwarding** state participate in GVRP (receiving and sending GVRP BPDU packets) and have their VLAN information diffused by GVRP.
  - If Multi Spanning Tree Protocol (MSTP) is enabled, GVRP can run in the spanning tree context to which VLAN1 belongs. You cannot specify other spanning tree context for GVRP.
  - If Single Spanning Tree Protocol (SSTP) is enabled, only ports in **Forwarding** state in the current spanning tree context participate in GVRP.
  - The parameters of a dynamic VLAN created through GVRP cannot be modified manually.
- Configure the timers.
  - GVRP uses the Hold, Leave, and LeaveAll timers to define the sending interval of various types of packets. The timers are controlled by the GVRP state machine and can be triggered by each other. The three timers are subject to this relationship: 3 x Hold ≤ Leave ≤ LeaveAll.
  - All devices that need to exchange GVRP information on the network must have consistent GVRP timer configuration; otherwise, the GVRP function will not take effect.
- Enable the GVRP function.
  - When GVRP is not enabled globally, GVRP configuration not take effect. Only when GVRP is enabled

globally, will GVRP configuration take effect.

- The information of super VLAN and sub VLAN cannot be synchronized to the interconnected devices through GVRP.

1.4.3 Prerequisites

- Configure the interface as a Layer 2 interface.

1.4.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of creating VLANs dynamically.

gvrp dynamic-vlan-creation enable

Creating VLANs dynamically is disabled by default.

(4) (Optional) Configure the GVRP timer.

gvrp timer { **join** *hold* | **leave** *leave* | **leaveall** *leaveall* }

By default, the delay before a port sends a Join or Leave message is 200 ms, the waiting time from receiving a Leave message by the port to deleting the port from the VLAN is 600 ms, and the time interval for the port to send a LeaveAll message is 10,000 ms.

a Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

b Configure the Layer 2 interface as a trunk port (global GVRP function only takes effect on a trunk port).

switchport mode trunk

A Layer 2 interface works in access mode by default.

c Return to the global configuration mode.

exit

(5) Enable the GVRP function globally.

gvrp enable

The GVRP function is disabled by default.

1.5 Configure GVRP Advertising Mode

1.5.1 Overview

On the device with GVRP enabled, the Trunk port collects or does not collect VLAN information of the port regularly according to the port's notification mode (Normal or Non Application). You can use this function to configure the notification mode of the interface.

- Normal: Collect VLAN information, encapsulate these VLAN information in GVRP message, send notification to the peer device, and externally notify the VLAN information on the device, including dynamic and static VLAN information, according to which the peer device determines the VLAN to be created.
- Non-Applicant: Do not collect the VLAN information of local port, and do not notify the VLAN information on local device.

1.5.2 Restrictions and Guidelines

- Use the **gvrp applicant state normal** command to enable the configuration to collect port VLAN information and send notifications.
- Use the **gvrp applicant state non-applicant** command to configure not to collect port VLAN information and not send notifications.

1.5.3 Prerequisites

- The interface is configured as a Layer 2 interface.
- Basic functions of GVRP are configured, including: enabling the dynamic VLAN creation function, configuring the Layer 2 interface as a Trunk port, and enabling the GVRP function globally.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the advertising mode on the interface.

gvrp applicant state { **normal** | **non-applicant** }

By default, the port advertising mode is Normal, the notification will be sent.

1.6 Configure GVRP Registration Mode

1.6.1 Overview

After receiving the GVRP message from the interconnected Trunk port, the peer device parses the VLAN information and chooses to process or not process the VLAN information according to the port registration mode (Normal or Disabled). You can use this function to configure the registration mode of the interface.

- Normal: Process VLAN information, dynamically create a non-existent VLAN and add the port receiving the message to the VLAN, or exit the VLAN.
- Disabled: The VLAN information in the message is not processed.

These two registration modes will not affect the static VLAN on the port. The static VLAN created by the user is always a Fixed Registrar.

1.6.2 Restrictions and Guidelines

- Use the **gvrp registration mode normal** command to allow dynamically create, register, or unregister VLANs on a port.
- Use the **gvrp registration mode disable** command to disallow dynamically create, register, or unregister VLANs on a port.
- If enabled, it creates a dynamic VLAN after receiving the peer VLAN information. If disabled, when GVRP message is received, dynamic VLAN will not be added.

1.6.3 Prerequisites

- The interface is configured as a Layer 2 interface.
- Basic functions of GVRP are configured, including: enabling the dynamic VLAN creation function, configuring the Layer 2 interface as a Trunk port, and enabling the GVRP function globally.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the registration mode of the port.

gvrp registration mode { **normal** | **disable** }

By default, the port registration mode is Normal, that is, the VLAN information is dynamically updated.

1.7 Configuring GVRP BPDU Tunnels

1.7.1 Overview

In the QinQ network, if GVRP of the user network and the SP network needs to be calculated separately without interfering with each other, you can configure the GVRP BPDU tunnel on the interface connected to the user network, so that the GVRP packets of the user network can be transmitted through the SP network tunnel.

The destination MAC address of GVRP BPDU packets is the dedicated multicast address 0180.c200.0006. To avoid impact on the SP network by GVRP packets of the user network, when GVRP packets of the user network enter an edge device of the SP network, the edge device changes the destination MAC address of the packets from the GVRP dedicated address (0180.c200.0006) to the tunnel address (01d0.f800.0006 by default) before forwarding on the SP network. After the packets are forwarded to an edge device at the other end, the destination MAC address is restored from the tunnel address (01d0.f800.0006 by default) to the GVRP dedicated address (0180.c200.0006), and the packets are forwarded to the user network at the other end. In this way, the GVRP packets of the user network are transmitted through the tunnel of the SP network.

1.7.2 Restrictions and Guidelines

- The tunnel function takes effect only when the GVRP BPDU tunnel is enabled in both global configuration mode and interface configuration mode. In the global configuration mode, run the **l2protocol-tunnel gvrp** command to enable the GVRP BPDU tunnel function globally. In Layer 2 Ethernet interface configuration mode or the Layer 2 link aggregation configuration mode, run the **l2protocol-tunnel gvrp enable** command to enable the GVRP BPDU tunnel function on a port.
- The optional tunnel addresses of GVRP packets are 01d0.f800.0006 (default value) and 011a.a900.0006.

1.7.3 Prerequisites

- The interface connecting the user network is configured as a Layer 2 interface.
- The interface connecting the user network is configured as a Dot1q-tunnel interface.
- The QinQ encapsulation strategy is configured on the interface connecting to the user network.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure an address for the GVRP tunnel.

l2protocol-tunnel gvrp tunnel-dmac *mac-address*

The GVRP tunnel address is 01d0.f800.0006 by default.

(4) Enable the GVRP BPDU tunnel function globally.

l2protocol-tunnel gvrp

The global GVRP BPDU tunnel function is disabled by default.

(5) Enter the interface configuration mode to configure the interface connecting to the user network.

- Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 link aggregation configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(6) Enable GVRP BPDU tunnel function on the interface.

l2protocol-tunnel gvrp enable

By default, GVRP BPDU tunnel function of the interface is disabled.

1.8 Configuring Transparent Transmission of GVRP BPDU

1.8.1 Overview

In IEEE 802.1Q, the destination MAC address of GVRP BPDU packets is the dedicated multicast address 0180.c200.0006. Generally, devices complying with IEEE 802.1Q do not forward GVRP BPDU frames with the destination MAC address 0180.c200.0006, no matter whether GVRP is enabled. If the device has GVRP enabled, it will use GVRP BPDU frames for GVRP calculation; otherwise, it will discard GVRP packets.

However, in specific applications, devices may be required to transparently transmit GVRP packets. For example, a device does not have GVRP enabled, but the device interconnected to it has GVRP enabled. To enable the devices at both ends to perform GVRP calculation normally, the local device needs to transparently transmit GVRP BPDU frames. In this case, the GVRP BPDU transparent transmission function can be enabled on interface connecting two devices to allow the interface to forward the packets with the destination MAC address of 0180.c200.0006.

1.8.2 Restrictions and Guidelines

- The GVRP BPDU transparent transmission function takes effect only when GVRP is disabled.

  When the device has GVRP enabled, this function cannot be used to transparently transmit GVRP BPDU frames. For example, in the QinQ network, both the SP network device and the user network device have GVRP enabled. If the SP network device needs to forward GVRP packets of the user network but does not forward GVRP packets of the SP network, the GVRP BPDU tunnel function is needed.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the transparent transmission function of GVRP BPDU packets.

bridge-frame forwarding protocol gvrp

The transparent transmission function of GVRP BPDU packets is disabled by default.

1.9 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

Caution

System resources are occupied when debugging information is output. Therefore, disable the debugging function immediately after use.

You can run the **clear** commands to clear information.

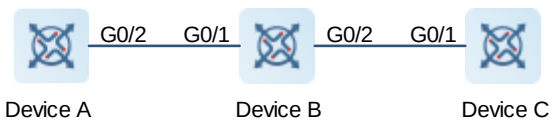
Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-2 Monitoring

Command	Purpose
clear gvrp statistics { *interface-type interface-number* | **all** }	Clears port statistics.
show gvrp statistics { *interface-type interface-number* | **all** }	Displays port statistics.
show gvrp status	Displays the current GVRP status.
show gvrp configuration	Displays the current GVRP configuration.
show l2protocol-tunnel gvrp	Displays the GVRP BPDU tunnel information.
debug gvrp event	Enables the GVRP event debugging function.
debug gvrp timer	Enables the GVRP timer debugging function.

1.10 Configuration Examples



1.10.1 Configuring Basic Functions of GVRP

1. Requirements

As indicated in Figure 1-3, The GVRP function is enabled in a topology to dynamically maintain the VLANs and the VLAN-port relationship.

2. Topology

Figure 1-3 Topology of GVRP Basic Functions

3. Notes

- On Devices A and C, configure VLANs used for communication on the user network.
- Enable GVRP on Devices A, B, and C, and enable the dynamic creation function of VLAN.
- Configure the ports connected between Devices A, B, and C as trunk ports, and ensure that the permitted VLAN lists of trunk ports include the communication VLANs.
- You are advised to enable STP to avoid loops.

4. Procedure

(1) Create VLANs for user network communication.

Create VLANs 2 to 10 for user network communication on Device A.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan range 2-10
DeviceA(config-vlan)# exit
```

Create VLANs 11 to 20 for user network communication on Device C.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# vlan range 11-20
DeviceC(config-vlan)# exit
```

(2) Enable the dynamic creation function of VLAN.

Enable the dynamic creation function of VLAN on Device A.

```
DeviceA(config)# gvrp dynamic-vlan-creation enable
```

Enable the dynamic creation function of VLAN on Device B.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# gvrp dynamic-vlan-creation enable
```

Enable the dynamic creation function of VLAN on Device C.

```
DeviceC(config)# gvrp dynamic-vlan-creation enable
```

(3) Configure the ports for connecting to the devices as trunk ports.

Configure the ports for the interconnected devices as trunk ports on Device A.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# switchport
DeviceA(config-if-GigabitEthernet 0/2)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
DeviceA(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan all
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

Configure the ports for the interconnected devices as trunk ports on Device B.

```
DeviceB(config)# interface range gigabitethernet 0/1-2
DeviceB(config-if-range)# switchport
DeviceB(config-if-range)# switchport mode trunk
DeviceB(config-if-range)# switchport trunk native vlan 1
```

```
DeviceB(config-if-range)# switchport trunk allowed vlan all
DeviceB(config-if-range)# exit
```

Configure the ports for the interconnected devices as trunk ports on Device C.

```
DeviceC(config)# interface gigabitethernet 0/1
DeviceC(config-if-GigabitEthernet 0/1)# switchport
DeviceC(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceC(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
DeviceC(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
DeviceC(config-if-GigabitEthernet 0/1)# exit
```

(4) Enable the GVRP function.

Enable the GVRP function on Device A.

```
DeviceA(config)# gvrp enable
```

Enable the GVRP function on Device B.

```
DeviceB(config)# gvrp enable
```

Enable the GVRP function on Device C.

```
DeviceC(config)# gvrp enable
```

5. Verification

(1) Before the GVRP function is enabled globally, check the static VLAN configuration of the device; check whether the interconnection interface are trunk ports and allow all VLANs to pass.

Only static VLANs exist on Device A; the interconnection port GigabitEthernet 0/2 is a trunk port and allows all VLANs to pass.

```
DeviceA# show vlan
VLAN        Name                  Status        Ports
----------   --------------------   ------------   -------------------------
       1   VLAN0001              STATIC       Gi0/1, Gi0/2, Gi0/3, Gi0/4
                                             Gi0/5, Gi0/6, Gi0/7, Gi0/8
     2-10   VLAN0002-VLAN0010       STATIC       Gi0/2
DeviceA# show interface gigabitethernet 0/2 switchport
Interface               Switchport Mode     Access Native Protected VLAN lists
------------------------ ---------- --------- ------ ------ ---------
--------------------
GigabitEthernet 0/2       enabled    TRUNK         1     Disabled  ALL
```

Only a static VLAN exists on Device B; the interconnection interface GigabitEthernet 0/1 and GigabitEthernet 0/2 are trunk ports and allow all VLANs to pass.

```
DeviceB# show vlan
VLAN        Name                  Status        Ports
----------   --------------------   ------------   -------------------------
       1   VLAN0001              STATIC       Gi0/1, Gi0/2, Gi0/3, Gi0/4
                                             Gi0/5, Gi0/6, Gi0/7, Gi0/8
DeviceB# show interface switchport
Interface               Switchport Mode     Access Native Protected VLAN lists
```

```
------------------------- ---------- --------- ------ ------ ---------
--------------------
GigabitEthernet 0/1       enabled    TRUNK         1     Disabled  ALL
GigabitEthernet 0/2       enabled    TRUNK         1     Disabled  ALL
```

Only static VLANs exist on Device C; the interconnection port GigabitEthernet 0/1 is a trunk port and allows all VLANs to pass.

```
DeviceC# show vlan
VLAN        Name                  Status        Ports
----------   --------------------   ------------   --------------------------
       1   VLAN0001              STATIC       Gi0/1, Gi0/2, Gi0/3, Gi0/4
                                             Gi0/5, Gi0/6, Gi0/7, Gi0/8
    11-20   VLAN0011-VLAN0020       STATIC       Gi0/1
DeviceA# show interface gigabitethernet 0/1 switchport
Interface               Switchport Mode     Access Native Protected VLAN lists
------------------------- ---------- --------- ------ ------ ---------
--------------------
GigabitEthernet 0/1       enabled    TRUNK         1     Disabled  ALL
```

(2) After the GVRP function is enabled globally, check the GVRP configuration of devices.

Check whether the GVRP function of Device A has been enabled, and the trunk port normally advertises the GVRP information and dynamically updates the VLAN information.

```
DeviceA# show gvrp configuration
Global GVRP Configuration:
GVRP Feature:enabled
GVRP dynamic VLAN creation:enabled
Join Timers(ms):200
Leave Timers(ms):600
Leaveall Timers(ms):1000
Port based GVRP Configuration:
       PORT            Applicant Status        Registration Mode
----------------------  --------------------    --------------------
GigabitEthernet 0/2          normal                 normal
```

Check whether the GVRP function of Device B has been enabled, and the trunk port normally advertises the GVRP information and dynamically updates the VLAN information.

```
DeviceB# show gvrp configuration
Global GVRP Configuration:
GVRP Feature:enabled
GVRP dynamic VLAN creation:enabled
Join Timers(ms):200
Leave Timers(ms):600
Leaveall Timers(ms):1000
Port based GVRP Configuration:
       PORT            Applicant Status        Registration Mode
----------------------  --------------------    --------------------
GigabitEthernet 0/1          normal                 normal
```

```
GigabitEthernet 0/2          normal                  normal
```

Check whether the GVRP function of Device C has been enabled, and the trunk port normally advertises the GVRP information and dynamically updates the VLAN information.

```
DeviceC# show gvrp configuration
Global GVRP Configuration:
GVRP Feature:enabled
GVRP dynamic VLAN creation:enabled
Join Timers(ms):200
Leave Timers(ms):600
Leaveall Timers(ms):1000
Port based GVRP Configuration:
       PORT             Applicant Status        Registration Mode
----------------------  --------------------    --------------------
GigabitEthernet 0/1          normal                  normal
```

(3) After the GVRP function is enabled globally, check the VLANs dynamically created by devices and check whether the trunk ports join dynamic VLANs.

Dynamic VLANs 11 to 20 are created on Device A, and the trunk port Gigabit Ethernet 0/2 joins the dynamic VLANs 11 to 20.

```
DeviceA(config)# show vlan
VLAN        Name                  Status        Ports
----------   ---------------------   ------------   --------------------------
       1   VLAN0001              STATIC       Gi0/1, Gi0/2, Gi0/3, Gi0/4
                                            Gi0/5, Gi0/6, Gi0/7, Gi0/8
     2-10   VLAN0002-VLAN0010       STATIC       Gi0/2
    11-20   DVLAN0011-DVLAN0020     DYNAMIC      Gi0/2
```

Dynamic VLANs 2 to 20 are created on Device B, and the trunk ports GigabitEthernet 0/1 and GigabitEthernet 0/2 join the dynamic VLANs 2 to 20.

```
DeviceB(config)# show vlan
VLAN        Name                  Status        Ports
----------   ---------------------   ------------   --------------------------
       1   VLAN0001              STATIC       Gi0/1, Gi0/2, Gi0/3, Gi0/4
                                            Gi0/5, Gi0/6, Gi0/7, Gi0/8
     2-20   DVLAN0002-DVLAN0020     DYNAMIC      Gi0/1, Gi0/2
```

Dynamic VLANs 2 to 10 are created on Device C, and the trunk port Gigabit Ethernet 0/1 joins the dynamic VLANs 2 to 10.

```
DeviceC(config)# show vlan
VLAN        Name                  Status        Ports
----------   ---------------------   ------------   --------------------------
       1   VLAN0001              STATIC       Gi0/1, Gi0/2, Gi0/3, Gi0/4
                                            Gi0/5, Gi0/6, Gi0/7, Gi0/8
     2-10   DVLAN0002-DVLAN0010     DYNAMIC      Gi0/1
    11-20   VLAN0011-VLAN0020       STATIC       Gi0/1
```

6. Configuration Files

- Device A configuration file

```
gvrp enable
gvrp dynamic-vlan-creation enable
!
vlan range 1-10
!
interface GigabitEthernet 0/2
 switchport
switchport mode trunk
switchport trunk native vlan 1
switchport trunk allowed vlan only 1-4094
```

- Device B configuration file

```
gvrp enable
gvrp dynamic-vlan-creation enable
!
vlan range 1
!
interface GigabitEthernet 0/1
 switchport
switchport mode trunk
switchport trunk native vlan 1
switchport trunk allowed vlan only 1-4094
!
interface GigabitEthernet 0/2
 switchport
switchport mode trunk
switchport trunk native vlan 1
switchport trunk allowed vlan only 1-4094
```

- Device C configuration file

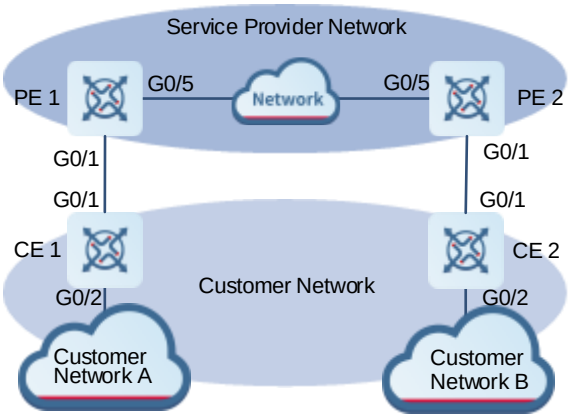
```
gvrp enable
gvrp dynamic-vlan-creation enable
!
vlan range 1,11-20
!
interface GigabitEthernet 0/1
 switchport
switchport mode trunk
switchport trunk native vlan 1
switchport trunk allowed vlan only 1-4094
```

7. Common Errors

- The interconnection interface of devices are not in trunk mode.
- The permitted VLAN list of the interconnection interface of devices does not contain the user communication

VLANs.

- The GVRP advertising mode and registration mode of trunk ports are not set to **Normal**.



1.10.2 Configuring GVRP BPDU Tunnels

1. Requirements

As indicated in Figure 1-4, the GVRP packets of the user network are transmitted through the tunnel of the SP network.

2. Topology

Figure 1-4 Topology of GVRP BPDU Tunnels

3. Notes

- Configure the basic functions of GVRP on PE 1 and PE 2, including enabling the dynamic creation function of VLAN, configuring the interconnection port GigabitEthernet 0/5 as trunk port, and enabling the GVRP function globally.
- Enable the basic QinQ function on the GigabitEthernet 0/1 connected to the user network on PE 1 and PE 2 so that data packets of the user network are transmitted within VLAN 200 on the SP network.
- Enable the GVRP tunnel function on the GigabitEthernet 0/1 connected to the user network on PE 1 and PE 2 so that the SP network can transmit GVRP packets of the user network through the GVRP BPDU tunnel.
- Configure the basic functions of GVRP on CE 1 and CE 2, including: enabling the dynamic VLAN creation function, configuring the uplink interface Gigabit Ethernet 0/1 as the Trunk port, and enabling the GVRP function globally.

4. Procedure

(1) Configure the basic functions of GVRP on the interconnection interface of SP devices.

Enable the GVRP function globally on PE 1 and on Gigabit Ethernet 0/5 in turn. Configure static VLAN 251 to verify the GVRP function.

```
PE1> enable
PE1# configure terminal
PE1(config)# vlan 251
PE1(config-vlan)# exit
PE1(config)# gvrp dynamic-vlan-creation enable
```

```
PE1(config)# interface gigabitethernet 0/5
PE1(config-if-GigabitEthernet 0/5)# switchport
PE1(config-if-GigabitEthernet 0/5)# switchport mode trunk
PE1(config-if-GigabitEthernet 0/5)# switchport trunk native vlan 1
PE1(config-if-GigabitEthernet 0/5)# switchport trunk allowed vlan all
PE1(config-if-GigabitEthernet 0/5)# exit
PE1(config)# gvrp enable
```

Enable the GVRP function globally on PE 2 and Gigabit Ethernet 0/5 in turn. Configure static VLAN 252 to verify the GVRP function.

```
PE2> enable
PE2# configure terminal
PE2(config)# vlan 252
PE2(config-vlan)# exit
PE2(config)# gvrp dynamic-vlan-creation enable
PE2(config)# interface gigabitethernet 0/5
PE2(config-if-GigabitEthernet 0/5)# switchport
PE2(config-if-GigabitEthernet 0/5)# switchport mode trunk
PE2(config-if-GigabitEthernet 0/5)# switchport trunk native vlan 1
PE2(config-if-GigabitEthernet 0/5)# switchport trunk allowed vlan all
PE2(config-if-GigabitEthernet 0/5)# exit
PE2(config)# gvrp enable
```

(2) Configure the basic QinQ function on SP devices. Use VLAN 250 to encapsulate the packets of users at two ends.

Configure the basic QinQ encapsulation on the port Gigabit Ethernet 0/1 connected to the user on PE 1.

```
PE1(config)# vlan 250
PE1(config-vlan)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# switchport
PE1(config-if-GigabitEthernet 0/1)# switchport mode dot1q-tunnel
PE1(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel native vlan 250
PE1(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel allowed vlan add
untagged 250
```

Configure the basic QinQ encapsulation on the port Gigabit Ethernet 0/1 connected to the user on PE 2.

```
PE2(config)# vlan 250
PE2(config-vlan)# exit
PE2(config)# interface gigabitethernet 0/2
PE2(config-if-GigabitEthernet 0/1)# switchport
PE2(config-if-GigabitEthernet 0/1)# switchport mode dot1q-tunnel
PE2(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel native vlan 250
PE2(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel allowed vlan add
untagged 250
```

(3) Enable the GVRP tunnel on SP devices.

Enable the GVRP tunnel on port Gigabit Ethernet 0/1 of PE 1 and globally in turn.

```
PE1(config-if-GigabitEthernet 0/1)# l2protocol-tunnel gvrp enable
```

```
PE1(config-if-GigabitEthernet 0/1)# exit
PE1(config)# l2protocol-tunnel gvrp
```

Enable the GVRP tunnel on port Gigabit Ethernet 0/1 of PE 2 and globally in turn.

```
PE2(config-if-GigabitEthernet 0/1)# l2protocol-tunnel gvrp enable
PE2(config-if-GigabitEthernet 0/1)# exit
PE2(config)# l2protocol-tunnel gvrp
```

(4) Configure the basic functions of GVRP on user network devices.

Enable the GVRP function globally on CE 1 and port Gigabit Ethernet 0/1 in turn.

```
CE1> enable
CE1# configure terminal
CE1(config)# vlan range 60-69
CE1(config-vlan)# exit
CE1(config)# gvrp dynamic-vlan-creation enable
CE1(config)# interface gigabitethernet 0/1
CE1(config-if-GigabitEthernet 0/1)# switchport
CE1(config-if-GigabitEthernet 0/1)# switchport mode trunk
CE1(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
CE1(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
CE1(config-if-GigabitEthernet 0/1)# exit
CE1(config)# gvrp enable
```

Enable the GVRP function globally on CE 2 and port Gigabit Ethernet 0/1 in turn.

```
CE2> enable
CE2# configure terminal
CE2(config)# vlan range 70-79
CE2(config-vlan)# exit
CE2(config)# gvrp dynamic-vlan-creation enable
CE2(config)# interface gigabitethernet 0/1
CE2(config-if-GigabitEthernet 0/1)# switchport
CE2(config-if-GigabitEthernet 0/1)# switchport mode trunk
CE2(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
CE2(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
CE2(config-if-GigabitEthernet 0/1)# exit
CE2(config)# gvrp enable
```

5. Verification

(1) Before the GVRP function is enabled globally, check the static VLAN configuration of the device; check whether the ports for advertising and processing GVRP packets are trunk ports and allow all VLANs to pass.

Only static VLANs exist on PE 1; the uplink port Gigabit Ethernet 0/5 is a trunk port and allows all VLANs to pass.

```
PE1# show vlan
VLAN      Name                          Status    Ports
---------- -------------------------------- ---------
-----------------------------------
       1 VLAN0001                      STATIC    Gi0/1, Gi0/2, Gi0/3, Gi0/4
```

```
                                          Gi0/5, Gi0/6, Gi0/7, Gi0/8
     250 VLAN0250                      STATIC    Gi0/1, Gi0/5
     251 VLAN0251                      STATIC    Gi0/5
PE1# show interface switchport
Interface             Switchport Mode     Access Native Protected VLAN lists
----------------------- ---------- --------- ------ ------ ---------
----------------------
GigabitEthernet 0/1     enabled    TUNNEL         250    Disabled  1,250
GigabitEthernet 0/5     enabled    TRUNK          1      Disabled  ALL
```

Only static VLANs exist on PE 2; the uplink port Gigabit Ethernet 0/5 is a trunk port and allows all VLANs to pass.

```
PE2# show vlan
VLAN      Name                          Status    Ports
---------- -------------------------------- ---------
-----------------------------------
       1 VLAN0001                      STATIC    Gi0/1, Gi0/2, Gi0/3, Gi0/4
                                          Gi0/5, Gi0/6, Gi0/7, Gi0/8
     250 VLAN0250                      STATIC    Gi0/1, Gi0/5
     252 VLAN0252                      STATIC    Gi0/5
PE2# show interface switchport
Interface            Switchport Mode     Access Native Protected VLAN lists
---------------------- ---------- --------- ------ ------ ---------
----------------------
GigabitEthernet 0/1    enabled    TUNNEL    1      250    Disabled  1,250
GigabitEthernet 0/5    enabled    TRUNK          1      Disabled  ALL
```

Only static VLANs exist on GE 1; the unlink port Gigabit Ethernet 0/1 is a trunk port and allows all VLANs to pass.

```
CE1# show vlan
VLAN      Name                          Status    Ports
---------- -------------------------------- ---------
-----------------------------------
       1 VLAN0001                      STATIC    Gi0/1,Gi0/2, Gi0/3, Gi0/4
                                          Gi0/5, Gi0/6, Gi0/7, Gi0/8
    60-69 VLAN0060-VLAN0069             STATIC    Gi0/1
CE1# show interface switchport
Interface             Switchport Mode     Access Native Protected VLAN lists
----------------------- ---------- --------- ------ ------ ---------
----------------------
GigabitEthernet 0/1     enabled    TRUNK          1      Disabled  ALL
```

Only static VLANs exist on CE 2; the uplink port Gigabit Ethernet 0/1 is a trunk port and allows all VLANs to pass.

```
CE2# show vlan
VLAN      Name                          Status    Ports
---------- -------------------------------- ---------
-----------------------------------
```

```
       1 VLAN0001                      STATIC    Gi0/1,Gi0/2, Gi0/3, Gi0/4
                                                 Gi0/5, Gi0/6, Gi0/7, Gi0/8
    70-79 VLAN0070-VLAN0079             STATIC    Gi0/1
CE2# show interface switchport
Interface            Switchport Mode     Access Native Protected VLAN lists
---------------------- ---------- --------- ------ ------ ---------
----------------------
GigabitEthernet 0/1    enabled    TRUNK         1     Disabled  ALL
```

(2) Check whether the QinQ function is enabled, the SP device port connected to the user is the Dot1q-tunnel port, and the GVRP tunnel function is enabled.

Check the GVRP BPDU tunnel configuration on PE 1, and check whether the interface type is **Dot1q-tunnel**.

```
PE1# show interfaces dot1q-tunnel
========Interface Gi0/1========
Native vlan: 250
Allowed vlan list:1,250,
Tagged vlan list:

PE1# show l2protocol-tunnel gvrp
L2protocol-tunnel: Gvrp Enable
L2protocol-tunnel destination mac address: 01d0.f800.0006
GigabitEthernet 0/1 l2protocol-tunnel gvrp enable
```

Check the GVRP BPDU tunnel configuration on PE 2, and check whether the interface type is **Dot1q-tunnel**.

```
PE2# show interfaces dot1q-tunnel
========Interface Gi0/1========
Native vlan: 250
Allowed vlan list:1,250,
Tagged vlan list:

PE2# show l2protocol-tunnel gvrp
L2protocol-tunnel: Gvrp Enable
L2protocol-tunnel destination mac address:01d0.f800.0006
GigabitEthernet 0/1 l2protocol-tunnel gvrp enable
```

(3) After the GVRP function is enabled globally using the **gvrp enable** command, check the GVRP configuration of devices.

Check whether the GVRP function of PE 1 has been enabled, and the trunk port normally advertises the GVRP information and dynamically updates the VLAN information.

```
PE1# show gvrp configuration
Global GVRP Configuration:
GVRP Feature:enabled
GVRP Dynamic VLAN Creation:enabled
Join Timers(ms):200
Leave Timers(ms):600
```

```
Leaveall Timers(ms):10000
Port based GVRP Configuration:
       PORT            Applicant Status        Registration Mode
----------------------  -------------------    --------------------
GigabitEthernet 0/5          normal                 normal
```

Check whether the GVRP function of PE 2 has been enabled, and the trunk port normally advertises the GVRP information and dynamicallyupdates the VLAN information.

```
PE2# show gvrp configuration
Global GVRP Configuration:
GVRP Feature:enabled
GVRP Dynamic VLAN Creation:enabled
Join Timers(ms):200
Leave Timers(ms):600
Leaveall Timers(ms):10000
Port based GVRP Configuration:
       PORT            Applicant Status        Registration Mode
----------------------  -------------------    --------------------
GigabitEthernet 0/5          normal                 normal
```

Check whether the GVRP function of CE 1 has been enabled, and the trunk port normally advertises the GVRP information and dynamicallyupdates the VLAN information.

```
CE1# show gvrp configuration
Global GVRP Configuration:
GVRP Feature:enabled
GVRP Dynamic VLAN Creation:enabled
Join Timers(ms):200
Leave Timers(ms):600
Leaveall Timers(ms):10000
Port based GVRP Configuration:
       PORT            Applicant Status        Registration Mode
----------------------  -------------------    --------------------
GigabitEthernet 0/1          normal                 normal
```

Check whether the GVRP function of CE 2 has been enabled, and the trunk port normally advertises the GVRP information and dynamicallyupdates the VLAN information.

```
CE2# show gvrp configuration
Global GVRP Configuration:
GVRP Feature:enabled
GVRP Dynamic VLAN Creation:enabled
Join Timers(ms):200
Leave Timers(ms):600
Leaveall Timers(ms):10000
Port based GVRP Configuration:
       PORT            Applicant Status        Registration Mode
----------------------  -------------------    --------------------
GigabitEthernet 0/1          normal                 normal
```

(4) After the GVRP function is enabled globally, check whether SP network devices can dynamically create VLANs on them; VLANs of user network will not be created dynamically. It indicates that the GVRP packets of user network do not affect the GVRP operation of SP devices.

Dynamic VLAN 252 has been created on PE 1, and the trunk port Gigabit Ethernet 0/5 joins the dynamic VLAN 252.

```
PE1(config)# show vlan
VLAN      Name                           Status    Ports
---------- -------------------------------- ---------
-----------------------------------
       1 VLAN0001                      STATIC    Gi0/1, Gi0/2, Gi0/3, Gi0/4
                                                 Gi0/5, Gi0/6, Gi0/7, Gi0/8
     250 VLAN0250                      STATIC    Gi0/1, Gi0/5
     251 VLAN0251                      STATIC    Gi0/5
     252 DVLAN0252                     DYNAMIC   Gi0/5
```

Dynamic VLAN 251 has been created on PE 2, and the trunk port Gigabit Ethernet 0/5 joins the dynamic VLAN 251.

```
PE2(config)# show vlan
VLAN      Name                           Status    Ports
---------- -------------------------------- ---------
-----------------------------------
       1 VLAN0001                      STATIC    Gi0/1, Gi0/2, Gi0/3, Gi0/4
                                                 Gi0/5, Gi0/6, Gi0/7, Gi0/8
     250 VLAN0250                      STATIC    Gi0/1, Gi0/5
     251 DVLAN0251                     DYNAMIC   Gi0/5
     252 VLAN0252                      STATIC    Gi0/5
```

(5) After the GVRP function is enabled globally, check whether user network devices dynamically create VLANs of user network. It indicates that the GVRP packets of user network are transmitted through the tunnels of SP devices.

Dynamic VLANs 70 to 79 have been created on CE 1, and the trunk port Gigabit Ethernet 0/1 joins the dynamic VLANs 70 to 79.

```
CE1(config)# show vlan
VLAN      Name                           Status    Ports
---------- -------------------------------- ---------
-----------------------------------
       1 VLAN0001                      STATIC    Gi0/1,Gi0/2, Gi0/3, Gi0/4
                                                 Gi0/5, Gi0/6, Gi0/7, Gi0/8
    60-69 VLAN0060-VLAN0069             STATIC    Gi0/1
    70-79 DVLAN0070-DVLAN0079           DYNAMIC   Gi0/1
```

Dynamic VLANs 60 to 69 have been created on CE 2, and the trunk port Gigabit Ethernet 0/1 joins the dynamic VLANs 60 to 69.

```
CE2(config)# show vlan
VLAN      Name                           Status    Ports
---------- -------------------------------- ---------
-----------------------------------
```

```
       1 VLAN0001                    STATIC    Gi0/1,Gi0/2, Gi0/3, Gi0/4
                                               Gi0/5, Gi0/6, Gi0/7, Gi0/8
    60-69 DVLAN0060-DVLAN0069          DYNAMIC   Gi0/1
    70-79 VLAN0070-VLAN0079            STATIC    Gi0/1
```

6. Configuration Files

- PE 1 configuration file

```

```

7. Common Errors

On the SP network, the configured GVRP BPDU tunnel addresses are inconsistent at two ends, causing that GVRP BPDU frames cannot be correctly transmitted.

1 Configuring QinQ

1.1 Introduction

1.1.1 Overview

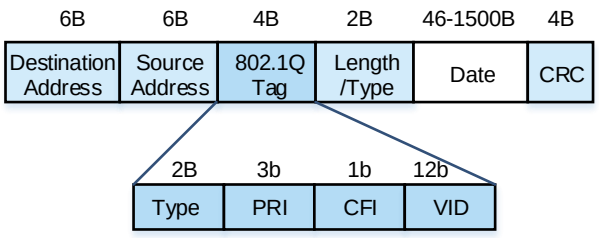
When a client packet enters a provider edge (PE), the QinQ technology first encapsulates the packet with a public virtual local area network (VLAN) tag before transmitting the packet in the SP network. The private VLAN tag, if any, in the client packet is regarded as data. Then, the packet carries two VLAN tags to pass through the SP network.

1.1.2 Background and Function

1. Background

On a metropolitan area network (MAN), SPs need a large number of VLANs to isolate and identify clients so as to achieve refined management. As a variety of services develop, SPs also need to differentiate services to provide different transmission pipelines and QoS policies. However, IEEE 802.1Q supports 4094 VLANs only, far from meeting the needs of SPs.

2. Function



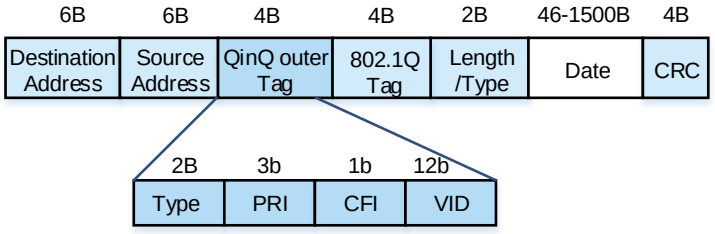
- QinQ is a kind of dual-tag encapsulation technology. It adds outer VLAN tags to packets in the SP network so that client VLANs in different private networks can be reused to increase the number of VLAN tags available to clients. The number of VLANs actually available to SPs is increased to 4094x4094.
- An outer tag is also equivalent to a tunnel, which enables transparent transmission of inner tags. This turns QinQ into a layer-2 VPN solution that is low in cost, easy to deploy, and suitable for small-sized networks.
- Inner and outer tags can also represent different information according to service requirements, helpful for SPs to segment and manage their services.

1.1.3 QinQ Packet Format

- Ethernet frame with a single VLAN tag

  The IEEE 802.1Q standard modifies the Ethernet frame format by adding a 4-byte 802.1Q tag between the source MAC address field and protocol type field. Figure 1-1 shows the frame format. The tag contains a VID (VLAN ID) field, which is used to indicate the VLAN where the frame is. Not all devices can identify 802.1Q frames with tags, and therefore Ethernet frames on VLANs can be tagged or untagged.

Figure 1-1 Frame Format of 802.1Q Encapsulation



- **Type**: Consisting of 2 bytes; 0x8100 indicates 802.1Q frame. Devices that do not support IEEE 802.1Q will drop such frames received.
- **PRI**: Consisting of 3 bits, indicating layer-2 priority. The value range is 0 to 7, corresponding to CoS priorities of QoS. A larger value indicates a higher priority.
- **CFI**: Consisting of 1 bit, used to distinguish Ethernet frame, FDDI frame, and token ring network frame; 0 indicates Ethernet frame.
- **VID**: Consisting of 12 bits, indicating the client VLAN ID; values 0 and 4095 are reserved and unavailable. The value range is from 1 to 4094.

- Ethernet frame with QinQ dual VLAN tags

  The QinQ function inserts a 4-byte QinQ outer tag (including four fields: **Type**, **PRI**, **CFI**, and **VID**) before the 802.1Q tag.

Figure 1-2 Frame Format of QinQ Encapsulation

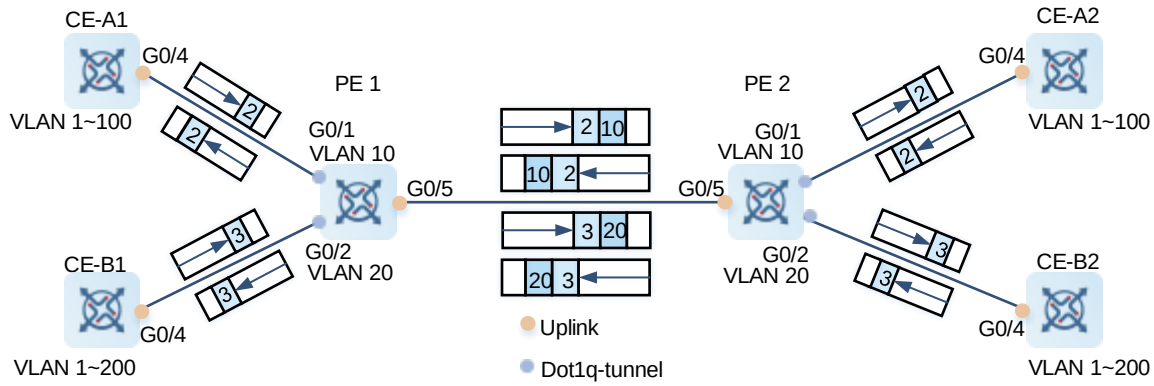
Type: Consisting of 2 bytes, also known as TPID; the default value is 0x8100, indicating 802.1Q frame. On the devices of some vendors, the TPID is set to 0x9100 or other values. TPID can be configured (Configuring TPID) to ensure that the TPIDs of packets to be forwarded are compatible with the TPIDs supported by third-party devices.

- **PRI**: Consisting of 3 bits, indicating priority; the default value 0 indicates a normal flow. The value of this field corresponds to the CoS value in the QoS policy. A larger value indicates a higher priority. The value of this field can be modified by configuring priority replication or priority mapping (Configuring Priority Replication or Priority Mapping) to define different transmission priority policies for packets.
- **CFI**: Consisting of 1 bit, used to distinguish Ethernet frame, FDDI frame, and token ring network frame; value 0 indicates Ethernet frame.
- **VID**: Consisting of 12 bits, indicating the SP VLAN ID. The value is from 1 to 4094.

1.1.4 QinQ Packet Forwarding

1. QinQ Encapsulation

The ingress of an SP's QinQ edge device is called dot1q-tunnel port. All the frames entering the edge device, no matter whether they carry the 802.1Q tag or not, will be packaged with the SP tag and then be forwarded. As shown in Figure 1-3, when a packet of CE-A1 is forwarded to PE 1, the dot1q-tunnel port encapsulates the packet with a VLAN 10 tag, and then forwards the packet from the uplink port. This process is called QinQ encapsulation. QinQ encapsulation is classified into Basic QinQ Encapsulation and Selective QinQ Encapsulation. Selective QinQ encapsulation is further classified into client tag-based encapsulation and ACL-based encapsulation.



2. QinQ Forwarding

A QinQ-encapsulated packet will be transmitted in the SP network. Generally, devices directly forward the QinQ packet with dual tags. During the transmission, you may need to modify the VIDs in the inner and outer tags. In this case, you can configure a modification policy on the access, trunk, hybrid, or uplink port to modify QinQ tags (Modifying QinQ Tag).

3. QinQ Decapsulation

When a packet with an SP tag is forwarded to PE 2, PE 2 will forward the packet to the dot1q-tunnel port with native VLAN set to VLAN 10. The dot1q-tunnel port then strips the outer tag of the packet and sends the packet to CE-A2. This process is called QinQ decapsulation. The decapsulation mode must be consistent with the encapsulation mode.

Figure 1-3 QinQ Packet Forwarding Process

Note

- The QinQ encapsulation and decapsulation functions are usually used on client-oriented interfaces to implement classification, package management, and transmission of client data.
- QinQ termination means that, after receiving packets, the device identifies and strips the dual VLAN tags, and then sends the packets to other service modules for processing. The QinQ termination function is usually used on a server or network core device to terminate client VLAN tags and realize the functions such as client location or service identification. QinQ termination is not QinQ decapsulation. QinQ decapsulation strips only the outer tag, while QinQ termination strips the dual tags.

1.1.5 Basic QinQ Encapsulation

In the QinQ scenario, the PE edge port connected to the client network will first encapsulate the outer tag for the user packets, and then transmit the packets in the ISP network. The edge port must be configured as a dot1q tunnel port. One dot1q tunnel port can have one native VLAN and several allowed VLANs. Allowed VLANs are divided into Tagged VLANs and Untagged VLANs. The dot1q tunnel port can only be connected to trunk links.

The basic QinQ encapsulation mode is based on the process that the interface encapsulates the packets with tags. The VLAN ID in the tag is the native VLAN of dot1q-tunnel port. Therefore, the VLAN of the ISP network must be configured as the native VLAN of the dot1q tunnel port. To ensure the communication of upstream and downstream packets, the native VLAN must be added to the allowed untagged VLAN list of the port.

After receiving packets, the dot1q-tunnel port regards all the packets as untagged regardless of whether they carry tags, determines whether the packets belong to the native VLAN of the local interface, learns the corresponding relationship between the client-end MAC address and the native VLAN, and stores it in the MAC address table. After that, the interface adds a tag with VID set to the native VLAN to the packets and then forwards the packets.

If the original packet does not carry a VLAN tag, the packet will have only one tag with native VLAN ID after undergoing QinQ encapsulation. If the original packet carries a VLAN tag, the packet will carry dual tags after undergoing QinQ encapsulation and be transmitted in the SP network.

By default, the native VLAN of dot1q-tunnel port is VLAN 1 and the only one allowed VLAN is untagged VLAN 1. "Untagged" in the QinQ function means that the outer tag of QinQ is not carried, because the dot1q-tunnel port must strip the outer tag before sending the packet back to the client network.

Weaknesses: The basic QinQ encapsulation cannot distinguish the types of client packets received by the interface or select the VLAN used for packet encapsulation, and therefore it is not flexible enough.

1.1.6 Selective QinQ Encapsulation

Selective QinQ encapsulation flexibly adds different outer VLAN tags to data flows according to rules.

Selective QinQ implements two encapsulation modes:

- Add an outer VLAN tag based on the inner client VLAN tag.

  The selective QinQ based on C-Tag can distinguish different types of data flows according to the client VLAN tag, and encapsulate different outer tags to implement transparent transmission.

- Add an outer VLAN tag based on the packet content ACL.

  The selective QinQ based on ACL can distinguish the MAC address, IP protocol, source address, destination address, and priority of service flows, or the interface number of applications by using ACL policies, and encapsulate different service flows with different VLAN tags to implement transparent transmission. In this case, the VLAN ID in the VLAN tag is not necessarily the native VLAN of the interface.

When using this function, in addition to configuring the selective QinQ encapsulation policy, you also need to add the outer VLAN to the list of allowed VLANs of the dot1q-tunnel port.

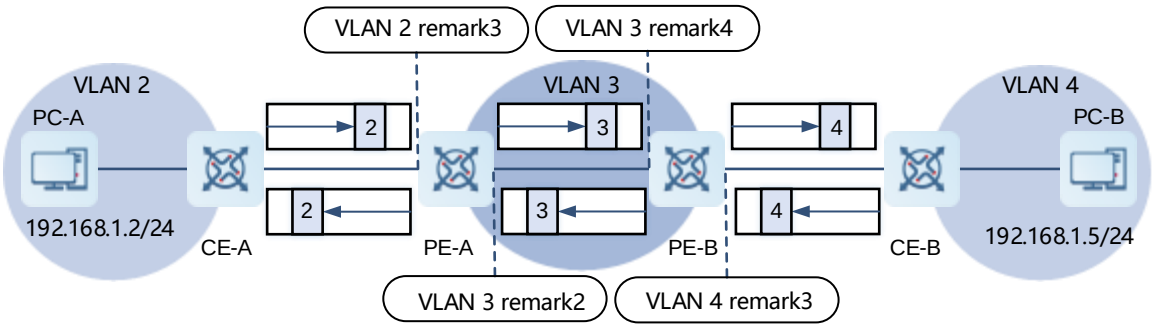
Weaknesses: After the dot1q-tunnel port receives a packet, the learned MAC address entry is the corresponding relationship between the native VLAN and the client MAC address; the packet returned by the peer end belongs to the outer VLAN, and the corresponding entries of the outer VLAN and the client-end MAC address cannot be found in the MAC address table, which will cause the device to perform flooding so as to find the egress of packets.

To solve this problem, use the function in MAC Address Replication to replicate the MAC address of the native VLAN to the outer VLAN.

1.1.7 Modifying QinQ Tag

In the process of QinQ packet transmission, if the outer or inner tags of data packets in the SP network need to be modified due to the actual network topology requirement, the QinQ tag modifying function needs to be enabled. The device can distinguish the packets of different clients, different services, and different priorities based on policies, and modify the VLAN IDs for the inner or outer tags of packets.

1.1.8 VLAN-Mapping



The VLAN mapping function can convert client VLAN IDs and SP VLAN IDs to implement inter-VLAN layer-2 communication. This function takes effect on the access, trunk, hybrid, or uplink ports. VLAN mapping is a function of modifying tags, not adding tags.

As shown in Figure 1-4, when receiving a client packet of PC-A in VLAN 2, PE-A replaces private VLAN 2 in the packet with public VLAN 3 for transmission according to the configured mapping relationship VLAN 2 remark 3; when receiving a packet from public VLAN 3, PE-B maps public VLAN 3 to client VLAN 4 according to the mapping relationship VLAN 3 remark 4 so that PC-B can receive the packet. When receiving a client packet of PC-B in VLAN 4, PE-B restores private VLAN 4 in the packet to public VLAN 3 for transmission according to the mapping relationship VLAN 4 remark 3; when receiving a packet from public VLAN 3, PE-A restores public VLAN 3 to client VLAN 2 according to the mapping relationship VLAN 3 remark 2 so that PC-A can receive the response packet. In this way, inter-VLAN layer-2 communication is achieved between PC-A and PC-B.

If the planning of two client networks is asymmetric or the VLAN IDs of the new and old networks conflict with each other, the VLAN mapping function can be used to achieve inter-VLAN layer-2 communication. Two prerequisites are required for this communication mode:

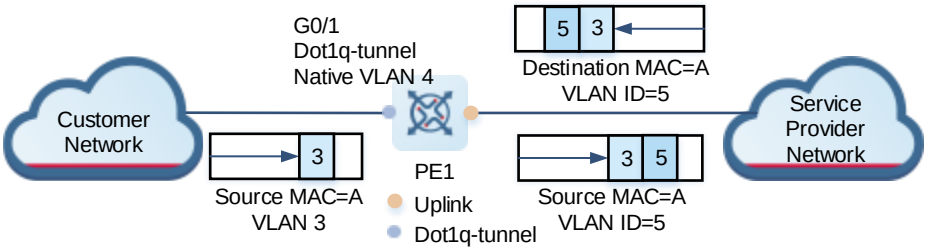
- The clients at two ends are in the same network segment. If the receiving and sending end clients are not in the same network segment, they will rely on layer-3 communication, and VLAN mapping makes no sense.
- The packet received by PE needs to carry a tag. Therefore, the uplink port of CE needs to send the packet carrying a tag.

Figure 1-4 Introduction to the VLAN Mapping Function

1.1.9 MAC Address Replication

- Source

After receiving a packet, the interface will learn the corresponding relationship between the source MAC address of the packet and the VLAN and write it to the MAC address table. If receiving a tagged packet, the access, trunk, hybrid, and uplink ports will learn the corresponding relationship between the VLAN ID and MAC address in the tag; if receiving an untagged packet, they will learn the corresponding relationship between the native VLAN and MAC address. After receiving packets, the dot1q-tunnel port regards all the packets as untagged regardless of whether they carry tags, and determines whether the packets belong to the native VLAN of the local interface. Therefore, the dot1q-tunnel port always learns the corresponding relationship between its native VLAN and client MAC address.



If basic QinQ encapsulation is used, the VLAN ID in the outer tag is native VLAN ID. When receiving a response packet from the peer end, the device can find the corresponding relationship between the client MAC address and the outer VLAN in the MAC address table. If selective QinQ encapsulation is used, the VLAN ID in the outer tag is not the native VLAN ID. When receiving a response packet from the peer end, the device cannot find the matched MAC address entry, and therefore it will perform packet flooding, occupying network resources and affecting the performance.

If the MAC address replication function is enabled, when learning a dynamic address, the interface can replicate the MAC address in the native VLAN to the VLAN where the outer tag is located, thus solving the problem of continuous flooding of the packets returned from the public network. Similarly, the MAC address in the VLAN where the outer tag is can also be replicated to the native VLAN to avoid continuous flooding of the packets from the client network to the public network.

- Principles

As shown in Figure 1-5, the interface connecting PE 1 and the client network is dot1q-tunnel, and native VLAN 4 is configured on this interface. Configure an ACL-based QinQ encapsulation policy, and encapsulate the packet with source MAC address A by using the outer tag VLAN 5. When receiving a packet of client network VLAN 3 and source MAC address A from the interface Gigabit Ethernet 0/1, PE 1 adds the outer tag of VLAN 5. At the same time, because the native VLAN of the receiving interface is VLAN 4, PE1 learns the entry <VLAN 4, MAC-A, GigabitEthernet 0/1>. When a response packet is returned, because the VLAN ID of its outer tag is 5, PE 1 will look for MAC-A in VLAN 5, but MAC-A is not learned into VLAN 5, and therefore this packet will be flooded. If MAC address replication is configured and MAC-A in VLAN 4 is replicated to VLAN 5, the dynamic MAC address entry <VLAN 5, MAC-A, GigabitEthernet 0/1> will be added to PE 1. When a response packet is returned, PE 1 can find that the packet should be forwarded to GigabitEthernet 0/1, thus avoiding flooding.

Figure 1-5 MAC Address Replication

1.1.10 Layer-2 Protocol Tunneling

- Source

Spanning Tree Protocol (STP) is an application that eliminates layer-2 loops by blocking redundant links on the network. It also provides the link backup function. It will transmit a special bridge protocol data unit (BPDU) packet on the network. After recognizing such a packet, the device will calculate the spanning tree according to the packet information, which may lead to modification of the network topology.

The generic attribute registration protocol VLAN registration protocol (GVRP) is an application used to dynamically configure and diffuse VLAN memberships. It will transmit special VLAN registration and deregistration packets on the network. After recognizing a GVRP packet, the device will modify the VLAN relationship according to the packet information, which will also affect the network topology.

To unify the internal topology of the client network when the client networks are interconnected across the SP network, run STP and GVRP on the client network. However, such a special layer-2 protocol packet will be

identified as a special packet by the SP device and participate in the SP topology calculation, affecting the SP network topology.

Therefore, the STP and GVRP packets of the client network must be transmitted through a tunnel in the SP network, so that the SP can forward the client's special packets as ordinary packets. The layer-2 packet tunnel function is needed in this case.

- Principles

When a layer-2 protocol packet of the client network enters a PE, the destination MAC address is changed to a private address for forwarding in the SP network. When the packet arrives at an edge device of the other end, the destination MAC address is changed to a public address before the packet is returned to the client network of the other end. This implements layer-2 protocol packet transmission through a tunnel in the SP network.

1.1.11 Protocols and Standards

- IEEE 802.1ad: IEEE Standard for Local and Metropolitan Area Networks---Virtual Bridged Local Area Networks---Amendment 4:Provider Bridges

1.2 Restrictions and Guidelines

- The QinQ feature only takes effect on a Layer 2 interface. A Layer 3 interface cannot be directly configured as a dot1q tunnel port, and must be configured as a Layer 2 interface first.
- You can use the **show interface switchport** command to view the interface type. If the Switchport field corresponding to the interface is "enabled", it means that the interface is a Layer 2 interface. If the Switchport field corresponding to the interface is "disabled", it means that the interface is a Layer 3 interface.
- You can use the **switchport** command to configure the interface as a Layer 2 interface. First, use the **no switchport mode** command to restore the mode of the Layer 2 interface to the default value, and then use the **no switchport** command to configure the Layer 2 interface as a Layer 3 interface. When the Layer 2/Layer 3 mode of the interface is modified, all properties of the interface are restored to the default values of the interface type.
- The IEEE 802.1x function cannot be enabled on an interface configured as a dot1q-tunnel port.
- The port security function cannot be enabled on an interface configured as a dot1q-tunnel port.
- When a dot1q-tunnel port is configured as the source port of the remote switched port analyzer (RSPAN), the packets whose outer tags contain VIDs consistent with the RSPAN VLAN IDs are monitored as a data flow.
- If you want to match the ACL applied to the dot1q-tunnel port with the VID in the client tag, use the **inner** keyword. See *Configuring ACL* in *ACL and QoS Configuration Guide*.
- After a switch port is enabled with QinQ, you must enable SVGL sharing before IGMP snooping. Otherwise, IGMP snooping will not work on the QinQ-enabled port. See *Configuring IGMP Snooping*.
- You are advised to configure the egress on the client network that is connected to the SP network as an uplink port. The SP TPID value for the uplink port of the client network must be the same as that for the downlink interface of the SP network.
- The default MTU value of an interface is 1,500 bytes. After added with an outer VLAN tag, a packet is four bytes longer. You are advised to increase the MTU value of each interface in the SP networks to at least 1,504 bytes.

1.3 Configuration Task Summary

1.3.1 Configuring Tag Adding

QinQ tag adding includes the following tasks:

(1) Configure the QinQ encapsulation mode of the dot1q-tunnel port. Select at least one of them to configure.

- Configuring Basic QinQ Encapsulation
- Configuring C-Tag-Based Selective QinQ Encapsulation
- Configuring ACL-Based Selective QinQ Encapsulation

(2) (Optional) Configuring MAC Address Replication

(3) (Optional) Configuring Priority Replication or Priority Mapping. The following configuration tasks are mutually exclusive.

- Configuring Priority Replication
- Configuring Priority Mapping

(4) (Optional)Configuring TPID

1.3.2 Configuring Tag Modification

Configure the tag modification mode. The following tasks are optional.

- Configuring QinQ Tag Modification Policy.
- Configuring VLAN-Mapping

1.3.3 Configuring Layer-2 Protocol Tunneling

Configuring Layer-2 Protocol Tunneling includes the following tasks:

- Configuring Layer-2 Protocol Tunneling. The following configuration tasks are optional.
  - Configuring STP Packet Tunneling
  - Configuring GVRP Packet Tunneling

1.4 Configuring Basic QinQ Encapsulation

1.4.1 Overview

Implement layer-2 VPN based on a port-based QinQ policy.

1.4.2 Restrictions and Guidelines

- Configure a VLAN of the SP network as the native VLAN of the dot1q-tunnel port. Because the trunk port will strip the tag of the packet whose VLAN ID is its native VLAN, do not configure the native VLAN of the trunk port in the SP network as the native VLAN of the dot1q-tunnel port.
- After the native VLAN of the dot1q-tunnel port is configured, the data of the VLAN cannot pass through the interface. The native VLAN must be added to the list of untagged VLANs allowed by the dot1q-tunnel port. After the configuration, the dot1q-tunnel port can output the packets of native VLAN without tags.
- If the native VLAN is added to the list of allowed tagged VLANs, packets of the native VLAN output from the dot1q-tunnel port will carry the tag of the SP VLAN, while the client device cannot identify the VLAN ID of SP

network. Therefore, in order to ensure normal communication of the uplink and downlink packets in the application of QinQ, the SP VLAN (native VLAN) must be added to the allowed VLAN list of the interface in the untagged form.

- If port-based QinQ is enabled, you do not need to add the VLAN of the client network to the allowed VLAN list of the dot1q-tunnel port. If selective QinQ is enabled, add the VLAN of the client network to the allowed VLAN list of the interface in the tagged or untagged form based on the actual conditions.

1.4.3 Prerequisites

- Configure the interface as a Layer 2 interface.

1.4.4 Procedure

(1) Create an SP VLAN.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create an SP VLAN.

vlan *svid*

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

(2) Enter the interface configuration mode, and configure the interface for connecting to the client network.

a Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

b Enter the Layer 2 aggregate interface configuration mode.

interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

c Configure the Layer 2 interface as a dot1q-tunnel port.

switchport mode dot1q-tunnel

An interface works in access mode by default.

d Configure to add the SP VLAN to the untagged VLAN list of the dot1q-tunnel port.

switchport dot1q-tunnel allowed vlan { [**add**] **untagged** *svid* | **remove** *other-vlan-id* }

By default, the allowed VLAN of dot1q-tunnel port is untagged VLAN 1.

(3) Configure the SP VLAN as the native VLAN of dot1q-tunnel port so that the client network data is transmitted through a tunnel on the SP VLAN.

switchport dot1q-tunnel native vlan *svid*

The native VLAN of the dot1q-tunnel port is VLAN 1 by default.

1.5 Configuring C-Tag-Based Selective QinQ Encapsulation

1.5.1 Overview

Encapsulate outer VLAN tags (S-Tags) in packets based on inner tags to ensure preferential transmission and management of layer-2 VPN and service flows.

1.5.2 Restrictions and Guidelines

- This function must be configured based on the basic QinQ, and prevails over the basic QinQ policy.
- In the network environment, for packets received on the dot1q-tunnel port, the VID of the outer tag needs to be modified according to the VID of the inner tag. With this command, you can add an outer VID the same as the inner VID to the packet so as to output the original VID tag packet from the egress.
- To continue to adopt the VLAN tag priority specified by the client network, you can configure priority replication to configure an outer tag the same as the inner tag.
- If the SP network requires the transmission of packets based on the priority of the outer tag, you also need to configure priority replication to set the CoS of the outer tag to the specified value.

Caution

- The priority of the VID change policies in a descending order: ACL-based > C-Tag-based > port-based.
- When a member is added to/deleted from a Layer 2 aggregate interface, the policy of adding or modifying the VID configured on the aggregate interface is deleted and needs to be reconfigured. You are advised to configure the VIP policy on an aggregate interface after configuring the members.
- You must configure the dot1q-tunnel port and the interface connected to the public network to permit packets with specified VLAN IDs (including the native VLAN ID) in the outer tag to pass through.

1.5.3 Prerequisites

Configure the interface as a Layer 2 interface.

1.5.4 Procedure

(1) Create an SP VLAN.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create a group of SP VLANs.

vlan range *svidA,svidB*

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

(2) Enter the interface configuration mode to configure the interface for connecting the client network.

o Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(3) Configure the Layer 2 Ethernet interface as a dot1q-tunnel port.

switchport mode dot1q-tunnel

A Layer 2 interface works in access mode by default.

(4) Configure to add the SP VLAN to the untagged VLAN list of the dot1q-tunnel port.

switchport dot1q-tunnel allowed vlan { [**add**] **untagged** *svidA,svidB* | **remove** *other-vlan-id* }

By default, the allowed VLAN of dot1q-tunnel port is untagged VLAN 1.

(5) Configure the C-Tag-based QinQ encapsulation rule. The packets of different client VLANs are allocated to different SP VLANs for transmission through a tunnel.

a The packets of client VLAN *cvid-lista* are allocated to the SP VLAN *svidA*.

dot1q outer-vid *svidA* **register inner-vid** *cvid-lista*

No policy of adding an outer VID based on the inner VID of packets is configured by default.

b The packets of client VLAN *cvid-listb* are allocated to the SP VLAN *svidB*.

dot1q outer-vid *svidB* **register inner-vid** *cvid-listb*

No policy of adding the outer VID based on the inner VID of packets is configured by default.

1.6 Configuring ACL-Based Selective QinQ Encapsulation

1.6.1 Overview

Encapsulate outer VLAN tags (S-Tags) in packets based on the ACL-based flow classification to allow the SP network to manage different services.

For input packets of dot1q-tunnel port on the network, if the outer tags with different VLAN IDs need to be added according to different packet contents, this function must be configured.

1.6.2 Restrictions and Guidelines

- To continue to adopt the VLAN tag priority specified by the client network, you can configure priority replication to configure an outer tag the same as the inner tag.
- If the SP network requires the transmission of packets based on the priority of the outer tag, you also need to configure priority replication to set the CoS of the outer tag to the specified value.
- The **expert access-list extended** command is used to configure the extended expert ACL and enter the extended expert ACL configuration mode. The command format is as follows: **expert access-list extended** { *acl-name* | *acl-number* }. *acl-name*: Extended expert ACL name. The value is a case-sensitive string of 1 to 99 characters. *acl-number*: Extended expert ACL number. The value range is from 2700 to 2899. For the sake of easy description, the **expert access-list extended** *acl-number* command is taken as an example in the configuration procedure.

  The **permit** command is used to add an ACL rule of the allowed type to an ACL. For the detailed syntax, see *Configuring ACL*. For the sake of easy description, the **permit** *ethernet-type any any* command is taken as an example in the configuration procedure.

Caution

- The policy of adding the VID based on ACL prevails over those based on C-Tag and port.
- When an ACL is deleted, the related policy will be automatically deleted.
- Upon receiving a packet with two or more tags, the dot1q-tunnel port cannot add an outer tag to the packet based on the flow-based matching rule.
- If a packet matches two or more data flow-based VID adding policies without priority, only one policy is executed. You are advised to specify the priority when configuring a policy.
- You must configure the dot1q-tunnel port and the interface connected to the public network to permit packets with specified VLAN IDs (including the native VLAN ID) in the outer tag to pass through.

1.6.3 Prerequisites

Configure the interface as a Layer 2 interface.

1.6.4 Procedure

(1) Create a traffic classification and define a packet matching rule.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create a professional extended ACL *acl-number-a* and enter the professional extended ACL configuration mode.

expert access-list extended *acl-number-a*

By default, there is no professional extended ACL rule in the ACL.

d Add an ACL rule of the allowed type to ACL *acl-number-a*.

permit *ethernet-type-a any any*

By default, there is no ACL rule of the allowed type in the ACL.

e Return to the global configuration mode.

exit

f Create a professional extended ACL *acl-number-b* and enter the professional extended ACL configuration mode.

expert access-list extended *acl-number-b*

By default, there is no professional extended ACL rule in the ACL.

g Add an ACL rule of the allowed type to ACL *acl-number-b*.

permit *ethernet-type-b any any*

By default, there is no ACL rule of the allowed type in the ACL.

h Return to the global configuration mode.

exit

(2) Create an SP VLAN.

a Create a group of SP VLANs.

vlan range *svidA,svidB*

Only VLAN 1 exists by default.

b Return to the global configuration mode.

exit

(3) Enter the interface configuration mode to configure the interface for connecting the client network.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the Layer 2 Ethernet interface as a dot1q-tunnel port.

switchport mode dot1q-tunnel

A Layer 2 interface works in access mode by default.

(5) Configure to add the SP VLAN to the untagged VLAN list of the dot1q-tunnel port.

switchport dot1q-tunnel allowed vlan { [**add**] **untagged** *svidA,svidB* | **remove** *other-vlan-id* }

By default, the allowed VLAN of dot1q-tunnel port is untagged VLAN 1.

(6) Configure the ACL-based QinQ encapsulation rule. The packets matching different ACL rules are allocated to different SP VLANs for transmission through a tunnel.

a The packets matching ACL *acl-number-a* are allocated to the SP VLAN *svidA*.

traffic-redirect access-group *acl-number-a* **nested-vlan** *svidA* **in**

The policy of adding an outer VLAN ID based on ACL is not configured by default.

b The packets matching ACL *acl-number-b* are allocated to the SP VLAN *svidB*.

traffic-redirect access-group *acl-number-b* **nested-vlan** *svidB* **in**

The policy of adding an outer VLAN ID based on ACL is not configured by default.

1.7 Configuring MAC Address Replication

1.7.1 Overview

If selective QinQ encapsulation is used, the VLAN ID in the outer tag is not the native VLAN ID. When receiving a response packet from the peer end, the device cannot find the matched MAC address entry, and therefore it will perform packet flooding, occupying network resources and affecting the performance.

If the MAC address replication function is enabled, when learning a dynamic address, the dot1q-tunnel port can replicate the MAC address in the native VLAN to the VLAN where the outer tag is located, thus solving the problem of continuous flooding of the packets returned from the public network. Similarly, the MAC address in the VLAN where the outer tag is can also be replicated to the native VLAN to avoid continuous flooding of the packets from the client network to the public network.

1.7.2 Restrictions and Guidelines

- The MAC address replication function cannot be configured on the host and promiscuous interfaces, or the destination interface with port security and imaging enabled, or the interface with the 802.1x function

enabled.

- After MAC address replication is disabled, the system will delete all the learned MAC address entries from the destination VLAN. The MAC address entries obtained through MAC address replication between VLANs cannot be deleted manually. When you need to delete these entries, disable MAC address replication.
- *mapping-id* indicates the index number of the MAC address replication policy. The value range is from 1 to 8, and therefore each port can be configured with up to eight destination VLANs.
- *source-vlan-list* indicates the source VLAN list. The value range is from 1 to 4094. One single command can contain one or more VLANs.
- *destination-vlan-id* indicates the destination VLAN. The value range is from 1 to 4094. Only one destination VLAN can be specified in one command. MAC address replication between VLANs can be configured on an interface for one single destination VLAN once only. To make modification, you need to delete the previous configuration before reconfiguration. MAC address replication takes effect even if the interface does not belong to the specified destination VLAN. MAC address replication does not support address replication to dynamic VLANs.
- MAC address replication replicates only dynamic addresses. Address replication is disabled when the address table is full. If source addresses already exist before replication is enabled, corresponding MAC addresses will not be replicated. Replicated addresses have a higher priority than dynamic addresses but have a lower priority than other types of addresses.
- When a MAC address ages, the replicated MAC address will also age. When the MAC address is deleted, the replicated address will be deleted automatically.
- This function does not support hot backup. After primary/secondary switchover occurs, you are advised to disable MAC address replication and then enable it again.

1.7.3 Prerequisites

Configure the interface as a Layer 2 interface.

1.7.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

(4) Configure the MAC address replication policy, and enable the MAC address replication function.

mac-address-mapping *mapping-id* **source-vlan** *source-vlan-list* **destination-vlan** *destination-vlan-id*

The MAC address replication function is disabled by default.

1.8 Configuring Priority Replication or Priority Mapping

1.8.1 Overview

This function configures the CoS value of the outer tag based on the user priority value (CoS) of the client VLAN tag by replication or mapping.

- Priority replication

  By default, the user priority (PRI) field of the Ethernet frame tag is 0, namely, the normal flow. To make the specified packet preferentially processed and transmitted, configure this field to change the priority of the packet. The value of this field corresponds to the CoS value in the QoS policy. The CoS-based QoS policy can be configured to ensure the processing priority of a service.

  If the VLAN tag of a client packet is configured with the CoS value of the user priority, and the QoS priority policy is configured in the SP network for the CoS value, the CoS value for the VLAN tag of client packet can be replicated as the CoS value of the outer tag, so that the client packet can be transmitted transparently and the QoS priority policy provided by the SP network can be used.

- Priority mapping

  When an outer VLAN tag is added, the user priority of the outer VLAN tag can be set according to the user priority of the inner VLAN tag through priority mapping so that the network QoS priority policy can be used after the packet is encapsulated with an outer VLAN tag.

  The SP network sets different QoS policies for multiple CoS values, corresponding to different service flow services. To make some client services be preferentially transmitted in the SP network, the priority mapping function can be configured. The CoS value of the outer VLAN tag can be specified according to the CoS value of the client inner VLAN tag, so that the packet can enjoy the QoS policy of the SP network after being encapsulated with the outer VLAN tag.

1.8.2 Restrictions and Guidelines

- Priority replication and priority mapping cannot be enabled on the same interface at the same time.
- Priority replication or priority mapping of client tags can be configured only on the dot1q-tunnel port.
- The order of priority effectiveness from high to low is: priority mapping, QoS based on ACL data flow, priority replication, and QoS based in trust mode.
- If the interface trust mode is not configured (i.e. interface Trust None), the priority mapping will not take effect. If the configured trust mode does not match the configured mapping rule, priority mapping will also not take effect.

1.8.3 Configuration Tasks

The following configuration tasks are mutually exclusive. Select one task.

- Configuring Priority Replication
- Configuring Priority Mapping

1.8.4 Configuring Priority Replication

1. Overview

It is assumed that the SP network is configured with the QoS policy based on the user priority value (CoS) of client VLAN tag. If the CoS value of an inner tag is 3, the CoS value of the outer tag can be set to 3 by configuring priority replication, so that the packet can enjoy the QoS policy with a priority of 3 as the inner tag after being encapsulated with the outer VLAN tag.

Configure priority replication to apply the QoS policy provided by the SP network for the client VLAN tag.

2. Prerequisites

- Configure the interface as a Layer 2 interface.
- Configure the Layer 2 interface as a dot1q tunnel port.
- Configure the QinQ encapsulation mode of the dot1q tunnel port.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the CoS priority for trusted packets of the interface.

mls qos trust cos

The default trust mode of an interface is untrust.

(5) Configure priority replication.

inner-priority-trust enable

The priority replication function is disabled by default.

1.8.5 Configuring Priority Mapping

1. Overview

It is assumed that the SP network is set with the QoS policy based on the user priority value (CoS) of client VLAN tag. Suppose the CoS value of an inner tag is 3. The CoS value of the outer tag can be set to 5 by configuring priority mapping (CoS-to-CoS), so that the packet can enjoy the QoS policy with a priority of 5 after being encapsulated with the outer VLAN tag.

If the user priority of the outer VLAN tag needs to be set according to the VLAN tag of the client to flexibly apply the QoS priority, configure the priority mapping policy.

2. Restrictions and Guidelines

- The value range of *inner-cos-value* and *outer-cos-value* are from 0 to 7.

- If priority mapping is not configured, the mapping rules shown in Table 1-1 are used by default.

Table 1-1 Default Priority Mapping

inner-cos-value	0	1	2	3	4	5	6	7
outer-cos-value	0	1	2	3	4	5	6	7

3. Prerequisites

- Configure the interface as a Layer 2 interface.
- Configure the Layer 2 interface as a dot1q tunnel port.
- Configure the QinQ encapsulation mode of the dot1q tunnel port.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the CoS priority for trusted packets of the interface.

mls qos trust cos

The default trust mode of an interface is untrust.

(5) (Optional) Disable priority replication.

no inner-priority-trust enable

The priority replication function is disabled by default.

(6) Configure priority mapping.

dot1q-tunnel cos *inner-cos-value* **remark-cos** *outer-cos-value*

No priority mapping rule is set by default.

1.9 Configuring TPID

1.9.1 Overview

An Ethernet frame tag consists of four fields: Tag Protocol Identifier (**TPID**, written as **Type** in the frame format map), User Priority (**PRI**), **CFI**, and **VLAN ID**.

The TPID value is 0x8100 by default, while the devices of some vendors set the TPID value for the outer tag of packets to 0x9100 or other values. To be compatible with these devices, this device supports port-based TPID modification for packets.

You can configure the TPID value of ports independently. When forwarding packets, these ports replace the TPID in the outer VLAN tag of the packets with the value set by the user, ensuring compatibility with the TPIDs of different vendors.

Purpose: The interface on the PE that connects to the public network needs to be configured as an uplink port. Configure the TPIDs in the tags on SP network devices to realize TPID compatibility with third-party devices. Perform the configuration in interface configuration mode of the uplink port.

1.9.2 Restrictions and Guidelines

- If a PE is connected to a third-party device on which the TPID is not the default value 0x8100 of IEEE 802.1Q, you need to configure the TPID on the interface connected to the third-party device.

Caution

Do not set the TPID to the following well-known types: 0x0806 (ARP), 0x0200 (PUP), 0x8035 (RARP), 0x0800 (IP), 0x86DD (IPv6), 0x8863/0x8864 (PPPoE), 0x8847/0x8848 (MPLS), 0x8137 (IPX/SPX), 0x8000 (IS-IS), 0x8809 (LACP), 0x888E (802.1x), 0x88A7 (cluster), and 0x0789 (reserved).

- TPIDs can be configured in interface configuration mode and global configuration mode.

1.9.3 Prerequisites

- Configure the interface as a Layer 2 interface.
- Configure the interface as an Uplink port.

1.9.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode, and configure the uplink port (the port where the SP's network edge device connects to the public network).

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the TPID value.

frame-tag tpid *tpid*

The TPID value is 0x8100 by default.

1.10 Configuring QinQ Tag Modification Policy

1.10.1 Overview

Packets encapsulated by QinQ carries double tags, and must be transmitted in the SP network. The Access, Trunk, Hybrid and Uplink ports of the device can receive and forward packets carrying double tags, while the dot1q tunnel port will discard packets carrying double tags.

In the SP network, the outer tag or inner tag of data packets of the SP network may need to be modified due to the actual networking topology requirements. In this case, the QinQ tag modifying function needs to be used. The device supports the following modification policies:

- Modify the outer VID based on the outer VID of packet

  For inbound packets on access, trunk, hybrid and uplink ports, this function can modify the VID of the outer tag to a different VID value according to the different VID in the inner tag of the packet.

- Modify the outer VID based on the inner VID of packet

  For inbound packets on access, trunk, hybrid and uplink ports, this function can modify the VID of the outer tag according to the inner and outer VID of the packet before the packet is forwarded.

- Modify the outer VID based on the outer and inner VIDs of packet

  For the inbound packets on access, trunk, hybrid and uplink ports, this function can modify the VID of the outer tag according to the VID in the outer tag of the packet before the packet is forwarded.

- Modify the outer VID based on the content of packet

  For the outbound packets on access, trunk, hybrid and uplink ports, this function can modify the VID of the inner tag based on the packet content identified by ACL.

- Modify the inner VID based on the content of packet

  For the outbound packets on access, trunk, hybrid and uplink ports, this function can modify the VID of the outer tag based on the packet content identified by ACL.

1.10.2 Restrictions and Guidelines

- The policy of modifying the VID based on ACL prevails over those based on port and C-Tag.
- The function of modifying VID according to packet content requires configuring ACL to distinguish data flow. When an ACL is deleted, the related policy will be automatically deleted.
- The modification policy takes effect only on the access, trunk, hybrid, and uplink ports.
- If a packet matches two or more VID modification policies without priority, only one policy is executed.
- *new-svid* indicates the VID of the outer tag after modification, *old-svid* indicates the VID of the outer tag before modification, *old-svid-list* indicates the VID list of the outer tag before modification, which are VLAN IDs of the SP network.
- *cvid-list* indicates the VID list of the inner tag after modification, *new-cvid* indicates the VID of the inner tag after modification, which are VLAN IDs of the client network.
- *acl-name* indicates the name of the ACL policy for matching data flow. The value is a case-sensitive string of 1-99 characters. *acl-number* indicates the number of the ACL policy for matching data flow. The value range of IP standard ACL is 1-99 and 1300-1999. The value range of IP extended ACL is 100-199 and 2000-2699. The value range of MAC standard ACL is 700-799. The value range of extended expert ACL is 2700-2899.

See *Configuring ACL* in *ACL and QoS Configuration Guide*.

1.10.3 Prerequisites

- Configure the interface as a Layer 2 interface.
- Configure the Layer 2 interface as an access, trunk, hybrid or uplink port.

1.10.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the tag modification policy of double-tagged inbound packets. Please select at least one of them to configure.

- Configure the policy of modifying the outer VID based on the inner VID of packet.

  dot1q relay-vid *new-svid* **translate inner-vid** *cvid-list*

  No policy of modifying the outer VID based on the inner VID of packets is configured by default.

- Configure the policy of modifying the outer VID based on the outer VID of the packet.

  dot1q relay-vid *new-svid* **translate local-vid** *old-svid-list*

  No policy of modifying the outer VID based on the outer VID of input packets is configured by default.

- Configure the policy of modifying the outer VID based on the outer and inner VIDs of packet.

  dot1q new-outer-vlan *new-svid* **translate old-outer-vlan** *old-svid* **inner-vlan** *cvid-list*

  No policy of modifying the outer VID based on the outer and inner VIDs of packet is configured by default.

(5) Configure the tag modification policy of double-tagged outbound packets. Please select at least one of them to configure.

- Configure the policy of modifying the inner VID based on the packet content.

  traffic-redirect access-group { *acl-name* | *acl-number* } **inner-vlan** *new-cvid* **out**

  No policy of modifying the inner VID based on packet content is configured by default.

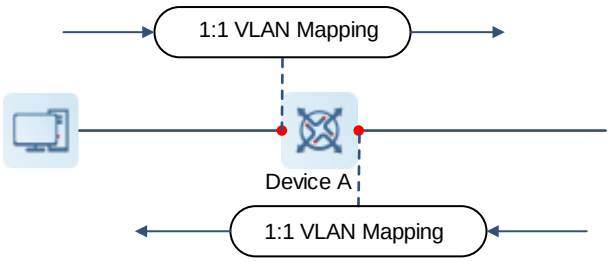
- Configure the policy of modifying the outer VID based on the packet content.

  traffic-redirect access-group { *acl-name* | *acl-number* } **outer-vlan** *new-svid* **in**

  No policy of modifying the outer VID based on the packet content is configured by default.

1.11 Configuring VLAN-Mapping

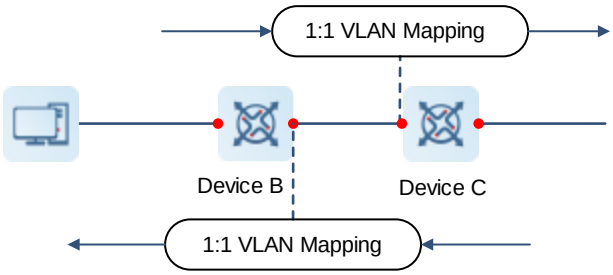
1.11.1 Overview



The function is used to replace the VLAN ID of a packet of the client network with a public VLAN ID so that the packet can be transmitted according to the VLAN rules of the public network; or replace the VLAN ID of a packet of the public network with a VLAN ID of the client network so that the packet can be transmitted according to VLAN planning of the client network.

1. 1:1 VLAN Mapping In

On the input interface of a device, the VID of the packet on one VLAN is modified to a VID of another VLAN. This mapping method is called one-to-one VLAN mapping in the input direction. This function is used for floor devices to use different VLANs to carry the same service from different clients and differentiate clients.

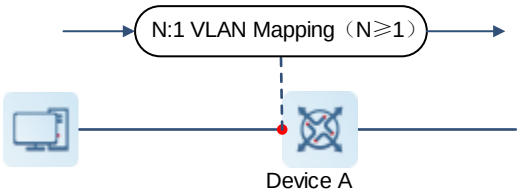


As shown in Figure 1-6, VLAN mapping in the input direction is configured on a single device (Device A). For uplink data flow, the VLAN mapping policy in the input direction is configured on the downlink port, and the original VLAN ID is mapped to a new VLAN ID before packet output from the uplink port. For downlink data flow, the VLAN mapping policy in the input direction is configured on the uplink port, and the packet VLAN ID is mapped to the original VLAN ID before packet output from the downlink port.

Figure 1-6 Configuring 1:1 VLAN Mapping in Input Direction on Single Device

As shown in Figure 1-7, VLAN mapping in the input direction is configured on two devices (Device B and Device C). For uplink data flow, the VLAN mapping policy in the input direction is configured on the downlink port of Device C, and the original VLAN ID is mapped to a new VLAN ID before packet output from the uplink port. For downlink data flow, the VLAN mapping policy in the input direction is configured on the uplink port of Device B, and the packet VLAN ID is mapped to the original VLAN ID before packet output from the downlink port.

Figure 1-7 Configuring 1:1 VLAN Mapping in Input Direction on Two Devices



2. N:1 VLAN Mapping in Inbound Direction

On the inbound interface of a device, the VIDs of the packets in multiple VLANs are modified to the VID of another VLAN. This mapping method is called N:1 VLAN mapping in the inbound direction. This function is typically enabled for campus devices to combine multiple VLANs carrying the same services for different users into one VLAN, thereby saving VLAN resources.

N:1 VLAN mapping needs to be configured only for incoming data flows because the device learns the source MAC address, source VID, and destination VID through the incoming packets. When receiving outgoing packets, the device automatically maps and restores the VID of the outgoing unicast packet according to the source entries. However, it cannot restore the VID for outgoing unknown, broadcast, or multicast packets.

Figure 1-8 shows VLAN mapping in the inbound direction configured on Device A.

Figure 1-8 Topology of VLAN Mapping in the Inbound Direction on Device A

1.11.2 Restrictions and Guidelines

- 1:1 VLAN Mapping In:

  For uplink data flow, the source VLAN is a client VLAN; the destination VLAN is an SP VLAN.

  For downlink data flow, the source VLAN is an SP VLAN; the destination VLAN is a client VLAN.
- When the VLAN mapping function in input direction is enabled, the VLAN ID of the packet sent to the CPU is the VLAN ID after modification. The interface only needs to allow the VLAN after modification to pass. If the VLAN data before modification does not need to be forwarded on the device, you do not need to create a VLAN before modification on the device.
- The VLAN tags of public network packets whose destination MAC address is multicast, broadcast, or unknown unicast address cannot be replaced with the VLAN tag of the client private network.
- VLAN mapping can be configured only on the access, trunk, hybrid, or uplink port. Do not configure VLAN mapping and selective QinQ on the same interface.
- The interface configured with VLAN mapping must be added to the mapped VLAN.

1.11.3 Prerequisites

- Configure the interface as a Layer 2 interface.
- Configure the Layer 2 interface as an Access, Trunk, Hybrid or Uplink port.

1.11.4 Procedure

(1) Create a VLAN after mapping.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create a VLAN after mapping.

vlan *destinationdest-vlan-id*

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

(2) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(3) Configure the VLAN mapping policyin the inbound direction on the interface.

vlan-mapping-in vlan *source-vlan-id* **remark** *destination-vlan-id*

No VLAN mapping policyin the inbound direction is configured bydefault.

Note

This section describes onlythe procedure of configuring one mapping policyon an interface, without reflecting the mapping logic. The mapping relationship needs to be configured on multiple interfaces to reflect the mapping logic.

1.12 Configuring Layer-2 Protocol Tunneling

1.12.1 Overview

BPDU tunneling is a layer-2 tunneling function based on the Layer 2 Tunnel Protocol (L2TP).

Spanning tree protocol packets use the dedicated multicast address 0180.c200.0000 as the destination MAC address. GVRP protocol packets use the dedicated multicast address 0180.c200.0006 as the destination MAC address. When the dot1q-tunnel port of the SP edge device receives these two types of packets, it will not treat them as ordinary client packets. The edge device will identify them as BPDU packets and will not forward them. The spanning tree calculation is performed according to the contents of the spanning tree BPDU, and VLAN information will be updated according to GVRP protocol packets by adding or deleting VLANs, which may affect the topology of the SP network.

When the STP or GVRP function is also enabled for the SP device, the BPDU tunnel function needs to be used to transmit the STP and GVRP packets of the client network in the SP network without affecting the SP network.

When the protocol packets on the client network enter the dot1q-tunnel of the PE, the destination MAC address is changed to the private address and then the packets are forwarded in the SP network. When the packets reach the PE at the other end, the destination MAC address is changed to the public address and the packets are transmitted on the client network at the other end. This achieves transmission of the protocol packets through the tunnel in the SP network, preventing the client network and the SP network from interfering with each other.

1.12.2 Restrictions and Guidelines

- If STP or GVRP is not enabled for the SP device, you can configure **bridge-frame forwarding protocol bpdu** to enable transparent transmission of BPDU packets.
- To make protocol tunneling effective on an interface, you need to first enable protocol tunneling in global configuration mode. When the protocol tunneling function on an interface takes effect, the interface does not participate in protocol calculation. If the dot1q-tunnel receives a packet whose destination MAC address is a special multicast address, there is an error in the networking and the packet will be dropped directly.

1.12.3 Configuration Tasks

The configuration includes the following tasks:

- Configuring STP Packet Tunneling
- Configuring GVRP Packet Tunneling

1.12.4 Configuring STP Packet Tunneling

1. Overview

If the STP function is enabled for the SP device and STP BPDU packets of the client network need to be transmitted, this function must be configured.

- When the spanning tree protocol packets in the client network enters the dot1q tunnel port of the edge device, its destination MAC address is changed from the public address 0180.c200.0000 to the private address (default is 01d0. f800.0005) before forwarding the packets in the SP network.
- After packets are forwarded to the edge device at the other end, the destination MAC address is changed from the private address (the default is 01d0. f800.0005) to the public address 0180.c200.0000 before and transmitting the packets in the client network at the other end.

2. Restrictions and Guidelines

- The STP tunneling function takes effect only when it is enabled in global configuration mode and interface configuration mode respectively.
- The optional tunnel addresses of STP packets are 01d0.f800.0005 (default value), 011a.a900.0005, 010f.e200.0003, 0100.0ccd.cdd0, 0100.0ccd.cdd1, and 0100.0ccd.cdd2.

3. Prerequisites

- Configure the interface as a Layer 2 interface.
- Configure the Layer 2 interface as a dot1q tunnel port.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the STP tunneling function globally.

l2protocol-tunnel stp

The STP packet tunneling function is disabled by default.

(4) (Optional) Configure a tunnel address in the corresponding protocol.

l2protocol-tunnel stp tunnel-dmac *mac-address*

The STP packet tunnel address is 01d0.f800.0005 by default.

(5) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(6) Enable STP packet tunnelling function on the dot1q-tunnel port.

l2protocol-tunnel stp enable

The STP packet tunneling function is disabled on the dot1q-tunnel port by default.

1.12.5 Configuring GVRP Packet Tunneling

1. Overview

If the GVRP function is enabled for the SP device and GVRP BPDU packets of the client network need to be transmitted, this function must be configured.

- When the spanning tree protocol packets in the client network enters the dot1q tunnel port of the edge device, its destination MAC address is changed from the public address 0180.c200.0000 to the private address (default is 01d0. f800.0006) before forwarding the packets in the SP network.
- After packets are forwarded to the edge device at the other end, the destination MAC address is changed from the private address (the default is 01d0. f800.0006) to the public address 0180.c200.0000 before and transmitting the packets in the client network at the other end.

2. Restrictions and Guidelines

- The GVRP tunneling function takes effect only when it is enabled in global configuration mode and interface configuration mode respectively.
- The optional tunnel addresses of GVRP packets are 01d0.f800.0006 (default value) and 011a.a900.0006.

3. Prerequisites

- Configure the interface as a Layer 2 interface.
- Configure the Layer 2 interface as a dot1q tunnel port.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the GVRP tunneling function globally.

l2protocol-tunnel gvrp

The GVRP packet tunneling function is disabled by default.

(4) (Optional) Configure a tunnel address in the corresponding protocol.

l2protocol-tunnel gvrp tunnel-dmac *mac-address*

The GVRP packet tunnel address is 01d0.f800.0006 by default.

(5) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(6) Enable GVRP packet tunneling function on dot1q-tunnel port.
l2protocol-tunnel gvrp enable

The GVRP packet tunneling function is disabled for the dot1q-tunnel port by default.

1.13 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

This section also describes the **debug** command used for outputting debugging information.

Caution

System resources are occupied when debugging information is output. Therefore, disable the debugging function immediately after use.

You can run the **clear** commands to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-2 Monitoring

Command	Purpose
show dot1q-tunnel [**interfaces** *interface-type interface-number*]	Displays whether the dot1q-tunnel function is enabled on the interface.
show interfaces dot1q-tunnel	Displays configuration of the dot1q-tunnel port.
show registration-table [**interfaces** *interface-type interface-number*]	Displays the policy of adding the VID based on the protocol on the dot1q-tunnel port.
show translation-table [**interfaces** *interface-type interface-number*]	Displays the policy of modifying the VID based on the access, trunk, and hybrid ports.
show interfaces [*interface-type interface-number*] **vlan-mapping**	Displays the VLAN mapping policy on the interface.

Command	Purpose
show traffic-redirect [**interfaces** *interface-type interface-number*]	Displays the policy of modifying or adding the VID based on data flow.
show frame-tag tpid interfaces [*interface-type interface-number*]	Displays the TPID configuration of the interface.
show inner-priority-trust [**interfaces** *interface-type interface-number*]	Displays the configuration of priority replication.
show interfaces [*interface-type interface-number*] **remark**	Displays the configuration of priority mapping.
show interfaces mac-address-mapping	Displays the configuration of MAC address replication.
show l2protocol-tunnel { **gvrp** | **stp** }	Displays the layer-2 tunnel configuration.
debug bridge qinq	Enables the QinQ debugging function.

1.14 Configuration Examples

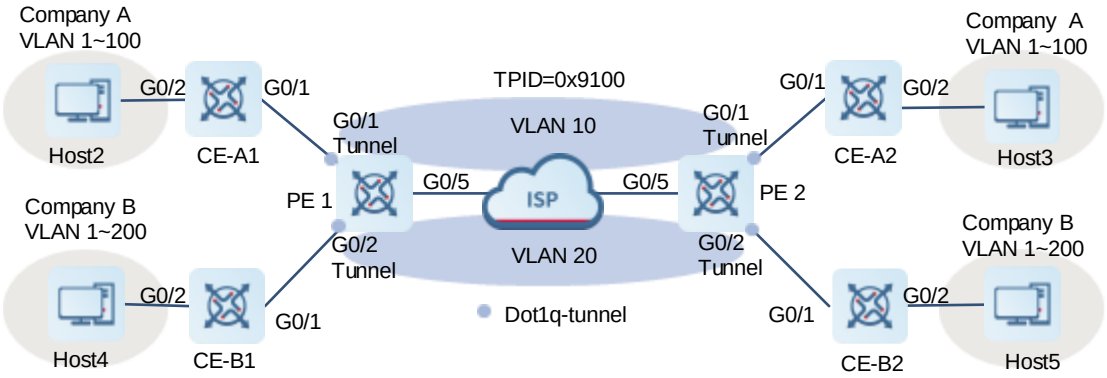
1.14.1 Configuring Basic QinQ to Implement Layer-2 VPN

1. Requirements

An SP provides a VPN for Company A and Company B, as shown in Figure 1-9. Basic QinQ is enabled on PEs to meet the layer-2 VPN requirement. On the public network, Company A and Company B belong to different VLANs, and client data packets are transmitted on different native VLANs to implement the simple layer-2 VPN.

- Company A uses public VLAN 10. In Area 1, clients are connected through CE-A1 and access the public network through PE 1; in Area 2, clients are connected through CE-A2, and access the public network through PE 2. The dot1q-tunnel port first encapsulates the client data packets of Company B with one VLAN 10 tag, and then forwards them on the public network.
- Company B uses public VLAN 20. In Area 1, clients are connected through CE-B1 and access the public network through PE 1; in Area 2, clients are connected through CE-B2, and access the public network through PE 2. The dot1q-tunnel first encapsulates the client data packets of Company B with one VLAN 20 tag, and then forwards them on the public network.

The client VLANs in Company A and Company B are transparent to the public network. The client VLANs can be reused without conflicts. Therefore, client VLANs do not need to be configured on the SP device, but need to be configured only on the CE device.



- The office network VLAN of Company A ranges from 1 to 100.
- The office network VLAN of Company B ranges from 1 to 200.

The priority replication and priority mapping functions of CoS can be configured on the dot1q-tunnel of the PE, and the QoS policy of CoS is configured to enable the client data packets to enjoy different QoS policies.

Generally, the TPID of the device is 0x8100 specified in IEEE 802.1Q. Because there are some devices in the SP network whose TPID is 0x9100, the TPID value needs to be modified on the uplink port of PE to ensure compatibility with these devices.

2. Topology

Figure 1-9 Basic QinQ Implements Layer-2 VPN

3. Notes

- Configure the interfaces on PE 1 and PE 2 connected to CE-A1, CE-A2, CE-B1 and CE-B2 as dot1q-tunnels. The public network transmission VLAN is the native VLAN of the dot1q-tunnel, and belongs to the allowed untagged VLAN list of the port.
- Configure the interface on the PE that connects to the public network as a trunk, hybrid, or uplink port. When the connection interface between SP devices is a trunk or hybrid port, do not configure the native VLAN of the trunk or hybrid port as the native VLAN of dot1q-tunnel port. The reason is that, when the packets of the native VLAN is output from the trunk or hybrid port, the interface will strip the tag from the packet.
- The client VLAN is configured on the CE according to the user's needs, and the uplink port on the CE is configured as trunk, hybrid, or uplink port.

4. Procedure

(1) Configure the basic QinQ transmission channel VLAN 10 of Company A. VLAN 10 is the native VLAN of the dot1q-tunnel, and belongs to the allowed untagged VLAN list of the dot1q-tunnel.

On PE 1, configure VLAN 10 to implement tunnel transmission for the data of Company A's network.

```
PE1> enable
PE1# configure terminal
PE1(config)# vlan 10
PE1(config-vlan)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# switchport
PE1(config-if-GigabitEthernet 0/1)# switchport mode dot1q-tunnel
PE1(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel native vlan 10
PE1(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel allowed vlan add
untagged 10
PE1(config-if-GigabitEthernet 0/1)# exit
```

On PE 2, configure VLAN 10 to implement tunnel transmission for the data of Company A's network.

```
PE2> enable
PE2# configure terminal
PE2(config)# vlan 10
PE2(config-vlan)# exit
PE2(config)# interface gigabitethernet 0/1
PE2(config-if-GigabitEthernet 0/1)# switchport
PE2(config-if-GigabitEthernet 0/1)# switchport mode dot1q-tunnel
PE2(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel native vlan 10
PE2(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel allowed vlan add
untagged 10
PE2(config-if-GigabitEthernet 0/1)# exit
```

(2) Configure the basic QinQ transmission channel VLAN 20 of Company B. VLAN 20 is the native VLAN of the dot1q-tunnel, and belongs to the allowed untagged VLAN list of the dot1q-tunnel.

On PE 1, configure VLAN 20 to implement tunnel transmission for the data of Company B's network.

```
PE1(config)# vlan 20
PE1(config-vlan)# exit
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# switchport
PE1(config-if-GigabitEthernet 0/2)# switchport mode dot1q-tunnel
PE1(config-if-GigabitEthernet 0/2)# switchport dot1q-tunnel native vlan 20
PE1(config-if-GigabitEthernet 0/2)# switchport dot1q-tunnel allowed vlan add
untagged 20
PE1(config-if-GigabitEthernet 0/2)# exit
```

On PE 2, configure VLAN 20 to implement tunnel transmission for the data of Company B's network.

```
PE2(config)# vlan 20
PE2(config-vlan)# exit
PE2(config)# interface gigabitethernet 0/2
PE2(config-if-GigabitEthernet 0/2)# switchport
PE2(config-if-GigabitEthernet 0/2)# switchport mode dot1q-tunnel
PE2(config-if-GigabitEthernet 0/2)# switchport dot1q-tunnel native vlan 20
PE2(config-if-GigabitEthernet 0/2)# switchport dot1q-tunnel allowed vlan add
untagged 20
PE2(config-if-GigabitEthernet 0/2)# exit
```

(3) Configure the interface on the PE for connecting to the public network as a trunk port. VLAN 10 and VLAN 20 need to be added to the allowed VLAN list of the trunk port, but cannot be the native VLAN of the trunk port.

Configure the interface on PE 1 for connecting to the public network as a trunk port, and modify the TPID value of output packets to 0x9100.

```
PE1(config)# interface gigabitethernet 0/5
PE1(config-if-GigabitEthernet 0/5)# switchport
PE1(config-if-GigabitEthernet  0/5)# switchport mode trunk
PE1(config-if-GigabitEthernet 0/5)# switchport trunk native vlan 1
PE1(config-if-GigabitEthernet 0/5)# switchport trunk allowed vlan all
```

```
PE1(config-if-GigabitEthernet 0/5)# frame-tag tpid 9100
PE1(config-if-GigabitEthernet 0/5)# end
PE1# write
```

Configure the interface on PE 2 for connecting to the public network as a trunk port, and modify the TPID value of output packets to 0x9100.

```
PE2(config)# interface gigabitethernet 0/5
PE2(config-if-GigabitEthernet 0/5)# switchport
PE2(config-if-GigabitEthernet  0/5)# switchport mode trunk
PE2(config-if-GigabitEthernet 0/5)# switchport trunk native vlan 1
PE2(config-if-GigabitEthernet 0/5)# switchport trunk allowed vlan all
PE2(config-if-GigabitEthernet 0/5)# frame-tag tpid 9100
PE2(config-if-GigabitEthernet 0/5)# end
PE2# write
```

(4) On the CE, configure the interface for connecting to the PE as a trunk port, and configure the interface for connecting to the user terminal as an access port and add it to the client VLAN.

Create client VLANs 1–100 on CE-A1; configure the interface GigabitEthernet 0/1 for connecting to the PE as a trunk port; configure one client interface GigabitEthernet 0/2 to join VLAN 60 (the configuration of other client interfaces is omitted here).

```
CE-A1> enable
CE-A1# configure terminal
CE-A1(config)# vlan range 1-100
CE-A1(config-vlan)# exit
CE-A1(config)# interface gigabitethernet 0/1
CE-A1(config-if-GigabitEthernet 0/1)# switchport
CE-A1(config-if-GigabitEthernet 0/1)# switchport mode trunk
CE-A1(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
CE-A1(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
CE-A1(config-if-GigabitEthernet 0/1)# exit
CE-A1(config)# interface gigabitethernet 0/2
CE-A1(config-if-GigabitEthernet 0/2)# switchport
CE-A1(config-if-GigabitEthernet 0/2)# switchport mode access
CE-A1(config-if-GigabitEthernet 0/2)# switchport access vlan 60
```

Create client VLANs 1–100 on CE-A2; configure the interface GigabitEthernet 0/1 for connecting to the PE as a trunk port; configure one client interface GigabitEthernet 0/2 to join VLAN 60 (the configuration of other client interfaces is omitted here).

```
CE-A2> enable
CE-A2# configure terminal
CE-A2(config)# vlan range 1-100
CE-A2(config-vlan)# exit
CE-A2(config)# interface gigabitethernet 0/1
CE-A2(config-if-GigabitEthernet 0/1)# switchport
CE-A2(config-if-GigabitEthernet 0/1)# switchport mode trunk
CE-A2(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
CE-A2(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
```

```
CE-A2(config-if-GigabitEthernet 0/1)#exit
CE-A2(config)# interface gigabitethernet 0/2
CE-A2(config-if-GigabitEthernet 0/2)# switchport
CE-A2(config-if-GigabitEthernet 0/2)# switchport mode access
CE-A2(config-if-GigabitEthernet 0/2)# switchport access vlan 60
```

Create client VLANs 1–200 on CE-B1; configure the interface GigabitEthernet 0/1 for connecting to the PE as a trunk port; configure one client interface GigabitEthernet 0/2 to join VLAN 60 (the configuration of other client interfaces is omitted here).

```
CE-B1> enable
CE-B1# configure terminal
CE-B1(config)# vlan range 1-200
CE-B1(config-vlan)# exit
CE-B1(config)# interface gigabitethernet 0/1
CE-B1(config-if-GigabitEthernet 0/1)# switchport
CE-B1(config-if-GigabitEthernet 0/1)# switchport mode trunk
CE-B1(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
CE-B1(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
CE-B1(config-if-GigabitEthernet 0/1)# exit
CE-B1(config)# interface gigabitethernet 0/2
CE-B1(config-if-GigabitEthernet 0/2)# switchport
CE-B1(config-if-GigabitEthernet 0/2)# switchport mode access
CE-B1(config-if-GigabitEthernet 0/2)# switchport access vlan 60
```

Create client VLANs 1–200 on CE-B2; configure the interface GigabitEthernet 0/1 for connecting to the PE as a trunk port; configure the client interface GigabitEthernet 0/2 to join VLAN 60 (the configuration of other client interfaces is omitted here).

```
CE-B2> enable
CE-B2# configure terminal
CE-B2(config)# vlan range 1-200
CE-B2(config-vlan)# exit
CE-B2(config)# interface gigabitethernet 0/1
CE-B2(config-if-GigabitEthernet 0/1)# switchport
CE-B2(config-if-GigabitEthernet 0/1)# switchport mode trunk
CE-B2(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
CE-B2(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
CE-B2(config-if-GigabitEthernet 0/1)# exit
CE-B2(config)# interface gigabitethernet 0/2
CE-B2(config-if-GigabitEthernet 0/2)# switchport
CE-B2(config-if-GigabitEthernet 0/2)# switchport mode access
CE-B2(config-if-GigabitEthernet 0/2)# switchport access vlan 60
```

5. Verification

(1) Displaythe interface configuration of PEs.

Displaythe interface configuration of PE 1.

```
PE1# show interfaces switchport
```

```
Interface                    Switchport Mode     Access Native Protected VLAN
lists
------------------------------ ---------- --------- ------ ------ ---------
---------------
GigabitEthernet 0/1            enabled    TUNNEL        10    Disabled  1,10
GigabitEthernet 0/2            enabled    TUNNEL        20    Disabled  1,20
GigabitEthernet 0/5            enabled    TRUNK         1     Disabled  ALL
```

Displaythe interface configuration of PE 2.

```
PE2# show interfaces switchport
Interface                    Switchport Mode     Access Native Protected VLAN
lists
------------------------------ ---------- --------- ------ ------ ---------
---------------
GigabitEthernet 0/1            enabled    TUNNEL        10    Disabled  1,10
GigabitEthernet 0/2            enabled    TUNNEL        20    Disabled  1,20
GigabitEthernet 0/5            enabled    TRUNK         1     Disabled  ALL
```

(2) Displaythe dot1q-tunnel configuration of PEs.

Displaythe dot1q-tunnel configuration of PE 1.

```
PE1# show interfaces dot1q-tunnel
========Interface Gi0/1========
Native vlan: 10
Allowed vlan list:1,10,
Tagged vlan list:
========Interface Gi0/2========
Native vlan: 20
Allowed vlan list:1,20,
Tagged vlan list:
```

Displaythe dot1q-tunnel configuration of PE 2.

```
PE2# show interfaces dot1q-tunnel
========Interface Gi0/1========
Native vlan: 10
Allowed vlan list:1,10,
Tagged vlan list:
========Interface Gi0/2========
Native vlan: 20
Allowed vlan list:1,20,
Tagged vlan list:
```

(3) Displaythe uplink port configuration of PEs.

Displaythe uplink port configuration of PE 1.

```
PE1# show frame-tag tpid
Ports        Tpid
------------  ----------
Gi0/5        0x9100
```

Displaythe uplink port configuration of PE 2.

```
PE2# show frame-tag tpid
Ports        Tpid
------------  ----------
Gi0/5        0x9100
```

(4) Displaythe CE configuration of CompanyA.

Displaythe configuration of CE-A1.

```
CE-A1(config)# show interface switchport
Interface                    Switchport Mode     Access Native Protected VLAN
lists
------------------------------ ---------- --------- ------ ------ ---------
----------------
GigabitEthernet 0/1            enabled    TRUNK     1      1      Disabled  ALL
GigabitEthernet 0/2            enabled    ACCESS    60     1      Disabled  ALL
```

Displaythe configuration of CE-A2.

```
CE-A2(config)#show interface switchport
Interface                    Switchport Mode     Access Native Protected VLAN
lists
------------------------------ ---------- --------- ------ ------ ---------
----------------
GigabitEthernet 0/1            enabled    TRUNK     1      1      Disabled  ALL
GigabitEthernet 0/2            enabled    ACCESS    60     1      Disabled  ALL
```

(5) Take Hosts 2 and 3 as examples to verify that clients in CompanyAcan implement layer-2 interworking.

Configure an IP address for Host 2.

```
Host2> enable
Host2# configure terminal
Host2(config)#interface gigabitethernet 0/1
Host2(config-if-GigabitEthernet 0/1)#no switchport
Host2(config-if-GigabitEthernet 0/1)#ip address 192.168.60.2/24
```

Configure an IP address for Host 3.

```
Host3> enable
Host3# configure terminal
Host3(config)#interface gigabitethernet 0/1
Host3(config-if-GigabitEthernet 0/1)#no switchport
Host3(config-if-GigabitEthernet 0/1)#ip address 192.168.60.3/24
```

Verify that Host 2 can ping through Host 3.

```
Host2# ping 192.168.60.3
Sending 5, 100-byte ICMP Echoes to 192.168.60.3, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 3/4/6 ms.
```

(6) Take Hosts 4 and 5 as examples to verify that clients in CompanyB can implement layer-2 interworking.

Configure an IP address for Host 4.

```
Host4> enable
Host4# configure terminal
Host4(config)#interface gigabitethernet 0/1
Host4(config-if-GigabitEthernet 0/1)#no switchport
Host4(config-if-GigabitEthernet 0/1)#ip address 192.168.60.4/24
```

Configure an IP address for Host 5.

```
Host5> enable
Host5# configure terminal
Host5(config)#interface gigabitethernet 0/1
Host5(config-if-GigabitEthernet 0/1)#no switchport
Host5(config-if-GigabitEthernet 0/1)#ip address 192.168.60.5/24
```

Verify that Host 4 can ping through Host 5.

```
Host4# ping 192.168.60.5
Sending 5, 100-byte ICMP Echoes to 192.168.60.5, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 3/4/6 ms.
```

(7) Host 2 in Company A cannot ping through Host 5 in Company B, which indicates that clients in different companies cannot implement layer-2 interworking.

```
Host2# ping 192.168.60.5
Sending 5, 100-byte ICMP Echoes to 192.168.60.5, timeout is 2 seconds:
  < press Ctrl+C to break >
.....
Success rate is 0 percent (0/5).
```

6. Configuration Files

- Configuration files of PE 1 and PE 2

```
vlan range 1,10,20
!
interface GigabitEthernet 0/1
switchport
 switchport mode dot1q-tunnel
 switchport dot1q-tunnel allowed vlan add untagged 10

```

7. Common Errors

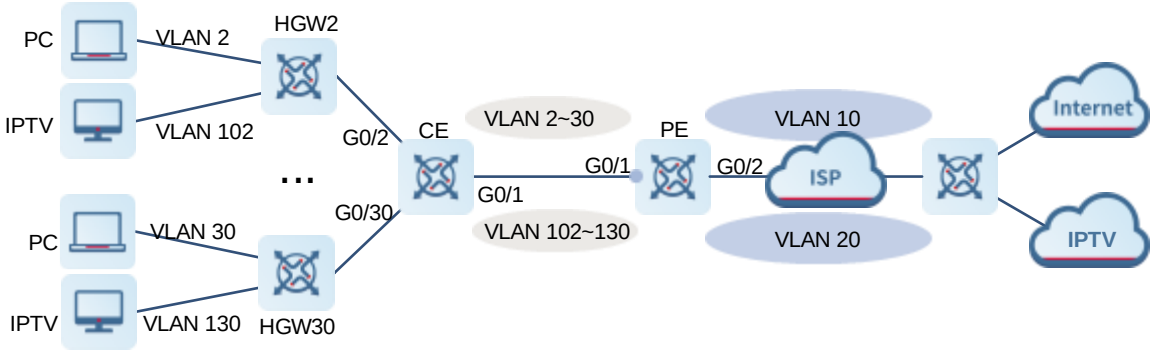
- The same company has different native VLANs on the dot1q-tunnel ports of PE 1 and PE 2, which leads to the failure of interworking.
- The native VLAN of the dot1q-tunnel is not added to the allowed VLAN list of the interface in the untagged form.
- The TPID value of a third-party device is not the default value 0x8100, but the TPID is not configured on the egress connected to the third-party device, and therefore the packet cannot be recognized by the third-party device.

1.14.2 Configuring C-Tag-Based Selective QinQ to Implement Layer-2 VPN and Service Flow Management

1. Requirements

Broadband Internet access and IPTV are important services carried by the metropolitan area network (MAN). MAN SPs allocate different service flows to different SP VLANs to achieve differentiated management, and provide QoS policy services for these VLANs or CoSs.

The basic QinQ function can encapsulate the client data packets received by the tunnel port only with the outer tag with the same VLAN ID, and the VLAN ID of outer tags is the native VLAN of the dot1q-tunnel; the basic QinQ cannot meet the requirement for differentiating SP VLANs in multi-service scenarios.



Selective QinQ can flexibly add the SP outer tag (S-Tag) according to the tag (C-Tag) of client packets, encapsulate the client service flows received by the same dot1q-tunnel into different SP VLANs, and use the QoS policy of SP network to guarantee reliability while transparently transmitting client data.

As shown in Figure 1-10, devices involved include provider edges (PEs), customer edges (CEs), and home gateways (HGWs) 1–30.

- The broadband Internet access data and IPTV service data are allocated to different VLANs. VLANs 2–30 are for client broadband Internet access service flows, and VLANs 102–130 are for client IPTV service flows.
- On the public network, the broadband Internet access data is transmitted through SP VLAN 10 to implement data communication with the Internet; the IPTV service flow is transmitted through VLAN 20 to implement data communication with the IPTV network. The dot1q-tunnel is configured on PE, and different VLANs are encapsulated to distinguish different service data. Client VLANs 2–30 are encapsulated as SP VLAN 10, while client VLANs 102–130 are encapsulated as SP VLAN 20.
- Client network packets carry tags and contain the CoS priority. The SP network enables the priority replication function on PEs, and uses the CoS value for the inner tag of packets in the outer tag so that service flows of the client network can use the QoS policy of the SP network to ensure transmission.

2. Topology

Figure 1-10 Configuring C-Tag-based Selective QinQ to Implement Layer-2 VPN and Service Flow Management

3. Notes

- Configure the interface GigabitEthernet 0/1 of PE for connecting to CE as dot1q-tunnel. Add SP VLANs 10 and 20 to the untagged VLAN list of the dot1q-tunnel connected to the client network so that the packets from the peer end return to the dot1q-tunnel and the SP tag is stripped when packet output.
- On the downlink interface of PE, configure the selective QinQ function of adding outer VLAN tags based on C-Tag. If the dot1q-tunnel receives the frames of client VLANs 2–30 (C-Tag), the frames will be encapsulated with the tag (S-Tag) of SP VLAN 10; if the dot1q-tunnel receives the frames of client VLANs 102–130 (C-Tag), the frames will be encapsulated with the tag (S-Tag) of SP VLAN 20.
- The SP network provides the CoS-based QoS priority policy. You can configure priority replication to replicate the CoS value of the client VLAN tag to the CoS of the outer VLAN tag so that the packet

encapsulated with the outer tag is transmitted based on the priority policy for the client VLAN tag.

- The interface of PE for connecting to the public network is configured as an uplink port to transmit the data of VLAN 10 and VLAN 20.
- The interface of CE for connecting to the PE is configured as an uplink port to transmit the data of VLANs 2–30 and VLANs 102–130.
- The interface of CE for connecting to HGW is configured as a trunk port, and the VLAN transmitted by HGW device is added to the allowed VLAN list of the trunk port. The clients adopting HGW 2 use VLAN 2 to transmit broadband Internet access data and VLAN 102 to transmit IPTV data. The clients adopting HGW 30 use VLAN 30 to transmit broadband Internet access data and VLAN 130 to transmit IPTV data. The configurations of other clients are similar.

4. Procedure

(1) Configure the C-Tag-based QinQ encapsulation rule.

Add SP VLAN 10 and VLAN 20 to the untagged VLAN list of the dot1q-tunnel GigabitEthernet 0/1.

```
PE> enable
PE# configure terminal
PE(config)# vlan range 10,20
PE(config-vlan-range)# exit
PE(config)# interface gigabitethernet 0/1
PE(config-if-GigabitEthernet 0/1)# switchport
PE(config-if-GigabitEthernet 0/1)# switchport mode dot1q-tunnel
PE(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel native vlan 1
PE(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel allowed vlan add
untagged 1,10,20
```

If the dot1q-tunnel receives the frames of client VLANs 2–30 (C-Tag), the frames will be encapsulated with the tag (S-Tag) of SP VLAN 10.

```
PE(config-if-GigabitEthernet 0/1)# dot1q outer-vid 10 register inner-vid 2-30
```

If the dot1q-tunnel receives the frames of client VLANs 102–130 (C-Tag), the frames will be encapsulated with the tag (S-tag) of SP VLAN 20.

```
PE(config-if-GigabitEthernet 0/1)# dot1q outer-vid 20 register inner-vid 102-130
```

(2) On the dot1q-tunnel, replicate the priority of inner tag in the client packet to the outer tag.

```
PE(config-if-GigabitEthernet 0/1)# mls qos trust cos
PE(config-if-GigabitEthernet 0/1)# inner-priority-trust enable
PE(config-if-GigabitEthernet 0/1)# exit
```

(3) Configure the interface on the PE for connecting to the public network as an uplink port.

```
PE(config)# interface gigabitethernet 0/2
PE(config-if-GigabitEthernet 0/2)# switchport
PE(config-if-GigabitEthernet 0/2)# switchport mode uplink
PE(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
PE(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan all
PE(config-if-GigabitEthernet 0/2)# end
PE# write
```

(4) Create a client VLAN on CE, and configure the interface for connecting PE as an uplink port.

```
CE> enable
CE# configure terminal
CE(config)# vlan range 2-30,102-130
CE(config-vlan)# exit
CE(config)# interface gigabitethernet 0/1
CE(config-if-GigabitEthernet 0/1)# switchport
CE(config-if-GigabitEthernet 0/1)# switchport mode uplink
CE(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
CE(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
CE(config-if-GigabitEthernet 0/1)# exit
```

(5) Configure the interface on the CE for connecting to the HGW as a trunk port. Gigabit Ethernet 0/2 and Gigabit Ethernet 0/30 are taken as examples below. The configurations of the other interface are similar.

```
CE(config)# interface gigabitethernet 0/2
CE(config-if-GigabitEthernet 0/2)# switchport
CE(config-if-GigabitEthernet 0/2)# switchport mode trunk
CE(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
CE(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan only 2,102
CE(config-if-GigabitEthernet 0/2)# exit
CE(config)# interface gigabitethernet 0/30
CE(config-if-GigabitEthernet 0/30)# switchport
CE(config-if-GigabitEthernet 0/30)# switchport mode trunk
CE(config-if-GigabitEthernet 0/30)# switchport trunk native vlan 1
CE(config-if-GigabitEthernet 0/30)# switchport trunk allowed vlan only 30,130
CE(config-if-GigabitEthernet 0/30)# end
CE# write
```

5. Verification

(1) Displaythe PE configuration.

Displaythe interface configuration of the PE.

```
PE# show interfaces switchport
Interface                    Switchport Mode     Access Native Protected VLAN
lists
------------------------------ ---------- --------- ------ ------ ---------
----------------
GigabitEthernet 0/1            enabled    TUNNEL        1     Disabled  1,10,20
GigabitEthernet 0/2            enabled    UPLINK        1     Disabled  ALL
```

Display the dot1q-tunnel configuration of the PE. The outer tag VLAN has been added to the allowed VLAN list of the interface.

```
PE# show interfaces dot1q-tunnel
========Interface Gi0/1========
Native vlan: 1
Allowed vlan list:1,10,20
Tagged vlan list:
```

Verify that the encapsulation policyrelationship for adding S-tags based on C-tags is correct.

```
PE# show registration-table
Ports    Type          Outer-VID    Inner-VID-list
------   ----------     ----------   --------------
Gi0/1    Add-outer      10           2-30
Gi0/1    Add-outer      20           102-130
```

Displaythe priority replication relationship of the interface.

```
PE# show inner-priority-trust interfaces gigabitethernet 0/1
Port   Inner-priority-trust
-----  -------------------
Gi0/1  Enable
```

(2) Displaythe CE configuration.

Displaythe interface configuration of the CE.

```
CE# show interfaces switchport
Interface                    Switchport Mode     Access Native Protected VLAN
lists
------------------------------- ---------- --------- ------ ------ ---------
----------------
GigabitEthernet 0/1            enabled    Uplink        1     Disabled  ALL
GigabitEthernet 0/2            enabled    Trunk         1     Disabled  2,102
GigabitEthernet 0/3            enabled    Trunk         1     Disabled  3,103
……
GigabitEthernet 0/30           enabled    Trunk         1     Disabled  30,130
```

6. Configuration Files

- Configuration file of the PE

```

switchport trunk allowed vlan only 2,102
!
interface GigabitEthernet 0/30
 switchport
switchport mode trunk
switchport trunk native vlan 1switchport trunk allowed vlan only 30,130
```

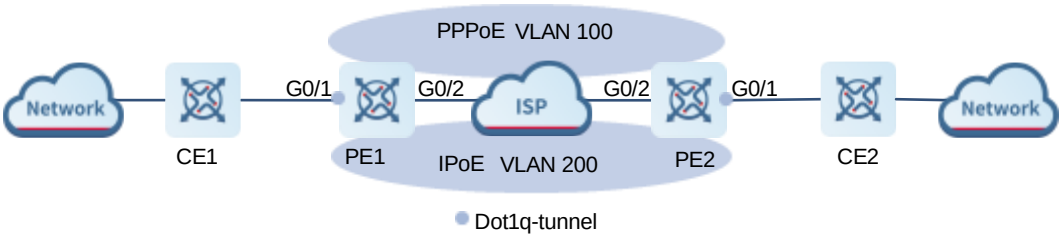
1.14.3 Configuring ACL-Based Selective QinQ to Implementing Layer-2 VPN and Service Flow Management

1. Requirements

If the service flows of client network are not classified according to VLAN, but according to the MAC address, IP address, or protocol type, or there are a large number of old low-end network access devices on the client network and the service flows cannot be effectively distinguished using VLAN ID, the packets from the client network cannot be encapsulated with outer tags based on their C-tags to realize transparent transmission and implement QoS policies.

ACL can classify service flows according to the MAC address, IP address, or protocol type, and selective QinQ can distinguish different service flows using ACL, add and modify outer tags, and assign different service data to different VLANs and implement the VPN channel for transparent transmission of client services. If the SP network provides different QoS service policies for different services, it can guarantee first transmission of high-priority services.

As shown in Figure 1-11, internal networks of the company's branches in two cities are connected to CE 1 and CE 2, and then connected to the SP network through PE 1 and PE 2.



The selective QinQ function based on ACL is used on PE 1 and PE 2 to encapsulate different service data of the company with different outer VLAN tags so that the data can be transmitted through the SP network transparently and the branches can access each other's network.

- ACL 1 identifies service flows of PPPoE type and allocates the service flows to VLAN 100 for transmission.
- ACL 2 identifies service flows of IPTV (IPoE) type and allocates the service flows to VLAN 200 for transmission.

The SP network sets the QoS policy based on CoS. You can modify the CoS values of packets through priority mapping on PE 1 and PE 2 to ensure preferential transmission of service flows of the client network using the QoS policy of the SP network.

2. Topology

Figure 1-11 Configuring ACL-based Selective QinQ to Implement Layer-2 VPN and Service Flow Management

3. Notes

- Configure the ACL policy on PE 1 and PE 2 to distinguish different service flows of the client network: the protocol type of PPPoE packets is 0x8863 or 0x8864, and that of IPoE packets is 0x0800. Configure the interface for connecting to the CE as dot1q-tunnel, and configure the selective QinQ function based on ACL. The configuration of PE 2 is similar to that of PE 1. Only PE 1 is taken as an example in the configuration procedure.
- The SP network provides a CoS-based QoS priority policy, and the packets of client network are attached with tags. You can configure priority mapping to modify the CoS value of the outer tag. In this way, the packet is transmitted based on the corresponding QoS priority policy of the SP after being encapsulated with an outer tag, and flexible control is implemented on the packet priority on the dot1q-tunnel.

4. Procedure

(1) On the PE, create an ACL for distinguishing service flows.

```
PE1> enable
PE1# configure terminal
PE1(config)# expert access-list extended acl1
PE1(config-exp-nacl)# permit 0x8863 any any
PE1(config-exp-nacl)# permit 0x8864 any any
PE1(config-exp-nacl)# exit
PE1(config)# expert access-list extended acl2
PE1(config-exp-nacl)# permit 0x0800 any any
PE1(config-exp-nacl)# exit
```

(2) Configure the ACL-based QinQ encapsulation rule.

Add the SP VLAN 100 and VLAN 200 to the untagged VLAN list of the dot1q-tunnel GigabitEthernet 0/1.

```
PE1(config)# vlan rang 100,200
PE1(config-vlan-range)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# switchport
PE1(config-if-GigabitEthernet 0/1)# switchport mode dot1q-tunnel
PE1(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel native vlan 1
PE1(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel allowed vlan add
untagged 1,100,200
```

If the dot1q-tunnel receives frames matching ACL1, the frames will be encapsulated with the tag of SP VLAN 100.

```
PE1(config-if-GigabitEthernet 0/1)# traffic-redirect access-group acl1
nested-vlan 100 in
```

If the dot1q-tunnel receives frames matching ACL2, the frames will be encapsulated with the tag of SP VLAN 200.

```
PE1(config-if-GigabitEthernet 0/1)# traffic-redirect access-group acl2
nested-vlan 200 in
```

Configure the MAC address replication function to replicate the learned MAC address from the default native VLAN 1 of the dot1q-tunnel to VLAN 100 of outer tag.

```
PE1(config-if-GigabitEthernet 0/1)# mac-address-mapping 1 source-vlan 1
destination-vlan 100
```

(3) Configure the outer tag priority of packets according to the inner tag priority of packets.

```
PE1(config-if-GigabitEthernet 0/1)# mls qos trust cos
PE1(config-if-GigabitEthernet 0/1)# no inner-priority-trust enable
PE1(config-if-GigabitEthernet 0/1)# dot1q-tunnel cos 3 remark-cos 5
PE1(config-if)# exit
```

(4) Configure the interface connected to the public network as an uplink port.

```
PE1(config)# interface gigabitethernet 0/2
PE1(config-if-GigabitEthernet 0/2)# switchportPE1(config-if-GigabitEthernet
0/2)# switchport mode uplink
PE1(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
PE1(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan
allPE1(config-if-GigabitEthernet 0/2)# end
PE1# write
```

5. Verification

(1) Displaythe interface configuration of the PE.

```
PE1# show interfaces switchport
Interface                   Switchport Mode     Access Native Protected VLAN
lists
------------------------------ ---------- --------- ------ ------ ---------
----------------
GigabitEthernet 0/1            enabled    TUNNEL        1     Disabled
1,100,200
GigabitEthernet 0/2            enabled    UPLINK        1     Disabled  ALL
```

(2) Verify the encapsulation policyfor adding tags based ACL.

```
PE1# show traffic-redirect
Ports      Type        VID    Match-filter
-------    ----------    -----   ------------
Gi0/1      Nested-vid   100       acl1
Gi0/1      Nested-vid   200       acl2
```

(3) Displaythe priority mapping relationship on the interface.

```
PE1# show interfaces gigabitethernet 0/1 remark
Ports       From COS  To COS
----------- --------- --------
Gi0/1       3       5
```

(4) The clients of the same service in the company's branch can realize layer-2 VPN interworking. Specific service data can enjoy a higher transmission priority.

6. Configuration Files

Configuration files of PE 1 and PE 2

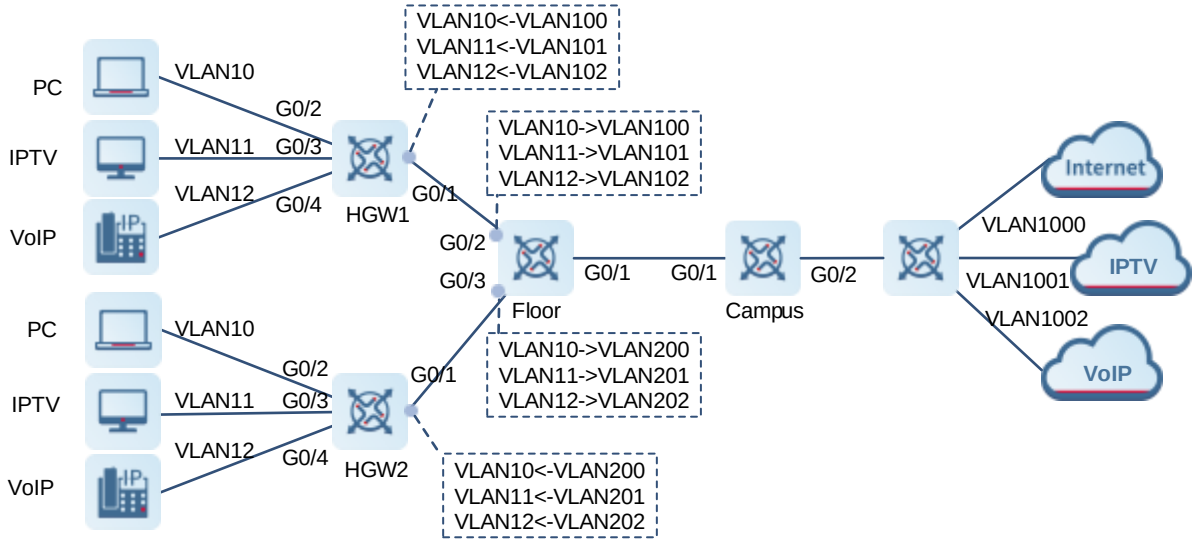
```
expert access-list extended acl1
 10 permit 0x8863 any any
 20 permit 0x8864 any any
!
expert access-list extended acl2
 10 permit 0x800 any any
!
vlan range 1,100,200
!
interface GigabitEthernet 0/1
switchport
 switchport mode dot1q-tunnel
 switchport dot1q-tunnel allowed vlan add untagged 1,100,200
switchport dot1q-tunnel native vlan 1
dot1q-tunnel cos 3 remark-cos 5
traffic-redirect access-group acl1 nested-vlan 100 in
 traffic-redirect access-group acl2 nested-vlan 200 in
mls qos trust cos
!
interface GigabitEthernet 0/2
 switchport
switchport mode uplink
switchport trunk native vlan 1
switchport trunk allowed vlan only 1-4094
```

7. Common Errors

- The ACL policy is configured incorrectly. The ACL policy number is not in the parameter range. The ACL name is already taken.
- Priority replication is not disabled before priority mapping is configured.
- The MAC address replication function is not configured, which may lead to packet flooding.

1.14.4 Configuring VLAN-Mapping to Implement Aggregation of Different Services

1. Requirements



As shown in Figure 1-12, in a campus network environment, different services on the HGW are differentiated using different VLANs. VLAN 10 is used for PC services, VLAN 11 for IPTV services, and VLAN 12 for VoIP services.

For the sake of easy deployment, the same VLAN is used for the same service of HGW 1 and HGW 2, and the packets of the same service from different homes are isolated using the VLAN mapping function on the floor devices, thus avoiding confusion of the packets from different homes.

Packets of the same service from different homes are sent from campus devices through the same VLAN to save VLAN resources.

2. Topology

Figure 1-12 Configuring VLAN-Mapping to Implement Aggregation of Different Services

3. Notes

- HGW 1

  Create a VLAN after mapping, configure GigabitEthernet 0/1 as an uplink port, and configure the VLAN mapping policy for the input direction on GigabitEthernet 0/1 for the downlink data: Map VLAN 100 as VLAN 10 for forwarding to Gigabit Ethernet 0/2; map VLAN 101 as VLAN 11 for forwarding to Gigabit Ethernet 0/3; map VLAN 102 as VLAN 12 for forwarding to Gigabit Ethernet 0/4. If VLAN 200, VLAN 201, and VLAN 202 are not created, their data will be dropped even if the data is forwarded to Gigabit Ethernet 0/1.

  Configure Gigabit Ethernet 0/2, Gigabit Ethernet 0/3, and Gigabit Ethernet 0/4 as an access port, and add them to the VLAN where the corresponding service is.

- HGW 2

  Create a VLAN after mapping, configure GigabitEthernet 0/1 as an uplink port, and configure the VLAN mapping policy for the input direction on GigabitEthernet 0/1 for the downlink data: Map VLAN 200 as VLAN 10 for forwarding to Gigabit Ethernet 0/2; map VLAN 201 as VLAN 11 for forwarding to Gigabit Ethernet 0/3;

map VLAN 202 as VLAN 12 for forwarding to Gigabit Ethernet 0/4. If VLAN 100, VLAN 101, and VLAN 102 are not created, their data will be dropped even if the data is forwarded to Gigabit Ethernet 0/1.

Configure Gigabit Ethernet 0/2, Gigabit Ethernet 0/3, and Gigabit Ethernet 0/4 as an access port, and add them to the VLAN where the corresponding service is.

- Floor device

  Create a VLAN after mapping, and configure GigabitEthernet 0/1 of the floor device as an uplink port.

  Configure the downlink interface GigabitEthernet 0/2 as an uplink port, and configure the VLAN mapping policy for the input direction for the uplink data on HGW 1: Map VLAN 10 as VLAN 100; map VLAN 11 as VLAN 101; map VLAN 12 as VLAN 102. To avoid waste of the bandwidth, configure GigabitEthernet 0/2 to allow only the data of VLANs 100–102 to pass through.

  Configure the downlink interface GigabitEthernet 0/3 as an uplink port, and configure the VLAN mapping policy for the input direction for the uplink data on HGW 2: Map VLAN 10 as VLAN 200; map VLAN 11 as VLAN 201; map VLAN 12 as VLAN 202. To avoid waste of the bandwidth, configure GigabitEthernet 0/3 to allow only the data of VLANs 200 to 202 to pass through.

- Campus device

  On Gigabit Ethernet 0/1, configure the C-tag-based QinQ encapsulation policy to encapsulate the packets of the same service with the same outer tag for transmission an access port: the data frames of VLAN 100 and VLAN 200 are encapsulated as frames of VLAN 1000 and forwarded to the Internet for communication; the data frames of VLAN 101 and VLAN 201 are encapsulated as frames of VLAN 1001 and forwarded to the IPTV network; the data frames of VLAN 102 and VLAN 202 are encapsulated as frames of VLAN 1002 and forwarded to the VoIP network.

  Configure GigabitEthernet 0/2 as an uplink port.

4. Procedure

(1) Configure HGW 1.

Create a VLAN after mapping, configure the uplink port, and configure the VLAN mapping policy for input direction for the downlink data.

```
HGW1> enable
HGW1# configure terminal
HGW1(config)# vlan range 10-12
HGW1(config-vlan-range)# exit
HGW1(config)# interface gigabitethernet 0/1
HGW1(config-if-GigabitEthernet 0/1)# switchport
HGW1(config-if-GigabitEthernet 0/1)# switchport mode uplink
HGW1(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
HGW1(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
HGW1(config-if-GigabitEthernet 0/1)# vlan-mapping-in vlan 100 remark 10
HGW1(config-if-GigabitEthernet 0/1)# vlan-mapping-in vlan 101 remark 11
HGW1(config-if-GigabitEthernet 0/1)# vlan-mapping-in vlan 102 remark 12
HGW1(config-if-GigabitEthernet 0/1)# exit
```

Configure the downlink interface as an access port, and add it to the VLAN where the corresponding service is.

```
HGW1(config)# interface range gigabitethernet 0/2-4
HGW1(config-if-range)# switchport
HGW1(config-if-range)# switchport mode access
HGW1(config-if-range)# exit
HGW1(config)# interface gigabitethernet 0/2
HGW1(config-if-GigabitEthernet 0/2)# switchport access vlan 10
HGW1(config-if-GigabitEthernet 0/2)# exit
HGW1(config)# interface gigabitethernet 0/3
HGW1(config-if-GigabitEthernet 0/3)# switchport access vlan 11
HGW1(config-if-GigabitEthernet 0/3)# exit
HGW1(config)# interface gigabitethernet 0/4
HGW1(config-if-GigabitEthernet 0/4)# switchport access vlan 12
HGW1(config-if-GigabitEthernet 0/4)# end
HGW1# write
```

(2) Configure HGW 2.

Create a VLAN after mapping, configure the uplink port, and configure the VLAN mapping policy for input direction for the downlink data.

```
HGW2> enable
HGW2# configure terminal
HGW2(config)# vlan range 10-12
HGW2(config-vlan-range)# exit
HGW2(config)# interface gigabitethernet 0/1
HGW2(config-if-GigabitEthernet 0/1)# switchport
HGW2(config-if-GigabitEthernet 0/1)# switchport mode uplink
HGW2(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
HGW2(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
HGW2(config-if-GigabitEthernet 0/1)# vlan-mapping-in vlan 200 remark 10
HGW2(config-if-GigabitEthernet 0/1)# vlan-mapping-in vlan 201 remark 11
HGW2(config-if-GigabitEthernet 0/1)# vlan-mapping-in vlan 202 remark 12
```

Configure the downlink interface as an access port, and add it to the VLAN where the corresponding service is.

```
HGW2(config)# interface range gigabitethernet 0/2-4
HGW2(config-if-range)# switchport
HGW2(config-if-range)# switchport mode access
HGW2(config-if-range)# exit
HGW2(config)# interface gigabitethernet 0/2
HGW2(config-if-GigabitEthernet 0/2)# switchport access vlan 10
HGW2(config-if-GigabitEthernet 0/2)# exit
HGW2(config)# interface gigabitethernet 0/3
HGW2(config-if-GigabitEthernet 0/3)# switchport access vlan 11
HGW2(config-if-GigabitEthernet 0/3)# exit
HGW2(config)# interface gigabitethernet 0/4
HGW2(config-if-GigabitEthernet 0/4)# switchport access vlan 12
HGW2(config-if-GigabitEthernet 0/4)# end
HGW2# write
```

(3) Configure the floor device.

Create a VLAN after mapping, and for the uplink data of HGW 1, create the VLAN mapping policy for input direction on the downlink interface.

```
Floor> enable
Floor# configure terminal
Floor(config)# vlan range 100-102
Floor(config-vlan-range)# exit
Floor(config)# interface gigabitethernet 0/2
Floor(config-if-GigabitEthernet 0/2)# switchport
Floor(config-if-GigabitEthernet 0/2)# switchport mode uplink
Floor(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
Floor(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan only 100-102
Floor(config-if-GigabitEthernet 0/2)# vlan-mapping-in vlan 10 remark 100
Floor(config-if-GigabitEthernet 0/2)# vlan-mapping-in vlan 11 remark 101
Floor(config-if-GigabitEthernet 0/2)# vlan-mapping-in vlan 12 remark 102
Floor(config-if-GigabitEthernet 0/2)# exit
```

Create a VLAN after mapping, and for the uplink data of HGW 2, create the VLAN mapping policy for input direction on the downlink interface.

```
Floor(config)# vlan range 200-202
Floor(config-vlan-range)# exit
Floor(config)# interface gigabitethernet 0/3
Floor(config-if-GigabitEthernet 0/3)# switchport
Floor(config-if-GigabitEthernet 0/3)# switchport mode uplink
Floor(config-if-GigabitEthernet 0/3)# switchport trunk native vlan 1
Floor(config-if-GigabitEthernet 0/3)# switchport trunk allowed vlan only 200-202
Floor(config-if-GigabitEthernet 0/3)# vlan-mapping-in vlan 10 remark 200
Floor(config-if-GigabitEthernet 0/3)# vlan-mapping-in vlan 11 remark 201
Floor(config-if-GigabitEthernet 0/3)# vlan-mapping-in vlan 12 remark 202
Floor(config-if-GigabitEthernet 0/3)# exit
```

Configure the uplink port.

```
Floor(config)# interface gigabitethernet 0/1
Floor(config-if-GigabitEthernet 0/1)# switchport
Floor(config-if-GigabitEthernet 0/1)# switchport mode uplink
Floor(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
Floor(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
Floor(config-if-GigabitEthernet 0/1)# end
Floor# write
```

(4) Configure the campus device.

Configure the C-Tag-based QinQ encapsulation rule.

```
Campus> enable
Campus# configure terminal
Campus(config)# vlan range 1000-1002
Campus(config-vlan-range)# exit
Campus(config)# interface gigabitethernet 0/1
```

```
Campus(config-if-GigabitEthernet 0/1)# switchport
Campus(config-if-GigabitEthernet 0/1)# switchport mode dot1q-tunnel
Campus(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel native vlan 1
Campus(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel allowed vlan add
untagged 1,1000-1002
Campus(config-if-GigabitEthernet 0/1)# dot1q outer-vid 1000 register inner-vid
100,200
Campus(config-if-GigabitEthernet 0/1)# dot1q outer-vid 1001 register inner-vid
101,201
Campus(config-if-GigabitEthernet 0/1)# dot1q outer-vid 1002 register inner-vid
102,202
```

Configure the uplink port.

```
Campus(config)# interface gigabitethernet 0/2
Campus(config-if-GigabitEthernet 0/2)# switchport
Campus(config-if-GigabitEthernet 0/2)# switchport mode uplink
Campus(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
Campus(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan all

Campus(config-if-GigabitEthernet 0/2)# end
Campus# write
```

5. Verification

(1) Verify the configuration of HGW 1.

Displaythe VLAN configuration of HGW 1.

```
HGW1# show vlan
VLAN      Name                           Status    Ports
---------- -------------------------------- ---------
-----------------------------------
       1 VLAN0001                       STATIC    Gi0/1, Gi0/5, Gi0/6, Gi0/7
                                                  Gi0/8
      10 VLAN0010                       STATIC    Gi0/1, Gi0/2
      11 VLAN0011                       STATIC    Gi0/1, Gi0/3
      12 VLAN0012                       STATIC    Gi0/1, Gi0/4
```

Displaythe interface configuration of HGW 1.

```
HGW1# show interface switchport
Interface           Switchport Mode     Access Native Protected VLAN lists
-------------------- ---------- --------- ------ ------ ---------
----------------------
GigabitEthernet 0/1   enabled    UPLINK         1      Disabled  ALL
GigabitEthernet 0/2   enabled    ACCESS    10          Disabled  ALL
GigabitEthernet 0/3   enabled    ACCESS    11          Disabled  ALL
GigabitEthernet 0/4   enabled    ACCESS    12          Disabled  ALL
```

Displaythe VLAN mapping rule of HGW 1.

```
HGW1# show interfaces vlan-mapping
```

```
Ports       type   Status    Destination-Vlan   Source-Vlan-list
----------  -----  --------- ----------------   ----------------
Gi0/1       in     active    10              100
Gi0/1       in     active    11              101
Gi0/1       in     active    12              102
```

(2) Verify the configuration of HGW 2.

Verify that the VLAN configuration of HGW 2 is the same as that of HGW 1.

```
HGW2# show vlan
VLAN      Name                           Status    Ports
---------- -------------------------------- ---------
-----------------------------------
       1 VLAN0001                      STATIC    Gi0/1, Gi0/5, Gi0/6, Gi0/7
                                                 Gi0/8
      10 VLAN0010                      STATIC    Gi0/1, Gi0/2
      11 VLAN0011                      STATIC    Gi0/1, Gi0/3
      12 VLAN0012                      STATIC    Gi0/1, Gi0/4
```

Verify that the interface configuration of HGW 2 is the same as that of HGW 1.

```
HGW2# show interface switchport
Interface           Switchport Mode     Access Native Protected VLAN lists
--------------------- ---------- --------- ------ ------ ---------
----------------------
GigabitEthernet 0/1   enabled    UPLINK         1      Disabled  ALL
GigabitEthernet 0/2   enabled    ACCESS    10          Disabled  ALL
GigabitEthernet 0/3   enabled    ACCESS    11          Disabled  ALL
GigabitEthernet 0/4   enabled    ACCESS    12          Disabled  ALL
```

Display the VLAN mapping rule of HGW 2. The VLAN mapping rule is different from that of HGW 1.

```
HGW2# show interfaces vlan-mapping
Ports       type   Status    Destination-Vlan   Source-Vlan-list
----------  -----  --------- ----------------   ----------------
Gi0/1       in     active    10              200
Gi0/1       in     active    11              201
Gi0/1       in     active    12              202
```

(3) Verify the configuration of the floor device.

Display the VLAN configuration of the floor device.

```
Floor# show vlan
VLAN      Name                           Status    Ports
---------- -------------------------------- ---------
-----------------------------------
       1 VLAN0001                      STATIC    Gi0/1, Gi0/4, Gi0/5, Gi0/6
                                                 Gi0/7, Gi0/8
  100-102 VLAN0100-VLAN0102              STATIC    Gi0/1, Gi0/2
  200-202 VLAN0100-VLAN0102              STATIC    Gi0/1, Gi0/3
```

Display the interface configuration of the floor device.

```
Floor# show interface switchport
Interface           Switchport Mode     Access Native Protected VLAN lists
-------------------- ---------- --------- ------ ------ ---------
----------------------
GigabitEthernet 0/1   enabled    UPLINK         1     Disabled  ALL
GigabitEthernet 0/2   enabled    UPLINK         1     Disabled  100-102
GigabitEthernet 0/3   enabled    UPLINK         1     Disabled  200-202
```

Displaythe VLAN mapping rule of the floor device.

```
Floor# show interfaces vlan-mapping
Ports       type   Status    Destination-Vlan   Source-Vlan-list
-----------  -----  ---------  ----------------   ----------------
Gi0/2       in     active    100              10
Gi0/2       in     active    101              11
Gi0/2       in     active    102              12
Gi0/3       in     active    200              10
Gi0/3       in     active    201              11
Gi0/3       in     active    202              12
```

(4) Verify the configuration of the campus device.

Displaythe interface configuration.

```
Campus# show interfaces switchport
Interface                     Switchport Mode     Access Native Protected VLAN
lists
-------------------------------- ---------- --------- ------ ------ ---------
----------------
GigabitEthernet 0/1            enabled    TUNNEL         1     Disabled
1,1000-1002
GigabitEthernet 0/2            enabled    UPLINK         1     Disabled  ALL
```

Display the dot1q-tunnel configuration. The outer tag VLAN has been added to the allowed VLAN list of the interface.

```
Campus# show interfaces dot1q-tunnel
========Interface Gi0/1========
Native vlan: 1
Allowed vlan list:1,1000-1002
Tagged vlan list:
```

Displaythe mapping policyrelationship for adding S-tags based on C-tags.

```
Campus# show registration-table
Ports    Type           Outer-VID    Inner-VID-list
------    ----------      ----------   --------------
Gi0/1    Add-outer      1000          100,200
Gi0/1    Add-outer      1001          101,201
Gi0/1    Add-outer      1002          102,202
```

6. Configuration Files

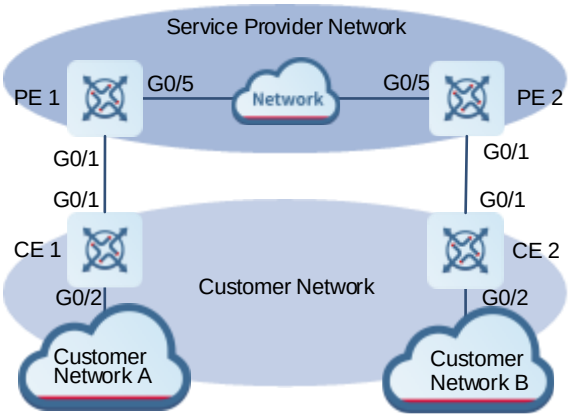
1.14.5 Configuring Layer-2 Protocol Tunneling Based on QinQ

1. Requirements



As shown in Figure 1-13, the upper part of the typical topology of QinQ network is the SP network, and the lower part is the client network. The SP network consists of PE 1 and PE 2. Customer Network A and Customer Network B are a user's two sites in different regions. CE 1 and CE 2 are access devices from the client network to the SP network, and access the SP network through PE 1 and PE 2 respectively.

The layer-2 protocol tunneling is configured to transparently transmit layer-2 protocol packets from one end to the other end of the client network so that the layer-2 protocols of the client network and the SP network are calculated separately without interference.

- Configure the STP protocol tunneling function based on user requirements to realize tunnel transmission of BPDU packets of the client network in the SP network and to perform unified spanning tree calculation for the cross-regional client network across the SP network.
- Configure the GVRP protocol tunneling function based on user requirements to realize tunnel transmission of GVRP packets of the client network and perform dynamic VLAN configuration of the client network across the SP network.

2. Topology

Figure 1-13 Configuring QinQ to Implement Layer-2 Protocol Tunneling

3. Notes

- On PE 1 and PE 2, configure the STP and GVRP tunneling functions globally.
- Configure the QinQ encapsulation mode. Basic QinQ is taken as an example (for details, see "1.14.1 Configuring Basic QinQ to Implement Layer-2 VPN") to configure the native VLAN of dot1q-tunnel as VLAN 10, and VLAN 10 is used as the public network transmission channel. A client data packet is first encapsulated with one VLAN 10 tag, and then forwarded on the public network.
- Enable the STP and GVRP tunneling functions on the interface GigabitEthernet 0/1 of PE 1 and PE 2.
- Configure the uplink port of PE 1 and PE 2.

4. Procedure

Both PE 1 and PE 2 need to be configured. The configuration method on the two devices is the same. PE 1 is taken as an example below.

(1) Enable the STP and GVRP tunneling functions globally.

```
PE1> enable
PE1# configure terminal
PE1(config)# l2protocol-tunnel stp
PE1(config)# l2protocol-tunnel gvrp
```

(2) Configure the basic QinQ transmission channel VLAN 10. VLAN 10 is the native VLAN of the dot1q-tunnel, and belongs to the allowed untagged VLAN list of the dot1q-tunnel.

```
PE1(config)# vlan 10
PE1(config-vlan)# exit
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# switchport
PE1(config-if-GigabitEthernet 0/1)# switchport mode dot1q-tunnel
PE1(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel native vlan 10
PE1(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel allowed vlan add
untagged 10
```

(3) Enable the STP and GVRP tunneling functions on the dot1q-tunnel.

```
PE1(config-if-GigabitEthernet 0/1)# l2protocol-tunnel stp enable
PE1(config-if-GigabitEthernet 0/1)# l2protocol-tunnel gvrp enable
PE1(config-if-GigabitEthernet 0/1)# exit
```

(4) Configure the uplink port.

```
PE1(config)# interface gigabitethernet 0/5
PE1(config-if-GigabitEthernet 0/5)# switchport
PE1(config-if-GigabitEthernet 0/5)# switchport mode uplink
PE1(config-if-GigabitEthernet 0/5)# end
PE1# write
```

5. Verification

Verify that the STP tunneling function is enabled globally and on the interface at the same time. c

```
PE1# show l2protocol-tunnel stp
L2protocol-tunnel: Stp Enable
L2protocol-tunnel destination mac address: 01d0.f800.0005
GigabitEthernet 0/1 l2protocol-tunnel stp enable
```

Verify that the GVRP tunneling function is enabled globally and on the interface at the same time. The verification methods on PE1 and PE2 are the same. PE1 is taken as an example.

Verify PE 1.

```
PE1# show l2protocol-tunnel gvrp
L2protocol-tunnel: Gvrp Enable
L2protocol-tunnel destination mac address: 01d0.f800.0006
GigabitEthernet 0/1 l2protocol-tunnel gvrp enable
```

6. Configuration Files

Configuration files of PE 1 and PE 2

```
l2protocol-tunnel stp
l2protocol-tunnel gvrp
!
vlan range 1,10
!
interface GigabitEthernet 0/1
switchport
 switchport mode dot1q-tunnel
 switchport dot1q-tunnel allowed vlan add untagged 10
 switchport dot1q-tunnel native vlan 10
l2protocol-tunnel stp enable
l2protocol-tunnel gvrp enable
!
interface GigabitEthernet 0/5
 switchport
switchport mode uplink
switchport trunk native vlan 1
switchport trunk allowed vlan only 1-4094
```

7. Common Errors

- The layer-2 tunneling function is not enabled globally and on the interface at the same time, and therefore it fails to take effect.
- In the SP network, the configured BPDU tunnel addresses are inconsistent, and therefore BPDU frames of the client network cannot be correctly transmitted.

1 Configuring STP

1.1 Introduction

1.1.1 Overview

The Spanning Tree Protocol (STP) is a Layer 2 management protocol used to eliminate Layer 2 loops by blocking redundant links in the network. It enables a backup link in the case of a link failure.

As the network evolves, multiple STP versions become available. This device supports STP, Rapid Spanning Tree Protocol (RSTP), Multiple Spanning Tree Protocol (MSTP), Multiple VLAN Spanning Tree (MVST), and Rapid Multiple VLAN Spanning Tree (Rapid-MVST).

1.1.2 Background and Functions

1. 802.1D STP

To prevent single point of failures (SPOFs), Layer 2 devices enhance line reliability by adding redundant lines. One of the most economical ways is to add loops. However, loops may cause broadcast storms and Media Access Control (MAC) address flapping. Therefore, the STP protocol arises.

STP can block certain interfaces through calculations to generate an optimal loop-free topology of a LAN. If a line fault is detected, STP restores the blocked interfaces, enables the backup link, and updates the topology automatically.

STP cannot enter forwarding state quickly but needs 50 seconds to complete topology convergence. All virtual local area networks (VLANs) in an LAN share one spanning tree. Packets of all the VLANs are forwarded along this spanning tree, and the bandwidth of redundant lines is wasted. VLAN data may be isolated at Layer 2, and Layer 2 loops do not exist in some circumstances. However, STP cannot recognize VLANs, and packets from interfaces in the same VLAN may be intercepted by blocking ports, resulting in a communication failure.

2. 802.1w RSTP

RSTP is compatible with STP backward. Apart from the conventional STP functions of eliminating loops and enabling backup links, RSTP solves the problem of entering forwarding state rapidly. If all bridges in a LAN support RSTP and are properly configured, once the network topology changes, RSTP takes only less than 1s to regenerate a topology tree.

Although RSTP can complete convergence quickly, it cannot identify VLANs just as STP does not.

3. 802.1s MSTP

MSTP resolves defects of STP and RSTP. It not only supports fast convergence but also forwards traffic of different VLANs along their respective paths, thereby providing a better load balancing mechanism for redundant links. STP/RSTP works based on ports while MSTP works based on instances. An instance is a collection of multiple VLANs. Binding multiple VLANs to one instance can reduce communication costs and improve resource usage. MSTP can implement the following functions:

- When lines are normal, MSTP can eliminate loops and prevent broadcast storms and MAC address flapping, to ensure normal Layer 2 communication.
- When a line is faulty, MSTP enables a backup link to enhance the link reliability. It can complete convergence rapidly to enhance the link availability.
- MSTP can generate multiple spanning trees by VLAN instance to implement traffic balancing.

4. MVST

MVST is a spanning tree protocol developed based on the Electrical and Electronics Engineers (IEEE) 802.1D standard and allows you to enable spanning tree separately in multiple VLANs. Different from STP, RSTP, or MSTP, you need to enable spanning tree loop-prevention in the specified VLAN on demand when you use MVST. Spanning tree calculation takes effect only in the VLANs with spanning tree enabled.

5. Rapid-MVST

As an improvement to MVST, Rapid-MVST introduces the quick handshake proposal/agreement mechanism defined in IEEE 802.1w to achieve the effects of fast convergence.

1.1.3 STP

1. Overview

STP, defined by the Institute of IEEE 802.1D standard, is used to break physical loops at the data link layer in a LAN and prevent broadcast storms, so as to implement link redundancy.

Layer 2 devices connected using single lines have no redundant lines and devices. Any SPOF can cause device disconnection and the line reliability is low. When a redundant line is added, a Layer 2 loop will form and the SPOF can be eliminated.

The adding of a redundant line brings two new problems:

- Once a broadcast frame appears in a Layer 2 loop, it will be flooded continuously by Layer 2 devices and a broadcast storm will be incurred, which will heavily consume device resources and network bandwidth.
- In a loop topology, a Layer 2 device may receive packets from the same source MAC address through two ports of two paths, causing MAC address flapping and the failure of the device to work properly.

Therefore, for Layer 2 Ethernet, only one valid channel is required to forward data between two LANs. Ideally, when a Layer 2 loop exists on a network, a specific port can be blocked to invalidate the redundant link so as to break the loop; when a network fault occurs, the specific port can be enabled to restore a redundant link to the valid state. It is difficult to attain this ideal effect via manual control. Therefore, the STP protocol emerges to automatically complete this work:

- Devices with STP enabled exchange specific STP Protocol Packets, that is, bridge protocol data units (BPDUs), and elect Device Roles (root bridge and non-root bridge) and Port Roles (root port, designated port, and blocking port) based on Key Information of BPDUs. Different port roles are in different Port States and have different functions. They form a Generating a Spanning Tree Topology in a LAN.

- Protocol packets are used to monitor the line status to Maintaining a Spanning Tree Topology. Once a fault is found, STP rectifies the fault and automatically Updating a Spanning Tree Topology.

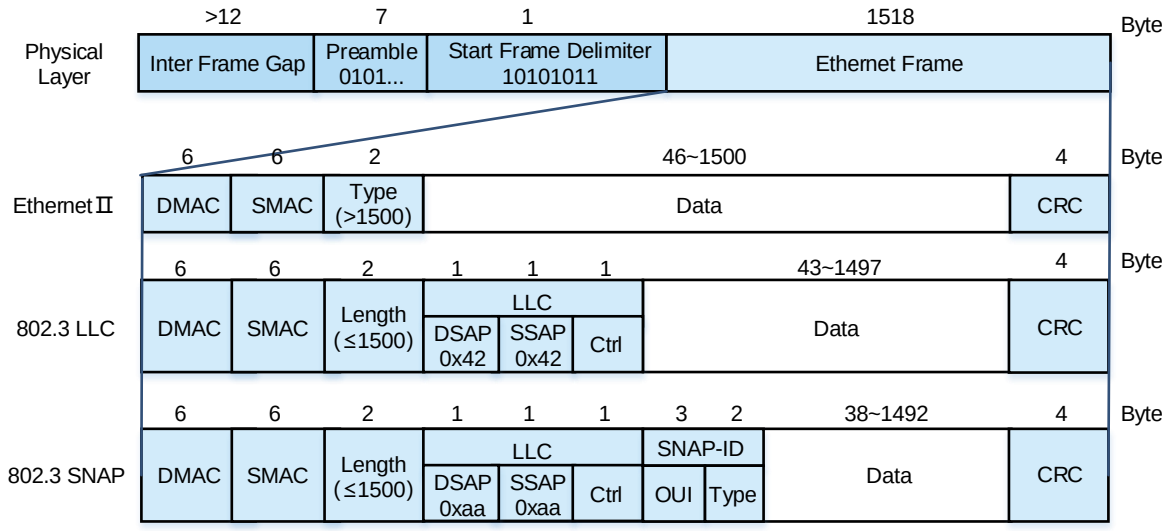
2. STP Protocol Packets

STP uses two types of protocol packets: configuration BPDU and topology change notification (TCN) BPDU.

- Configuration BPDU: A configuration BPDU contains 35 bytes, which provide information required for calculating the spanning tree topology (root bridge ID, root path cost, designated bridge ID, and designated port ID) and information required for maintaining the spanning tree (**Message Age**, **Max Age**, **Hello Time**, and **Forward Delay**). When STP is enabled on a designated port, the port sends configuration BPDUs at an interval of **Hello Time**. When a device receives a configuration BPDU from a root port, it sends the configuration BPDU to each designated port on the device, and the designated ports generate their own BPDUs. If the configuration BPDU received by a designated port from the line has a lower priority than the BPDU generated by the designated port itself (see 1.1.3 3. Key Information of BPDUs), the designated port sends its BPDU to the downstream device.
- TCN BPDU: A TCN BPDU contains four bytes. On a bridge with at least one designated port, when a port on the bridge transitions to forwarding or blocking state, the network topology has changed. The bridge will send a TCN BPDU to inform the upstream device of the network topology change. When the upstream device receives the TCN BPDU through a designated port, it sets TCA in the configuration BPDU to 1 and instructs the downstream device to stop sending the TCN BPDU. The upstream device also sends a copy of the TCN BPDU to its upstream device until the TCN BPDU reaches the root bridge. By setting the TC flag bit in the configuration BPDU to 1, the root bridge informs all bridges in the spanning tree of the network topology change, and asks them to clear dynamic MAC address entries of ports and relearn MAC addresses. A shorter MAC address aging time facilitates fast convergence of the topology.

BPDUs are encapsulated in IEEE 802.3 logical link control (LLC) Ethernet frames. The format differences between BPDUs and other Ethernet frames are as follows.

Figure 1-1 Formats of Ethernet Frames



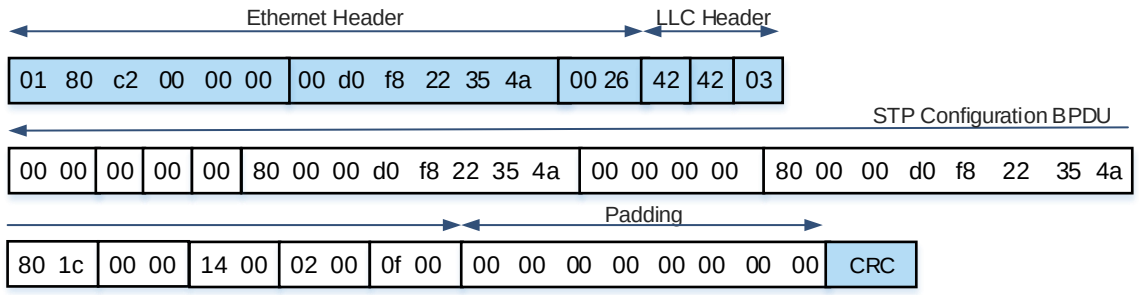


Figure 1-2 is an actual STP configuration BPDU taken as an example.

Figure 1-2 STP Configuration BPDU

The header of an IEEE 802.3 Ethernet frame contains 14 bytes in three fields in the header, as described in Table 1-1.

Table 1-1 Description of Fields in the Header of an IEEE 802.3 Ethernet Frame

Field	Bytes	Description
DMAC	6	Destination MAC address. According to the protocol, the destination address of the Ethernet frame used for encapsulating a BPDU is fixed to the multicast address 0180.c200.0000. A device receiving a frame with such a destination address will not forward the frame.
SMAC	6	Source MAC address of the device sending the BPDU. The value in the example is 00-d0-f8-22-35-4a.
Length	2	The value is 0x0026, indicating that the packet length is 38 bytes (3 bytes of the LLC header and 35 bytes of the BPDU).

The LLC header occupies three bytes in three fields, as described in Table 1-2.

Table 1-2 Description of Fields in the LLC Header of an Ethernet Frame

Field	Bytes	Description
DSAP	1	Destination service access point. The value is 0x42.
SSAP	1	Source service access point. The value is 0x42.
Control	1	This field stores various control information and identifies the type of an LLC frame. The value is 0x03.

The bytes behind the LLC header is a BPDU. There are four types of BPDUs for STP, RSTP, and MSTP, which are differentiated using different PVIDs and BPDU type values. A configuration BPDU of STP occupies 35 bytes in 12 fields, as described in Table 1-3. The last part is an 8-byte filling field and a 4-byte CRC field. They form a 64-byte Ethernet frame.

Table 1-3 Format of an STP Configuration BPDU

Field	Bytes	Description
PID	2	Protocol identifier. The value is 0x0000.
PVID	1	Protocol version identifier. 0x00 indicates an STP packet.
BPDU Type	1	BPDU packet type. 0x00 indicates a configuration BPDU of STP.
Flags	1	The value is 0x00 in the example. Configuration BPDUs of STP use only bit 7 and bit 0 and other bits are not used. Bit 7: Topology change acknowledgment (TCA). An upstream device sets bit 7 in a configuration BPDU to 1 and sends the BPDU to notify the downstream device of the topology change and requests the downstream device to stop sending the TCN BPDU. Bit 0: Topology change (TC). The root bridge sets bit 0 in a configuration BPDU to 1 and sends the BPDU to instruct the downstream device to directly delete MAC address entries of the bridges.
Root ID	8	Identifier of the root bridge recognized by the device. It consists of a 2-byte bridge priority and a 6-byte bridge MAC address. In the example, the priority value is 0x8000, which indicates 32768, and the bridge MAC address is 00-d0-f8-22-35-4a.
RPC	4	Root path cost, which is the cumulative cost from the port to the root bridge. The value is 0x00-00-00-00 in the example.
Bridge ID	8	Bridge identifier of the device. It consists of a 2-byte bridge priority and a 6-byte bridge MAC address. In the example, the priority value is 0x8000, which indicates 32768, and the bridge MAC address is 00-d0-f8-22-35-4a.
Port ID	2	Identifier of the port that sends the BPDU. It consists of a 1-byte priority and 1-byte port ID. In the example, the priority value is 0x80, which indicates 128, and the port ID is 1c.
Message Age	2	Age of the BPDU, which represents the time that the BPDU has been alive in the network. The value is 0x0000 in the example.
Max Age	2	Aging time of the BPDU. If a non-root bridge fails to receive a BPDU from the root bridge within the time of **Max Age**, the root bridge or the link to the root bridge is deemed as faulty. The value in the example is 0x1400 (low-order bytes on the left), indicating 20 seconds.
Hello Time	2	Interval for sending two adjacent BPDUs. The root bridge sends configuration BPDUs at an interval of **Hello Timer**. A non-root switch sends a configuration BPDU only after receiving the configuration BPDU from the upstream device. The value in the example is 0x0200 (low-order bytes on the left), indicating 2 seconds.

Field	Bytes	Description
FWD Delay	2	Forwarding delay. This time parameter controls the duration of listening and learning states. The value in the example is 0x0f00 (low-order bytes on the left), indicating 15 seconds.

A TCN BPDU consists of four bytes and contains only the **PID**, **PVID**, and **BPDU Type** fields. The packet format is described in Table 1-4.

Table 1-4 Format of an STP TCN BPDU

Field	Bytes	Description
PID	2	Protocol identifier. The value is 0x0000.
PVID	1	Protocol version identifier. 0x00 indicates an STP packet.
BPDU Type	1	BPDU packet type. 0x80 indicates a TCN BPDU of STP. When the downstream network topology changes, it is used to notify the upstream device of the network topology change. After receiving a TCN BPDU, a port copies the BPDU and forwards it to upstream devices till the root device receives the BPDU.

3. Key Information of BPDUs

- Priority vector

  Bridges exchange BPDUs to obtain information and generate a stable optimal tree topology. The most basic elements in the information are listed as follows:

  - Root ID: ID of the root bridge recognized by this local bridge. It consists of the bridge priority and MAC address of the root. The root bridge ID is the bridge ID of the root.
  - Root Path Cost: Path cost from this bridge to the root bridge.
  - Bridge ID: Each bridge has a unique bridge ID consisting of the bridge priority and MAC address.
  - Port ID: ID of each port, which consists of the port priority and port ID.

  These key elements constitute a priority vector <**Root ID**, **Root Path Cost**, **Bridge ID**, **Port ID**>. Bridges compare elements in the priority vector in sequence to determine the priority of BPDUs. A smaller priority element value indicates a higher priority. If a port of a bridge receives a BPDU with the priority higher than the BPDU priority of the port, the port saves and transmits the BPDU. If it receives a BPDU with the priority lower than the BPDU priority of the port, in case of STP, it discards the BPDU, but in case of RSTP or MSTP, it will send a Proposal BPDU to request the peer to recognize the local device as the upstream device. This mechanism ensures that high-priority BPDUs are transmitted throughout the network.

- Bridge ID

  According to IEEE 802.1W, a root ID is used to identify a root bridge in a spanning tree while a bridge ID is used to identify each bridge. When a device just runs STP, it uses its bridge ID as the root ID and STP compares root IDs to elect the root bridge according to algorithms. A bridge ID consists of eight bytes, with

the first two bytes of the bridge priority and the last six bytes of the bridge MAC address. A device compares the bridge priority first and then the MAC address during root bridge selection. A smaller value indicates a higher priority.

Bridge priority: To ensure network reliability, you are advised to specify bridge priorities during network planning, to prevent devices from electing the root bridge by comparing MAC addresses. In the 2-byte bridge priority, bit 1 to bit 12 indicate the system ID used for protocol extension and the value is **0** in RSTP. Bit 13 to bit 16 indicate the priority, which can be configured. If the configured priority is 0001 0000 0000 0000 (**4096** in decimal notation), the bridge priority is a multiple of 4096. Bit 13 to bit 16 can indicate 15 numbers from 0000 to 1111. Therefore, the priority is 4096 x 0 to 4096 x 15 in decimal notation.

Table 1-5 Bridge Priority Field (Two Bytes)

	Priority				**System ID**											
Bit	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
Value	32768	16384	8192	4096	2048	1024	512	256	128	64	32	16	8	4	2	1
-	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

- Port ID

  Each port participating in the spanning tree calculation must have a port ID, which is the port ID of a device.

  Format: A port ID consists of two bytes, with the first byte of the port priority and the second byte of the port ID.

  The default port priority is **128** and the port priority range is from 0 to 255. The port ID range is from 0 to 255, for example, the ID (0) of port GigabitEthernet 0/0 is smaller than that (1) of port GigabitEthernet 0/1.

- Root path cost

  Root path cost is the cumulative path cost from the port to the root bridge. A link between two directly connected ports is called a "segment". A segment with a higher network bandwidth has a lower path cost. The total cost calculated based on the path costs of all ports in the necessary lines from a port to the root is the cumulative path cost from the port to the root bridge. Table 1-6 shows the cost values supported by different protocols. Path cost values defined for the device are provided in Table 1-11.

Table 1-6 Path Costs Supported by Protocols

Bandwidth	**RPC Supported by IEEE 802.1t**	**RPC Supported by IEEE 802.1d**
10 Mbps	2000000	100
100 Mbps	200000	19
1 Gbps	20000	4
10 Gbps	2000	2

4. Device Roles

Devices with STP enabled exchange BPDUs and compare root IDs to elect device roles.

- Root bridge: Each spanning tree has a unique root.
- Designated bridge: A device in the shortest path between the local device and the root bridge, that is, the upstream device of the local device.
- Bridge: Generally the local device, that is, downstream device of a designated bridge. Designated bridges and bridges can be collectively referred to as non-root bridges.

5. Port Roles

The root bridge and non-root bridges elect different port roles by exchanging BPDUs.

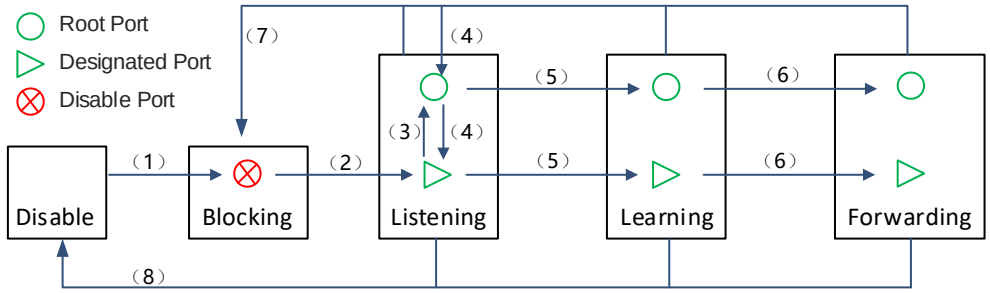
- Root port: A port with the shortest path from a non-root bridge to the root bridge.
- Designated port: Each port on the root bridge is a designated port. The root bridge connects to a root port of a non-root bridge through a designated port. The port that connects a designated bridge to a downstream device is also a designated port.
- Blocking port: A port on a non-root bridge that is in the blocking state.
- Disable port: A port in the Down state.

6. Port States

Ports work in different states and perform different functions according to the protocol. Table 1-7 lists functions corresponding to port states.

STP defines five port states: disabled, blocking, listening, learning, and forwarding. RSTP reduces port states to only three states: discarding, learning, and forwarding. MSTP uses the port states of RSTP.

Table 1-7 Port Roles, Port States, and Functions Supported by STP, RSTP, and MSTP



Note: In this table, R = root port, D = designated port, Blk=Blocking port, A = alternate port, B = backup port.

STP		RSTP and MSTP		Function				
Port Role	**Port State**	**Port Role**	**Port State**	**Receiving BPDUs**	**Sending BPDUs**	**MAC Address Learning**	**Receiving Data**	**Forwarding Data**
Disable	Disabled	Disable	Discarding	No	No	No	No	No
Blk	Blocking	A, B	Discarding	Blk, A, B	No	No	No	No
R, D	Listening	R, D	Discarding	R, D	D	No	No	No
	Learning		Learning	R, D	D	R, D	No	No
	Forwarding		Forwarding	R, D	D	R, D	R, D	R, D

After a topology becomes stable, only root ports and designated ports are in forwarding state and can send and receive data. Other ports are in blocking state and can only receive BPDUs. Different port roles have different functions in the same port state. For example, a root port cannot send but can receive BPDUs in forwarding state, while a designated port can send and receive BPDUs in forwarding state.

The port states can be transitioned according to the rules shown in Figure 1-3.

Figure 1-3 State Transition Rules of STP Ports

(1) After being initialized or enabled, a port enters blocking state.

(2) When STP is just running on a device, all the ports on the device enter listening state as designated ports, and send and receive BPDUs for election. After STP runs stably, if a blocking port fails to receive a BPDU within **MAX Age**, it becomes a designated port, transitions from blocking state to listening state, and receives and sends BPDUs for re-election.

(3) After election, if a port is elected as a root port, it only receives BPDUs but cannot send BPDUs.

(4) If a root port fails to receive a BPDU within **MAX Age**, the root is considered to be faulty, and the root port becomes a designated port and sends a BPDU.

(5) After a port is elected as a root port or designated port, it waits for one period of **Forward Delay**, transitions from listening state to learning state, and starts MAC address learning.

(6) Then, the port waits for another period of **Forward Delay**, transitions from learning state to forwarding state, and starts sending and receiving BPDUs.

(7) If the port is no longer a root port or designated port, it returns to blocking state.

(8) If a port is disabled or the link is faulty, the port returns to disable state.

7. Generating a Spanning Tree Topology

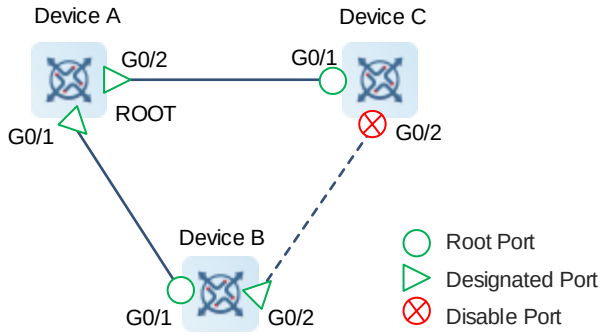
STP automatically calculates and generates a spanning tree topology for a LAN according to a set of bridge parameters configured by the user. Only appropriate configuration can ensure the fast generation of a stable topology. The steps for STP to generate a spanning tree topology are as follows:

(1) When a network starts to run STP, all switches consider themselves as root bridges and all ports on the switches are considered as designated ports. So, all ports enter listening state, broadcast configuration BPDUs, and receive BPDUs from the network. At this time, the root ID in the BPDU of each switch is the bridge ID of the switch.

(2) Each broadcast domain selects one root bridge. Each switch receives BPDUs from other switches and each BPDU contains the priority vector <**Root ID**, **Root Path Cost**, **Bridge ID**, **Port ID**>. According to the rule that a smaller value indicates a higher priority, each switch compares root IDs (which is the bridge ID of each switch at first) in BPDUs. When a port of a switch receives a smaller root ID, the root ID is updated in the **Root ID** field in the configuration BPDUs stored in all ports of the switch and then sent to other switches. After interaction, the bridge ID of the device with the highest priority is recorded as the root ID, indicating that the device is elected as the root bridge.

(3) All ports on the root bridge are designated ports. After waiting for one period of **Forward Delay**, designated ports transition from listening state to learning state to learn MAC addresses. After waiting for another period of **Forward Delay**, the designated ports transition from learning state to forwarding state and start receiving and sending packets.

(4) Each non-root bridge compares the cumulative path cost from each port to the root and elects the port with the smallest cost as the root port. Root ports only receive configuration BPDUs from designated ports and do not send configuration BPDUs. After waiting for one period of **Forward Delay**, root ports transition from listening state to learning state to learn MAC addresses. After waiting for another period of **Forward Delay**, root ports transition from learning state to forwarding state and start sending and receiving packets.



(5) A link between two directly connected switches is called a "segment". The priority vector <**Root ID**, **Root Path Cost**, **Bridge ID**, **Port ID**> is compared in sequence to select a designated port for each segment. After waiting for one period of **Forward Delay**, designated ports transition from listening state to learning state to learn MAC addresses. After waiting for another period of **Forward Delay**, the designated ports transition from learning state to forwarding state and start receiving and sending packets.

(6) The other ports are non-designated ports and are blocked. Such ports return to blocking state and only receive BPDUs. If a blocking port receives a high-priority BPDU within **MAX Age**, the current line from the peer device to the root is better and the blocking port remains in blocking state. If a blocking port fails to receive a high-priority BPDU within **MAX Age**, the current line from the peer device to the root is worse or even faulty. The blocking port transitions to listening state and sends its configuration BPDU to inform the peer device that the communication line passing through this port is better.

Note

- In STP and RSTP, the same device has the same bridge ID and the same port has the same port ID.
- In MSTP, different bridge IDs can be configured for the same device and different port IDs can be configured for the same port by instance.

Figure 1-4 Basic Topology of STP

8. Maintaining a Spanning Tree Topology

After a spanning tree topology becomes stable, only designated ports and root ports are in forwarding state while other ports are in blocking state. The root bridge continues to send configuration BPDUs at an interval of **Hello Time**. A downstream non-root bridge stores the optimal configuration BPDU received from the root port in the device, fills the bridge ID of the root bridge in the root ID, and then sends the configuration BPDU to the downstream device through a designated port. If a downstream device receives

a higher-priority BPDU from the upstream device within one period of **Max Age**, the network topology remains unchanged.

9. Updating a Spanning Tree Topology

Taking the topology shown in Figure 1-4 as an example, this section describes the update process of the spanning tree topology. The priority vector in the configuration BPDU packet sent by the interface is <RID, Cost, BID, PID>, and that saved by the interface is (RID, Cost, BID, PID). BIDs of Device A, Device B, and Device C are 1, 2, and 3 respectively. PIDs of ports GigabitEthernet 0/1 and GigabitEthernet 0/2 are 1 and 2 respectively. The lines are 1000M links and the path cost of each segment of line is 4.

- Device B and Device C consider themselves as root devices if the following situation occurs: Root bridge A malfunctions, Device B fails to receive BPDU<1,0,1,1> from the root bridge, and Device C fails to receive BPDU<1,0,1,2> from the root bridge within one period of **Max Age**. Then, port GigabitEthernet 0/2 of Device B sends BPDU<2,0,2,2>. Port GigabitEthernet 0/2 of Device C becomes a designated port and sends BPDU<3,0,3,2>. <2,0,2,2> has a higher priority than <3,0,3,2>. Therefore, Device B is elected as the root bridge and port GigabitEthernet 0/2 of Device C becomes a root port.
- Device C deems that root bridge A is faulty and considers itself as the root bridge if the following situation occurs: Port GigabitEthernet 0/2 of root bridge A or the link from root bridge A to Device C is faulty and downstream Device C fails to receive BPDU<1,0,1,2> from root bridge A through the root port GigabitEthernet 0/1 within one period of **Max Age**. Blocking port GigabitEthernet 0/2 (that can only receive BPDUs but cannot send BPDUs) of Device C becomes a designated port, transitions from blocking state to listening port, and sends BPDU<3,0,3,2>. Port GigabitEthernet 0/2 of Device C receives BPDU<1,4,2,2> from designated port GigabitEthernet 0/2 of Device B and finds that the root ID has a higher priority than the root ID in Device C. Device C considers Device A as the root bridge again, updates the spanning tree topology, and sets port GigabitEthernet 0/2 as the root port. After waiting for one period of **Forward Delay**, GigabitEthernet 0/2 transitions to learning state to learn MAC addresses. After waiting for another period of **Forward Delay**, GigabitEthernet 0/2 transitions to forwarding state to forward data, implementing link auto-recovery. In this case, the link recovery needs **Max Age** + 2 x FWD time. The default link recovery time is 50s, that is, 20 + 2 x 15 = 50.
- Device B deems that root bridge A is faulty and considers itself as the root bridge if the following situation occurs: Port GigabitEthernet 0/1 of Device A or the link from root bridge A to Device B is faulty and downstream Device B fails to receive BPDU<1,0,1,1> from root bridge A through the root port GigabitEthernet 0/1 within one period of **Max Age**. The BPDU sent by port GigabitEthernet 0/2 of Device B changes from <1,4,2,2> (Device A functions properly) to <2,0,2,2> (Device A is faulty). Blocking port GigabitEthernet 0/2 of Device C finds that the BPDU sent from port GigabitEthernet 0/2 of Device B has a lower priority than the configuration BPDU<1,4,3,2> stored by the blocking port itself, and discards the BPDU sent from Device B. If blocking port GigabitEthernet 0/2 of Device C fails to receive a BPDU with the priority higher than that of the BPDU stored in the blocking port within one period of **Max Age**, the blocking port becomes a designated port and sends its stored BPDU<1,4,3,2> to Device B. Device B find that BPDU<1,4,3,2> has a higher priority than BPDU<2,0,2,2> stored in port GigabitEthernet 0/2 of Device B, deems that Device A is the root bridge, and sets port GigabitEthernet 0/2 as the root port. After two periods of **Forward Delay** elapse, port GigabitEthernet 0/2 of Device B transitions to forwarding state to forward data, implementing link auto-recovery in the STP network.
- If a port on a downstream device changes to down state, the device sends a TCN BPDU to the upstream device to notify the upstream device of the topology change. After receiving the TCN BPDU from the

downstream device, the upstream device sets bit 7 (indicating TCA) in the **Flags** field of the configuration BPDU to **1**, and sends the configuration BPDU to the downstream device, indicating that the upstream device has known the topology change and requesting the downstream device to stop sending the TCN BPDU. Only the designated port of the upstream device processes TCN BPDUs. Non-designated ports discard TCN BPDUs directly once they receive such BPDUs. The upstream device copies the TCN BPDU and forwards it to its upstream device through the root port. The TCN BPDU is forwarded segment by segment until it reaches the root bridge. After receiving the TCN BPDU from a downstream device, the root bridge sets bit 7 (indicating TCA) in the **Flags** field of the configuration BPDU to **1** and sends the configuration BPDU to the downstream device, indicating that the upstream device has known the topology change and requesting the downstream device to stop sending the TCN BPDU. In addition, the root bridge sets bit 0 (indicating a TC) in the **Flags** field of the configuration BPDU to **1** to ask all downstream devices to clear dynamic MAC address entries of ports and relearn MAC addresses due to the topology change.

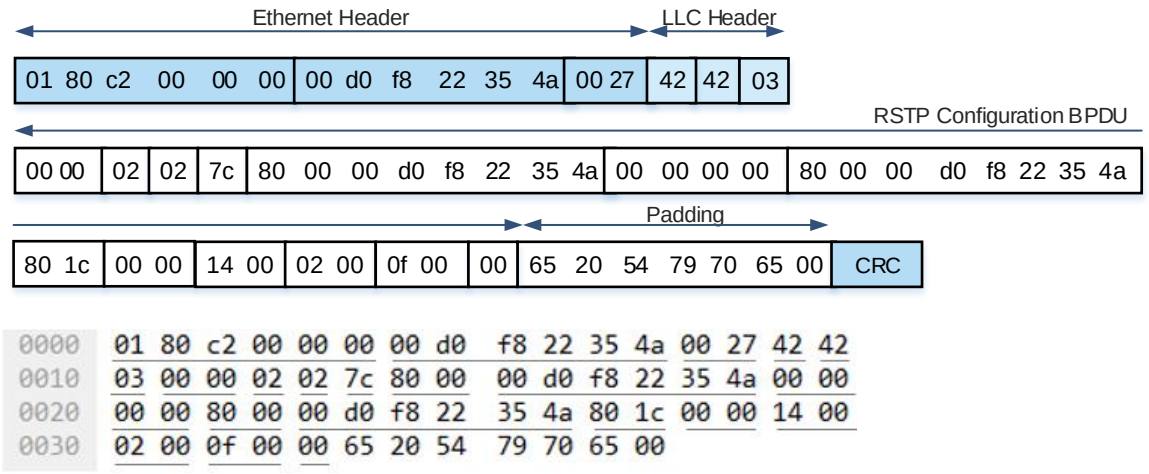
- If a new Device D is connected to Device B and the port status of Device B becomes up, Device B will also notify others of the topology change. Device D will send and receive BPDUs. If Device D has a higher priority than the original root (Device A), great changes may be incurred to the spanning tree. In conclusion, STP is not stable.

10. Drawbacks of STP

- Topology convergence is slow. After port role election is complete, STP waits for twice the period of **Forward Delay** (15s by default) before entering forwarding state, namely, STP needs to wait 30 seconds (that is, 2 x 15). Every time the topology changes, a bridge needs to re-elect the root port and designated ports after the period of **MAX Age** (20s by default), and then wait for twice the period of **Forward Delay** before entering forwarding state. Therefore, it takes about 50s (that is, 20 + 2 x 15 = 50 seconds) to generate a stable topology. STP requires the root bridge to actively send configuration BPDUs and other devices to forward the BPDUs. This mechanism leads to slow network convergence.
- If the network topology changes frequently, the network will be frequently disconnected, which is unacceptable to users.

1.1.4 RSTP

1. Overview



RSTP, defined by IEEE 802.1W, evolves from STP and is compatible with IEEE 802.1D STP downward. RSTP has all functions of the conventional STP protocol and is capable of preventing loops and providing redundant links. Compared with STP, RSTP shortens the time required for network topology convergence. If all the bridges in a LAN support RSTP and are configured properly, once the network topology changes, the time required by RSTP to re-generate the topology tree is less than 1s while STP needs about 50s.

2. RSTP Protocol Packets

RSTP needs only one type of protocol packet: configuration BPDU. The packet format is slightly different from that in STP. The configuration BPDU of RSTP is also called rapid spanning tree BPDU (RST BPDU).

When a topology changes, RSTP no longer uses a TCN BPDU to notify the topology change. Instead, RSTP sets the TC bit in the **Flags** field of the RST BPDU to **1** and notifies the entire network of the topology change via RST BPDU flooding.

Figure 1-5 Configuration BPDU of RSTP

As shown in Figure 1-5, the **Length** field is 0x0027, which indicates that the BPDU length is 39 bytes, including a 3-byte LLC header and a 36-byte RST BPDU. The fields of a RST BPDU packet are described in Table 1-8. The 39 bytes, plus the last 7 padding bytes and the 4 CRC bytes, together form a 64 byte Ethernet frame.

Table 1-8 Format of an RST BPDU

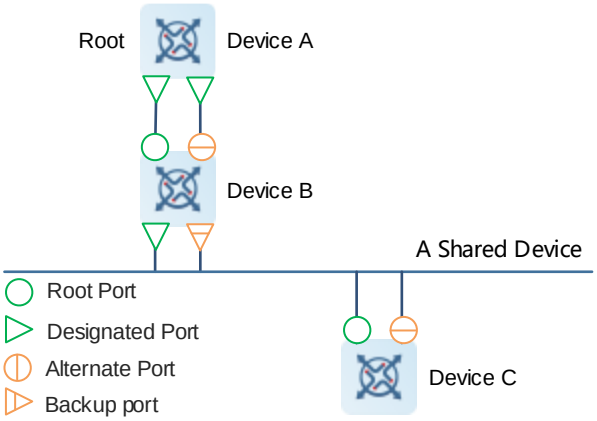
Field	Bytes	Description
PID	2	Protocol identifier. The value is **0x0000**.
PVID	1	Protocol version identifier. The value is **0x02**, indicating an RSTP packet. Devices running STP will discard RST BPDUs upon receiving.
BPDU Type	1	BPDU packet type. The value is **0x02**, indicating an RST BPDU.
Flags	1	An RST BPDU uses all the eight bits. In the example, the value is 0x7c, that is, 0111 1100. Bit 7: TCA. The value **1** indicates that a topology change is known. Bit 6: Agreement. The value **1** indicates consent to status switching. Bit 5: Forwarding. The value **1** indicates that forwarding is allowed. Bit 4: Learning. The value **1** indicates that learning is allowed. Bit 3 and bit 2: Port role. **00**: Unknown. **01**: Root port. **10**: Alternate/Backup. **11**: Designated port. Bit 1: Proposal. The value **1** indicates sending a proposal to request status switching. Bit 0: TC. The value **1** indicates notifying the topology change.
Root ID	8	Identifier of the root bridge recognized by the device. It consists of a 2-byte bridge priority and a 6-byte bridge MAC address.
RPC	4	Root path cost, which is the cumulative path cost from the port to the root bridge.

Field	Bytes	Description
Bridge ID	8	Bridge identifier of the device. It consists of a 2-byte bridge priority and a 6-byte bridge MAC address.
Port ID	2	Identifier of the port that sends the BPDU. It consists of a 1-byte priority and 1-byte port ID.
Message Age	2	Age of the BPDU, which represents the time that the BPDU has been alive in the network.
Max Age	2	Aging time of the BPDU.
Hello Time	2	Interval for sending two adjacent BPDUs. After an RSTP topology becomes stable, a non-root switch automatically sends configuration BPDUs at an interval of **Hello Timer** regardless of whether it receives the configuration BPDU from the root bridge. If a non-root bridge fails to receive a BPDU from the root within the time of **Time-factor** x **Hello Time**, it considers the root bridge or the link to the root bridge to be faulty. **Time-factor** is a multiple of **Hello Time** and can be configured.
FWD Delay	2	Forwarding delay. This time parameter controls the duration of listening and learning states.
Ver 1 Length	1	The value is 0x00, indicating that the BPDU does not contain content of Version 1. STP does not have this field.

3. Port Roles

RSTP uses alternate ports and backup ports to replace blocking ports, and adds the edge port auto-identification function. Therefore, RSTP supports six types of ports:

- Root port: A port with the shortest path to the root bridge.
- Alternate port: A backup port of a root port. Once the root port fails, the alternate port becomes the root port immediately.
- Designated port: A port that connects a root bridge or upstream bridge to a downstream device.
- Backup port: A backup port of a designated port. When a root bridge or upstream bridge has two interfaces to connect to the same downstream bridge, the interface with a higher priority is the designated port and the interface with a lower priority is the backup port. Once the designated port fails, the backup port becomes the designated port immediately.
- Edge port: A port connected to a terminal. Edge ports do not participate in spanning tree calculation. They can rapidly enter forwarding state with no need to wait for twice the period of **Forward Delay**. An edge port that receives a BPDU automatically becomes a non-edge port.
- Disable port: A port in down state.



Improvement effects:

- The work mechanism of the alternate port and backup port enables a device to restore the network connectivity within several milliseconds after discovering a topology change, with no need to transmit configurations.

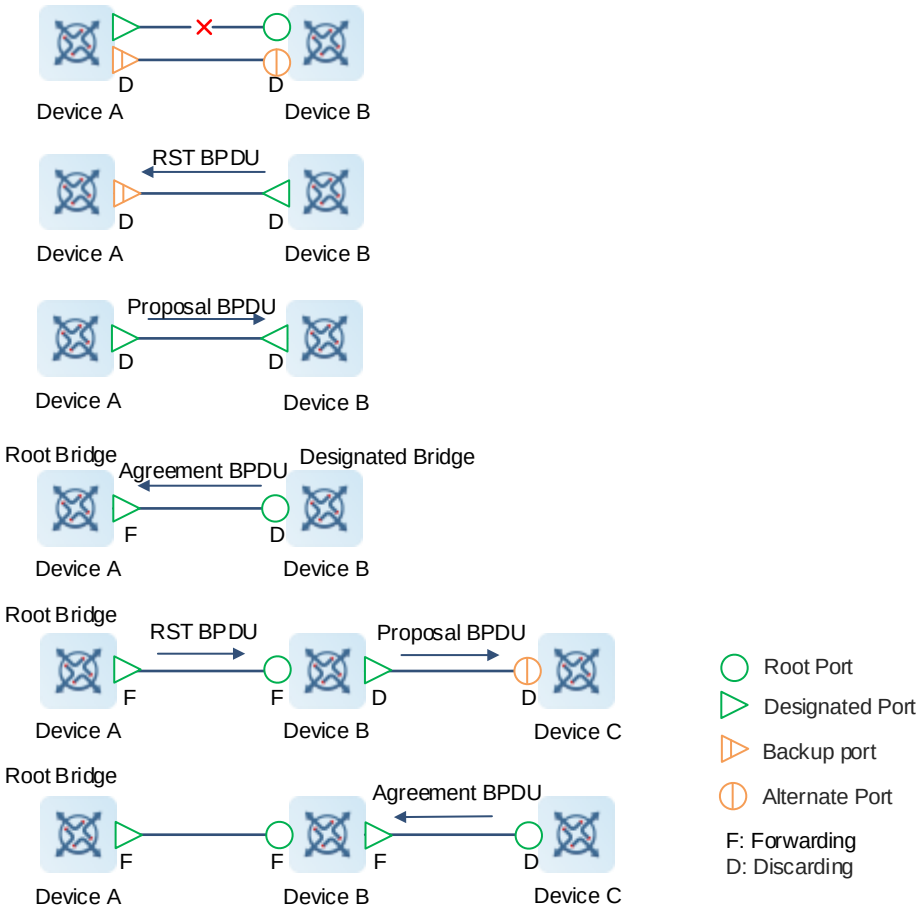
- The status change of an edge port will neither affect the network connectivity nor cause loops. Edge ports can enter forwarding state without delay.

Figure 1-6 shows port roles. The port priority sequence is as follows unless otherwise specified: root port > designated port > alternate port > backup port.

Figure 1-6 RSTP Port Roles

4. BPDU Processing of RSTP

In RSTP, a device processes BPDUs in a different way.



- Independent Hello: After an STP topology becomes stable, the root bridge sends configuration BPDUs at an interval of **Hello Timer**. Non-root switches send configuration BPDUs only after receiving the configuration BPDU from the upstream device, resulting in long convergence time in the case of a topology change. After an RSTP topology is stable, non-root switches automatically send configuration BPDUs at an interval of **Hello Timer** regardless of whether they receive configuration BPDUs from the root bridge.
- Fast fault detection: In STP, if a non-root switch fails to receive a BPDU from the upstream device within one period of **MAX Age**, the switch considers the upstream device to be faulty. In RSTP, if a non-root switch fails to receive a BPDU from the upstream device within three periods of **Hello Time**, it considers the upstream device to be faulty. The value range of **Max Age** is from 6 to 40, in seconds, the default value is **20**, and it takes at least 6s to detect the upstream device fault. The value range of **Hello Time** is from 1 to 10, in seconds, the default value is **2**, and it takes at least 3s to detect the upstream device fault. Therefore, RSTP supports a shorter fault detection time.
- Fast convergence: In STP, all ports discard low-priority BPDUs upon receipt. If a blocking port fails to receive a high-priority BPDU within one period of **MAX Age**, the port changes to the designated port and sends its BPDU to the peer. In RSTP, when a downstream device receives a BPDU from the upstream device and finds that the priority of the BPDU is lower than that of the BPDU stored in the port, it sends its stored BPDU to the upstream device immediately. The upstream device compares the received BPDU with its own BPDU and updates the BPDU stored in the local port. This mechanism can accelerate topology convergence.

5. Fast Convergence of RSTP

In STP, to transition from listening state to learning state and then to forwarding state, a port needs to wait for two periods of **Forward Delay**. The value range of **Forward Delay** is from 4 to 30, in seconds, the default value is **15**, and therefore, the default waiting time is **30**s. In RSTP, a port enters discarding state after role election is

complete, and then performs a Proposal/Agreement handshake with the connected bridge so as to quickly enter forwarding state. Figure 1-7 shows a fast convergence process of RSTP for example.

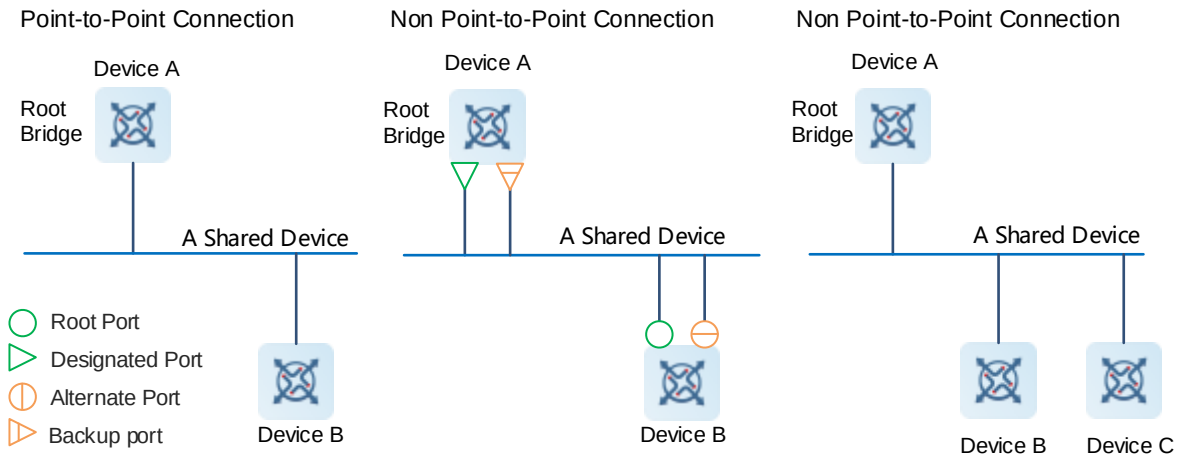
Figure 1-7 Fast Convergence of RSTP

(1) Proposal: If the root port of Device B fails to receive a BPDU from the upstream device within three periods of **Hello Time**, it considers the upstream device to be faulty. Device B returns to the initial state, considers itself as the root, and sets all its ports as designated ports (in discarding state) to send RST BPDUs. The alternate port (if Device A is not the root) or backup port (if Device A is the root) of Device A receives an RST BPDU from Device B. If Device A finds that the RST BPDU from Device B has a lower priority than its RST BPDU, Device A sets its port as a designated port (in discarding state), sets the **Proposal** bit in the configuration BPDU of the port to **1**, and sends a Proposal BPDU to Device B to request Device B to recognize Device A as the root bridge.

(2) Agreement: Device B receives the Proposal BPDU from Device A. If the BPDU of Device A is superior to that of Device B, Device B considers Device A as the root bridge (Device A may be the root or an intermediate device between Device B and the root). The port receiving the Proposal BPDU on Device B becomes the root port, and the root port stops sending RST BPDUs. Before a port transitions to forwarding state, Device B needs to block non-edge designated ports to prevent loops. The time required by ports to transition to -discarding state may be different. Devices use a set of synchronization variables to indicate whether the port state transition is complete. Device B sets the **Sync** variable to **1** for all ports. After all the ports enter discarding state, the **Synced** variable of all the ports is set to **1**. Then, the **Synced** variable of the root port is set to **1**, indicating that all the ports have been transitioned to the correct state. The root port sets the

Proposal bit to **0** and the **Agreement** bit to **1** in the Proposal BPDU received from Device Aand keeps other content of the BPDU unchanged, to create an Agreement BPDU. Then, the root port sends the BPDU to Device A.

(3) Forwarding: The designated port of Device A enters forwarding state after receiving the Agreement BPDU, and sends the RST BPDU with the **Forwarding** bit set to **1** at an interval of **Hello Time**. After receiving the RST BPDU, the root port of Device B enters forwarding state.



(4) Extension proposal: The designated port of Device B sends a Proposal BPDU with both **Proposal** and **Agreement** bits set to **1** to the downstream device, to request the downstream device to recognize Device B as the upstream device and extend the spanning tree. Theoretically, RSTP can recover the network tree topology immediately and achieve fast convergence once the network topology changes.

Improvement effect: Non-edge designated ports are blocked actively, without waiting for the period of **Forward Delay**. Hence, the convergence is accelerated. Network connectivity can be restored within the time of exchanging two handshake BPDUs, and the delay incurred by handshakes is less than 1s.

Caution

The above "handshake" process must meet one condition: Ports must be in a point-to-point connection state. Otherwise, the ports cannot shake hands and fast convergence cannot be achieved. To make RSTP-compliant devices function as they should, you are advised to connect devices in a point-to-point way.

Figure 1-8 Examples of Point-to-Point Connection and Non Point-to-Point Connection

6. Drawbacks of RSTP

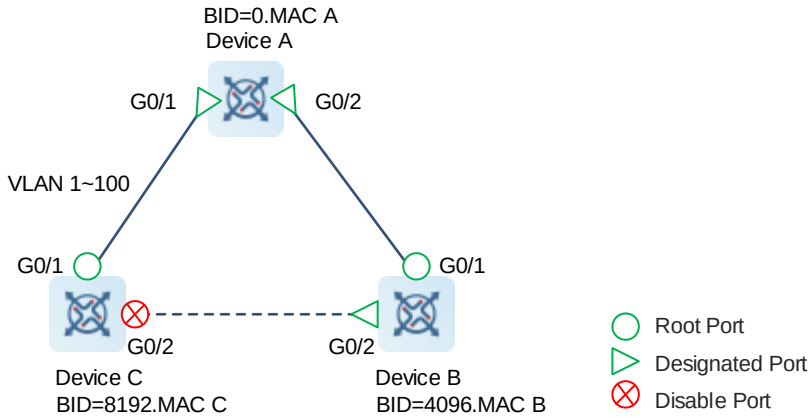
- RSTP creates only one spanning tree in the whole switching network, which cannot prevent performance degradation caused by the network expansion. Therefore, when using RSTP, it is not recommended that the number of devices between any two nodes running STP/RSTP in the network exceed 7.
- RSTP can only implement redundant backup but does not support load balancing based on VLAN traffic.
- STP and RSTP calculate the spanning tree topology based on devices (nodes), and the impact of VLANs is not taken into account. In a particular topology, ports in the same VLAN may be blocked and fail to communicate with each other. This problem and the solution will be detailed in the MSTP section.

1.1.5 MSTP

1. Overview

MSTP, defined by the IEEE 802.1s standard, is capable of ironing out drawbacks of STP, RSTP (only one spanning tree is generated for a device), and Multiple VLAN Spanning Tree (MVST) (one spanning tree is generated for each VLAN).

- After MSTP is deployed, if a loop arises in a network, MSTP performs topology calculation, and eliminates possible loops in the network by blocking redundant links.
- When an active path fails, MSTP activates the redundant backup link to restore the network connectivity.
- MSTP supports fast convergence.
- MSTP forwards the traffic of different VLANs along their respective spanning trees, which provides a better load balancing mechanism for redundant links.



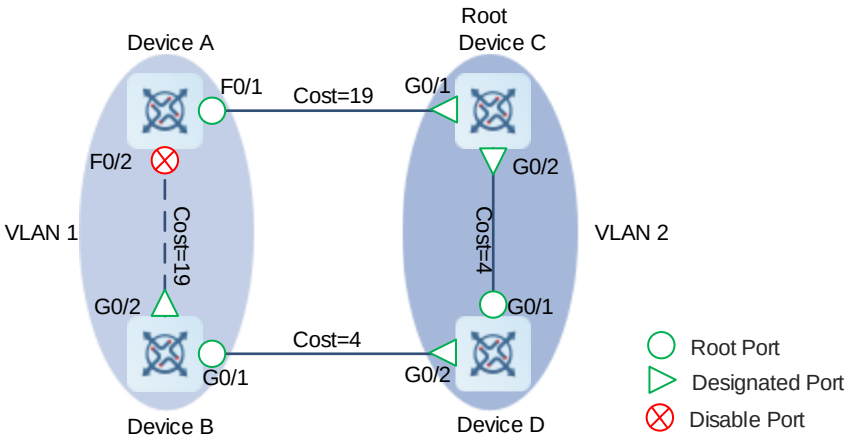
2. Origin of MSTP

The conventional STP and RSTP protocols have the following two problems and MSTP emerges as a solution to them.

- Both STP and RSTP block redundant lines and concentrate traffic on the active link, which leads to a waste of bandwidth of the redundant link and heavy traffic on the active link, resulting in traffic imbalance.

As shown in Figure 1-9, assume that the rate of each segment of link is 1 Gbps. If Devices A, B, and C run STP, the STP algorithm first elects Device A as the root based on the bridge ID. On non-root bridge B, the STP algorithm compares <**Root Path Cost**, **Bridge ID**, **Port ID**> in sequence, and selects port GigabitEthernet 0/1 as the designated port based on the root path cost. STP performs the same operation on Device C. Ports on the directly connected segment between Device C and Device B have the same root path cost. Port GigabitEthernet 0/2 of Device B is elected as the designated port based on the bridge ID, and port GigabitEthernet 0/2 of Device C is blocked. Port GigabitEthernet 0/2 of Device C cannot make communication due to STP blocking. VLANs 1–100 can be configured only on port GigabitEthernet 0/1 of Device C. It is impossible to implement traffic sharing by configuring port GigabitEthernet 0/1 of Device C to allow VLANs 1–50 and port GigabitEthernet 0/2 of Device C to allow VLANs 51–100.

Figure 1-9 Traffic Sharing Failure in STP



- In special cases, STP and RSTP may block links in the same VLAN, causing interfaces within the same

VLAN to be unable to communicate with each other.

As shown in Figure 1-10, Devices A and B are in VLAN 1, and Devices C and D are in VLAN 2. Assume that the topology tree calculated by STP is shown in the figure. Port FastEthernet 0/2 of Device A is blocked, and the link between Devices A and B is blocked. VLAN 1 is not configured on Devices C and D, and Devices C and D cannot forward packets of VLAN 1. As a result, Devices A and B in VLAN 1 cannot communicate with each other.

Figure 1-10 Communication Failure in the Same VLAN Caused by STP

3. Instance and Instance Mapping

The collection of one or more VLANs on one device is called a Multiple Spanning Tree Instance (MSTI) or instance for short. If a device supports a maximum of 65 instances, instance **0** exists by default and cannot be deleted, and instances 1–64 can be created or deleted. Users can allocate VLANs 1–4094 to different instances as required, and unallocated VLANs belong to instance **0** by default. The mapping between MSTIs and VLANs is called instance mapping, as shown in Table 1-9.

Table 1-9 Mappings Between MSTIs and VLANs

Instance	VLAN Mapped
0	1–2, 4, 11–4094
1	3, 5-7
2	8–10

Note

You are advised to disable MSTP before configuring mappings between MSTIs and VLANs, and then enable MSTP after configuration, to ensure stable convergence of the network topology.

4. Multiple Spanning Tree Region

Devices that run the MSTP protocol, have the same configuration name, revision number, and instance mappings constitute a multiple spanning tree (MST) region. Configuration names, revision numbers, and instance mappings are recorded in the **MST CFG ID** field of MST BPDUs and they can be configured.

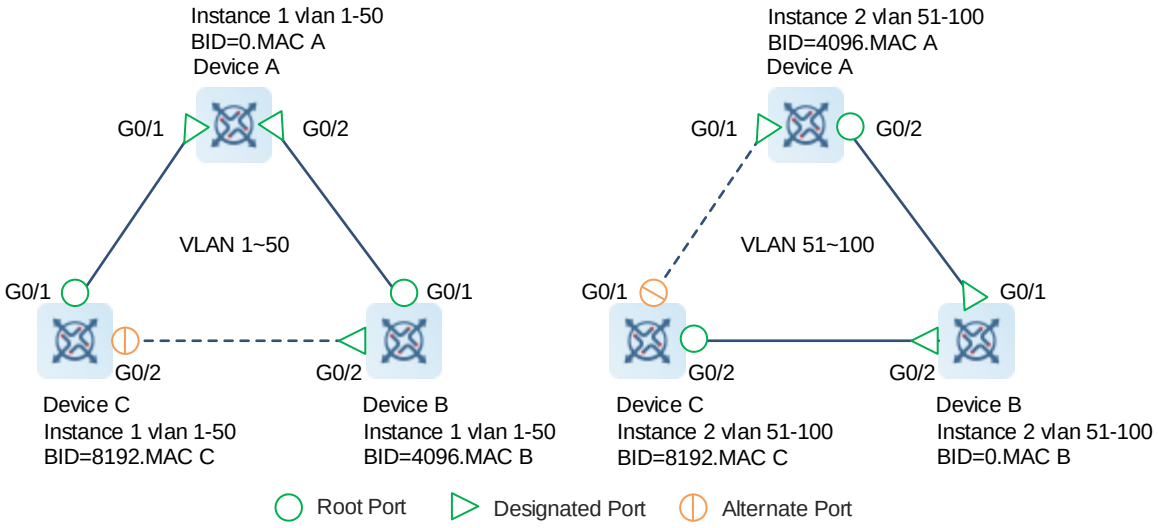
- Configuration name: A string of 32 bytes used to identify an MST region.
- Revision number: A 2-byte non-negative integer used to identify an MST region.
- Instance mapping: The mappings between MSTIs and VLANs are encrypted into a 16-byte digest. One MST region can contain multiple MSTIs.

MST regions are independent of each other. If a port on a device receives a BPDU with **MST CFG ID** same as that of the MST BPDU of the device, the device deems that the peer device and the device belong to the same MST region. Otherwise, the device deems that the peer device belongs to a different MST region. The load sharing advantage of MSTP can be reflected only after multiple devices are configured to the same MST region. Therefore, MST regions need to be properly divided and devices in the same MST region need to have the same **MST CFG ID**.

5. Instance Spanning Tree

One instance spanning tree can be generated for each instance. Each instance calculates and generates an instance spanning tree based on MSTI configuration messages in MST BPDUs. Information contained in MST configuration messages is described in Table 1-10.

If a device contains only one instance or MST configuration messages of multiple instances are the same, the same instance spanning tree will be generated, which is useless in traffic sharing. If VLANs are allocated to different instances to form multiple VLAN groups and different bridge priorities and port priorities are configured for different instances, multiple different instance spanning trees can be generated for the instances in the region to share VLAN traffic. The spanning tree of each instance is not affected by the spanning trees of other instances.



⚠ Caution

"MSTI configuration messages" of instances need to be manually modified so that spanning trees of instances are different, that is, the selected root, designated ports, blocking ports, and active links are different for different instances. In this way, VLAN traffic sharing can come into play.

MSTP calculates the topology for each instance in the same way as RSTP. In each instance, MSTP first elects the root bridge by comparing the root ID, and all ports on the root bridge are designated ports. Then, MSTP compares key elements in the priority vector <**Root ID**, **Root Path Cost**, **Bridge ID**, **Port ID**> on non-root bridges to elect root ports. Afterwards, MSTP compares the two ports of each directly connected network segment, and elects the port with a higher priority as the designated port and the one with a lower priority as the alternate port. Devices produce multiple instance spanning trees by means of MST BPDU interaction and calculation. Each instance provides a single loop-free network topology for VLAN groups in the instance, and the topologies of different VLAN groups are different.

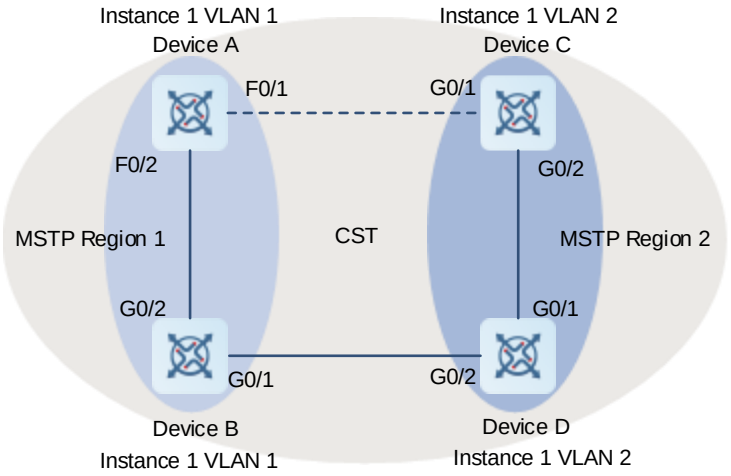
For example, after MSTP runs in the topology as shown in Figure 1-9, the calculated topology is shown in Figure 1-11.

Figure 1-11 Traffic Sharing Implemented by MSTP

In instance 1, devices elect Device A as the root by comparing root IDs (bridge IDs of the devices at this moment). Devices compare the root path cost and elect port GigabitEthernet 0/1 of Device B and port GigabitEthernet 0/1 of Device C as the root ports. In the directly connected network segment between Devices C and B, the two devices have the same root ID (0.MAC A). Bridge ID of Device B is smaller than that of Device C, and therefore, port GigabitEthernet 0/2 of Device B is elected as the designated port and port GigabitEthernet 0/2 of Device C is elected as the alternate port. When port GigabitEthernet 0/1 of Device C malfunctions, port GigabitEthernet 0/2 of Device C becomes the root port immediately.

In instance 2, devices elect Device B as the root by comparing root IDs (bridge IDs of the devices at this moment). Devices compare the root path cost and elect port GigabitEthernet 0/2 of Device A and port GigabitEthernet 0/2 of Device C as the root ports. In the directly connected network segment between Devices A and C, the two devices have the same root ID (0.MAC B). Bridge ID of Device A is smaller than that of Device C, and therefore, port GigabitEthernet 0/1 of Device A is elected as the designated port and port GigabitEthernet 0/1 of Device C is elected as the alternate port. When port GigabitEthernet 0/2 of Device C malfunctions, port GigabitEthernet 0/1 of Device C becomes the root port immediately.

It can be seen that different spanning trees are calculated for instance 1 and instance 2 due to different bridge IDs. Consequently, packets of VLANs 1–50 are forwarded along the spanning tree of instance 1 and packets of VLANs 51–100 are forwarded along the spanning tree of instance 2, implementing VLAN traffic sharing.



Users can, as needed, configure different instances for different VLAN groups, Configuring the Bridge Priority and Port Priority by instance, Configuring the Port Path Cost, and plan VLAN groups to forward traffic through different paths.

6. Common Spanning Tree

Devices with different instances and VLAN mapping configurations do not belong to the same MST region and each MST region is a whole. Therefore, one MST region can be considered as one node. The inter-node spanning tree calculated via STP is called a common spanning tree (CST). Instances with the same ID can exist in different MST regions, for example, instance 1 exists in two MST regions. Though the instance IDs are the same, instance spanning trees are generated independently for the instances and the instances are

unrelated to each other and unrelated to the CST. If two MST regions are configured in a topology shown in Figure 1-10, the calculated topology is shown in Figure 1-12 after MSTP runs.

Figure 1-12 Preventing a Communication Failure of Ports in the Same VLAN by MSTP

Devices A and B (both instance 1 VLAN 1) have the same instance mapping. There is no loop in MST region 1, and therefore, no port is blocked in this region.

Devices C and D (both instance 1 VLAN 2) have the same instance mapping. There is no loop in MST region 2, and therefore, no port is blocked in this region.

MST region 1 and MST region 2 can be considered as two nodes and there are loops between the two nodes. Therefore, a link is blocked according to the configuration to prevent loops and ensure that the intra-VLAN communication is not affected.

7. Common and Internal Spanning Trees

In a topology as shown in Figure 1-13, there are three MST regions. In each MST region, one instance spanning tree is generated for each instance. As shown in Figure 1-14, in region 2, one spanning tree is generated for instance 0, instance 1, and instance 2 each. According to the MSTP protocol, the spanning tree of instance 0 represents the region and is called an internal spanning tree (IST).

Each MST region is considered as a node, and one spanning tree is calculated between nodes according to the STP protocol. This spanning tree is called a common spanning tree (CST). As shown in Figure 1-13, a spanning tree connected using blue lines indicates an IST in a region while a spanning tree connected using orange lines indicates an inter-region CST.

ISTs and a CST constitute a common and internal spanning tree (CIST).

CIST root: Root of a CIST. It is also the root of a CST, that is, CST root. In the CST calculation, the device with the smallest bridge ID is elected as the CIST root. As shown in Figure 1-13, assume that Device A has the smallest bridge ID. Device A is elected as the CIST root.

Region root: In an IST, the device with the smallest root path cost to the CIST root is elected as the region root of the IST, which is also called master bridge. CIST root A is also the region root of region 1. As shown in Figure 1-13, assume that Device B in region 2 has the smallest root path cost to Device A. Device B is elected as the region root of region 2. Device B may not be directly connected to Device A but may through other devices in region 1. Likewise, Device C is elected as the region root of region 3.

The region root of region 2 is Device B. Suppose that three spanning trees are calculated for the three instances in region 2, and the roots of the three spanning trees are all Device B. On Device B, the port with the smallest root path cost to the CIST root is the master port. Therefore, compared with RSTP, MSTP adds two port roles: master port and region edge port.

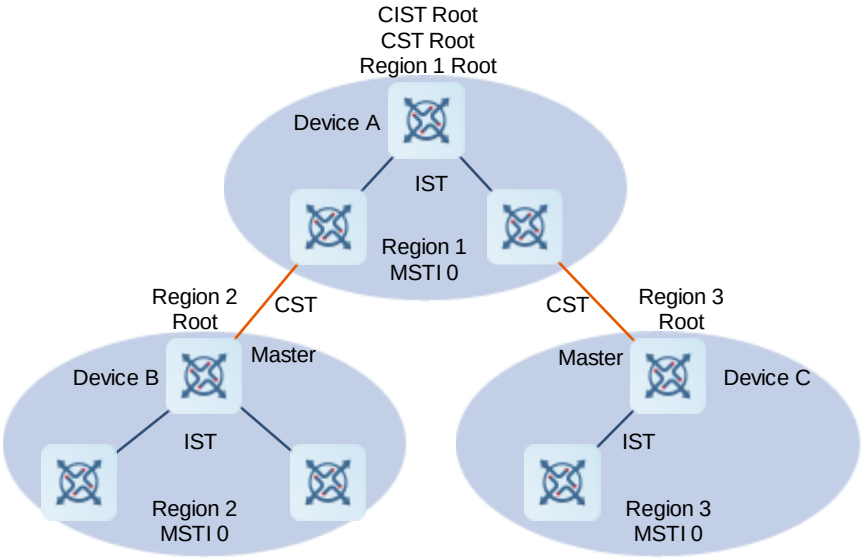
Caution

The **CIST Regional Root** field in MSTP packets indicates a region root rather than the CIST root.

A region root (represented by **CIST Regional Root**) may not be the device with the smallest bridge ID in a region but is the device with the smallest root path cost from the region to the CIST root.

To make the topology more stable, it is recommended that the "outlets" of different instance spanning trees in each region to the CIST root be configured on the same device of the region. As shown in Figure 1-14, the outlets of MSTI 1, MSTI 2, and MSTI 3 in region 2 to the CIST root are configured on Device B.

Figure 1-13 CIST Composed of ISTs and the CST



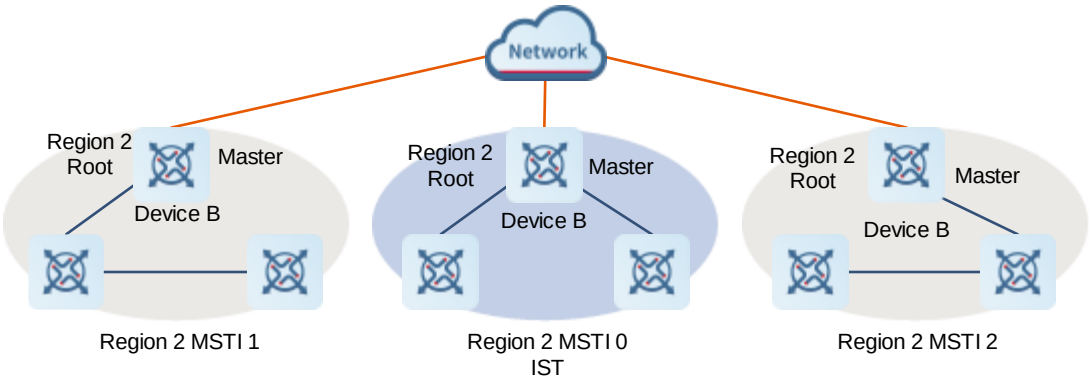


Figure 1-14 Three Spanning Trees Generated for the Three Instances in Region 2

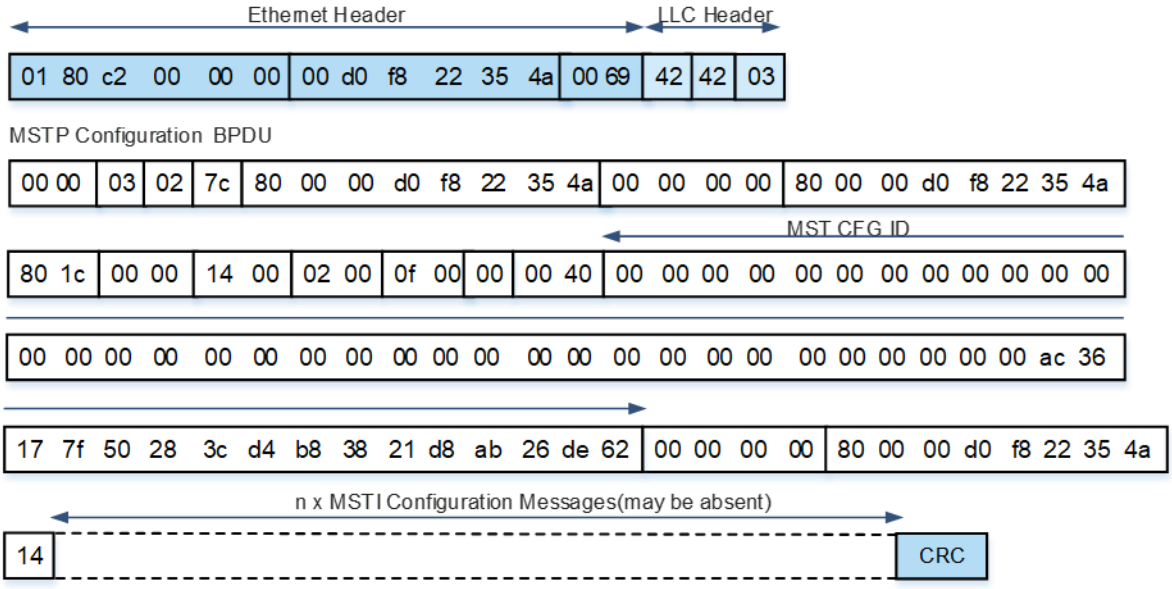
8. Port Roles



MSTP introduces a new port role to the region root: master port, which is the port with the smallest root path cost from a region to the CIST root. The master port is the "outlet" of all instances in a region, and all instances can forward data through the master port.

- Root port: A port with the shortest path to the root bridge.
- Designated port: A port that connects a bridge to the root bridge in each LAN.
- Alternate port: A backup of a root port. Once the root port fails, the alternate port becomes the root port immediately.
- Backup port: A backup of a designated port. When two ports on a bridge connect to the same LAN, the port with a higher priority is the designated port and the one with a lower priority is the backup port. Once the designated port fails, the backup port changes to the designated port immediately.
- Edge port: A port connected to a terminal. Edge ports do not participate in spanning tree calculation.
- Disable port: A port in down state.
- Master port: A port with the shortest path cost to the CIST root. It is the "outlet" of all MSTIs in an MST region.
- Region edge port: A port directly connected to other MST regions. A master port is a special region edge port.

9. MSTP Packets

MSTP uses MST BPDUs as the basis for spanning tree calculation. MST BPDUs can be used to calculate spanning tree topologies, maintain network topologies, and communicate topology change records.

Figure 1-15 Configuration BPDU of MSTP

As shown in Figure 1-15, the **Length** field is 0x0069, which indicates that the packet length is 105 bytes in this example, including a 3-byte LLC header and a 102-byte MST BPDU. This length is the minimum length of an MST BPDU. For both intra-region and inter-region MST BPDUs, the first 36 bytes are the same as those of an

RST BPDU. MSTP-specific fields start from the 37th byte, and the MSTI configuration message field at the end is composed of multiple MSTI configuration messages. The fields are described in Table 1-10.

Table 1-10 Format of an MST BPDU

Field	Bytes	Description
PID	2	Protocol identifier. The value is 0x0000.
PVID	1	Protocol version identifier. 0x03 indicates that the packet protocol is MSTP.
BPDU Type	1	BPDU packet type. The value is 0x02 for MSTP. 0x02 indicates that the BPDU type is MST BPDU.
CIST Flags	1	Configuration BPDUs of MSTP use all the eight bits. In the example, the value is 0x7c, that is, 0111 1100. Bit 7: TCA. An upstream device sets bit 7 in a configuration BPDU to **1** and sends the BPDU to notify the downstream device of the topology change and request the downstream device to stop sending the TCN BPDU. Bit 6: Agreement. The value **1** indicates consent to status switching. Bit 5: Forwarding. The value **1** indicates forwarding state. Bit 4: Learning. The value **1** indicates learning state. Bit 3 and bit 2: Port role. ● 00: Unknown. ● 01: Root port. ● 10: Alternate/Backup. ● 11: Designated port. Bit 1: Proposal. The value **1** indicates sending a proposal to request status switching. Bit 0: TC. The root bridge sets bit 0 in a configuration BPDU to **1** and sends the BPDU to instruct the downstream device to delete MAC address entries.
CIST Root ID	8	Bridge ID of the CIST root, which consists of a 2-byte root priority and a 6-byte root MAC address. In the example, the priority value is 0x8000, which indicates 32768, and the bridge MAC address is 00-d0-f8-22-35-4a.
CIST External Path Cost	4	CIST external path cost, which refers to the cumulative path cost from the MST region, to which the device belongs, to the CIST root. The CIST external path cost is calculated based on the link bandwidth, which is 0x00 00 00 00 in the example.
CIST Regional Root ID	8	CIST regional root identifier, that is, bridge ID of the IST master bridge. If the CIST root is in the region, the region root ID is the CIST root ID. In the example, the priority value is 0x8000, which indicates 32768, and the bridge MAC address is 00-d0-f8-22-35-4a.

Field	Bytes	Description
CIST Port ID	2	ID of a port in an IST. In the example, the priority value is 0x80, which indicates 128, and the port ID is 1c.
Message Age	2	Age of a BPDU, that is, keepalive time of the packet. The value is 0x0000 in the example.
Max Age	2	Maximum timeout time of a BPDU, after which the link to the root switch is considered to be faulty. The value in the example is 0x1400 (low-order bytes on the left), indicating 20 seconds.
Hello Time	2	Hello interval for sending two adjacent BPDUs. The default value is **2**s. The value in the example is 0x0200 (low-order bytes on the left), indicating 2 seconds.
FWD Delay	2	**Forward Delay** timer. The default value is **15**s. This field controls the duration of listening and learning states. The value in the example is 0x0f00 (low-order bytes on the left), indicating 15 seconds.
Ver 1 Length	1	Length of a Version1 BPDU. The value is fixed to 0x00.
Ver 3 Length	2	Length of a Version3 BPDU. The value is 0x0040 in the example.
MST CFG ID	51	MST configuration identifier, that is, MST region label information, which contains four fields. Interconnected devices with the same four fields in **MST CFG ID** belong to the same region. (1-byte) Configuration Identifier Format Selector: The value is fixed to 0x00. (32-byte) Configuration Name: Region name. The default value is all 0's. (2-byte) Revision Level: Revision number, which is a non-negative integer. The value is 0x0000. (16-byte) Configuration Digest: MSTI-VLAN instance mapping table. The HMAC-MD5 algorithm is used to encrypt the mappings between instances and VLANs in a region into a 16-byte digest.
CIST Internal RPC	4	CIST internal root path cost, which is the cumulative path cost from the local port to the master switch of the IST. The internal root path cost of a CIST is calculated based on the link bandwidth. The value is 0x00-00-00-00 in the example.
CIST Bridge ID	8	ID of the designated switch in the CIST. It consists of a 2-byte bridge priority and a 6-byte bridge MAC address. In the example, the priority value is 0x8000, which indicates 32768, and the bridge MAC address is 00-d0-f8-22-35-4a.
CIST R Hops	1	Number of remaining hops of a BPDU in a CIST. The default value is 0x14, which indicates 20 hops.

Field	Bytes	Description
MSTI Configuration Messages (may be absent)	16	MSTI configuration message. The configuration message of each MSTI occupies 16 bytes. If there are *n* MSTIs, they occupy *n* x 16 bytes. Fields in the configuration message of a single MSTI are described as follows: (1-byte) MSTI Flags: MSTI flag. (8-byte) MSTI Regional Root Identifier: MSTI region root ID. (4-byte) MSTI Internal Root Path Cost: Cumulative path cost from the local port to the MSTI region root switch. The internal root path cost of an MSTI is calculated based on the link bandwidth. (1-byte) MSTI Bridge Priority: Bridge priority of the device in the MSTI. (1-byte) MSTI Port Priority: Port priority of the device in the MSTI. (1-byte) MSTI Remaining Hops: Number of remaining hops of a BPDU in the MSTI.

1.1.6 MVST

1. Overview

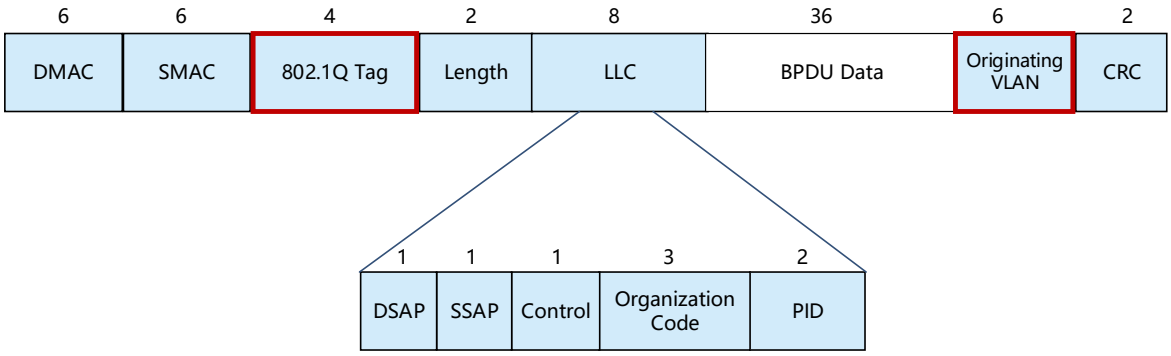
MVST is a spanning tree protocol developed based on the IEEE 802.1D standard and allows you to enable spanning tree separately in multiple VLANs. Featuring flexible deployment, you can enable loop-prevention in one or more VLANs based on actual needs.

The differences among STP, RSTP, MSTP and MVST are as follows:

- STP and RSTP must be enabled in the global configuration mode and spanning tree is calculated by interface. There is only one spanning tree globally and the interface in all the VLANs is in the same STP forwarding state.
- MSTP must be enabled in the global configuration mode, but VLANs can be bound to MSTP instances, with each instance calculating the spanning tree separately.
- MVST can be enabled by VLAN. If an interface is added to a VLAN, the interface participates in spanning tree calculation of this VLAN. Otherwise, the interface does not participate in the spanning tree calculation.

Developed based on IEEE 802.1D, MVST uses a processing mechanism similar to that of STP:

- Devices enabled with MVST exchange specific MVST Protocol Packets that are encapsulated by BPDU. Different from STP, MVST BPDUs are encapsulated in the IEEE 802.3 SNAP format. MVST elects the device roles (root bridge and non-root bridge) and port roles (root port, designated port, and blocking port) based on key information of BPDUs. Different port roles are in different port states and have different functions. They form a spanning tree topology in a VLAN.
- Protocol packets are used to monitor the line status to maintain the spanning tree topology.
- Once a fault is detected and restored, MVST automatically updates the spanning tree topology.



2. MVST Protocol Packets

The same as STP, MVST uses two types of protocol packets: configuration BPDU and TCN BPDU.

The configuration BPDU and TCN BPDU of MVST are similar to those of STP, with the following differences: MVST packets are encapsulated in the IEEE 802.3 SNAP format (as shown in Figure 1-1). 802.1Q VLAN tags

are inserted to MVST packets based on the VLAN in which MVST is enabled. The **Originating VLAN** field is added to the end of STP configuration BPDU for carrying the MVST VLAN information.

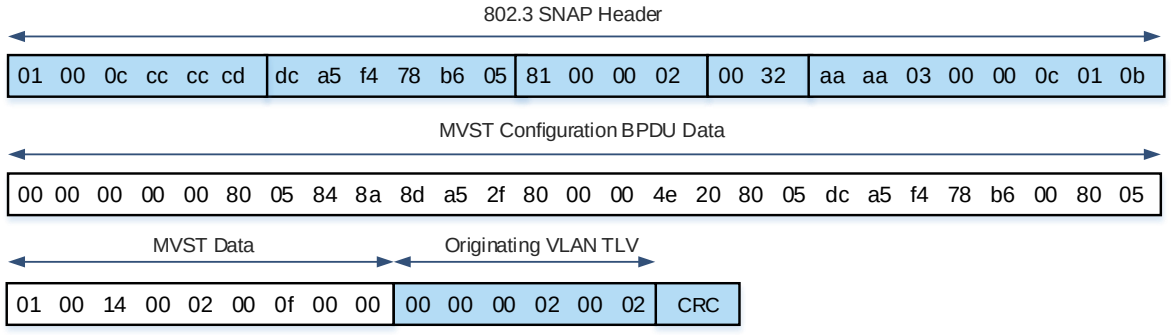


Figure 1-1 Encapsulation Structure of MVST BPDUs

- Configuration BPDU
  The length of a packet is 64 bytes with no IEEE 802.1Q tag encapsulated and is 68 bytes with an IEEE 802.1Q tag encapsulated. Configure BPDU to contain information used to calculate the STP topology, including the root bridge ID, root path metric, designated bridge ID, designated port ID, and the information used to maintain the STP, such as **Message Age**, **Max Age**, **Hello Time**, and **Forward Delay**. When STP is enabled on a designated port, the port sends configuration BPDUs at an interval of **Hello Time**. When a device receives a configuration BPDU from a root port, it sends the configuration BPDU to each designated port on the device, and the designated ports generate their own BPDUs. If the configuration BPDU received by a designated port from the line has a lower priority than the BPDU generated by the designated port itself (see 1.1.3 3. Key Information of BPDUs), the designated port sends its BPDU to the downstream device.
- TCN BPDU
  A TCN BPDU contains 60 bytes. On a bridge with at least one designated port, when a port on the bridge transitions to forwarding or blocking state, the network topology has changed. The bridge will send a TCN BPDU to inform the upstream device of the network topology change. When the upstream device receives the TCN BPDU through a designated port, it sets TCA in the configuration BPDU to 1 and instructs the downstream device to stop sending the TCN BPDU. The upstream device also sends a copy of the TCN BPDU to its upstream device until the TCN BPDU reaches the root bridge. By setting the TC flag bit in the configuration BPDU to 1, the root bridge informs all bridges in the spanning tree of the network topology change, and asks them to clear dynamic MAC address entries of ports and relearn MAC addresses. A shorter MAC address aging time facilitates fast convergence of the topology.

Figure 1-2 shows the constitution of MVST configuration BPDUs.

Figure 1-2 MVST Configuration BPDU

The IEEE 802.3 Ethernet header with a length of 14 bytes has three fields when it is not encapsulated with an IEEE 802.1Q tag. Otherwise, the header has four fields and a length of 18 bytes. The packet in the example is encapsulated with an IEEE 802.1Q tag. Table 1-1 shows the field description.

Table 1-1 Description of Fields in the Header of an IEEE 802.3 Ethernet Frame

Field	Bytes	Description
DMAC	6	Destination MAC address. For an Ethernet frame with MVST-encapsulated BPDU, it has a fixed destination address of multicast address 0100.0ccc.cccd. Such frames are not forwarded once received by a device.
SMAC	6	Source MAC address of the device sending the BPDU. The value in the example is dca5.f478.b605.
802.1Q Tag	4	Field added according to IEEE 802.1Q. Whether this field is encapsulated depends on the configuration of the interface and VLAN. For details, see *Configuring VLAN*. In the example, the complete value of this field is **0x81000002**. This field includes the following information: ● Type: 2-byte field. The value **0x8100** identifies an IEEE 802.1Q frame. In the example, the packet is encapsulated with an 802.1Q tag, so the corresponding field value is **0x8100**. ● PRI: 3-bit field, indicating the Layer 2 priority. The value range is from 0 to 7, corresponding to the CoS priority of QoS. A larger value indicates a higher priority. The value is **0** in the example. ● CFI: 1-bit field used to distinguish Ethernet frames, FDDI frames, and token ring frames. **0** indicates an Ethernet frame. The value is **0** in the example. VID: 12-bit field. It indicates the ID of a VLAN to which packets belong. The value range is from 1 to 4094, and the value 0 and 4095 are reserved. The value is **2** in the example.
Length	2	The value is **0x0032**, indicating that the packet length is 50 bytes (the LLC header occupies 8 bytes, the BPDU packet occupies 36 bytes, and the originating VLAN TLV occupies 6 bytes).

The LLC header consists of 8 bytes, which is SNAP encapsulated and divided into 5 fields. Table 1-2 shows the field description.

Table 1-2 Description of Fields in the LLC Header of an Ethernet Frame

Field	Bytes	Description
DSAP	1	Destination service access point. The value is 0xaa.
SSAP	1	Source service access point. The value is 0xaa.
Control	1	This field stores various control information and identifies the type of an LLC frame. The value is 0x03.
OUI	3	Organization unique identifier, which is **0x00000c**.

Field	Bytes	Description
PID	1	Protocol ID. The value of this field in MVST packets is **0x010b**.

The bytes following the LLC header is a BPDU. The BPDU packet format and content of MVST is generally the same as that of STP, except that one more bit is added at the end. Table 1-3 shows the field description.

Table 1-3 Format of an MVST Configuration BPDU

Field	Bytes	Description
PID	2	Protocol identifier. The value is 0x0000.
PVID	1	Protocol version identifier. 0x00 indicates an STP packet.
BPDU Type	1	BPDU packet type. 0x00 indicates a configuration BPDU of STP.
Flags	1	The value is 0x00 in the example. Configuration BPDUs of STP use only bit 7 and bit 0 and other bits are not used. ● Bit 7: Topology change acknowledgment (TCA). An upstream device sets bit 7 in a configuration BPDU to 1 and sends the BPDU to notify the downstream device of the topology change and requests the downstream device to stop sending the TCN BPDU. ● Bit 0: Topology change (TC). The root bridge sets bit 0 in a configuration BPDU to 1 and sends the BPDU to instruct the downstream device to directly delete MAC address entries of the bridges.
Root ID	8	Identifier of the root bridge recognized by the device. It consists of a 2-byte bridge priority and a 6-byte bridge MAC address. In the example, the priority value is 0x8000, which indicates 32768, and the bridge MAC address is 00-d0-f8-22-35-4a.
RPC	4	Root path cost, which is the cumulative cost from the port to the root bridge. The value is 0x00-00-00-00 in the example.
Bridge ID	8	Bridge identifier of the device. It consists of a 2-byte bridge priority and a 6-byte bridge MAC address. In the example, the priority value is 0x8000, which indicates 32768, and the bridge MAC address is 00-d0-f8-22-35-4a.
Port ID	2	Identifier of the port that sends the BPDU. It consists of a 1-byte priority and 1-byte port ID. In the example, the priority value is 0x80, which indicates 128, and the port ID is 1c.
Message Age	2	Age of the BPDU, which represents the time that the BPDU has been alive in the network. The value is 0x0000 in the example.

Field	Bytes	Description
Max Age	2	Aging time of the BPDU. If a non-root bridge fails to receive a BPDU from the root bridge within the time of **Max Age**, the root bridge or the link to the root bridge is deemed as faulty. The value in the example is 0x1400 (low-order bytes on the left), indicating 20 seconds.
Hello Time	2	Interval for sending two adjacent BPDUs. The root bridge sends configuration BPDUs at an interval of **Hello Timer**. A non-root switch sends a configuration BPDU only after receiving the configuration BPDU from the upstream device. The value in the example is 0x0200 (low-order bytes on the left), indicating 2 seconds.
FWD Delay	2	Forwarding delay. This time parameter controls the duration of listening and learning states. The value in the example is 0x0f00 (low-order bytes on the left), indicating 15 seconds.
Reserved	1	Reserved. The value is **0x00**.

A TCN BPDU consists of four bytes and contains only the **PID**, **PVID**, and **BPDU Type** fields. The packet format is described in Table 1-4.

Table 1-4 Format of an MVST TCN BPDU

Field	Bytes	Description
PID	2	Protocol identifier. The value is 0x0000.
PVID	1	Protocol version identifier. 0x00 indicates an STP packet.
BPDU Type	1	BPDU packet type. 0x80 indicates a TCN BPDU of STP. When the downstream network topology changes, it is used to notify the upstream device of the network topology change. After receiving a TCN BPDU, a port copies the BPDU and forwards it to upstream devices till the root device receives the BPDU.

The Originating VLAN TLV field is 6 bytes long and is added only after BPDU packets of MVST. Table 1-5 shows the format.

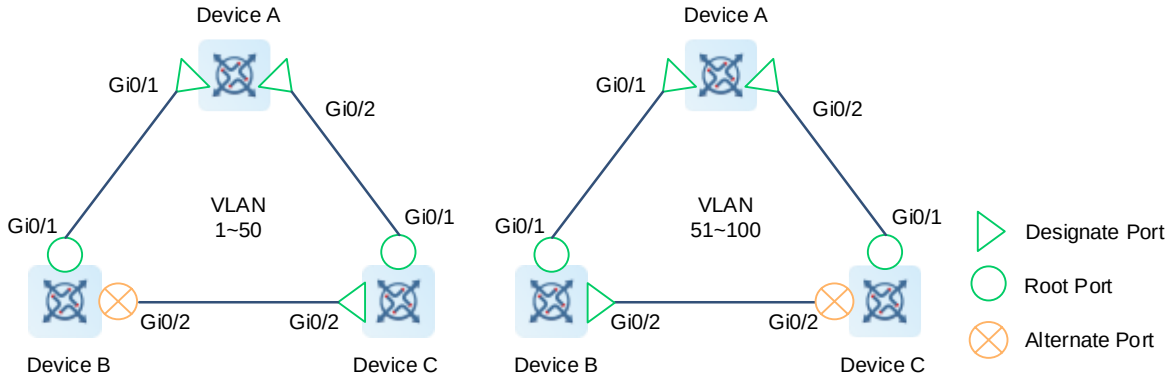

Table 1-5 Originating VLAN TLV Format

Field	Bytes	Description
Type	2	Type. The value for the originating VLAN TLV is **0x0000**.
Length	2	Total length of valid fields following this field. The value is **0x02** for the originating VLAN TLV.
Originating VLAN	2	VLAN ID of the packet sender. The value is **0x02** in the example, indicating that the VLAN ID of the packet sender is 2.

3. BPDU Processing of MVST

The calculation method of MVST is basically the same as that of STP. On the basis of STP, MVST further supports spanning tree calculation by VLAN and allows users to adjust the bridge priority of each network bridge in a specific VLAN on demand to block different interfaces in different spanning trees for different VLANs, implementing VLAN-based load balancing. In the topology as shown in **Figure 1-3**, in VLANs 1–50, you can adjust the priorities of the devices to make Device A the root bridge, Device C with the second-highest priority, and Device B with the lowest priority, thus blocking Device B. In VLANs 51–100, you can adjust the priorities of the devices to make Device A the root bridge, Device B with the second-highest priority, and Device C with the lowest priority, thus blocking Device C.

Figure 1-3 Traffic Balancing Using MVST

1.1.7 Rapid-MVST

1. Overview

Rapid-MVST is developed based on the IEEE 802.1w standard, and it is derived from and backward compatible with MVST. Rapid-MVST supports all functions of MVST and can prevent loops and provide link redundancy. Compared with MVST, Rapid-MVST takes less time to converge the network topology. If all network bridges in a LAN support Rapid-MVST and all the configurations are proper, it takes less than 1 second for Rapid-MVST to regenerate a topology tree in case of network topology changes. However, MVST requires about 50 seconds.

2. Rapid-MVST Protocol Packets

Similar to RSTP, Rapid-MVST needs only one type of protocol packet: configuration BPDU. The packet format is the same as that of MVST configuration BPDU and is called Rapid-MVST BPDU in the following parts. **Table 1-6** lists the differences between MVST configuration BPDU and Rapid-MVST configuration BPDU.

Table 1-6 Differences Between MVST Configuration BPDU and Rapid-MVST Configuration BPDU

Field	MVST Configuration BPDU	Rapid-MVST Configuration BPDU
PVID	0x00	0x02
BPDU Type	0x00	0x02

Field	MVST Configuration BPDU	Rapid-MVST Configuration BPDU
Flags	MVST configuration BPDUs use only bits 7 and 0, and other bits are not used. ● Bit 7: TCA. An upstream device sets bit 7 in a configuration BPDU to 1 and sends the BPDU to notify the downstream device of the topology change and request the downstream device to stop sending the TCN BPDU. ● Bit 0: TC. [[!100!]]The root bridge sets bit 0 in a configuration BPDU to 1 and sends the BPDU to instruct the downstream device to directly delete MAC address entries of the bridges.	Rapid-MVST BPDUs use all the eight bits. ● Bit 7: TCA. The value 1 indicates that a topology change is known. ● Bit 6: agreement. The value 1 indicates consent to status switching. ● Bit 5: forwarding. The value 1 indicates that forwarding is allowed. ● Bit 4: learning. The value 1 indicates that learning is allowed. ● Bit 3 and bit 2: port role. ○ 00: unknown. ○ 01: root port. ○ 10: Alternate / Backup ○ 11: designated port. ● Bit 1: proposal. The value 1 indicates sending a proposal to request status switching. ● Bit 0: TC. The value 1 indicates notifying the topology change.
Reserved	This field is not used in MVST configuration BPDUs and is filled with 0x00.	In Rapid-MVST, this field indicates ver 1 length. For details, see .Table 1-8

Rapid-MVST no longer notifies topology changes through MVST TCN BPDUs. Instead, the TC bit in the **Flags** field of Rapid-MVST BPDU is set to 1 to quickly instruct network-wide devices to perform topology convergence through the TC packet.

3. Fast Convergence of Rapid-MVST

Similar to RSTP, Rapid-MVST adopts a calculation method defined in the IEEE 802.1D standard. The difference is that RSTP is applied to an interface but Rapid-MVST is applied to interfaces added to a VLAN. In addition, Rapid-MVST uses the Proposal/Agreement mechanism to quickly enter the forwarding state through Proposal/Agreement handshake with the directly connected network bridge. The working principles are as the same as those of RSTP. For details on the process, see section 1.1.4 5. Fast Convergence of RSTP.

1.1.8 Protocols and Standards

- IEEE 802.1D: Standard for Local and Metropolitan Area Networks: Media Access Control (MAC) Bridges
- IEEE 802.1w: IEEE Standard for Information Technology -Telecommunications and Information Exchange Between Systems - Local and Metropolitan Area Networks - Common Specifications - Part 3: Media Access Control (MAC) Bridges:Amendment 2:Rapid Reconfiguration
- IEEE 802.1s: IEEE Standards for Local and Metropolitan Area Networks - Amendment to 802.1Q Virtual Bridged Local Area Networks: Amendment 3: Multiple Spanning Trees

1.2 Restrictions and Guidelines

- The MSTP feature only takes effect on a Layer 2 interface. A Layer 3 interface cannot be directly configured as a dot1q tunnel port, and must be configured as a Layer 2 interface first.
- You can use the **show interface switchport** command to view the interface type. If the Switchport field corresponding to the interface is "enabled", it means that the interface is a Layer 2 interface. If the Switchport field corresponding to the interface is "disabled", it means that the interface is a Layer 3 interface.
- You can use the **switchport** command to configure the interface as a Layer 2 interface. First, use the **no switchport mode** command to restore the mode of the Layer 2 interface to the default value, and then use the **no switchport** command to configure the Layer 2 interface as a Layer 3 interface. When the Layer 2/Layer 3 mode of the interface is modified, all properties of the interface are restored to the default values of the interface type.

1.3 Configuration Task Summary

1.3.1 Configuring STP

The STP basic configuration includes the following tasks:

(1) Configuring the Spanning Tree Mode

(2) (Optional) Configuring the Bridge Priority and Port Priority

(3) (Optional) Configuring the Port Path Cost. Select at least one of the following to configure.

- Configuring the Path Cost Calculation Method
- Configuring the Path Cost Value

(4) (Optional) Configuring Spanning Tree Time Parameters

(5) Enabling the STP Function

1.3.2 Configuring RSTP

The RSTP basic configuration includes the following tasks:

(1) Configuring the Spanning Tree Mode

(2) (Optional) Configuring the Bridge Priority and Port Priority

(3) (Optional) Configuring the Port Path Cost. Select at least one of the following to configure.

- Configuring the Path Cost Calculation Method
- Configuring the Path Cost Value

(4) (Optional) Configuring Spanning Tree Time Parameters

(5) (Optional) Configuring Fast Convergence of Spanning Trees

(6) (Optional) Enabling Protocol Migration

(7) Enabling the STP Function

1.3.3 Configuring MSTP

The MSTP basic configuration includes the following tasks:

(1) Configuring the Spanning Tree Mode

(2) Configuring an MST Region

(3) Configuring the Bridge Priority and Port Priority

(4) (Optional) Configuring the Port Path Cost. Select at least one of the following to configure.

- Configuring the Path Cost Calculation Method
- Configuring the Path Cost Value

(5) (Optional) Configuring Spanning Tree Time Parameters

(6) (Optional) Configuring the Maximum Hop Count for BPDUs

(7) (Optional) Configuring Fast Convergence of Spanning Trees

(1) (Optional) Configuring Spanning Tree Compatibility for Interfaces

(2) Enabling the STP Function

1.3.4 Configuring Advanced Functions for Spanning Trees

Configuring advanced functions for spanning trees includes the following tasks. In networking applications, these functions are used to enhance the stability, robustness, and anti-attack capability of protocols based on the network topology and application characteristics, so as to meet the application requirements of protocols in different user scenarios. The following configuration tasks are all optional. When performing the following configuration, be sure to complete the configuration and then enable spanning tree protocols.

- Enabling the V-STP Function
- Configuring Port Protection
  - Configuring Root Guard
  - Configuring Loop Guard
- Configuring BPDU Source MAC Address Check
- Configuring an Edge Port
  - Configuring Autoedge
  - Configuring the Port Fast Attribute
- Configuring BPDU Guard or BPDU Filter
  - Configuring BPDU Guard
  - Configuring BPDU Filter
- Configuring TC Attack Defense Functions
  - Configuring TC Protection
  - Configuring TC Guard
  - Configuring TC Filter
- Configuring BPDU Tunnel

1.3.5 Configuring BPDU Transparent Transmission

When STP/RSTP/MSTP is not enabled on a device, if the spanning tree between the device and the interconnected device needs to be calculated properly, BPDU transparent transmission needs to be configured on the device to transparently transmit BPDU frames.

- Configuring BPDU Transparent Transmission

1.3.6 Configuring MVST

The MVST basic configuration includes the following tasks:

(1) Configuring the Spanning Tree Mode

(2) (Optional) Configuring the Bridge Priority and Port Priority

(3) (Optional) Configuring the Port Path Cost. Select at least one of the following to configure.

(4) Configuring the Path Cost Calculation Method

(5) Configuring the Path Cost Value

(6) (Optional) Configuring Spanning Tree Time Parameters

(7) Enabling the STP Function

1.3.7 Configuring Rapid-MVST

The Rapid-MVST basic configuration includes the following tasks:

(1) Configuring the Spanning Tree Mode

(2) (Optional) Configuring the Bridge Priority and Port Priority

(3) (Optional) Configuring the Port Path Cost. Select at least one of the following to configure.

(4) Configuring the Path Cost Calculation Method

(5) Configuring the Path Cost Value

(6) (Optional) Configuring Spanning Tree Time Parameters

(7) (Optional) Configuring Fast Convergence of Spanning Trees

(8) (Optional) Enabling Protocol Migration

(9) Enabling the STP Function

1.4 Configuring the Spanning Tree Mode

1.4.1 Overview

According to IEEE 802.1 protocol standards, STP, RSTP, and MSTP are mutually compatible, without any configuration by the user. Spanning trees generated using MVST or Rapid-MVST may not be compatible with those generated using STP, RSTP, or MSTP. Therefore, a spanning tree mode can be configured to resolve the incompatibility that occurs when the devices of some vendors do not implement the standards. Users can switch the spanning tree mode to a lower version if devices of other vendors are incompatible with this device.

1.4.2 Restrictions and Guidelines

- If the STP mode is switched to RSTP mode, the convergence time is the convergence time of STP at the first topology change and the convergence time of RSTP at the second topology change.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the spanning tree mode.

spanning-tree mode { **mstp** | **mvst** | **rapid-mvst** | **rstp** | **stp** }

The default spanning tree mode is MSTP.

1.5 Configuring an MST Region

1.5.1 Overview

This section describes how to configure an MST region to change device members in the MST region, so as to affect the spanning tree topology.

1.5.2 Restrictions and Guidelines

- To enable multiple devices to belong to the same MST region, you need to configure the same configuration name, revision number, and instance mappings for the devices.
- One VLAN belongs to only one instance. By default, all VLANs are in Instance 0. In MST configuration mode, you can use the **instance instance**-*id* **vlan vlan**-*range* command to move the VLAN *vlan-range* to the *instance-id*. *instance-id* indicates the spanning tree instance number. The value range is 0-64. VLAN range refers to the list of VLAN IDs. The value range is 1-4094.
- You can use the **no instance** *instance-id* or **default instance** *instance-id* command to delete an instance (not Instance 0), and move all VLANs in the instance (not Instance 0) to Instance 0. The value of *instance-id* cannot be 0, and the value range is 1-64.
- You can use the **no instance** *instance-id* **vlan** *vlan-range* command (with the parameter **vlan** *vlan-range*) to move all VLANs in the instance (not Instance 0) to Instance 0. The value of *instance-id* cannot be 0, and the value range is 1-64. If there are multiple VLANs in a specified instance, you can use the command with parameter to move some VLANs to Instance 0, and some VLANs remain in the specified instance. If all VLANs in the specified instance are moved to Instance 0, the specified instance will be automatically deleted.

1.5.3 Prerequisites

Only MSTP supports instance configuration. If the spanning tree mode is not MSTP, run the **spanning-tree mode mstp** command to set the spanning tree mode to MSTP first.

You are advised to configure instance-VLAN mappings when STP is disabled, to ensure the stability and convergence of the network topology. If STP has been enabled, run the **no spanning-tree** command to disable STP. Enable STP only after completing the instance-VLAN mapping configuration.

1.5.4 Procedure

(1) Create VLANs.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Create a group of VLANs.

vlan { *vlan-id* | **range** *vlan-range* }

Only VLAN 1 exists by default.

d Return to the global configuration mode.

exit

(2) Configure instance-VLAN mappings.

a Enter the MST configuration mode.

spanning-tree mst configuration

b Create an instance, and move the VLAN from the original instance to this instance.

instance *instance-id* **vlan** *vlan-range*

Only instance **0** exists and all VLANs belong to instance **0** by default.

(3) (Optional) Configure a name of an MST region.

name *name*

The default name of an MST region is an empty string.

(4) (Optional) Configure a revision number for the MST region.

revision *version*

The default revision number of an MST region is **0**.

1.6 Configuring the Bridge Priority and Port Priority

1.6.1 Overview

The bridge priority concerns the root bridge election as well as the topology of the entire network. Configure the bridge priority when the user needs to change the root or topology of a network.

The port priority concerns the port role election as well as ports entering forwarding state. If a loop arises in a region, the port with a higher priority is preferentially selected to transition to forwarding state. When ports share the same priority, the port with a smaller port ID is selected to transition to forwarding state. Configure the port priority when the user needs to change ports entering forwarding state.

1.6.2 Restrictions and Guidelines

- In **mst** *instance-id*, the value range of an instance ID is from 0 to 64 and the default value is **0**. When the spanning tree works in STP/RSTP mode, the instance ID can only be 0.
- The **vlan** *vlan-list* option can be used in MVST and Rapid-MVST modes. The *vlan-list* parameter indicates a string of VLAN IDs, such as 1–10,20–30,40,50.
- The options of bridge priority indicated by **priority** include 16 values, all of which are multiples of 4096, that is, 0, 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. The default value is **32768**. It is recommended that the user configure a smaller bridge priority for core devices to ensure the network stability. Different bridge priorities can be configured for different instances, and each instance runs an independent STP based on the configuration. Devices in different regions care about the priority of only instance 0.

Caution

When the device is in MVST or Rapid-MVST mode, reducing the bridge priority of the root bridge is a high-risk operation. This operation triggers a re-election for the root bridge in the spanning tree. During the election, the spanning tree status of the port experiences temporary flapping and intermittent traffic interruption occurs.

- The options of **port-priority** include 16 values, which are multiples of 16, that is, 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. The default value is **128**. Different port priorities can be configured for different instances on the same port, and an independent spanning tree can be generated for each instance based on the configuration. The changed port priority takes effect only if the port priority is changed on designated ports.

1.6.3 Prerequisites

- Configure the interface as a Layer 2 interface.

1.6.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the bridge priority.

spanning-tree [**mst** *instance-id* | **vlan** *vlan-list*] **priority** *priority*

The default bridge priority is **32768**.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(5) Configure the port priority.

spanning-tree [**mst** *instance-id* | **vlan** *vlan-list*] **port-priority** *port-priority*

The default port priority is **128**.

1.7 Configuring the Port Path Cost

1.7.1 Overview

The port path cost determines the root port election result on a device. A device elects the port with the minimum root path cost as the root port. The root path cost is the sum of path costs of all ports in the path from a device to the root.

The port path cost also affects the BPDU priority as well as the overall network topology. When devices compare the BPDU priority, the root path cost is compared if BPDUs have the same root ID and bridge ID.

The user can configure the port path cost to determine the port or path, through which packets pass preferentially.

1.7.2 Configuration Tasks

The configuration includes the following tasks:

(1) Configuring the Path Cost Calculation Method

(2) Configuring the Path Cost Value

1.7.3 Configuring the Path Cost Calculation Method

1. Overview

By default, the device automatically calculates the port path cost according to the physical interface rate, and the calculation method in the specification (as shown in Table 1-11). The cost of path with high rate is low, and vice versa. This calculation method can calculate the optimal spanning tree topology.

The standard of port path cost must be unified throughout the network. The user should be able to modify the method of automatic calculation of port path cost of a device when necessary.

2. Restrictions and Guidelines

- IEEE 802.1d Short: The range of the port path cost is from 1 to 65535. Aggregate interface cost = Physical port cost x 95%.
- IEEE 802.1t Long: The range of the port path cost is from 1 to 200000000. Aggregate interface cost = Physical port cost x 95%.
- IEEE 802.1t Long Standard: The range of the port path cost is from 1 to 200000000. Aggregate interface cost = Physical port cost/Linkupcnt. At this moment, the cost value of the aggregate interface will change with the number of member ports, which will lead to the network topology change. For configurations of aggregate interfaces and the Link Aggregation Control Protocol (LACP), see *Configuring Aggregated Port*.
  - When an aggregate interface is a static aggregate interface, **Linkupcnt** refers to the number of member ports in Link Up state.
  - When an aggregate interface is an LACP aggregate interface, **Linkupcnt** refers to the number of member ports participating in the aggregate interface data forwarding.
  - When no member port of an aggregate interface is in Link Up state or forwarding data, the value of **Linkupcnt** is **1**.

Table 1-11 Port Path Costs Calculated Based on the Link Rate

Port Rate	Port	IEEE 802.1d Short	IEEE 802.1t Long	IEEE 802.1t Long Standard
10 Mbps	Common port	100	2000000	2000000
	Aggregate interface	95	1900000	2000000/Linkupcnt
100 Mbps	Common port	19	200000	200000
	Aggregate interface	18	190000	200000/Linkupcnt

Port Rate	Port	IEEE 802.1d Short	IEEE 802.1t Long	IEEE 802.1t Long Standard
1000 Mbps	Common port	4	20000	20000
	Aggregate interface	3	19000	20000/Linkupcnt
10000 Mbps	Common port	2	2000	2000
	Aggregate interface	1	1900	20000/Linkupcnt

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure port path cost.

spanning-tree pathcost method { **long** | **long standard** | **short** }

The port path cost is calculated using the long method in the IEEE 802.1t standard by default.

1.7.4 Configuring the Path Cost Value

1. Overview

In order to ignore the impact of the physical interface rate and strictly control the spanning tree calculation results, you can configure port path cost as a specified value. After configuration, the device no longer calculates the port path cost based on the physical interface rate.

2. Restrictions and Guidelines

- In MSTP application, you can configure different path costs for different instances on an interface so that different instance spanning trees are generated for the instances to implement load sharing.
- **mst** *instance-id*: Specifies the instance ID. The value range is from 0 to 64 and the default value is **0**.
- The **vlan** *vlan-list* option can be used in MVST and Rapid-MVST modes. The *vlan-list* parameter indicates a string of VLAN IDs, such as 1–10,20–30,40,50.
- **cost** *cost*: Specifies the path cost value. The value range is from 1 to 200000000. A larger value of *cost* indicates a greater path cost.

3. Prerequisites

- Configure the interface as a Layer 2 interface.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the port path cost.

spanning-tree [**mst** *instance-id* | **vlan** *vlan-list*] **cost** *cost*

The port path cost is calculated based on the interface link rate by default.

1.8 Configuring Spanning Tree Time Parameters

1.8.1 Overview

The timer in STP affects the spanning tree election and recovery performance.

You can use the **spanning-tree** command to configure the following time parameters. Each configuration command can only carry one parameter. Only one of the following time parameters can be carried in the **spanning-tree** command:

- Interval for port state change (**Forward Time**)
- BPDU transmission interval (**Hello Time**)
- BPDU expiration time (**Max Age**)
- Number of BPDUs sent per second (**TX Hold Count**)
- Spanning tree timeout factor (**Factor**)

1.8.2 Restrictions and Guidelines

- **forward-time** *forward*: Specifies the port status change interval, in seconds. It refers to the interval for a port to transition from listening state to learning state or from learning state to forwarding when STP runs on a device or RSTP runs in STP compatible mode. It indicates the delay in the port status change. The value range is from 4 to 30, and the default value is **15**. If **Forward Delay** is too small, a temporary loop may occur. If **Forward Delay** is too large, the network recovery time may be very long.
- **hello-time** *hello*: Indicates the interval for the device to send BPDUs, in seconds. The value range is from 1 to 10, and the default value is **2**. If **Hello Time** is too small, the resource consumption of the device and network may increase. If the value is too small, the downstream device may mistakenly consider the uplink to be faulty, especially when packet loss occurs occasionally.
- **max-age** *age*: Indicates the maximum expiration time of BPDUs, in seconds. When the time expires, BPDUs will be discarded. The value range is from 6 to 40, and the default value is **20**. If **Max Age** is too small, link congestion may be wrongly judged as a link fault and the spanning tree is calculated very frequently. If the value is too large, the link fault cannot be found in time, resulting in poor network auto-recovery capability.

  Each device running STP or RSTP is a separate region, and is not allocated to a region with any other devices. Though MSTP uses the hop count mechanism to represent the lifecycle of BPDUs, the **Message Age** and **Max Age** mechanisms are still retained in order to be compatible with STP and RSTP outside regions.

- The value ranges of **forward-time, hello-time, and max-age** are related. Changing one of them will affect the value ranges of the other two parameters. Their restrictive relationship is as follows: 2 x (Hello Time + 1s) ≤ Max Age ≤ 2 x (Forward Delay – 1s). The configured three parameters must meet this condition. Otherwise, the topology may be unstable. In addition, the three parameters need to match the network size. A larger network diameter needs larger values of the parameters. You are advised to adopt automatic calculation according to the protocol to avoid manual configuration.
- **tx-hold-count** *count*: Configures the maximum number of BPDUs that can be sent per second. The value range is from 1 to 10 and the default value is **3**.
- **timer-factor** *factor*: Configures the packet receiving timeout factor. Timeout time = Timeout factor (indicated by *factor*) x Hello Time. If a device fails to receive a BPDU from the upstream device within the timeout time, the spanning tree is re-calculated. The value range is from 1 to 30, and the default value is **3**.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the interval for the status change of a spanning tree port.

spanning-tree forward-time *forward*

The default interval for the status change of a spanning tree port is 15s.

(4) Configure the interval for a spanning tree port to send BPDUs.

spanning-tree hello-time *hello*

The default interval for sending BPDUs is 2s.

(5) Configure the maximum number of BPDUs that can be sent by a spanning tree port.

spanning-tree tx-hold-count *count*

Three BPDUs are sent per second by default.

(6) Configure the maximum timeout time of spanning tree BPDUs.

spanning-tree max-age *age*

The default expiration time of BPDUs is 20s.

(7) Configure the spanning tree timeout factor.

spanning-tree timer-factor *factor*

The default spanning tree timeout factor is 3.

1.9 Configuring the Maximum Hop Count for BPDUs

1.9.1 Overview

MST regions do not use the **Message Age** and **Max Age** mechanisms to calculate whether BPDUs time out but use the maximum hop count mechanism for calculation. The maximum hop count mechanism is similar to the Time to Live (TTL) of IP packets. The maximum hop count of BPDUs affects the BPDU lifetime, and thus affects the network topology.

In an MST region, the BPDU hop count decreases by 1 each time the BPDU passes through one device from the region root until the remaining hop count is 0, indicating that the BPDU times out. Devices discard received BPDUs with the hop count of 0.

The maximum hop count of BPDUs is 20 by default. The value does not need to be changed for a network with the scale less than 20 hops, but needs to be changed to match the actual network situation when the network scale is greater than 20 hops. Changing the maximum hop count will affect all instances.

1.9.2 Restrictions and Guidelines

Hop-count:-count: Indicates the number of devices that a BPDU can pass through before it is discarded. The value range is from 1 to 40 and the default value is **20**.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the maximum hop count for BPDUs.

spanning-tree max-hops *hop-count*

The maximum hop count of BPDUs is 20 by default.

1.10 Configuring Fast Convergence of Spanning Trees

1.10.1 Overview

In a full-duplex point-to-point link, an interface supporting RSTP first enters discarding state after port role election is complete, and then performs a Proposal/Agreement handshake with the connected bridge to quickly enter forwarding state.

Only ports in point-to-point connection state support fast convergence. Ports in shared connection state do not support fast convergence. See 1.1.4 5 Fast Convergence of RSTP.

1.10.2 Restrictions and Guidelines

- If the connection type is not configured, the device automatically sets the connection type of an interface based on the duplex state of the interface. When an interface works in full-duplex mode, the connection type of the interface is point-to-point. When an interface works in half-duplex mode, the connection type of the interface is shared (non point-to-point).
- You can forcibly configure the interface connection type. The parameter **point-to-point** indicates the point-to-point connection type and **shared** indicates the shared connection type.
- You can use the **show spanning-tree** [**mst** *instance-id*] { *port-index* | **interface** *interface-type interface-number* [**link-type**] } command to view the configuration results.

1.10.3 Prerequisites

- Configure the interface as a Layer 2 interface.

1.10.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure fast convergence for spanning trees.

spanning-tree link-type { **point-to-point** | **shared** }

By default, if an interface works in full-duplex mode, the connection type is point-to-point. If an interface works in half-duplex mode, the connection type is shared.

1.11 Enabling Protocol Migration

1.11.1 Overview

1. Compatibility of Different Protocols

If a device running STP receives an RST BPDU or MST BPDU, it ignores or discards the BPDU, resulting in incompatibility between the device running STP and other devices running RSTP or MSTP.

However, a device running RSTP or MSTP can recognize and process STP protocol packets from other devices. RSTP and MSTP are capable of automatically determining the protocol type supported by the connected bridge based on the version of received BPDUs. If the peer supports STP, after port role election is complete, RSTP and MSTP wait for twice the period of **Forward Delay** (30s by default) before entering forwarding state according to the STP status transition mechanism.

RSTP can process the CIST part of MST BPDUs. Therefore, MSTP does not have to send RST BPDUs to ensure RSTP compatibility.

Each device running STP or RSTP is a separate region, and does not belong to the same region with any other devices.

2. Protocol Migration Principle

When both RSTP and STP are used, a problem shown in Figure 1-16 may occur: Device A supports RSTP, Device B supports only STP, and the two devices are connected to each other. Device A judges that the peer device supports only STP, and sends STP BPDUs to ensure compatibility with the peer device. After Device B is replaced with Device C supporting RSTP, Device A still runs STP and sends STP BPDUs to the peer device. In this case, Device C mistakenly judges that Device A supports only STP. Finally, both devices run STP and the spanning tree convergence speed is greatly reduced. Hence, the protocol migration function emerges.

The protocol migration function enabled on Device C clears the original protocol and forces Device C to send RST BPDUs. Device A switches to the RSTP mode when finding that the connected bridge supports RSTP. Then, the two devices run RSTP.

When finding that the peer device supports RSTP, the user can enable the protocol migration function to force the local device to send RST BPDUs to achieve protocol migration of the local and peer devices.

Figure 1-16 Forcing Protocol Migration to RSTP

1.11.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Clear the original protocol and force the device to migrate to the RSTP protocol.

clear spanning-tree detected-protocols [**interface** *interface-type interface-number*]

1.12 Configuring Spanning Tree Compatibility for Interfaces

1.12.1 Overview

After the spanning tree compatibility function is enabled on an interface, STP calculates whether the interface participates in the calculation of a specified instance based on the VLAN, to which the interface belongs, and the mapping between the VLAN and the instance. When the interface sends a BPDU, only the MSTI configuration message of the instance calculated by the interface, is carried to ensure compatibility with other devices.

For example, instances 0 (exists by default), 1 and 2 exist on a device. Port GigabitEthernet 0/1 belongs only to VLAN 10, and VLAN 10 belongs to instance 1. If the spanning tree compatibility mode is enabled on port GigabitEthernet 0/1, the BPDU sent by port GigabitEthernet 0/1 carries only information of instance 0 (the port participates in calculation of this instance by default) and instance 1, with no information of instance 2.

1.12.2 Prerequisites

- Configure the interface as a Layer 2 interface.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure spanning tree compatibility for an interface.

spanning-tree compatible enable

The spanning tree compatibility function of interfaces is disabled by default.

1.13 Enabling the STP Function

1.13.1 Overview

Unless otherwise specified, STP should be enabled on each device.

1.13.2 Restrictions and Guidelines

STP and the Transparent Interconnection of Lots of Links (TRILL) protocol of data centers are mutually exclusive.

1.13.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the STP function.

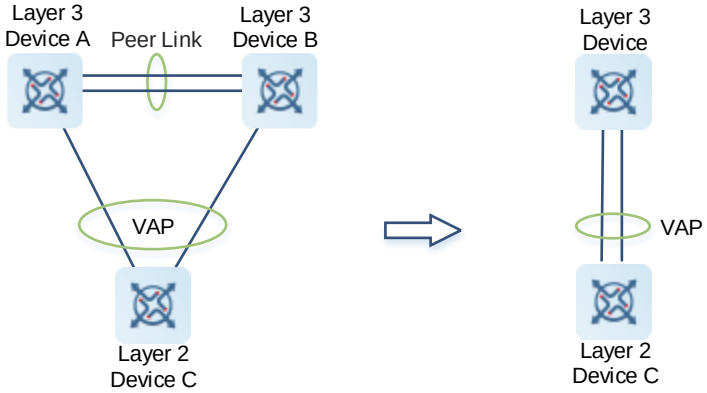
spanning-tree

The STP function is disabled by default.

1.14 Enabling the V-STP Function

1.14.1 Overview

The Multichassis Link Aggregation Group (M-LAG) is a virtualization technology that aggregates inter-device links. The M-LAG system consists of two independent devices. Access devices that support link aggregation group connect to this system through aggregate interfaces. The system virtualizes two devices into one logical device to improve the reliability from link level to device level. M-LAG implements only Layer 2 virtualization. The two devices are still independent devices. They can be upgraded independently without affecting the normal operation of the other device.



V-STP is not a protocol, but a technology that virtualizes multiple M-LAG devices into a network bridge to participate in spanning tree calculation, without affecting the implementation of the STP, RSTP, and MSTP protocols. The protocol packets and interface status depend on the spanning tree working mode STP, RSTP or MSTP.

V-STP is dedicated for M-LAG scenarios, which can meet the requirements of Layer 2 loop protection in single and multi-level M-LAG scenarios. You can use the **spanning-tree v-stp enable** command to enable the V-STP function.

1. Basic concepts of M-LAG

Figure 1-1 shows the basic topology of M-LAG.

Figure 1-1 Basic Topology of M-LAG

- Domain ID
  Domain ID is the unique identifier of the M-LAG system to distinguish different M-LAGs. Two devices in the M-LAG are paired by synchronizing with each other and comparing their domain ID. If the domain ID of the two devices are the same, an M-LAG system is formed.
- Virtual Aggregation Port (VAP)
  Device A and Device B form a pair of virtual AP groups with a pair of aggregate interface connected to the same access device Device C, also known as VAP member ports, for dual access of access devices. Only a Layer 2 aggregate interface can join the virtual AP group. Different access devices access different virtual groups. For Device C, Device A and Device B are logically the same device.
- Peer Link
  The link between Device A and Device B is called the Peer Link, which is used to synchronize data and transmit some traffic. The interface directly connected to both ends of the Peer Link is called the Peer Link interface. The Peer Link interface must be configured as an aggregate interface. In order to enhance the reliability of data transmission between M-LAG devices, TCP is used to transmit synchronous data between devices. Therefore, it is necessary to configure an SVI on the Peer Link link, and to configure Layer 3 reachbiality between M-LAG master and slave devices.
- Active and standby devices
  After the devices in the M-LAG system are paired successfully by identifying the domain ID, the active device and the standby device are selected through negotiation by synchronizing and comparing the M-LAG priority and the device MAC address. The device with higher M-LAG priority is selected as the active device. If the M-LAG priorities are the same, the device with a smaller MAC address is selected as the master device.

2. Working principle of V-STP

If the V-STP function is enabled on both the M-LAG active and standby devices, the active and standby devices will be virtualized into a network bridge and participate in the spanning tree calculation of interconnected devices outside the M-LAG domain, so as to achieve the purpose of spanning tree virtualization and block Layer 2 loops in the scenario.

The V-STP function can be enabled in STP, RSTP and MSTP modes. For the V-STP function to take effect, the following preconditions must be met:

- Enable the spanning tree function and V-STP function on the network bridge with M-LAG function enabled.
- M-LAG member devices can be connected successfully. See *Configuring M-LAG* in *Reliability Configuration Guide* for details.
- The spanning tree configuration of M-LAG member devices must be the same, that is, the MST configuration information, bridge priority, port priority and port path cost of the VAP group must be the same. Otherwise, the V-STP function will not take effect.

The M-LAG active and standby devices with the V-STP function enabled send consistent BPDU packets as a virtual bridge, called V-STP BPDU. Like ordinary BPDU packets, the packets contain the priority vector <Root ID, Root Path Cost, Bridge ID, Port ID>. Interconnected devices outside the M-LAG domain determine the priority of V-STP BPDU by comparing the size of priority elements in the vector in turn.

- M-LAG active and standby devices have the same bridge priority. For example, in Figure 1-1, the bridge priority of Device A and Device B must be the same and higher than that of Device C. After the M-LAG devices successfully establish the connection and complete the active and standby negotiation, the system selects the device with a smaller MAC address from the M-LAG active and standby devices and use the device MAC address as the MAC address of the virtual bridge, and generates the Bridge ID based on the bridge priority to participate in the spanning tree calculation externally.
- The port priority of the VAP group is the same (the default value can be used), and the system selects a smaller port ID to generate the port ID of the VAP group.
- The port path cost of the VAP group is the same (the default value can be used), so the root path cost calculated on the active and standby devices is the same.

The active and standby devices calculate the spanning tree respectively, and then periodically synchronize the spanning tree results calculated by the device to the peer M-LAG member devices. Finally, by comparing the spanning tree calculation results of the device and the peer M-LAG member, the device with a lower path cost is selected as the forwarding path to block redundant links.

1.14.2 Restrictions and Guidelines

- In global configuration mode, run the **spanning-tree v-stp enable** command to enable the V-STP function or run the **no spanning-tree v-stp enable** command to disable the V-STP function.

1.14.3 aggregate interfaceProcedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the V-STP function.

spanning-tree v-stp enable

The V-STP function is disabled by default.

1.15 Configuring Port Protection

1.15.1 Overview

A root bridge may receive a configuration BPDU with a higher priority due to a misconfiguration or a malicious attack using illegitimate packets in the network, and lose the current root bridge role. This can cause an incorrect network topology change. To prevent this situation, you can configure the root guard function on designated ports of the root bridge.

If the root port, master port, and alternate port on a non-root bridge periodically receive BPDUs with a higher priority from the upstream bridge, the spanning tree topology will keep unchanged. If they fail to receive high-priority BPDUs from the upstream bridge, they judge that the upstream device is faulty. Then, the bridge considers itself as the root and sets all ports as designated ports, which cause loops. To prevent this situation, you can configure the loop guard function on the above ports to enhance the device stability.

1.15.2 Restrictions and Guidelines

A device cannot be a root bridge and a non-root bridge at the same time. Therefore, root guard and loop guard cannot take effect on a port at the same time.

1.15.3 Configuration Tasks

The configuration includes the following tasks. The configuration steps below are mutually exclusive. Select one of them for configuration.

- Configuring Root Guard
- Configuring Loop Guard

1.15.4 Configuring Root Guard

1. Overview

In the network design, the root bridge and backup root bridge are usually classified into the same region. Designated ports on a root bridge may receive configuration BPDUs with a higher priority due to a misconfiguration or a malicious attack, and the root bridge loses the current root bridge role. As a result, incorrect network topology change is incurred. To prevent this situation, you can configure the root guard function on designated ports of the root bridge.

After the root guard function is enabled, the device interfaces are designated ports in all instances. If a port receives a high-priority BPDU, the port enters blocking state due to root-inconsistent. If the port fails to receive a high-priority BPDU within a period of time, it returns to the normal state.

When a port enters blocking state due to root guard, you can manually restore the port to the normal state by using two methods:

- Run the **no spanning-tree guard root** command to disable the root guard function on the port.
- Run the **spanning-tree guard none** command to disable the guard function on the port.

Caution

- When the root guard function is configured on a non-designated port, the function forcibly sets the non-designated port as a designated port. The port will inevitably receive a high-priority BPDU according to the network design, and the port will enter blocking state due to root-inconsistent. Therefore, configuring root guard on a non-designated port can cause a communication failure.

- If a port receives a BPDU with a higher priority in an instance, it enters blocking state in this instance. If a port receives a BPDU with a higher priority in instance **0**, the port enters blocking state in all instances.

2. Restrictions and Guidelines

- In Layer 2 Ethernet interface configuration mode or Layer 2 aggregate port configuration mode, run the **spanning-tree guard root** command to enable the root guard function on an interface, or run the **no spanning-tree guard root** command to disable the root guard function of the interface.
- When a port is blocked due to root guard, you can run the **spanning-tree guard none** command in Layer 2 Ethernet interface configuration mode or Layer 2 aggregate interface configuration mode to disable the root guard function and restore the port to the normal state.

3. Prerequisites

- Configure the interface as a Layer 2 interface.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Enable the root guard function.

spanning-tree guard root

The root guard function is disabled on an interface by default.

1.15.5 Configuring Loop Guard

1. Overview

The root port or alternate port of a non-root bridge may fail to receive BPDUs due to a unidirectional link failure, and the port becomes a designated port and enters forwarding state. As a result, loops occur in the network. To prevent this situation, you can configure loop guard on a non-root bridge.

After loop guard is enabled, when the root port or alternate port fails to receive BPDUs and changes to a designated port, the port will remain in discarding state until it receives a BPDU for spanning tree calculation.

⚠ Caution

- Before the MSTP process is restarted, a port enters the loop guard blocking state. After the MSTP process is restarted, if the port still fails to receive BPDUs, the port changes to a designated port and enters forwarding state, causing loops in the network. Therefore, you are advised to figure out the cause that a port enters the loop guard blocking state and rectify the fault before the MSTP process is restarted. Otherwise, the spanning tree topology is still abnormal after the MSTP process is restarted.

2. Restrictions and Guidelines

- You can configure the loop guard function in the global configuration mode or interface configuration mode. Please select one configuration mode to configure this function.
- In global configuration mode, run the **spanning-tree loopguard default** command to enable the loop guard function on all Layer 2 Ethernet interface and Layer 2 aggregate interfaces, or run the **no spanning-tree loopguard default** command to disable the loop guard function of all Layer 2 Ethernet interface and Layer 2 aggregateinterfaces.
- InLayer 2 Ethernet interface and Layer 2 aggregate interface configuration mode, run the **spanning-tree guard loop** command to enable the loop guard function on an interface or run the **no spanning-tree guard loop** command to disable the loop guard function of the interface.

3. Prerequisites

- Configure the interface as a Layer 2 interface.

4. Procedure(global configuration mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the loop guard function on all Layer 2 Ethernet interface and Layer 2 aggregate interfaces.

spanning-tree loopguard default

The loop guard function is enabled on allLayer 2 Ethernet interface and Layer 2 aggregateinterfaces by default.

5. Procedure (interface configuration mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.
  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }
- Enter the Layer 2 aggregate interface configuration mode.
  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Enable the loop guard function.

spanning-tree guard loop

The loop guard function is disabled on an interface by default.

1.16 Configuring BPDU Source MAC Address Check

1.16.1 Overview

This section describes how to enable the BPDU source MAC address check function to prevent BPDU attacks. After the function is enabled on a device, the device receives only BPDU frames from specified source MAC addresses and discards other BPDU frames.

1. BPDU Source MAC Address Check

If the peer device connects to the local device in a point-to-point manner and the MAC address of the peer device is certain, the BPDU source MAC address check function can be configured on the local device. After this function is enabled, the device receives only BPDU frames matching the designated source MAC address and discards all the other BPDU frames. Therefore, when the device encounters BPDU packet attacks, illegitimate BPDU packets can be identified and discarded to prevent the MSTP function failure due to the attacks.

2. Filtering of BPDUs with Invalid Length

If the Ethernet length field in a BPDU frame exceeds 1,500, this illegitimate BPDU frame will be discarded.

1.16.2 Restrictions and Guidelines

- In Layer 2 Ethernet interface configuration mode or Layer 2 aggregate interface configuration mode, run the **bpdu src-mac-check** *mac-address* command to enable the BPDU source MAC address check function on an interface, or run the **no bpdu src-mac-check** command to disable the BPDU source MAC address check function of the interface.
- *mac-address* indicates that only BPDU frames with the source MAC address matching this address are received. Only one filter MAC address can be configured for one interface.
- If the configured MAC address is incorrect, required BPDU frames may be discarded.

1.16.3 Prerequisites

Configure an interface as a Layer 2 interface.

1.16.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Enable BPDU source MAC address check so that only BPDUs with the source MAC address matching *mac-address* are received.

bpdu src-mac-check *mac-address*

The BPDU source MAC address check function is disabled on an interface by default.

1.17 Configuring an Edge Port

1.17.1 Overview

After the spanning tree role election is complete, a designated port needs to wait for twice the period of **Forward Delay** (2 x 15 = 30s) before entering forwarding state. Designated ports can be converted into edge ports via automatic recognition or manual configuration. Edge ports can rapidly enter forwarding state without waiting for twice the period of **Forward Delay.** If an edge port receives a BPDU, it enters the disabled state, changes to a non-edge port, and participates in the spanning tree calculation.

- Autoedge

  If the autoedge function is enabled on a designated port and the port fails to receive a BPDU from the downstream device within a certain period of time (3s), the port judges that the connected peer device is a network terminal. Then, the designated port changes to an edge port and rapidly enters forwarding state.

- Port fast

  If you are sure that a designated port is directly connected to a network terminal, you can manually configure port fast rather than rely on the autoedge function. A manually configured edge port rapidly enters forwarding state without waiting for twice the period of **Forward Delay**.

1.17.2 Restrictions and Guidelines

When autoedge conflicts with the edge port manually configured via port fast, the manual configuration prevails.

Unless otherwise specified, do not disable the autoedge function.

- You can use the **show spanning-tree** [**mst** *instance-id*] { *port-index* | **interface** *interface-type interface-number* [**portfast**] } command to check the configuration result.

1.17.3 Configuration Tasks

The configuration includes the following tasks:

- Configuring Autoedge
- Configuring the Port Fast Attribute

1.17.4 Configuring Autoedge

1. Overview

After the spanning tree role election is complete, a designated port needs to wait for twice the period of **Forward Delay** (2 x 15 = 30s) before entering forwarding state. If the autoedge function is enabled on a designated port and the port fails to receive a BPDU from the downstream device within a certain period of time (3s), the port judges that the connected peer device is a network terminal. Then, the designated port changes to an edge port and directly enters forwarding state. If an edge port receives a BPDU, it enters the disabled state, changes to a non-edge port, and participates in the spanning tree calculation.

Caution

- STP does not support this function.

- This function applies only to designated ports, and takes effect only in the process of fast negotiation between a designated port and a downstream port and the designated port has not entered forwarding state in this process. If a designated port has been in forwarding state, the autoedge function does not take effect. For example, if the BPDU filter function is enabled on a port and the port has transitioned to forwarding state, the autoedge function does not take effect. It takes effect only when the designated port restarts fast negotiation (for example, the network cable is removed and then inserted).

2. Restrictions and Guidelines

You can use the **spanning-tree autoedge disabled** command to disable the autoedge function.

3. Prerequisites

- Configure the interface as a Layer 2 interface.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

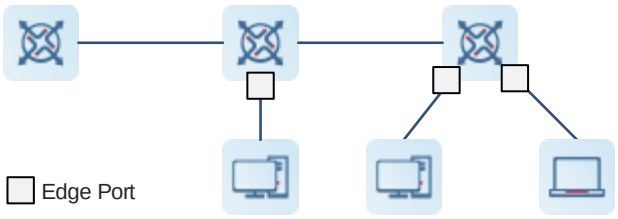
  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the autoedge function.

spanning-tree autoedge [**disabled**]



The autoedge function is enabled by default.

1.17.5 Configuring the Port Fast Attribute

1. Overview

After the spanning tree role election is complete, a designated port needs to wait for twice the period of **Forward Delay** (2 x 15 = 30s) before entering forwarding state. The autoedge function is enabled on a designated port by default. If the port fails to receive a BPDU from the downstream device within a period of time (3s), it is automatically recognized as an edge port. If a designated port fails to receive a BPDU within the timeout time due to poor network condition, packet loss, or packet transmission/receiving delay, the device mistakenly judges that the designated port connects to a network terminal and automatically identifies the designated port as an edge port. In this network condition, you are advised to disable the autoedge function, and manually configure the interface connected to a terminal as an edge port according to the network plan. When you are sure that a designated port is directly connected to a network terminal, configure the port fast attribute manually rather than rely on the autoedge function. A manually configured edge port enters forwarding state without waiting for twice the period of **Forward Delay.** If an edge port receives a BPDU, it enters the disabled state, changes to a non-edge port, and participates in the spanning tree calculation.

Figure 1-17 Positions of Edge Ports

2. Restrictions and Guidelines

- Oly a Layer 2 Ethernet interface or Layer 2 aggregate interface can be configured as an edge port.
- In global configuration mode, you can use the **spanning-tree portfast default** command to configure all Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces as edge ports, use the **no spanning-tree portfast default** command to restore all Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces as non-edge ports.
- In Layer 2 Ethernet interface configuration mode or Layer 2 aggregate interface configuration mode, you can use the **spanning-tree portfast** command to configure this interface as an edge port, and use the **spanning-tree portfast disabled** command to restore this interface as a non-edge port.

3. Prerequisites

- Configure the interface as a Layer 2 interface.

4. ProcedureProcedure (global configuration mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

- Configure all Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces as edge ports.
  spanning-tree portfast default

  by default, an interface is a non-edge port.

5. Procedure (interface configuration mode)

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }
- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure this interface as an edge port.

spanning-tree portfast

1.18 Configuring BPDU Guard or BPDU Filter

1.18.1 Overview

If a device interface is directly connected to a network terminal, BPDU guard or BPDU filter can be configured on the interface to prevent illegitimate access, BPDU attacks, or loops in downstream devices. BPDU guard and BPDU filter can be enabled globally and take effect only on edge ports, or enabled and take effect only on specific interfaces.

1.18.2 Restrictions and Guidelines

BPDU guard has a higher priority than BPDU filter. If both BPDU filter and BPDU guard are enabled on an interface, only BPDU guard takes effect.

- You can use the **show spanning-tree** [**mst** *instance-id*] { *port-index* | **interface** *interface-type interface-number* [**bpdufilter** | **bpduguard**] } command to check the configuration result.

1.18.3 Configuration Tasks

The configuration includes the following tasks:

- Configuring BPDU Guard
- Configuring BPDU Filter

1.18.4 Configuring BPDU Guard

1. Overview

Edge ports do not receive BPDUs in normal cases. If an edge port is attacked by forged BPDUs or an illegitimate device is added to the network, the edge port will receive BPDUs, change to a non-edge port, and participate in spanning tree calculation, resulting in network flapping.

The BPDU guard function aims to defend against BPDU packet attacks and illegitimate access. If this function is enabled, a port enters the error-disabled state when receiving a BPDU, indicating that a port exception occurs. Then, the device disables the port, which can be restored to the normal state only through the errdisable recovery function.

2. Restrictions and Guidelines

BPDU guard can be enabled globally or on specific interfaces. The global BPDU guard function takes effect only on edge ports. The BPDU guard function takes effect on interfaces regardless of whether the interfaces are edge ports.

- In the global BPDU guard configuration command, the **no** parameter is used to disable the global BPDU guard function.
- In the interface BPDU guard configuration command, the **disabled** parameter is used to disable the BPDU guard function on a specific interface.
- A port in error-disabled state can be restored automatically or manually. The **errdisable recovery** [**interval** *seconds*] command is used to configure the auto-recovery interval, in seconds. The value range is from 30 to 86400. The errdisable recovery function is disabled on a port by default and no default recovery interval is

available. To restore a port in error-disabled state manually, run the **errdisable recovery** command. See *Configuring Ethernet Interface* in the *Interface Configuration Guide*.

3. Prerequisites

- Configure the interface as a Layer 2 interface.

4. Procedure (global configuration mode)

(1) Enter the privileged EXEC mode.
enable

(2) Enter the global configuration mode.
configure terminal

- Enable the global BPDU guard function. The function takes effect only on edge ports.
spanning-tree portfast bpduguard default

  By default, the global BPDU guard function is disabled.

5. Procedure (interface configuration mode)

(1) Enter the privileged EXEC mode.
enable

(2) Enter the global configuration mode.
configure terminal

(3) Enter the interface configuration mode.
- Enter the Layer 2 Ethernet interface configuration mode.
interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }
- Enter the Layer 2 aggregate interface configuration mode.
interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Enable the BPDU guard function.
spanning-tree bpduguard enable

By default, the interface BPDU guard function is disabled.

1.18.5 Configuring BPDU Filter

1. Overview

BPDU filter helps prevent BPDU attacks. You can enable BPDU filter globally or on a specified interface. When BPDU filter is enabled and takes effect on an interface, the interface neither sends nor receives BPDUs, but directly enters forwarding state.

2. Restrictions and Guidelines

BPDU filter can be enabled globally or on specific interfaces. The global BPDU filter function takes effect only on edge ports. The BPDU guard function takes effect on interfaces regardless of whether the interfaces are edge ports.

- In the global BPDU filter configuration command, the **no** parameter is used to disable the global BPDU filter function.
- In the interface BPDU filter configuration command, the **enable** parameter is used to enable the BPDU filter function and the **disabled** parameter is used to disable the BPDU filter function.

3. Prerequisites

- Configure the interface as a Layer 2 interface.

4. Procedure (global configuration mode)

(1) Enter the privileged EXEC mode.
enable

(2) Enter the global configuration mode.
configure terminal

- Enable the global BPDU filter function. The function takes effect only on edge ports.
spanning-tree portfast bpdufilter default

  By default, the global BPDU filter function is disabled.

5. Procedure (interface configuration mode)

(1) Enter the privileged EXEC mode.
enable

(2) Enter the global configuration mode.
configure terminal

(3) Enter the interface configuration mode.
- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }
- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the BPDU filter function.
- Enable the BPDU filter function.

  spanning-tree bpdufilter enable
- Disable the BPDU filter function.
spanning-tree bpdufilter disabled

  By default, the interface BPDU filter function is disabled.

1.19 Configuring TC Attack Defense Functions

1.19.1 Overview

When the downstream network topology in port forwarding state changes (from Blocking to Forwarding, for example), a port generates a TC packet (that is, TCN BPDU; see Table 1-4 for details) to notify the upstream device of the spanning tree change. After receiving the TCN BPDU, the port copies the BPDU and forwards it to upstream devices until the root bridge receives the BPDU. This is called TC diffusion. After receiving a TC packet, a device deletes dynamic MAC addresses and ARP entries that have been learned, and a Layer 3 device also enables the fast forwarding module to change the port status of ARP entries.

If a device is attacked by forged TC packets, it frequently performs the deletion operation, which occupies excessive device resources and makes the device overburdened. After TC packet attacks diffuse to the whole network, the performance of devices throughout the network will deteriorate and the network stability will be affected. Therefore, TC protection, TC guard, and TC filter arise to solve this problem.

- TC protection

After TC protection is enabled on a device, the device performs only one deletion operation within a period of time (generally 4s) after receiving TC packets, and monitors whether any TC packet is received in this period. If the device receives TC packets in this period, it performs another deletion operation after the period expires, to prevent frequent deletion of MAC address entries and ARP entries.

- TC guard

TC protection can reduce the frequency of deleting dynamic MAC address entries and ARP entries, but many deletion operations still need to be performed in the case of TC packet attacks, which affects the normal operation of devices. In addition, TC packets still are diffused in the network and the entire network is affected. For this, the TC guard function emerges.

After TC guard is enabled on a port, TC packets generated or received by the port will not be diffused to other ports of the device that participate in spanning tree calculation, so as to effectively control possible TC attacks in the network and retain the network stability. Especially on Layer 3 devices, this function can effectively prevent interruption of core routes caused by access device flapping.

- TC filter

TC guard blocks the diffusion of all TC packets, including normal TC packets generated in the case of a topology change. As a result, devices in the network cannot perceive the topology change and fail to clear MAC address entries and ARP entries of relevant ports in time, and errors occur in data forwarding. Hence, the TC filter function emerges.

TC filter refers that a port does not process TC packets received from other ports but processes TC packets generated due to the normal topology change of the port.

This function solves the problems of MAC address entry clearing and core route interruption caused by frequent up/down state switching of ports with port fast not configured. It also ensures that core routing entries are updated in time when a topology change occurs.

1.19.2 Restrictions and Guidelines

It is recommended that the TC attack defense functions be enabled only when the network is attacked by TC packets.

1.19.3 Configuration Tasks

The configuration includes the following tasks:

- Configuring TC Protection
- Configuring TC Guard
- Configuring TC Filter

1.19.4 Configuring TC Protection

1. Overview

After TC protection is enabled, the device performs only one deletion operation within a period of time (generally 4s) after receiving TC packets. This can prevent frequent deletion of MAC address entries and ARP entries.

2. Restrictions and Guidelines

TC protection can be enabled or disabled only globally and takes effect on all Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces.

- Run the **spanning-tree tc-protection** command to enable TC protection, or run the **no spanning-tree tc-protection** command to disable TC protection.

3. Prerequisites

- Configure the interface as a Layer 2 interface.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable TC guard on all Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces.

spanning-tree tc-protection

TC guard is disabled globally by default.

1.19.5 Configuring TC Guard

1. Overview

After the TC guard function is enabled, TC packets received over an interface are not flooded to other interfaces, which effectively controls TC attacks and maintains network stability.

The TC guard function is divided into global TC guard function and interface TC guard function.

- In the global configuration mode, TC guard function takes effect on all Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces if enabled. In this case, all ports will not diffuse TC packets to other ports. TC guard is suitable to be enabled on desktop access devices.
- In the Layer 2 Ethernet interface configuration mode or the Layer 2 aggregate interface configuration mode, the TC guard function only takes effect on the current interface. In this case, this interface will not diffuse TC packets to other ports. TC guard is suitable to be enabled on the uplink port, especially the port connecting the aggregation switch to the core switch.

2. Restrictions and Guidelines

- In global configuration mode, run the **spanning-tree tc-protection tc-guard** command to enable the TC guard function globally, or run the **no spanning-tree tc-protection tc-guard** command to disable the TC guard function globally.
- In interface configuration mode, run the **spanning-tree tc-guard** command to enable the TC guard function on an interface, or run the **no spanning-tree tc-guard** command to disable the TC guard function on an interface.
- If no TC attack exists in a network but TC guard is configured, the spread of normal TC packets is contained. When the topology changes, the device fails to clear learned MAC addresses and a packet forwarding error may occur. Enabling the TC guard function will also limit the transmisson of normal TC packets. When the spanning tree network topology changes, the device cannot obtain the topology change information, and

cannot clear MAC addresses in time, which may lead to packet forwarding errors. If the topology cannot be restored automatically, communication may be interrupted. Therefore, it is recommended to enable this function only when there is an illegal TC packet attack in the network.

3. Prerequisites

- Configure the interface as a Layer 2 interface.

4. Procedure (global configuration mode)

(1) Enter the privileged EXEC mode.
enable

(2) Enter the global configuration mode.
configure terminal

- Enable TC guard on all Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces.
spanning-tree tc-protection tc-guard

  By default, TC guard is disabled globally.

5. Procedure (interface configuration mode)

(1) Enter the privileged EXEC mode.
enable

(2) Enter the global configuration mode.
configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Enable TC guard on the interface.
spanning-tree tc-guard

By default, TC guard is disabled on an interface.

1.19.6 Configuring TC Filter

1. Overview

TC filter enables a port not to process received TC packets but to process TC packets generated by the port due to topology changes.

2. Restrictions and Guidelines

TC filter can be enabled or disabled only on interfaces and takes effect on specific interfaces.

- In Layer 2 Ethernet interface configuration mode or Layer 2 aggregate interface configuration mode, run the **spanning-tree ignore tc** command to enable the TC filter function or run the **no spanning-tree ignore tc** command to disable the TC filter function.

3. Prerequisites

Configure the interface as a Layer 2 interface.

4. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Enable TC filter on an interface.

spanning-tree ignore tc

TC filter is disabled on an interface by default.

1.20 Configuring BPDU Tunnel

1.20.1 Overview

BPDU tunnel is a Layer 2 tunnel function based on the Layer 2 Tunnel Protocol (L2TP).

A 802.1Q (QinQ) network is usually divided into the customer network and service provider network. The basic principle of QinQ is described as follows: When a user packet is sent to a provider edge (PE), the PE considers the VLAN tag in the user packet as data, and encapsulates the VLAN tag of the service provider network into the packet so that the user packet carries two VLAN tags to traverse the service provider network. In the service provider network, the packet is forwarded based on the outer VLAN tag. When the packet leaves the service provider network, the outer VLAN tag is removed.

STP BPDUs use the BPDU dedicated address 0180.c200.0000 as the destination MAC address. Therefore, the BPDUs of the customer network and service provider network have the same destination MAC address. When a Dot1q-tunnel interface of a PE receives a BPDU from the customer network, the PE recognizes the BPDU as an STP packet and does not forward it because the destination MAC address of the BPDU is the BPDU dedicated address (0180.c200.0000). In addition, the PE performs spanning tree calculation based on the BPDU content, which affects the topology of the service provider network. In order to prevent the customer network BPDUs from interfering with the spanning tree calculation of the service provider network, you need to differentiate customer network BPDUs from service provider network BPDUs, that is, modify the destination MAC address in customer network BPDUs.

After the BPDU tunnel function is enabled on a Dot1q-tunnel interface of a PE, if the interface receives a customer network BPDU, it changes the destination MAC address in the BPDU from the BPDU dedicated address (0180.c200.0000) to the tunnel address (01d0.f800.0005 by default) and forwards the BPDU in the service provider network. When the BPDU reaches a PE at the other end, the PE restores the destination MAC address of the BPDU from the tunnel address (01d0.f800.0005 by default) to the BPDU dedicated address (0180.c200.0000) and forwards the BPDU to the peer customer network. Customer network BPDUs are transmitted through BPDU tunnels in the service provider network. In this way, the STP calculations of the

customer network and service provider network are performed separately without interfering with each other. For details, see *Configuring QinQ* and *Configuring VPDN*.

1.20.2 Restrictions and Guidelines

- This function takes effect only when it is enabled in both global configuration mode and interface configuration mode.
  - Run the **l2protocol-tunnel stp** command to enable the global BPDU tunnel function or run the **no l2protocol-tunnel stp** command to disable the global BPDU tunnel function.
  - Run the **l2protocol-tunnel stp enable** command to enable the BPDU tunnel function or run the **no l2protocol-tunnel stp enable** command to disable the BPDU tunnel function.
- Run the **l2protocol-tunnel stp tunnel-dmac** *mac-address* command to configure a BPDU tunnel address. The optional tunnel addresses of STP packets include 01d0.f800.0005 (default), 011a.a900.0005, 010f.e200.0003, 0100.0ccd.cdd0, 0100.0ccd.cdd1, and 0100.0ccd.cdd2.

1.20.3 Prerequisites

Configure the interface as a Layer 2 interface.

1.20.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the global BPDU tunnel function.

l2protocol-tunnel stp

The global BPDU tunnel function is disabled by default.

(4) (Optional) Configure a BPDU tunnel address.

l2protocol-tunnel stp tunnel-dmac *mac-address*

The default BPDU tunnel address is 01d0.f800.0005.

(5) Enter the interface configuration mode of the port that connects the customer network.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(6) Enable the STP BPDU tunnel function on the interface.

l2protocol-tunnel stp enable

The STP BPDU tunnel function is disabled on the interface by default.

1.21 Configuring BPDU Transparent Transmission

1.21.1 Overview

According to the IEEE 802.1Q standard, BPDUs use 0180.c200.0000 as the destination MAC address. When a device supporting IEEE 802.1Q receives a frame with the destination address of 0180.c200.0000, it recognizes the frame as a BPDU and will not forward it.

However, in the actual network deployment, some BPDU frames need to be transparently transmitted by devices. For example, STP is disabled on Device A but enabled on Device B and Device C connected through Device A. In this case, Device A needs to transparently transmit BPDU frames so that Device B and Device C can normally calculate and generate spanning trees.

1.21.2 Restrictions and Guidelines

- BPDU transparent transmission takes effect only when STP is disabled. If STP is enabled on a device, the device does not transparently transmit BPDU frames. If STP is enabled on a service provider network device and the device is required to transmit customer network BPDUs without affecting the spanning tree of the service provider network, use the BPDU tunnel function.
- In global configuration mode, run the **bridge-frame forwarding protocol bpdu** command to enable the BPDU transparent transmission function, or run the **no bridge-frame forwarding protocol bpdu** command to disable the BPDU transparent transmission function.

1.21.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the BPDU transparent transmission function.

bridge-frame forwarding protocol bpdu

BPDU transparent transmission is disabled by default.

1.22 Configuring STP in the Specified VLAN

1.22.1 Overview

The STP function can be configured by VLAN to provide a more flexible spanning tree deployment mode and improve the spanning tree compatibility. Each VLAN can run an independent spanning tree and users can enable or disable the STP function in the specified VLAN based on actual needs to implement VLAN-based load balancing. This feature takes effect in MVST and Rapid-MVST modes. After you enable STP in the specified VLAN, if the allowed VLAN list of the interface contains this VLAN, the interface participates in spanning tree calculation in the VLAN. Otherwise, the interface does not participate in spanning tree calculation. If STP is not enabled in a VLAN, interfaces in this VLAN do not participate in the calculation but keeps the forwarding state.

1.22.2 Restrictions and Guidelines

- When you enable spanning tree by VLAN but the VLAN does not exist or the device is not in the MVST or Rapid-MVST mode, you can configure this feature. However, the configuration takes effect only when the corresponding VLAN is created and the device is switched to the MVST or Rapid-MVST mode.
- The software version must support the MVST or Rapid-MVST mode. To verify the support for MVST or Rapid-MVST, run the corresponding command to switch the spanning tree mode to MVST or Rapid-MVST.
- Before you enable spanning tree by VLAN, you are advised to switch the spanning tree mode to MVST or Rapid-MVST.
- It is recommended that trunk ports be used to connect this device to another device working in the MVST or Rapid-MVST mode. Do not use two types of ports, such as access port and trunk port.
- Interconnected devices in the spanning tree network must use the same spanning tree mode, such as STP, RSTP, MSTP, MVST, or Rapid-MVST.
- When two devices are interconnected in MVST or Rapid-MVST mode, the interconnected trunk ports must have the same native VLAN.

1.22.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Switch the spanning tree mode to MVST or Rapid-MVST.

spanning-tree mode { **mvst** | **rapid-mvst** }

(4) Enable STP by VLAN.

spanning-tree vlan *vlan-list*

STP is disabled in all VLANs by default.

1.23 Configuring a Proposal/Agreement Mechanism

1.23.1 Overview

You can configure a Proposal/Agreement mechanism for negotiation as needed, including normal mode and enhanced mode. Enhanced mode is enabled on an interface by default. For details, see IEEE802.1S. When the enhanced mode is used, the designated interface sends both Proposal and Agreement messages during negotiation so that the downstream device can immediately transition to forwarding state upon receiving the Agreement message. When the interface is configured as normal mode, the designated interface only sends the Proposal message during negotiation.

1.23.2 Restrictions and Guidelines

- When Ruijie devices interwork with third-party devices through STP, the port mode should be determined based on the Proposal/Agreement mechanism of the third-party devices.

1.23.3 Prerequisites

- Configure the interface as a Layer 2 interface.

1.23.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 2 aggregate interface configuration mode.

  interface { **aggregateport** *interface-number* | **range aggregateport** *interface-range* }

(4) Configure the negotiation mode of a Layer 2 Ethernet interface.

spanning-tree agree-mode [**enhance** | **normal**]

The enhanced mode is used by default.

1.24 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** commands to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging switch immediately after use.

Run the **clear** commands to clear information.

Caution

Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-12 Monitoring

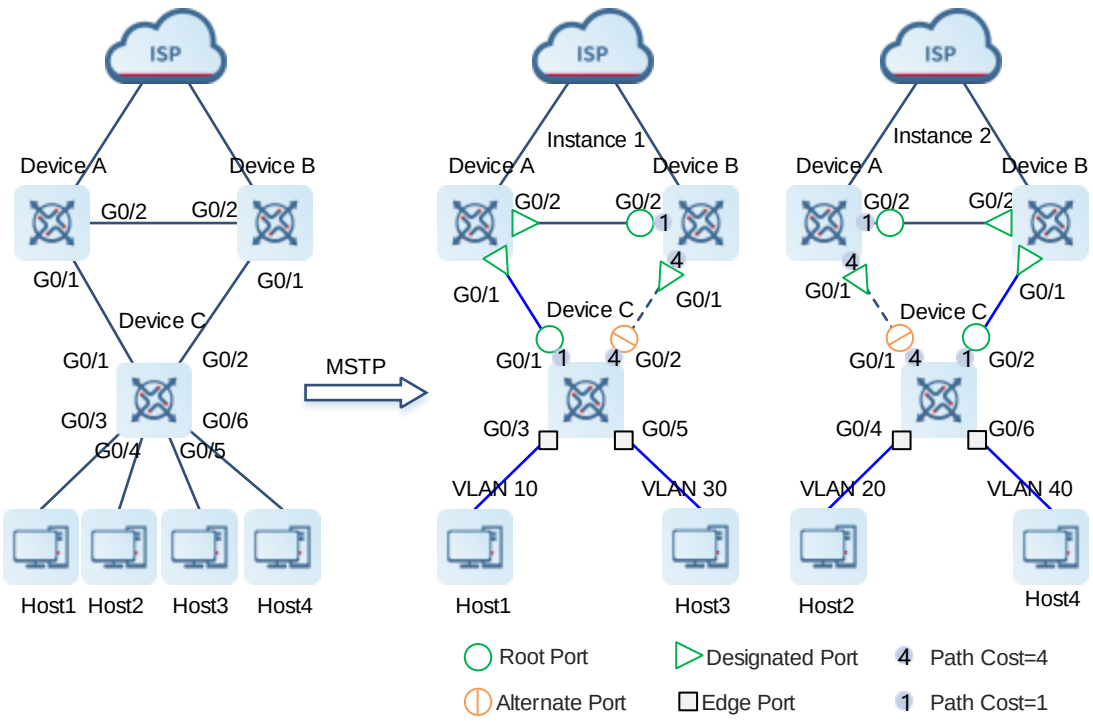
Command	Purpose
show spanning-tree [**forward-time** | **hello-time** | **max-age** | **max-hops** | **mst** *instance-id* | **pathcost method** | **tx-hold-count**]	Displays the global spanning tree configuration.
show spanning-tree counters	Displays statistics on sent and received STP packets.
show spanning-tree inconsistentports	Displays ports blocked due to root guard or loop guard.

Command	Purpose
show spanning-tree summary	Displays the spanning tree topology and port forwarding status.
show spanning-tree vlan { *vlan-list* | **all** }	Displays the spanning tree configuration and status information of the specified VLANs.
show spanning-tree v-stp information	Displays information about the V-STP function.
show spanning-tree [**mst** *instance-id*] **interface** *interface-type interface-number* [**bpdufilter** | **bpduguard** | **link-type** | **portfast**]	Displays the spanning tree configuration and status information of an interface by interface type and number.
show spanning-tree [**mst** *instance-id*] *port-index*	Displays the spanning tree configuration and status information of an interface by interface number.
show spanning-tree mst configuration	Displays the MST region configuration.
show spanning-tree mst *instance-id* **topochange record**	Displays the topology change information of an interface in a specified instance.
show l2protocol-tunnel stp	Displays BPDU tunnel information.
debug mstp all	Debugs STP, RSTP, and MSTP.
debug mstp gr	Debugs the spanning tree GR function.
debug mstp rx	Debugs the BPDU receiving.
debug mstp tx	Debugs BPDU transmission.
debug mstp event	Debugs spanning tree events.
debug mstp loopguard	Debugs spanning tree loop guard.
debug mstp rootguard	Debugs spanning tree root guard.
debug mstp bridgedetect	Debugs the bridge detect state machine.
debug mstp portinfo	Debugs the port information state machine.
debug mstp protomigrat	Debugs the port protocol migration state machine.
debug mstp topochange	Debugs the spanning tree topology changes.
debug mstp receive	Debugs the spanning tree receiving state machine.
debug mstp roletran	Debugs the port role transition state machine.
debug mstp statetran	Debugs the port state transition state machine.
debug mstp transmit	Debugs the MSTP transmission state machine.

Command	Purpose
clear spanning-tree counters [**interface** *interface-type interface-number*]	Clears statistics on packets sent and received by a port.
clear spanning-tree mst *instance-id* **topochange record**	Clears the STP topology change information.

1.25 Configuration Examples

1.25.1 Configuring MSTP



1. Requirements

The topology shown in Figure 1-18 includes two layers: Device A and Device B are in the core layer, Device C is in the access layer, and Device C connects to intranet terminals. There are four VLANs in the intranet. The configured MSTP needs to meet the following requirements:

- The spanning tree root bridge of VLAN 10 and VLAN 30 is Device A and data is forwarded through port GigabitEthernet 0/1 of Device C.
- The spanning tree root bridge of VLAN 20 and VLAN 40 is Device B and data is forwarded through port GigabitEthernet 0/2 of Device C.
- Enable loop guard on the root ports of Device C. Enable BPDU guard on the edge ports of Device C that connect to terminals.

2. Topology

Figure 1-18 Topology of Configuring MSTP Basic Topology

3. Notes

- Create the same VLANs on Devices A, B, and C and configure the same instance mappings: Map instance 1 to VLANs 10 and 30 and map instance 2 to VLANs 20 and 40. Instance 0 contains other VLANs that have not been created.
- The devices elect the device roles and port roles in the spanning tree by comparing the priority vector <**Root Identifier**, **Root Path Cost**, **Bridge ID**, **Port ID**>. Configure the bridge priorities and port path costs for instances so that the required topology is calculated. For the ease of management, configure the same spanning tree for instance 0 and instance 1.

  Instance 0 and instance 1:

  - Set the bridge priority to 4096 for Device A and 8192 for Device B, and use the default bridge priority 32768 (no configuration is required) for Device C so that Device A becomes the root bridge.
  - On Device B, set the path cost to 1 for port GigabitEthernet 0/2 and 4 for port GigabitEthernet 0/1 so that port GigabitEthernet 0/2 becomes the root port of Device B.
  - On Device C, set the path cost to 1 for port GigabitEthernet 0/1 and 4 for port GigabitEthernet 0/2 so that port GigabitEthernet 0/1 becomes the root port of Device C.
  - The bridge priority of Device B is 8192, which is higher than that of Device C (32768). Therefore, port GigabitEthernet 0/1 of Device B is elected as the designated port and port GigabitEthernet 0/2 of Device C is elected as the alternate port.

  Instance 2:

  - Set the bridge priority to 4096 for Device B and 8192 for Device A, and use the default bridge priority 32768 (no configuration is required) for Device C so that Device B becomes the root bridge.
  - On Device A, set the path cost to 1 for port GigabitEthernet 0/2 and 4 for port GigabitEthernet 0/1 so that port GigabitEthernet 0/2 becomes the root port of Device A.
  - On Device C, set the path cost to 1 for port GigabitEthernet 0/2 and 4 for port GigabitEthernet 0/1 so that port GigabitEthernet 0/2 becomes the root port of Device C.
  - The bridge priority of Device A is 8192, which is higher than that of Device C (32768). Therefore, port GigabitEthernet 0/1 of Device A is elected as the designated port and port GigabitEthernet 0/1 of Device C is elected as the alternate port.
- Configure MSTP loop guard on ports GigabitEthernet 0/1–0/2 of Device C. When the root port or backup port fails to receive BPDUs and changes to a designated port, the port will remain in discarding state until it receives BPDUs for spanning tree calculation.
- On Device C, configure ports GigabitEthernet 0/3–0/6 that connect to terminals as edge ports. The autoedge function is enabled by default. If ports GigabitEthernet 0/3–0/6 fail to receive BPDUs within 3s after being elected as designated ports, they are automatically recognized as edge ports and immediately enters forwarding state. Packet loss or packet transmission/receiving delay in the network may affect the autoedge function. Therefore, disable the autoedge function, manually configure the ports as edge ports, and enable the BPDU guard function.
- Enable the STP function globally on Devices A, B, and C and use the default MSTP mode.
- Configure interconnected ports among Devices A, and B, and C as trunk ports and configure the ports to allow all VLAN traffic to pass. Add the interfaces of Device C that connect to terminals to their respective

VLANs.

4. Procedure

(1) Configure Device A.

Create VLANs and configure instance mappings.

```
DeviceA>enable
DeviceA# configure terminal
DeviceA(config)# vlan range 10,20,30,40
DeviceA(config-vlan-range)# exit
DeviceA(config)# spanning-tree mst configuration
DeviceA(config-mst)# instance 1 vlan 10,30
DeviceA(config-mst)# instance 2 vlan 20,40
```

Set the bridge priority to 4094 for instances 0 and 1 and 8192 for instance 2.

```
DeviceA(config-mst)# spanning-tree mst 0 priority 4096
DeviceA(config)# spanning-tree mst configuration
DeviceA(config-mst)# spanning-tree mst 1 priority 4096
DeviceA(config)# spanning-tree mst configuration
DeviceA(config-mst)# spanning-tree mst 2 priority 8192
```

Configure port GigabitEthernet 0/2 as a trunk port. In instance 2, set the path cost of the port to 1.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# switchport
DeviceA(config-if-GigabitEthernet 0/2)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
DeviceA(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan all
DeviceA(config-if-GigabitEthernet 0/2)# spanning-tree mst 2 cost 1
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

Configure port GigabitEthernet 0/1 as a trunk port. In instance 2, set the path cost of the port to 4.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# switchport
DeviceA(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
DeviceA(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
DeviceA(config-if-GigabitEthernet 0/1)# spanning-tree mst 2 cost 4
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Enable the STP function globally.

```
DeviceA(config)# spanning-tree
DeviceA(config)# end
DeviceA# write
```

(2) Configure Device B.

Create VLANs and configure instance mappings.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# vlan range 10,20,30,40
```

```
DeviceB(config-vlan-range)# exit
DeviceB(config)# spanning-tree mst configuration
DeviceB(config-mst)# instance 1 vlan 10,30
DeviceB(config-mst)# instance 2 vlan 20,40
```

Set the bridge priority to 4094 for instance 2 and 8192 for instance 0 and instance 1.

```
DeviceB(config-mst)# spanning-tree mst 0 priority 8192
DeviceB(config)# spanning-tree mst configuration
DeviceB(config-mst)# spanning-tree mst 1 priority 8192
DeviceB(config)# spanning-tree mst configuration
DeviceB(config-mst)# spanning-tree mst 2 priority 4096
```

Configure port GigabitEthernet 0/2 as a trunk port. In instances 0 and 1, set the path cost of the port to 1.

```
DeviceB(config)# interface gigabitethernet 0/2
DeviceB(config-if-GigabitEthernet 0/2)# switchport
DeviceB(config-if-GigabitEthernet 0/2)# switchport mode trunk
DeviceB(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
DeviceB(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan all
DeviceB(config-if-GigabitEthernet 0/2)# spanning-tree mst 0 cost 1
DeviceB(config-if-GigabitEthernet 0/2)# spanning-tree mst 1 cost 1
DeviceB(config-if-GigabitEthernet 0/2)# exit
```

Configure port GigabitEthernet 0/1 as a trunk port. In instances 0 and 1, set the path cost of the port to 4.

```
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# switchport
DeviceB(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceB(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
DeviceB(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
DeviceB(config-if-GigabitEthernet 0/1)# spanning-tree mst 0 cost 4
DeviceB(config-if-GigabitEthernet 0/1)# spanning-tree mst 1 cost 4
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Enable the STP function globally.

```
DeviceB(config)# spanning-tree
DeviceB(config)# end
DeviceB# write
```

(3) Configure Device C.

Create VLANs and configure instance mappings.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# vlan range 10,20,30,40
DeviceC(config-vlan-range)# exit
DeviceC(config)# spanning-tree mst configuration
DeviceC(config-mst)# instance 1 vlan 10,30
DeviceC(config-mst)# instance 2 vlan 20,40
DeviceC(config-mst)# exit
```

Configure uplink port GigabitEthernet 0/1 as a trunk port. In instances 0 and 1, set the path cost of the port to 1. In instance 2, set the path cost of the port to 4. Configure loop guard on the uplink port.

```
DeviceC(config)# interface gigabitethernet 0/1
DeviceC(config-if-GigabitEthernet 0/1)# switchport
DeviceC(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceC(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
DeviceB(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
DeviceB(config-if-GigabitEthernet 0/1)# spanning-tree mst 0 cost 1
DeviceC(config-if-GigabitEthernet 0/1)# spanning-tree mst 1 cost 1
DeviceC(config-if-GigabitEthernet 0/1)# spanning-tree mst 2 cost 4
DeviceC(config-if-GigabitEthernet 0/1)# spanning-tree guard loop
DeviceC(config-if-GigabitEthernet 0/1)# exit
```

Configure uplink port GigabitEthernet 0/2 as a trunk port. In instance 2, set the path cost of the port to 1. In instances 0 and 1, set the port path cost to 4. Configure loop guard on the uplink port.

```
DeviceC(config)# interface gigabitethernet 0/2
DeviceC(config-if-GigabitEthernet 0/2)# switchport
DeviceC(config-if-GigabitEthernet 0/2)# switchport mode trunk
DeviceC(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
DeviceC(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan all
DeviceC(config-if-GigabitEthernet 0/2)# spanning-tree mst 0 cost 4
DeviceC(config-if-GigabitEthernet 0/2)# spanning-tree mst 1 cost 4
DeviceC(config-if-GigabitEthernet 0/2)# spanning-tree mst 2 cost 1
DeviceC(config-if-GigabitEthernet 0/2)# spanning-tree guard loop
DeviceC(config-if-GigabitEthernet 0/2)# exit
```

Add downlink ports GigabitEthernet 0/3–0/6 to VLANs. Configure the ports as edge ports and configure BPDU guard.

```
DeviceC(config)# interface gigabitethernet 0/3
DeviceC(config-if-GigabitEthernet 0/3)# switchport
DeviceC(config-if-GigabitEthernet 0/3)# switchport mode access
DeviceC(config-if-GigabitEthernet 0/3)# switchport access vlan 10
DeviceC(config-if-GigabitEthernet 0/3)# spanning-tree autoedge disabled
DeviceC(config-if-GigabitEthernet 0/3)# spanning-tree portfast
DeviceC(config-if-GigabitEthernet 0/3)# spanning-tree bpduguard enable
DeviceC(config-if-GigabitEthernet 0/3)# exit
DeviceC(config)# interface gigabitethernet 0/4
DeviceC(config-if-GigabitEthernet 0/4)# switchport
DeviceC(config-if-GigabitEthernet 0/4)# switchport mode access
DeviceC(config-if-GigabitEthernet 0/4)# switchport access vlan 20
DeviceC(config-if-GigabitEthernet 0/4)# spanning-tree autoedge disabled
DeviceC(config-if-GigabitEthernet 0/4)# spanning-tree portfast
DeviceC(config-if-GigabitEthernet 0/4)# spanning-tree bpduguard enable
DeviceC(config-if-GigabitEthernet 0/4)# exit
DeviceC(config)# interface gigabitethernet 0/5
DeviceC(config-if-GigabitEthernet 0/5)# switchport
DeviceC(config-if-GigabitEthernet 0/5)# switchport mode access
```

```
DeviceC(config-if-GigabitEthernet 0/5)# switchport access vlan 30
DeviceC(config-if-GigabitEthernet 0/5)# spanning-tree autoedge disabled
DeviceC(config-if-GigabitEthernet 0/5)# spanning-tree portfast
DeviceC(config-if-GigabitEthernet 0/5)# spanning-tree bpduguard enable
DeviceC(config-if-GigabitEthernet 0/5)# exit
DeviceC(config)# interface gigabitethernet 0/6
DeviceC(config-if-GigabitEthernet 0/6)# switchport
DeviceC(config-if-GigabitEthernet 0/6)# switchport mode access
DeviceC(config-if-GigabitEthernet 0/6)# switchport access vlan 40
DeviceC(config-if-GigabitEthernet 0/6)# spanning-tree autoedge disabled
DeviceC(config-if-GigabitEthernet 0/6)# spanning-tree portfast
DeviceC(config-if-GigabitEthernet 0/6)# spanning-tree bpduguard enable
DeviceC(config-if-GigabitEthernet 0/6)# exit
```

Enable the STP function globally.

```
DeviceC(config)# spanning-tree
DeviceC(config)# end
DeviceC# write
```

5. Verification

(1) Verify that instance mappings on the devices are the same.

Check instance mappings on Device A.

```
DeviceA# show spanning-tree mst configuration
Multi spanning tree protocol : Enable
Name    :
Revision : 0
Instance  Vlans Mapped
-------- ---------------------------------------------
0       : 1-9, 11-19, 21-29, 31-39, 41-4094
1       : 10, 30
2       : 20, 40
---------------------------------------------------
```

Check instance mappings on Device B.

```
DeviceB# show spanning-tree mst configuration
Multi spanning tree protocol : Enable
Name    :
Revision : 0
Instance  Vlans Mapped
-------- ---------------------------------------------
0       : 1-9, 11-19, 21-29, 31-39, 41-4094
1       : 10, 30
2       : 20, 40
---------------------------------------------------
```

Check instance mappings on Device C.

```
DeviceC# show spanning-tree mst configuration
```

```
Multi spanning tree protocol : Enable
Name    :
Revision : 0
Instance  Vlans Mapped
-------- ---------------------------------------------
0       : 1-9, 11-19, 21-29, 31-39, 41-4094
1       : 10, 30
2       : 20, 40
---------------------------------------------------
```

(2) Check the instance spanning tree topology and port forwarding status on Device A.

In instances 0 and 1, Device A (0074.9cee.f49e) is the root bridge. Ports GigabitEthernet 0/1–0/2 of Device A are designated ports. They are all in forwarding state.

```
DeviceA# show spanning-tree summary
Spanning tree enabled protocol mstp
MST 0 vlans map : 1-9, 11-19, 21-29, 31-39, 41-4094

Gi0/6           Desg FWD 20000     128     True     P2p
```

(5) Check "DesignatedRoot", "RootPort", and "RootCost" of each device in instance 1. Check the "DesignatedRoot","RootPort", and "RootCost" of each device in instances 0 and 2.

Device A is the root and the root path cost is 0.

```
DeviceA# show spanning-tree mst 1
###### MST 1 vlans mapped : 10, 30
BridgeAddr : 0074.9cee.f49e
Priority: 4096
TimeSinceTopologyChange : 0d:0h:16m:29s
TopologyChanges : 7
DesignatedRoot : 4097.0074.9cee.f49e
RootCost : 0
RootPort : 0
```

The root path cost from Device B to the root (4097.0074.9cee.f49e) through root port GigabitEthernet 0/2 is 1.

```
DeviceB# show spanning-tree mst 1
###### MST 1 vlans mapped : 10, 30
BridgeAddr : 00d0.f8ee.8c1e
Priority: 8192
TimeSinceTopologyChange : 0d:0h:16m:27s
TopologyChanges : 7
DesignatedRoot : 4097.0074.9cee.f49e
RootCost : 1
RootPort : GigabitEthernet 0/2
```

The root path cost from Device C to the root (4097.0074.9cee.f49e) through root port GigabitEthernet 0/1 is 1.

```
DeviceC# show spanning-tree mst 1
###### MST 1 vlans mapped : 10, 30
BridgeAddr : 0074.9cee.53ca
Priority: 32768
TimeSinceTopologyChange : 0d:0h:19m:48s
TopologyChanges : 5
DesignatedRoot : 4097.0074.9cee.f49e
RootCost : 1
RootPort : GigabitEthernet 0/1
```

(6) Verify that the loop guard function ("PortGuardmode:Guard loop") on uplink ports GigabitEthernet 0/1–0/2 of Device C is enabled. The following uses GigabitEthernet 0/1 as an example.

```
DeviceC# show spanning-tree interface gigabitethernet 0/1
PortAdminPortFast : Disabled
PortOperPortFast : Disabled
PortAdminAutoEdge : Enabled
PortOperAutoEdge : Disabled
PortAdminLinkType : auto
PortOperLinkType : point-to-point
PortBPDUGuard : Disabled
PortBPDUFilter : Disabled
PortGuardmode  : Guard loop

###### MST 0 vlans mapped :1-9, 11-19, 21-29, 31-39, 41-4094
PortState : forwarding

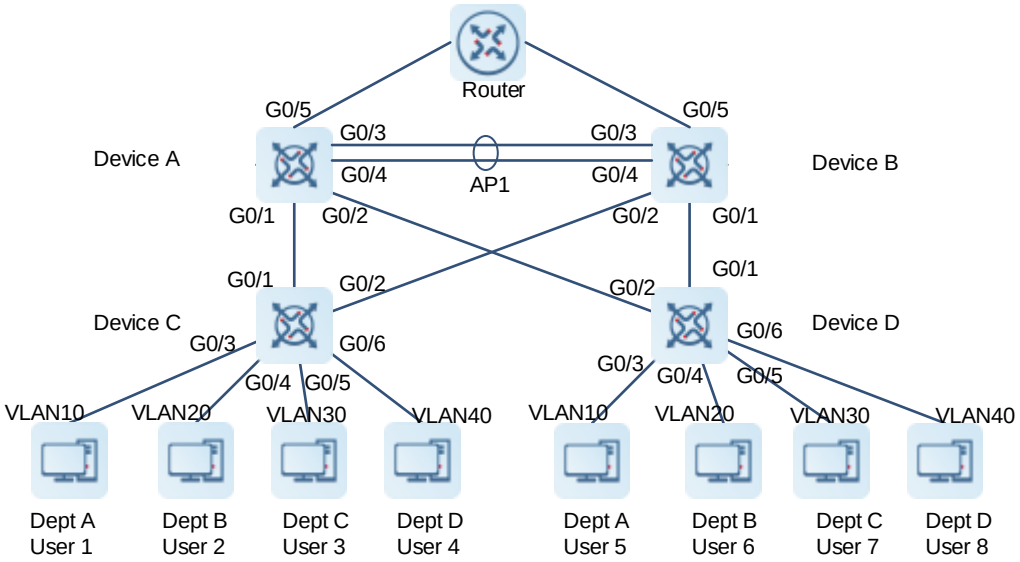
7. Common Errors

- When no bridge priority lower than that of the root bridge but higher than that of access devices is configured for non-root devices, the non-root core devices and access devices will determine upstream devices by comparing MAC addresses in the spanning tree calculation. As a result, the calculation result may not meet networking requirements.
- When no port path cost is configured for non-root devices, the spanning tree calculation result may not meet networking requirements due to different link conditions.
- The root guard function is configured on a root port, master port, or alternate port, and ports may be blocked incorrectly.

1.25.2 Configuring MSTP+VRRP



1. Requirements

The MSTP+VRRP dual-core solution is a typical application of MSTP. This solution uses a hierarchical network architecture and MSTP and Virtual Router Redundancy Protocol (VRRP) to implement redundant backup and VLAN load balancing, to enhance the network system availability. The highlight of this architecture is the hierarchical network structure. The capacity indicators, characteristics, and functions of network devices in each layer can be optimized based on their network locations and functions to boost the system stability and availability. This solution usually uses a three-layer (core layer, aggregation layer, and access layer) or two-layer (core layer and access layer) architecture. The topology shown in Figure 1-19 adopts a two-layer architecture. The networking requirements are as follows:

- Core layer: Configure multiple MSTP instances to achieve load balancing. Create instance 1 and instance 2. Map instance 1 to VLAN 10 and VLAN 30 and instance 2 to VLAN 20 and VLAN 40. Device A is the root bridge of instances 0 and instance 1 (instance 0 exists by default) as well as the VRRP master device of VLAN 10 and VLAN 30. Device B is the root bridge of instance 2 as well as the VRRP master device of VLANs 20 and 40.
- Access layer: Configure ports that are directly connected to terminals (such as PCs or servers) as edge ports and enable BPDU guard to prevent the access of unauthorized user devices.

2. Topology

Figure 1-19 Topology of Configuring MSTP+VRRP

3. Notes

- Configure MSTP.
  - Set the spanning tree mode to MSTP. The default spanning tree mode is MSTP and no configuration is required.
  - Configure an MST region. On Devices A, B, C, and D, map instance 1 to VLAN 10 and VLAN 30 and instance 2 to VLAN 20 and VLAN 40.
  - Set the bridge priority of instances 0 and 1 to 4096 on Device A and 8192 on Device B to make Device A become the root bridge of instances 0 and 1.
  - Set the bridge priority of instance 2 to 8192 on Device A and 4096 on Device B to make Device B become the root bridge of instance 2.
  - On access Devices C and D, instances 0, 1, and 2 use the default bridge priority (32768). Configure ports that connect to user terminals as edge ports so that they do not participate in spanning tree calculation. Enable BPDU guard on the ports.
- Configure monitoring ports for a VRRP group. Configure the uplink port of the master device as the VLAN monitoring port. Configure port GigabitEthernet 0/5 of Device A to monitor VLAN 10 and VLAN 30, and port GigabitEthernet 0/5 of Device B to monitor VLAN 20 and VLAN 40.

- In interface configuration mode of the uplink port, run the **no switchport** command to configure the monitoring port as a Layer 3 interface and configure an IP address for the port. Layer 3 interfaces do not participate in spanning tree calculation.
- In switch virtual interface (SVI) configuration mode of a VLAN, run the **vrrp** *group-id* **track** *interface-type interface-number* [*priority decrement*] command to configure a monitoring interface *interface-type interface-number* for the VRRP group *group-id* and VRRP priority change value *priority decrement*. When the link state of the monitored interface or IP route reachability status changes, VRRP priority will change, and the change value is *decrement*. When the link is interrupted, the priority is reduced. When the link recovers, the priority is restored. The value range is from 1 to 255 and the default value is **10**.

- Configure priority parameters: The VRRP priority change value needs to be taken into account together with the VRRP priority. In SVI configuration mode of a VLAN, run the **vrrp** *group-id* **priority** *priority* command to configure the VRRP priority. The value range of *priority* is from 1 to 254 and the default value is **100**. The default value of *priority decrement* is **10**. When the monitoring port is down, the VRRP priority is reduced to 90 (that is, 100 – 10).
  - In this example, raise the VRRP priority of VLANs 10 and 30 to 120 on the master device (Device A), use the default priority **100** on Device B, and set *priority decrement* to 30. When monitoring port GigabitEthernet 0/5 of Device A is down due to a fault, the VRRP priority of VLAN 10 and VLAN 30 is reduced by 30 to 90, which is lower than the default priority (100) on Device B. Therefore, data of VLAN 10 and VLAN 30 will be transmitted through Device B. When monitoring port GigabitEthernet 0/5 of Device A recovers, the VRRP priority of VLAN 10 and VLAN 30 is restored to 120, which is greater than the default priority on Device B. Therefore, data of VLAN 10 and VLAN 30 is transmitted through Device A. Then, VLAN 10 and VLAN 30 use Device A as the VRRP master device and Device B as the VRRP backup device.
  - Likewise, raise the VRRP priority of VLAN 20 and VLAN 40 to 120 on Device B and use the default priority (**100**) on Device A.
- Configure VRRP: Add SVIs of VLANs to a VRRP group and configure a virtual IP address for the VRRP group.
- Pay attention to the following when configuring SVI addresses: If the monitoring port is down and the VRRP priorities are the same on two devices after priority reduction, the SVI addresses of a VLAN on the two devices will be compared. A larger SVI address indicates a higher priority. Therefore, it is recommended that the SVI IP addresses of VLAN 10 and VLAN 30 on the master device (Device A) be greater than those of VLAN 10 and VLAN 30 on Device B. The same configuration applies to other VLANs.
- Configure an aggregate link between core devices. Configure the downlink ports of core devices and uplink ports of access devices as trunk ports. On access devices, configure ports that connect to user terminals as access ports and add them to VLANs.

4. Procedure

(1) Configure the MSTP function.

Configure the MSTP function for core Device A. Create VLANs, and map instance 1 to VLAN 10 and VLAN 30 and instance 2 to VLAN 20 and VLAN 40. Set the bridge priority to 4096 for instances 0 and 1 and 8192 for instance 2 to make Device A become the root bridge of instances 0 and 1. Enable MSTP.

```
DeviceA> enable
DeviceA# configure terminal
```

```
DeviceA(config)# vlan range 10,20,30,40
DeviceA(config-vlan-range)# exit
DeviceA(config)# spanning-tree mode mstp
DeviceA(config)# spanning-tree mst configuration
DeviceA(config-mst)# instance 1 vlan 10,30
DeviceA(config-mst)# instance 2 vlan 20,40
DeviceA(config-mst)# exit
DeviceA(config)# spanning-tree mst 0 priority 4096
DeviceA(config)# spanning-tree mst 1 priority 4096
DeviceA(config)# spanning-tree mst 2 priority 8192
DeviceA(config)# spanning-tree
```

Configure the MSTP function for core Device B. Create VLANs, and map instance 1 to VLAN 10 and VLAN 30 and instance 2 to VLAN 20 and VLAN 40. Set the bridge priority to 8192 for instances 0 and 1 and 4096 for instance 2 to make Device B become the root bridge of instance 2. Enable MSTP.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# vlan range 10,20,30,40
DeviceB(config-vlan-range)# exit
DeviceB(config)# spanning-tree mode mstp
DeviceB(config)# spanning-tree mst configuration
DeviceB(config-mst)# instance 1 vlan 10,30
DeviceB(config-mst)# instance 2 vlan 20,40
DeviceB(config-mst)# exit
DeviceB(config)# spanning-tree mst 0 priority 8192
DeviceB(config)# spanning-tree mst 1 priority 8192
DeviceB(config)# spanning-tree mst 2 priority 4096
DeviceB(config)# spanning-tree
```

Configure the MSTP function for access Devices C and D. The bridge priority does not need to be configured on access devices. Configure ports that are directly connected to user terminals as edge ports and enable BPDU guard on the ports. The configurations on Device D are similar to those on Device C. The following uses Device C as an example.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# vlan range 10,20,30,40
DeviceC(config-vlan-range)# exit
DeviceC(config)# spanning-tree mode mstp
DeviceC(config)# spanning-tree mst configuration
DeviceC(config-mst)# instance 1 vlan 10,30
DeviceC(config-mst)# instance 2 vlan 20,40
DeviceC(config-mst)# exit
DeviceC(config)# spanning-tree
DeviceC(config)# interface range gigabitethernet 0/3-6
DeviceC(config-if-range)# spanning-tree portfast
DeviceC(config-if-range)# spanning-tree bpduguard enable
DeviceC(config-if-range)# exit
```

(2) Configure monitoring ports for the VRRP group.

Configure port GigabitEthernet 0/5 of Device A as a Layer 3 interface and set the IP address to 10.10.1.1/24. Then, this port serves as the monitoring port of VLAN 10 and VLAN 30.

```
DeviceA(config)# interface gigabitethernet 0/5
DeviceA(config-if-GigabitEthernet 0/5)# no switchport
DeviceA(config-if-GigabitEthernet 0/5)# ip address 10.10.1.1 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/5)# exit
```

Configure port GigabitEthernet 0/5 of Device B as a Layer 3 interface and set the IP address to 10.10.2.1/24. Then, this port serves as the monitoring port of VLAN 20 and VLAN 40.

```
DeviceB(config)# interface gigabitethernet 0/5
DeviceB(config-if-GigabitEthernet 0/5)# no switchport
DeviceB(config-if-GigabitEthernet 0/5)# ip address 10.10.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/5)# exit
```

(3) Configure VRRP for VLAN 10 and VLAN 30 on core devices.

Configure the master device (Device A). Enter an SVI and configure an SVI address. Add the SVI to the VRRP group and configure a virtual gateway IP address for the VRRP group. Raise the VRRP priority to 120, configure port GigabitEthernet 0/5 as a monitoring port, and set priority decrement to 30.

```
DeviceA(config)# interface vlan 10
DeviceA(config-if-VLAN 10)# ip address 192.168.10.3 255.255.255.0
DeviceA(config-if-VLAN 10)# vrrp 10 ip 192.168.10.1
DeviceA(config-if-VLAN 10)# vrrp 10 priority 120
DeviceA(config-if-VLAN 10)# vrrp 10 track gigabitethernet 0/5 30
DeviceA(config-if-VLAN 10)# exit
DeviceA(config)# interface vlan 30
DeviceA(config-if-VLAN 30)# ip address 192.168.30.3 255.255.255.0
DeviceA(config-if-VLAN 30)# vrrp 30 ip 192.168.30.1
DeviceA(config-if-VLAN 30)# vrrp 30 priority 120
DeviceA(config-if-VLAN 30)# vrrp 30 track gigabitethernet 0/5 30
DeviceA(config-if-VLAN 30)# exit
```

Configure the backup device (Device B). Enter an SVI and configure an SVI address. Add the SVI to the VRRP group and configure a virtual gateway IP address for the VRRP group. On the backup device, use the default VRRP priority (100). No monitoring port needs to be configured.

```
DeviceB(config)# interface vlan 10
DeviceB(config-if-VLAN 10)# ip address 192.168.10.2 255.255.255.0
DeviceB(config-if-VLAN 10)# vrrp 10 ip 192.168.10.1
DeviceB(config-if-VLAN 10)# exit
DeviceB(config)# interface vlan 30
DeviceB(config-if-VLAN 30)# ip address 192.168.30.2 255.255.255.0
DeviceB(config-if-VLAN 30)# vrrp 30 ip 192.168.30.1
DeviceB(config-if-VLAN 30)# exit
```

(4) Configure VRRP for VLAN 20 and VLAN 40 on core devices.

Configure the master device (Device B). Enter an SVI and configure an SVI address. Add the SVI to the VRRP group and configure a virtual gateway IP address for the VRRP group. Raise the VRRP priority to 120, configure port GigabitEthernet 0/5 as a monitoring port, and set priority decrement to 30.

```
DeviceB(config)# interface vlan 20
DeviceB(config-if-VLAN 20)# ip address 192.168.20.3 255.255.255.0
DeviceB(config-if-VLAN 20)# vrrp 20 ip 192.168.20.1
DeviceB(config-if-VLAN 20)# vrrp 20 priority 120
DeviceB(config-if-VLAN 20)# vrrp 20 track gigabitethernet 0/5 30
DeviceB(config-if-VLAN 20)# exit
DeviceB(config)# interface vlan 40
DeviceB(config-if-VLAN 40)# ip address 192.168.40.3 255.255.255.0
DeviceB(config-if-VLAN 40)# vrrp 40 ip 192.168.40.1
DeviceB(config-if-VLAN 40)# vrrp 40 priority 120
DeviceB(config-if-VLAN 40)# vrrp 40 track gigabitethernet 0/5 30
DeviceB(config-if-VLAN 40)# exit
```

Configure the backup device (Device A). Enter an SVI and configure an SVI address. Add the SVI to the VRRP group and configure a virtual gateway IP address for the VRRP group. On the backup device, use the default VRRP priority (100). No monitoring port needs to be configured.

```
DeviceA(config)# interface vlan 20
DeviceA(config-if-VLAN 20)# ip address 192.168.20.2 255.255.255.0
DeviceA(config-if-VLAN 20)# vrrp 20 ip 192.168.20.1
DeviceA(config-if-VLAN 20)# exit
DeviceA(config)# interface vlan 40
DeviceA(config-if-VLAN 40)# ip address 192.168.40.2 255.255.255.0
DeviceA(config-if-VLAN 40)# vrrp 40 ip 192.168.40.1
DeviceA(config-if-VLAN 40)# exit
```

(5) Configure an aggregate link between VRRP core devices.

On Device A, configure ports GigabitEthernet 0/3 and 0/4 as AggregatePort 1 and set the aggregate interface to work in trunk mode.

```
DeviceA(config)# interface range gigabitethernet 0/3-4
DeviceA(config-if-range)# port-group 1
DeviceA(config-if-range)# exit
DeviceA(config)# interface aggregateport 1
DeviceA(config-if-AggregatePort 1)# switchport
DeviceA(config-if-AggregatePort 1)# switchport mode trunk
DeviceA(config-if-AggregatePort 1)# switchport trunk native vlan 1
DeviceA(config-if-AggregatePort 1)# switchport trunk allowed vlan all
DeviceA(config-if-AggregatePort 1)# exit
```

On Device B, configure ports GigabitEthernet 0/3 and 0/4 as AggregatePort 1 and set the aggregate interface to work in trunk mode.

```
DeviceB(config)# interface range gigabitethernet 0/3-4
DeviceB(config-if-range)# port-group 1
DeviceB(config-if-range)# exit
DeviceB(config)# interface aggregateport 1
```

```
DeviceB(config-if-AggregatePort 1)# switchport
DeviceB(config-if-AggregatePort 1)# switchport mode trunk
DeviceB(config-if-AggregatePort 1)# switchport trunk native vlan 1
DeviceB(config-if-AggregatePort 1)# switchport trunk allowed vlan all
DeviceB(config-if-AggregatePort 1)# exit
```

(6) Configure the downlink ports of core devices and the uplink ports of access devices as trunk ports.

Configure downlink ports GigabitEthernet 0/1–0/2 of Device A as trunk ports.

```
DeviceA(config)# interface range gigabitethernet 0/1-2
DeviceA(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode trunk
DeviceA(config-if-range)# switchport trunk native vlan 1
DeviceA(config-if-range)# switchport trunk allowed vlan all
DeviceA(config-if-range)# end
DeviceA# write
```

Configure downlink ports GigabitEthernet 0/1–0/2 of Device B as trunk ports.

```
DeviceB(config)# interface range gigabitethernet 0/1-2
DeviceB(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode trunk
DeviceA(config-if-range)# switchport trunk native vlan 1
DeviceA(config-if-range)# switchport trunk allowed vlan all
DeviceB(config-if-range)# end
DeviceB# write
```

Configure uplink ports GigabitEthernet 0/1–0/2 of Device C as trunk ports.

```
DeviceC(config)# interface range gigabitethernet 0/1-2
DeviceC(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode trunk
DeviceA(config-if-range)# switchport trunk native vlan 1
DeviceA(config-if-range)# switchport trunk allowed vlan all
DeviceC(config-if-range)# exit
```

Configure uplink ports GigabitEthernet 0/1–0/2 of Device D as trunk ports.

```
DeviceD(config)# interface range gigabitethernet 0/1-2
DeviceD(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode trunk
DeviceA(config-if-range)# switchport trunk native vlan 1
DeviceA(config-if-range)# switchport trunk allowed vlan all
DeviceD(config-if-range)# exit
```

(7) Set user ports on access devices to work in access mode and add them to VLANs..

Configure Device C.

```
DeviceC(config)# interface gigabitethernet 0/3
DeviceC(config-if-GigabitEthernet 0/3)# switchport
DeviceC(config-if-GigabitEthernet 0/3)# switchport mode access
DeviceC(config-if-GigabitEthernet 0/3)# switchport access vlan 10
DeviceC(config-if-GigabitEthernet 0/3)# exit
```

```
DeviceC(config)# interface gigabitethernet 0/4
DeviceC(config-if-GigabitEthernet 0/4)# switchport
DeviceC(config-if-GigabitEthernet 0/3)# switchport mode access

DeviceD(config-if-GigabitEthernet 0/6)# switchport access vlan 40
DeviceD(config-if-GigabitEthernet 0/6)# end
DeviceD# write
```

5. Verification

Run the **show spanning-tree summary** command to display the spanning tree topology.

View spanning tree topology on Device A. Device A (00d0.f822.3344) is the root.

```
DeviceA# show spanning-tree summary
Spanning tree enabled protocol mstp
```

```

7. Common Errors

- In the MSTP+VRRP topology, the MST region configurations on different devices are different.
- VLANs are not created before the mappings between instances and VLANs are configured.
- In the MSTP+VRRP topology, if some devices run STP or RSTP, the devices will be considered as different MST regions for spanning tree calculation. In this case, the calculated spanning tree will be different from expectations.

1.25.3 Configuring Spanning Tree Compatibility for MSTP Interfaces

1. Requirements

In the topology as shown in **Figure 1-20**, enable MSTP on Device A and Device B and configure the same instance mappings on the devices: Associate instance 1 with VLAN 10 and add port GigabitEthernet 0/1 to VLAN 10; associate instance 2 with VLAN 20 and add port GigabitEthernet 0/2 to VLAN 20. Configure spanning tree compatibility for interfaces so that BPDUs sent by interfaces carry only information about instances corresponding to the VLANs, to which the interfaces belong.

2. Topology

Figure 1-20 Topology of Spanning Tree Compatibility for MSTP Interfaces

3. Notes

- Adopt the same configurations on Device A and Device B. The following uses Device A as an example.
- Create VLAN 10, VLAN 20, instance 1, and instance 2. Associate instance 1 with VLAN 10 and instance 2 with VLAN 20. Add port GigabitEthernet 0/1 to VLAN 10 and port GigabitEthernet 0/2 to VLAN 20, and configure spanning tree compatibility for the ports. Enable the STP function.

4. Procedure

(1) Create VLAN 10, VLAN 20, instance 1, and instance 2. Associate instance 1 with VLAN 10 and instance 2 with VLAN 20.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan range 10,20
DeviceA(config-vlan-range)# exit
DeviceA(config)# spanning-tree mst configuration
DeviceA(config-mst)# instance 1 vlan 10
DeviceA(config-mst)# instance 2 vlan 20
DeviceA(config-mst)# exit
```

(2) Add port GigabitEthernet 0/1 to VLAN 10 and port GigabitEthernet 0/2 to VLAN 20, and configure spanning tree compatibility for the ports.

```
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# switchport
DeviceA(config-if-GigabitEthernet 0/1)# switchport mode access
DeviceA(config-if-GigabitEthernet 0/1)# switchport access vlan 10
DeviceA(config-if-GigabitEthernet 0/1)# spanning-tree compatible enable
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# switchport
DeviceA(config-if-GigabitEthernet 0/2)# switchport mode access
DeviceA(config-if-GigabitEthernet 0/2)# switchport access vlan 20
DeviceA(config-if-GigabitEthernet 0/2)# spanning-tree compatible enable
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

(3) Enable the STP function.

```
DeviceA(config)# spanning-tree
DeviceA(config)# end
DeviceA# write
```

5. Verification

(1) If no spanning tree compatibility is configured for interfaces, check the spanning tree configuration as follows.

Device A becomes the root of Device B because its bridge ID is smaller. Ports GigabitEthernet 0/1 and GigabitEthernet 0/2 of Device A are designated ports in their respective instances.

```
DeviceA# show spanning-tree summary
Spanning tree enabled protocol mstp

```

Check Device B. In the spanning tree of instance 1, port GigabitEthernet 0/1 belonging to VLAN 10 is the root port and port GigabitEthernet 0/2 belonging to VLAN 20 is the alternate port. Port GigabitEthernet 0/2 rejects traffic of VLAN 10 to pass. Therefore, the alternate port cannot serve as an alternative to the root port. In the spanning tree of instance 2, port GigabitEthernet 0/2 belonging to VLAN 20 is the root port and port GigabitEthernet 0/1 belonging to VLAN 10 is the alternate port. Port GigabitEthernet 0/1 rejects traffic of VLAN 20 to pass. Therefore, the alternate port cannot serve as an alternative to the root port.

6. Configuration Files

Configuration files of Devices A and B

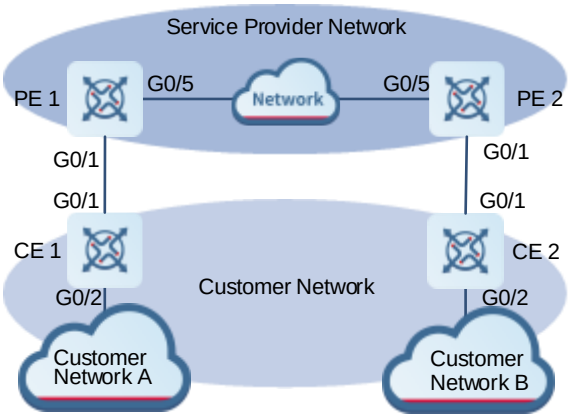
```
spanning-tree mst configuration
 instance 0 vlan 1-9, 11-19, 21-4094
 instance 1 vlan 10
 instance 2 vlan 20
!
spanning-tree
!
vlan range 1,10,20
!
interface GigabitEthernet 0/1
switchport
switchport mode access
 switchport access vlan 10
spanning-tree compatible enable
!
interface GigabitEthernet 0/2
switchport
switchport mode access
```

```
switchport access vlan 20
spanning-tree compatible enable
```

7. Common Errors

- If the VLAN lists configured on interfaces at both ends of a link are inconsistent, communication may fail after VLANs are pruned by the spanning tree compatibility function of the interfaces.
- If different instances are not configured or interfaces permit the traffic of all VLANs to pass, the spanning tree compatibility function cannot perform spanning tree pruning based on instances. In this case, there is no necessary to configure the spanning tree compatibility function.

1.25.4 Configuring BPDU Tunnel



1. Requirements

In the typical QinQ network topology shown in Figure 1-21, the upper part is the service provider network while the lower part is the customer network. The service provider network consists of two PEs: PE 1 and PE 2. Customer Network A and Customer Network B are two sites of the same customer in different regions. CE 1 and CE 2 are access devices for connecting the customer networks to the service provider network, and they connect to the service provider network respectively through PE 1 and PE 2.

Configure a Layer 2 protocol tunnel to transparently transmit Layer 2 protocol packets from the customer network at one end to the customer network at the other end so that the spanning trees of the customer network and service provider network are separately calculated without interference. According to the needs of the customer, configure the STP tunnel function to transmit BPDUs from the customer network through a tunnel in the service provider network so that the spanning tree is calculated in a unified manner for the cross-region customer network, independent of the service provider network.

2. Topology

Figure 1-21 Topology of Configuring BPDU Tunnel

3. Notes

- Configure MSTP on PE 1 and PE 2. Configure the bridge priority to make PE 1 become the root of instances 0 and 1, and PE 2 the root of instance 2. Enable STP.
- Configure the QinQ encapsulation mode (for example, basic QinQ) on PE 1 and PE 2. Configure VLAN 10 as the native VLAN of Dot1q-tunnel ports and add VLAN 10 to the permitted untagged VLAN list of the

tunnel ports. Configure VLAN 10 as the public network transmission channel. VLAN 10 is encapsulated into the user data packets before they are forwarded in the public network. Configure port GigabitEthernet 0/1 as a Dot1q-tunnel port and enable the STP tunnel function. Enable the global STP tunnel function.

- Configure the uplink ports of PE 1 and PE 2 as the uplink ports.
- Configure STP on CE 1 and CE 2. Set the bridge priority to 0, configure timer parameters, and enable STP on CE 1.
- Configure the uplink and downlink ports of CE 1 and CE 2 as trunk ports.

4. Procedure

(1) Configure MSTP on PE 1 and PE 2.

Set the bridge priority to 4094 for instances 0 and 1 and 8192 for instance 2 on PE 1.

```
PE1> enable
PE1# configure terminal
PE1(config)# vlan range 10,20,30,40
PE1(config-vlan-range)# exit
PE1(config)# spanning-tree mst configuration
PE1(config-mst)# instance 1 vlan 10,30
PE1(config-mst)# instance 2 vlan 20,40
PE1(config-mst)# spanning-tree mst 0 priority 4096
PE1(config)# spanning-tree mst configuration
PE1(config-mst)# spanning-tree mst 1 priority 4096
PE1(config)# spanning-tree mst configuration
PE1(config-mst)# spanning-tree mst 2 priority 8192
PE1(config)# spanning-tree
```

Set the bridge priority to 4094 for instance 2 and 8192 for instances 0 and 1 on PE 2.

```
PE2> enable
PE2# configure terminal
PE2(config)# vlan range 10,20,30,40
PE2(config-vlan-range)# exit
PE2(config)# spanning-tree mst configuration
PE2(config-mst)# instance 1 vlan 10,30
PE2(config-mst)# instance 2 vlan 20,40
PE2(config-mst)# spanning-tree mst 0 priority 8192
PE2(config)# spanning-tree mst configuration
PE2(config-mst)# spanning-tree mst 1 priority 8192
PE2(config)# spanning-tree mst configuration
PE2(config-mst)# spanning-tree mst 2 priority 4096
PE2(config)# spanning-tree
```

(2) Configure the basic QinQ transmission channel VLAN 10 on PE 1 and PE 2. Enable the interface STP tunnel function and global STP tunnel function. The configurations on PE 1 are the same as those on PE 2. The following uses PE 1 as an example.

```
PE1(config)# interface gigabitethernet 0/1
PE1(config-if-GigabitEthernet 0/1)# switchport
PE1(config-if-GigabitEthernet 0/1)# switchport mode dot1q-tunnel
```

```
PE1(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel native vlan 10
PE1(config-if-GigabitEthernet 0/1)# switchport dot1q-tunnel allowed vlan add
untagged 10
PE1(config-if-GigabitEthernet 0/1)# l2protocol-tunnel stp enable
PE1(config-if-GigabitEthernet 0/1)# exit
PE1(config)# l2protocol-tunnel stp
```

(3) Configure the uplink ports of PE 1 and PE 2 as the uplink ports. The configurations on PE 1 are the same as those on PE 2. The following uses PE 1 as an example.

```
PE1(config)# interface gigabitethernet 0/5
PE1(config-if-GigabitEthernet 0/5)# switchport
PE1(config-if-GigabitEthernet 0/5)# switchport mode uplink
PE1(config-if-GigabitEthernet 0/5)# switchport trunk native vlan 1
PE1(config-if-GigabitEthernet 0/5)# switchport trunk allowed vlan all
PE1(config-if-GigabitEthernet 0/5)# end
PE1# write
```

(4) Configure STP on CE 1 and CE 2.

Set the spanning tree mode to STP and bridge priority to 0, configure timer parameters, and enable STP on CE 1.

```
CE1> enable
CE1# configure terminal
CE1(config)# spanning-tree mode stp
CE1(config)# spanning-tree priority 0
CE1(config)# spanning-tree hello-time 4
CE1(config)# spanning-tree max-age 25
CE1(config)# spanning-tree forward-time 18
CE1(config)# spanning-tree
```

Set the spanning tree mode to STP and enable STP on CE 2.

```
CE2> enable
CE2# configure terminal
CE2(config)# spanning-tree mode stp
CE2(config)# spanning-tree
```

(5) Configure the uplink and downlink ports of CE 1 and CE 2 as trunk ports. The configurations on CE 1 are the same as those on CE 2. The following uses CE 1 as an example.

```
CE1(config)# interface range gigabitethernet 0/1-2
CE1(config-if-range)# switchport
CE1(config-if-range)# switchport mode trunk
CE1(config-if-range)# switchport trunk native vlan 1
CE1(config-if-range)# switchport trunk allowed vlan all
CE1(config-if-range)# end
CE1# write
```

5. Verification

(1) Check Dot1q-tunnel port configurations on PE 1 and PE 2. The configurations on PE 1 are the same as those on PE 2. The following uses PE 1 as an example.

```
PE1# show interfaces dot1q-tunnel
========Interface Gi0/1========
Native vlan: 10
Allowed vlan list:1,10,
Tagged vlan list:
```

(2) Verify that the STP tunnel function is enabled in both global configuration mode and interface configuration mode on PE 1 and PE 2. The configurations on PE 1 are the same as those on PE 2. The following uses PE 1 as an example.

```
PE1# show l2protocol-tunnel stp
L2protocol-tunnel: Stp Enable
L2protocol-tunnel destination mac address: 01d0.f800.0005
GigabitEthernet 0/1 l2protocol-tunnel stp enable
```

(3) Check that PE 1 and PE 2 have independent spanning tree topologies.

Check the spanning tree topology on PE 1. For instances 0 and 1, PE 1 is the root of PE 2 and port GigabitEthernet 0/5 is the designated port. For instance 2, PE 2 is the root of PE 1 and port GigabitEthernet 0/5 is the root port. Port GigabitEthernet 0/1 that connects to CE 1 of the customer network is not included in the spanning tree topologies of PE 1 and PE 2. The spanning tree time parameters (**Hello Time**: **2 sec**; **Forward Delay**: **15 sec**; **Max Age**: **20 sec**) of PE 1 use default values and are not affected by the configurations of CE 1.

```
PE1# show spanning-tree summary

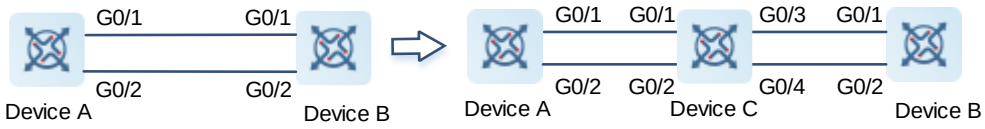
7. Common Errors

- The Layer 2 protocol tunnel function is not enabled in both global configuration mode and interface configuration mode. As a result, the BPDU tunnel function does not take effect.
- The BPDU tunnel addresses configured in the service provider network are inconsistent. As a result, BPDU frames from the customer network cannot be correctly transmitted.



1.25.5 Configuring BPDU Transparent Transmission

1. Requirements

In the topology as shown in Figure 1-22, Device A is connected to Device B and MSTP is enabled on them. Device A is the root of Device B. One Device C with STP disabled is added between Device A and Device B. Configure the BPDU transparent transmission function on Device C to transmit STP packets of Device A and Device B so that Device A and Device B can still conduct calculation together and generate spanning trees.

2. Topology

Figure 1-22 Topology of Configuring BPDU Transparent Transmission

3. Notes

- On Device A, configure STP, set the bridge priority to 0 (smaller than the default value **32768**), and set the priority of port GigabitEthernet 0/2 to 16 (smaller than the default value **128**). In this way, Device A becomes the root bridge of Device B and port GigabitEthernet 0/2 of Device B becomes the root port.
- Enable STP on Device B.
- Configure BPDU transparent transmission on Device C.
- Configure interconnected ports as trunk ports.

4. Procedure

(1) On Device A, configure the interconnected ports as trunk ports. Configure the device priority and port priority and enable the STP function.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# spanning-tree mst 0 priority 0
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# switchport
DeviceA(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
DeviceA(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# switchport
DeviceA(config-if-GigabitEthernet 0/2)# switchport mode trunk
DeviceA(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
DeviceA(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan all
DeviceA(config-if-GigabitEthernet 0/2)# spanning-tree mst 0 port-priority 16
DeviceA(config-if-GigabitEthernet 0/2)# exit
DeviceA(config)# spanning-tree
```

(2) On Device B, enable the STP function and configure the interconnected ports as trunk ports.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# spanning-tree
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# switchport
DeviceB(config-if-GigabitEthernet 0/1)# switchport mode trunk
DeviceB(config-if-GigabitEthernet 0/1)# switchport trunk native vlan 1
DeviceB(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan all
DeviceB(config-if-GigabitEthernet 0/1)# exit
DeviceB(config)# interface gigabitethernet 0/2
DeviceB(config-if-GigabitEthernet 0/2)# switchport
DeviceB(config-if-GigabitEthernet 0/2)# switchport mode trunk
DeviceB(config-if-GigabitEthernet 0/2)# switchport trunk native vlan 1
DeviceB(config-if-GigabitEthernet 0/2)# switchport trunk allowed vlan all
```

(3) On Device C, configure BPDU transparent transmission and configure the interconnected ports as trunk ports.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# no spanning-tree
DeviceC(config)# bridge-frame forwarding protocol bpdu
DeviceC(config)# interface range gigabitethernet 0/1-4
DeviceC(config-if-rang)# switchport
DeviceC(config-if-rang)# switchport mode trunk
DeviceC(config-if-rang)# switchport trunk native vlan 1
DeviceC(config-if-rang)# switchport trunk allowed vlan all
```

5. Verification

(1) When Device C is not connected, check the spanning tree topology.

Check the spanning tree topology of Device A. Device A is the root.

```
DeviceA# show spanning-tree summary
Spanning tree enabled protocol mstp
MST 0 vlans map : ALL
  Root ID    Priority    0
             Address     0074.9cee.53ca
             this bridge is root
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

  Bridge ID  Priority    0
             Address     0074.9cee.53ca
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

Interface       Role Sts Cost      Prio    OperEdge Type
---------------- ---- --- ---------- -------- -------- ----------------
Gi0/1           Desg FWD 20000     128     False    P2p
Gi0/2           Desg FWD 20000     16      False    P2p
```

Check the spanning tree topology of Device B. Device A is the root of Device B. The port priority of Device A is changed. Therefore, port GigabitEthernet 0/2 of Device B becomes the root port and port GigabitEthernet 0/1 becomes an alternate port.

```
DeviceB# show spanning-tree summary
Spanning tree enabled protocol mstp
MST 0 vlans map : ALL
  Root ID    Priority    0
             Address     0074.9cee.53ca
             this bridge is root
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

  Bridge ID  Priority    8192
             Address     00d0.f8ee.8c1e
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

Interface       Role Sts Cost      Prio    OperEdge Type
---------------- ---- --- ---------- -------- -------- ----------------
Gi0/1           Altn BLK 20000     128     False    P2p
Gi0/2           Root FWD 20000     128     False    P2p
```

(2) After Device C is connected to the topology, check the spanning tree topology.

Check the spanning tree topology on Device A. The spanning tree topology of Device A keeps unchanged.

```
DeviceA# show spanning-tree summary
Spanning tree enabled protocol mstp
MST 0 vlans map : ALL
  Root ID    Priority    0
             Address     0074.9cee.53ca
             this bridge is root
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec
```

```
  Bridge ID  Priority    0
           Address     0074.9cee.53ca
           Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

Interface       Role Sts Cost      Prio    OperEdge Type
---------------- ---- --- ---------- -------- -------- ----------------
Gi0/1           Desg FWD 20000     128     False    P2p
Gi0/2           Desg FWD 20000     16      False    P2p
```

Check the spanning tree topology on Device B. Device A is still the root of Device B, but port GigabitEthernet 0/1 of Device B becomes the root port, and port GigabitEthernet 0/2 becomes an alternate port. After Device C is configured to transparently transmit STP packets, ports GigabitEthernet 0/1 and 0/2 of Device B can receive BPDUs from port GigabitEthernet 0/2 of Device A. Therefore, the root port cannot be elected based on the port priority and port GigabitEthernet 0/1 of Device B is elected as the root port because of its smaller port ID.

```
DeviceB# show spanning-tree summary
Spanning tree enabled protocol mstp
MST 0 vlans map : ALL
  Root ID    Priority    0
           Address     0074.9cee.53ca
           this bridge is root
           Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

  Bridge ID  Priority    8192
           Address     00d0.f8ee.8c1e
           Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

switchport trunk allowed vlan only 1-4094
```

1.25.6 Configuring V-STP

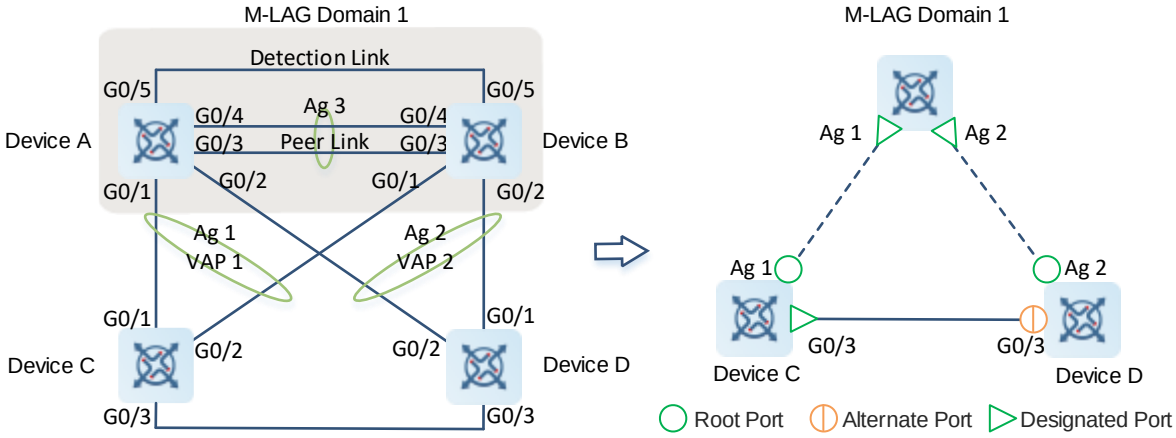
1. Requirements

In the topology as shown in Figure 1-23, Device A and Device B form an M-LAG Domain 1. aggregate interface

- GigabitEthernet 0/3 and 0/4 join AggregatePort 3, which is used as the peer link of M-LAG to synchronize data and transmit partial traffic.

As the dual-active detection link of Device A and Device B, Gigabit Ethernet 0/5 is used to detect the dual-active status of M-LAG devices when the Peer Link fails.

- The two GigabitEthernet 0/1 interfaces of the downstream Device C are added to AggregatePort 1 as VAP 1 of the M-LAG.
- The two GigabitEthernet 0/2 interfaces of the downstream Device D are added to AggregatePort 2 as VAP 2 of the M-LAG.



Uplink ports GigabitEthernet 0/1 and 0/2 of Device C are added to AggregatePort 1.

Uplink ports GigabitEthernet 0/1 and 0/2 of Device D are added to AggregatePort 2.

To prevent Layer 2 loops, you can configure a bridge priority of 4094 for Device A and Device B, enable the V-STP virtual spanning tree function on Device A and Device B to virtualize Device A and Device B into M-LAG Domain 1 for spanning tree calculation, and enable the normal spanning tree function on Device C and Device D.

2. Topology

Figure 1-23 Topology of Configuring V-STP

3. Procedure

(1) Configure the M-LAG function on Device A.

(2) Create AggregatePort 3 and configure it as a Peer Link port. Configure GigabitEthernet 0/3 and 0/4 as member ports of AggregatePort 3.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface aggregateport 3
DeviceA(config-if-AggregatePort 3)# switchport
```

```
DeviceA(config-if-AggregatePort 3)# switchport mode trunk
DeviceA(config-if-AggregatePort 3)# switchport trunk native vlan 1
DeviceA(config-if-AggregatePort 3)# switchport trunk allowed vlan all
DeviceA(config-if-AggregatePort 3)# peer-link
DeviceA(config-if-AggregatePort 3)# exit
DeviceA(config)# interface gigabitethernet 0/3
DeviceA(config-if-GigabitEthernet 0/3)# description
link-to-DeviceB-G0/3-peerlink
DeviceA(config-if-GigabitEthernet 0/3)# port-group 3 mode active
DeviceA(config-if-GigabitEthernet 0/3)# exit
DeviceA(config)# interface gigabitethernet 0/4
DeviceA(config-if-GigabitEthernet 0/4)# description
link-to-DeviceB-G0/4-peerlink
DeviceA(config-if-GigabitEthernet 0/4)# port-group 3 mode active
DeviceA(config-if-GigabitEthernet 0/4)# exit
```

Configure the IP address of the Layer 3 SVI of the Peer Link as 20.20.20.1/24.

```
DeviceA(config)# interface vlan 1
DeviceA(config-if-VLAN 1)# ip address 20.20.20.2/24
DeviceA(config-if-VLAN 1)# exit
```

Configure the IP address of the local port Gigabit Ethernet 0/5 of the dual-active detection channel as 192.168.3.1/24.

```
DeviceA(config)# interface gigabitethernet 0/5
DeviceA(config-if-GigabitEthernet 0/5)# description link-to-DeviceB-G0/5
DeviceA(config-if-GigabitEthernet 0/5)# no switchport
DeviceA(config-if-GigabitEthernet 0/5)# ip address 192.168.3.1/24
DeviceA(config-if-GigabitEthernet 0/5)# exit
```

Configure the VAP domain ID as 1 and enter the VAP domain configuration mode. Configure the local IP address of the data synchronization channel as 20.20.20.1, and the peer IP address as 20.20.20.2. Configure the local IP address of the dual-active detection channel as 192.168.3.1, and the peer IP address as 192.168.3.2.

```
DeviceA(config)# vap domain 1
DeviceA(config-vap-domain)# data-sync local 20.20.20.1 peer 20.20.20.2
DeviceA(config-vap-domain)# peer-keepalive local 192.168.3.1 peer 192.168.3.2
DeviceA(config-vap-domain)# exit
```

Configure VAP 1: Create AggregatePort 1 and join VAP 1. Configure GigabitEthernet 0/1 of the downstream Device C as a member port of AggregatePort 1.

```
DeviceA(config)# interface aggregateport 1
DeviceA(config-if-AggregatePort 1)# switchport
DeviceA(config-if-AggregatePort 1)# switchport mode trunk
DeviceA(config-if-AggregatePort 1)# switchport trunk native vlan 1
DeviceA(config-if-AggregatePort 1)# switchport trunk allowed vlan all
DeviceA(config-if-AggregatePort 1)# vap 1
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# description link-to-DeviceC-G0/1
```

```
DeviceA(config-if-GigabitEthernet 0/1)# port-group 1 mode active
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Configure VAP 2: Create AggregatePort 2 and join VAP 2. Configure GigabitEthernet 0/2 of the downstream Device D as a member port of AggregatePort 2.

```
DeviceA(config)# interface aggregateport 2
DeviceA(config-if-AggregatePort 2)# switchport
DeviceA(config-if-AggregatePort 2)# switchport mode trunk
DeviceA(config-if-AggregatePort 2)# switchport trunk native vlan 1
DeviceA(config-if-AggregatePort 2)# switchport trunk allowed vlan all
DeviceA(config-if-AggregatePort 2)# vap 2
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# description link-to-DeviceD-G0/2
DeviceA(config-if-GigabitEthernet 0/2)# port-group 2 mode active
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

(3) Configure the M-LAG function on Device B.

Create AggregatePort 3 and configure it as the Peer Link port. Configure GigabitEthernet 0/3 and 0/4 as member ports of AggregatePort 3.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# interface aggregateport 3
DeviceB(config-if-AggregatePort 3)# switchport
DeviceB(config-if-AggregatePort 3)# switchport mode trunk
DeviceB(config-if-AggregatePort 3)# switchport trunk native vlan 1
DeviceB(config-if-AggregatePort 3)# switchport trunk allowed vlan all
DeviceB(config-if-AggregatePort 3)# peer-link
DeviceB(config-if-AggregatePort 3)# exit
DeviceB(config)# interface gigabitethernet 0/3
DeviceB(config-if-GigabitEthernet 0/3)# description
link-to-DeviceA-G0/3-peerlink
DeviceB(config-if-GigabitEthernet 0/3)# port-group 3 mode active
DeviceB(config-if-GigabitEthernet 0/3)# exit
DeviceB(config)# interface gigabitethernet 0/4
DeviceB(config-if-GigabitEthernet 0/4)# description
link-to-DeviceA-G0/4-peerlink
DeviceB(config-if-GigabitEthernet 0/4)# port-group 3 mode active
DeviceB(config-if-GigabitEthernet 0/4)# exit
```

Configure the IP address of the Layer 3 SVI of the Peer Link as 20.20.20.2/24.

```
DeviceB(config)# interface vlan 1
DeviceB(config-if-VLAN 1)# ip address 20.20.20.1/24
DeviceB(config-if-VLAN 1)# exit
```

Configure the IP address of the local GigabitEthernet 0/5 of the dual-active detection channel as 192.168.3.2/24.

```
DeviceB(config)# interface gigabitethernet 0/5
DeviceB(config-if-GigabitEthernet 0/5)# description link-to-DeviceA-G0/5
```

```
DeviceB(config-if-GigabitEthernet 0/5)# no switchport
DeviceB(config-if-GigabitEthernet 0/5)# ip address 192.168.3.2/24
```

Configure the VAP domain ID as 1 and enter the VAP domain configuration mode. Configure the local IP address of the data synchronization channel as 20.20.20.2, and the peer IP address as 20.20.20.1. Configure the local IP address of the dual-active detection channel as 192.168.3.2, and the peer IP address as 192.168.3.1.

```
DeviceB(config)# vap domain 1
DeviceB(config-vap-domain)# data-sync local 20.20.20.2 peer 20.20.20.1
DeviceB(config-vap-domain)# peer-keepalive local 192.168.3.2 peer 192.168.3.1
DeviceB(config-vap-domain)# exit
```

Configure VAP 1: Create AggregatePort 1 and join VAP 1. Configure GigabitEthernet 0/1 of the downstream Device C as a member port of AggregatePort 1.

```
DeviceB(config)# interface aggregateport 1
DeviceB(config-if-AggregatePort 1)# switchport
DeviceB(config-if-AggregatePort 1)# switchport mode trunk
DeviceB(config-if-AggregatePort 1)# switchport trunk native vlan 1
DeviceB(config-if-AggregatePort 1)# switchport trunk allowed vlan all
DeviceB(config-if-AggregatePort 1)# vap 1
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# description link-to-DeviceC-G0/2
DeviceB(config-if-GigabitEthernet 0/1)# port-group 1 mode active
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Configure VAP 2: Create AggregatePort 2 and join VAP 2. Configure GigabitEthernet 0/2 of the downstream Device D as a member port of AggregatePort 2.

```
DeviceB(config)# interface aggregateport 2
DeviceB(config-if-AggregatePort 2)# switchport
DeviceB(config-if-AggregatePort 2)# switchport mode trunk
DeviceB(config-if-AggregatePort 2)# switchport trunk native vlan 1
DeviceB(config-if-AggregatePort 2)# switchport trunk allowed vlan all
DeviceB(config-if-AggregatePort 2)# vap 2
DeviceB(config)# interface gigabitethernet 0/2
DeviceB(config-if-GigabitEthernet 0/2)# description link-to-DeviceD-G0/1
DeviceB(config-if-GigabitEthernet 0/2)# port-group 2 mode active
DeviceB(config-if-GigabitEthernet 0/2)# exit
```

(4) Create AggregatePort 1 on Device C, and configure the uplink interfaces GigabitEthernet 0/1 and 0/2 as member ports of AggregatePort 1.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# interface aggregateport 1
DeviceC(config-if-AggregatePort 1)# switchport
DeviceC(config-if-AggregatePort 1)# switchport mode trunk
DeviceC(config-if-AggregatePort 1)# switchport trunk native vlan 1
DeviceC(config-if-AggregatePort 1)# switchport trunk allowed vlan all
DeviceC(config-if-AggregatePort 1)# exit
```

```
DeviceC(config)# interface gigabitethernet 0/1
DeviceC(config-if-GigabitEthernet 0/1)# description link-to-DeviceA-G0/1
DeviceC(config-if-GigabitEthernet 0/1)# switchport
DeviceC(config-if-GigabitEthernet 0/1)# port-group 1 mode active
DeviceC(config-if-GigabitEthernet 0/1)# exit
DeviceC(config)# interface gigabitethernet 0/2
DeviceC(config-if-GigabitEthernet 0/2)# description link-to-DeviceB-G0/1
DeviceC(config-if-GigabitEthernet 0/2)# switchport
DeviceC(config-if-GigabitEthernet 0/2)# port-group 1 mode active
DeviceC(config-if-GigabitEthernet 0/2)# exit
```

(5) Create AggregatePort 2 on Device D, and configure the uplink interfaces GigabitEthernet 0/1 and 0/2 as member ports of AggregatePort 2.

```
DeviceD> enable
DeviceD# configure terminal
DeviceD(config)# interface aggregateport 2
DeviceD(config-if-AggregatePort 2)# switchport
DeviceD(config-if-AggregatePort 2)# switchport mode trunk
DeviceD(config-if-AggregatePort 2)# switchport trunk native vlan 1
DeviceD(config-if-AggregatePort 2)# switchport trunk allowed vlan all
DeviceD(config-if-AggregatePort 2)# exit
DeviceD(config)# interface gigabitethernet 0/1
DeviceD(config-if-GigabitEthernet 0/1)# description link-to-DeviceB-G0/2
DeviceD(config-if-GigabitEthernet 0/1)# switchport
DeviceD(config-if-GigabitEthernet 0/1)# port-group 2 mode active
DeviceD(config-if-GigabitEthernet 0/1)# exit
DeviceD(config)# interface gigabitethernet 0/2
DeviceD(config-if-GigabitEthernet 0/2)# description link-to-DeviceA-G0/2
DeviceD(config-if-GigabitEthernet 0/2)# switchport
DeviceD(config-if-GigabitEthernet 0/2)# port-group 2 mode active
DeviceD(config-if-GigabitEthernet 0/2)# exit
```

(6) Configure a virtual spanning tree on Device A and Device B. The default MSTP mode is adopted, and the spanning tree configuration on Device A and Device B must be consistent.

On Decide A, configure the bridge priority as 4096, and enable the V-STP spanning tree function.

```
DeviceA(config)# spanning-tree priority 4096
DeviceA(config)# spanning-tree
DeviceA(config)# spanning-tree v-stp enable
```

On Decide B, configure the bridge priority as 4096, and enable the V-STP spanning tree function.

```
DeviceB(config)# spanning-tree priority 4096
DeviceB(config)# spanning-tree
DeviceB(config)# spanning-tree v-stp enable
```

(7) Enable the normal spanning tree function on Device C and Device D.

Enable the spanning tree function on Device C.

```
DeviceC(config)# spanning-tree
```

Enable the spanning tree function on Device D.

```
DeviceD(config)# spanning-tree
```

4. Verification

(1) Run the **show vap summary** command to check whether M-LAG has been established successfully.

Check the establishment of M-LAG on Device A. Device A is the Master, AggregatePort 3 of the peer link is Up, and AggregatePort 1 and AggregatePort 2 of the downstream channel are Up.

```
DeviceA# show vap summary

M-LAG domain                : 1
M-LAG role                  : Master
Local address               : 20.20.20.1
Peer address                : 20.20.20.2
Negotiation status          : ok
Peer keepalive status       : alive
Consistency check mode      : disable

Peer-link       Status
---------------------------
Ag3             UP

Group ID  VAP Port  Local-Status  Peer-Status
---------------------------------------------
1       Ag1      UP          UP
2       Ag2      UP          UP
```

Check the establishment of M-LAG on Device B. Device B is the Slave, AggregatePort 3 of the peer link is Up, and AggregatePort 1 and AggregatePort 2 of the downstream channel are Up.

```
DeviceB# show vap summary
M-LAG domain                : 1
M-LAG role                  : Slave
Local address               : 20.20.20.2
Peer address                : 20.20.20.1
Negotiation status          : ok
Peer keepalive status       : alive
Consistency check mode      : disable

Peer-link       Status
---------------------------
Ag3             UP

Group ID  VAP Port  Local-Status  Peer-Status
---------------------------------------------
1       Ag1      UP          UP
2       Ag2      UP          UP
```

(2) Run the **show** spanning-tree v-stp **information** command to check whether the V-STP function is enabled.

Check whether the V-STP function is enabled on Device A. The value in Local bridge mac field indicates that the MAC address of local bridge is 00d0.f822.363c, and the value in Selected bridge mac field indicates that the MAC address of the virtual bridge is 00d0.f822.363c.

```
DeviceA# show spanning-tree v-stp information

V-STP status              : enable
Local bridge mac           : 00d0.f822.363c
Selected bridge mac        : 00d0.f822.363c
Peerlink Port             : AggregatePort3
Calculate Virtual Index    : 0
Mlag Remote device connected : Y

MST 0 Root Port        : None
```

Check whether the V-STP function is enabled on Device B. The value in Local bridge mac field indicates that the MAC address of local bridge is 8005.8822.b170, and the value in Selected bridge mac field indicates that the MAC address of the virtual bridge is 00d0.f822.363c.

```
DeviceB# show spanning-tree v-stp information

V-STP status              : enable
Local bridge mac           : 8005.8822.b170
Selected bridge mac        : 00d0.f822.363c
Peerlink Port             : AggregatePort 3
Calculate Virtual Index    : 4095
Mlag Remote device connected : Y

MST 0 Root Port        : None
```

(3) Run the **show spanning-tree summary** command to check the STP calculation results.

Check the STP calculation results of Device A. Device A (00d0.f822.363c) is the root. MAC address in the Bridge ID of the device is 00d0.f822.363c. AggregatePort 1 and AggregatePort 2 of Devcie A are Designated ports and are in Forwarding state.

```
DeviceA# show spanning-tree summary
Spanning tree enabled protocol mstp
MST 0 vlans map : ALL
  Root ID    Priority    4096
             Address     00d0.f822.363c
             this bridge is root
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

  Bridge ID  Priority    4096
             Address     00d0.f822.363c
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

Interface       Role Sts Cost      Prio    OperEdge Type
---------------- ---- --- ---------- -------- -------- ----------------
```

```
Ag1            Desg FWD 19000     128     False    P2p
Ag2            Desg FWD 19000     128     False    P2p
```

Check the STP calculation results of Device B. Device A (00d0.f822.363c) is the root. MAC address in the Bridge ID of the device is 00d0.f822.363c, not 8005.8822.b467, which is the MAC address of Device B, indicating that the V-STP function virtualizes the M-LAG active and standby devices into a bridge device M-LAG Domain 1 (00d0. f822.363c) for calculation, and the MAC address of Device A is the Bridge ID of M-LAG Domain 1. AggregatePort 1 and AggregatePort 2 of Devcie B are Designated ports and are in Forwarding state.

```
DeviceB#show spanning-tree summary
Spanning tree enabled protocol mstp
MST 0 vlans map : ALL
  Root ID    Priority    4096
             Address     00d0.f822.363c
             this bridge is root
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

  Bridge ID  Priority    4096
             Address     00d0.f822.363c
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

Interface       Role Sts Cost      Prio    OperEdge Type
---------------- ---- --- ---------- -------- -------- ----------------
Ag1            Desg FWD 19000     128     True     P2p
Ag2            Desg FWD 19000     128     False    P2p
```

Check the STP calculation results of Device C. M-LAG Domain 1 (00d0.f822.363c) formed by Device A and Device B is the root. AggregatePort 1 of Devcie C is the Root port, and GigabitEthernet 0/3 is the Designated port, and both ports are in Forwarding state.

```
DeviceC# show spanning-tree summary
Spanning tree enabled protocol mstp
MST 0 vlans map : ALL
  Root ID    Priority    4096
             Address     00d0.f822.363c
             this bridge is root
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

  Bridge ID  Priority    32768
             Address     0074.9cee.53ca
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

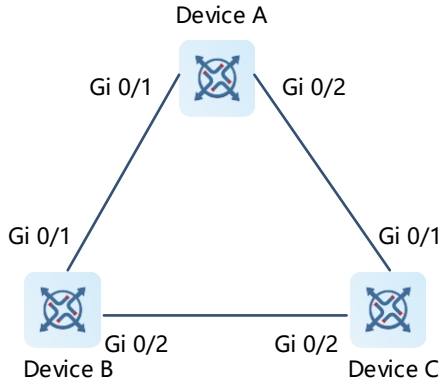
6. Common Errors

- If the M-LAG member devices are not connected successfully, the spanning tree cannot be virtualized successfully. In this case, check whether the state of the M-LAG aggregate interface is correct and whether the interface configuration is correct.
- V-STP is disabled on an M-LAG member device in the M-LAG scenario, leading to a V-STP calculation error.
- M-LAG member devices have different bridge priorities and MSTP region configurations, and APs added to the same VAP group have different port costs and port priorities, which result in a V-STP calculation error.



1.25.7 Configuring MVST

1. Requirements

As shown in Figure 1-18, Device A, Device B, and Device C form a loop topology. All the three devices must support MVST.

2. Topology

Figure 1-1 MVST Topology

3. Procedure

(1) Configure MVST on Device A.

Create VLANs 1–3 and configure the interfaces connecting to other devices as trunk interfaces.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# vlan rang 1-3
DeviceA(config-vlan-range)# exit
DeviceA(config)# interface range gigabitethernet 0/1-2
DeviceA(config-if-range)# switchport
DeviceA(config-if-range)# switchport mode trunk
```

Set the spanning tree mode to MVST, enable the STP function in VLANs 1–3, set the global bridge priority to 0 in VLANs 1–3, and then enable the STP function globally.

```
DeviceA(config)# spanning-tree mode mvst
DeviceA(config)# spanning-tree vlan 1-3
```

```
DeviceA(config)# spanning-tree vlan 1-3 priority 0
DeviceA(config)# spanning-tree
```

(2) Configure MVST on Device B.

Create VLANs 1–3 and configure the interfaces connecting to other devices as trunk interfaces.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# vlan rang 1-3
DeviceB(config-vlan-range)# exit
DeviceB(config)# interface range gigabitethernet 0/1-2
DeviceB(config-if-range)# switchport
DeviceB(config-if-range)# switchport mode trunk
```

Set the spanning tree mode to MVST, enable the STP function in VLANs 1–3, set the global bridge priority to 12288 in VLANs 1–3, and then enable the STP function globally.

```
DeviceB(config)# spanning-tree mode mvst
DeviceB(config)# spanning-tree vlan 1-3
DeviceB(config)# spanning-tree vlan 1-3 priority 12288
DeviceB(config)# spanning-tree
```

(3) Configure MVST on Device C.

Create VLANs 1–3 and configure the interfaces connecting to other devices as trunk interfaces.

```
DeviceC> enable
DeviceC# configure terminal
DeviceC(config)# vlan rang 1-3
DeviceC(config-vlan-range)# exit
DeviceC(config)# interface range gigabitethernet 0/1-2
DeviceC(config-if-range)# switchport
DeviceC(config-if-range)# switchport mode trunk
```

Set the spanning tree mode to MVST, enable the STP function in VLANs 1–3, and then enable the STP function globally.

```
DeviceC(config)# spanning-tree mode mvst
DeviceC(config)# spanning-tree vlan 1-3
DeviceC(config)# spanning-tree
```

4. Verification

(1) Run the **show spanning-tree vlan all** command to display the spanning tree status of all VLANs with MVST enabled.

Check whether the MVST configuration takes effect on Device A. In VLANs 1–3, Device A (c470.abe1.8856) is the root. In VLANs 1–3, GigabitEthernet 0/1 and GigabitEthernet 0/2 on Device A are designated ports (Desg) in Forwarding (FWD) state.

```
DeviceA# show spanning-tree vlan all

Spanning tree enabled protocol stp
VLAN 1 :
  Root ID    Priority    0
```

```
          System ID extension   1
          Address    c470.abe1.8856
          this bridge is root
          Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

  Bridge ID  Priority   0
          System ID extension   1
          Address    c470.abe1.8856
          Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

Gi0/2          Desg FWD 20000     128     False   P2p

VLAN 3 :
  Root ID   Priority   0
          System ID extension   3
          Address    c470.abe1.8856
          this bridge is Desg
          Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

  Bridge ID  Priority   0
          System ID extension   3
          Address    c470.abe1.8856
          Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

Interface       Role Sts Cost      Prio    OperEdge Type
---------------- ---- --- ---------- -------- -------- ----------------
```

```
Gi0/1          Desg FWD 20000     128     False   P2p
Gi0/2          Desg FWD 20000     128     False   P2p
```

Check whether the MVST configuration takes effect on Device B. In VLANs 1–3, Device A (c470.abe1.8856) is the root. In VLANs 1–3, GigabitEthernet 0/1 on Device B is root port (Root) in Forwarding (FWD) state and GigabitEthernet 0/2 on Device B is designated port (Desg) in Forwarding (FWD) state.

```
DeviceB# show spanning-tree vlan all

Spanning tree enabled protocol stp
VLAN 1 :
  Root ID    Priority    0
             System ID extension    1
             Address     c470.abe1.8856
             this bridge is root
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

  Bridge ID  Priority    12288
             System ID extension    1
             Address     c470.abe1.8860
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

Interface       Role Sts Cost      Prio    OperEdge Type
---------------- ---- --- ---------- -------- -------- ----------------
Gi0/1          Root FWD 20000     128     False   P2p

5. Configuration Files

- Device A configuration file

```
hostname DeviceA
spanning-tree mode mvst
spanning-tree vlan 1-3
spanning-tree vlan 1-3 priority 0
spanning-tree
vlan range 1-3
!
interface GigabitEthernet0/1
switchport mode trunk
!
interface GigabitEthernet0/2
switchport mode trunk
!
```

- Device B configuration file

```
hostname DeviceB
spanning-tree mode mvst
spanning-tree vlan 1-3
spanning-tree vlan 1-3 priority 12288
spanning-tree
vlan range 1-3
```

```
!
interface GigabitEthernet0/1
switchport mode trunk
!
interface GigabitEthernet0/2
switchport mode trunk
!
```

- Device C configuration file

```
hostname DeviceC
spanning-tree mode mvst
spanning-tree vlan 1-3
spanning-tree
vlan range 1-3
!
interface GigabitEthernet0/1
switchport mode trunk
!
interface GigabitEthernet0/2
switchport mode trunk
!
```

6. Common Errors

- The spanning tree function can be enabled in a VLAN before the VLAN is created. If the interface does not participate in MVST calculation, check whether the VLAN is created.
- If two devices are interconnected using MVST, the interconnected interfaces must work in the same mode. If the interfaces work in different modes, such as access port and trunk port, an error may occur during spanning tree calculation.
- Interconnected devices in the spanning tree network use different spanning tree modes, such as STP, RSTP, MSTP, MVST, or Rapid-MVST, so the spanning tree calculation result does not meet the expectations.
- When two devices are interconnected in MVST or Rapid-MVST mode, the interconnected trunk ports cannot use different native VLANs.

1 Configuring ERPS

1.1 Introduction

1.1.1 Overview

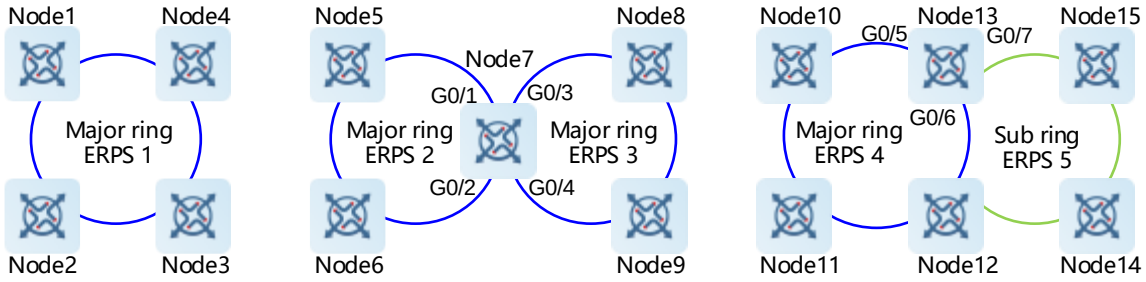
Ethernet Ring Protection Switching (ERPS), also known as G.8032, is a ring protection protocol developed by the International Telecommunication Union (ITU). It is a data link layer protocol specially designed for Ethernet rings. ERPS prevents broadcast storms caused by data loops when an Ethernet ring network is intact, and can rapidly perform link switching and recover the communication between nodes when a link is disconnected in the Ethernet ring, so as to implement data link redundancy.

Currently, the Spanning Tree Protocol (STP) is another solution to the Layer 2 network loop problem. STP is at mature application stage but requires a relatively long (within seconds) convergence time. Compared with STP, ERPS provides faster convergence, with the Layer 2 convergence time less than 50 ms.

1.1.2 Control VLAN and Data VLAN

ERPS supports two types of virtual local area networks (VLANs): control VLANs and data VLANs.

- Control VLAN: Also known as the Ring Auto Protection Switching VLAN (R-APS VLAN) for transmitting ERPS protocol packets. On a device, the ports connecting to an ERPS ring belong to a control VLAN, and only such ports can be added to a control VLAN.
- Data VLAN: A data VLAN is used to transmit data packets. Both ERPS ports and non-ERPS ports can be assigned to a data VLAN. A data VLAN is also known as a protected VLAN.



1.1.3 Basic Model of an Ethernet Ring

A group of interconnected devices in the same control VLAN (R-APS VLAN) constitute an Ethernet ring (ERPS ring), in which each device is called a node. ERPS rings can be classified into major rings and subrings based on whether a ring is closed.

1. Major Ring and Subring

- Major ring and major ring link: A major ring is a topology of a closed network connected in a ring, such as the blue rings shown in Figure 1-1. In an ERPS ring, links that belong to and are controlled by a major ring are called major ring links.
- Subring and subring link: A subring is a topology of a non-closed network attached to a major ring, such as the green ring shown in Figure 1-1. In an ERPS ring, links that belong to and are controlled by a subring are called subring links.
- R-APS virtual channel in a subring: A channel used to transmit subring protocol packets in a major ring. It belongs to a major ring rather than a subring. For example, the link between node 12 and node 13 as shown in Figure 1-1 is an R-APS virtual channel.

Figure 1-1 Basic Topologies of Ethernet Rings

2. Basic Topologies

Major rings, subrings, and nodes can form basic topologies with different characteristics, depending on the connection modes, as shown in Figure 1-1.

- Single ring: Major ring ERPS 1 (node 1-2-3-4) constitutes a single-ring topology.
- Tangent rings: A topology in which two ERPS rings share one device is called tangent rings. Major ring ERPS 2 (node 5-6-7) and major ring ERPS 3 (node 7-8-9) constitute a tangent-ring topology, and are tangent to each other on one node, namely, node 7.
- Intersecting rings: A topology in which two ERPS rings share two devices is called intersecting rings. Major ring ERPS 4 (node 13-10-11-12) and subring ERPS 5 (node 13-15-14-12) constitute an intersecting-ring topology, and intersect on two directly connected intersecting nodes, namely, node 13 and node 12.

In practice, a network is a combination of multiple basic topologies, with multiple major rings and multiple subrings.

3. Node

According to the different topological relationships between nodes and Ethernet rings, nodes are classified into single-ring nodes, tangent nodes, and intersecting nodes by role.

- Single-ring node: In an Ethernet ring, the nodes that belong to only one Ethernet ring (either major ring or subring) are called single-ring nodes. Two interfaces need to be provided on a single-ring node so that the node can be added to one ERPS ring. As shown in Figure 1-1, nodes 1-4 in the single-ring topology, nodes 5, 6, 8, and 9 in the tangent-ring topology, and nodes 10, 11, 14, and 15 in the intersecting-ring topology are all single-ring nodes.
- Tangent node: A device shared in tangent rings is called a tangent node. Four interfaces need to be provided on each tangent node, with two added to a major ring and the other two added to another major ring. As shown in Figure 1-1, node 7 in the tangent-ring topology is a tangent node.
- Intersecting node: The nodes in intersecting rings that belong to multiple rings are called intersecting nodes. The intersecting nodes must be connected directly without any other nodes in between. Three interfaces need to be provided on a tangent node, with two added to a major ring and the other added to a subring. As shown in Figure 1-1, nodes 12 and 13 in the intersecting-ring topology are intersecting nodes. ERPS rings can intersect with other multiple ERPS rings and share links to implement data link redundancy. Services can be quickly switched from a failed link in one ERPS ring to a normal link.

4. Ring Member Port

An Ethernet ring has two ring member ports on each node that it passes through: the **west** and **east** ports. As shown in Figure 1-1:

- If an ERPS ring is a closed major ring, each node that the ring passes through has two interfaces used as the **west** and **east** ports for adding the node to the ERPS ring. For example, on node 7, GigabitEthernet 0/1 and 0/2 are added to the major ring ERPS 2, and GigabitEthernet 0/3 and 0/4 are added to the major ring ERPS 3. On node 13, GigabitEthernet 0/5 and 0/6 are added to the major ring ERPS 4.
- If an ERPS ring is a non-closed subring (in an intersecting-ring topology), a non-intersecting node has two interfaces used as the **west** and **east** ports for adding the node to the ERPS subring, such as node 15. On an intersecting node, only one physical port is added to the ERPS subring as a ring member port, and the other ring member port is a virtual channel (indicated by **virtual-channel**). For example, on node 13, only GigabitEthernet 0/7 is added to the subring ERPS 5.

There are two states for a port running the ERPS protocol: forwarding and discarding. Their functions are listed in Table 1-1.

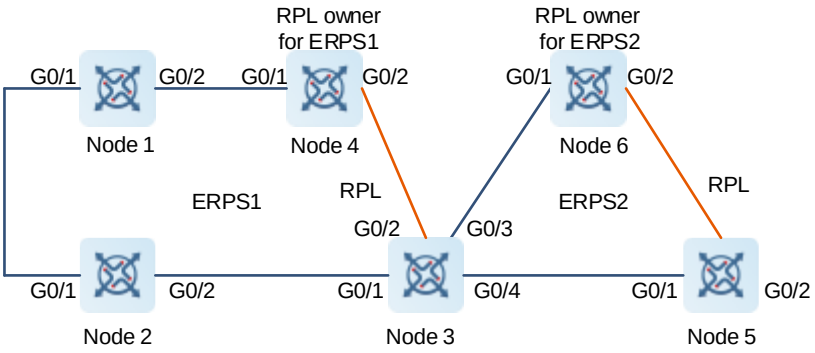
Table 1-1 ERPS Protocol Port States

Port State	Receiving Protocol Packets	Sending Protocol Packets	Address Learning	Receiving Data Packets	Sending Data Packets
Discarding	Yes	Yes	No	No	No
Forwarding	Yes	Yes	Yes	Yes	Yes

1.1.4 RPL and Nodes

An Ethernet ring can be in either of the following two states regardless of whether it is a major ring or subring:

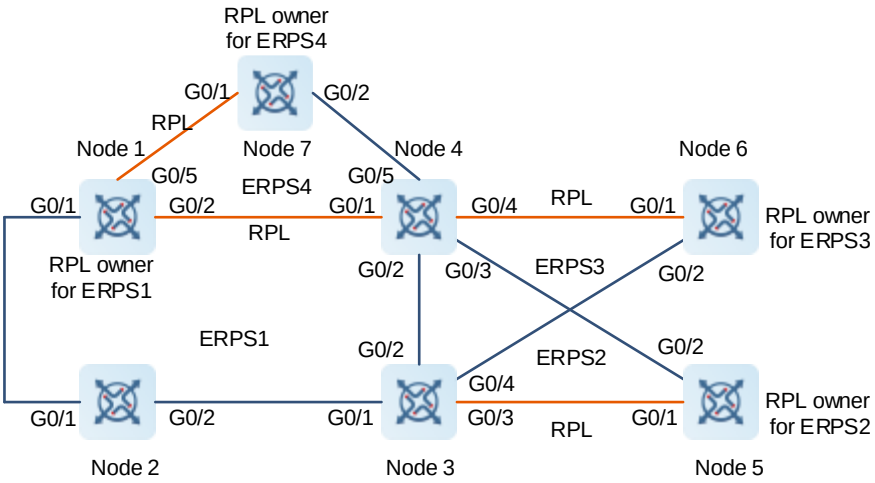
- Idle state: The physical links in the entire ring network are connected.
- Protection state: A physical link in the ring network is disconnected.



Ring protection link (RPL): When the physical links in a ring network are connected, the ERPS ring is in the idle state, and the links in the logic blocking state are RPLs. Each Ethernet ring has only one RPL. For example, the links indicated by the orange lines shown in Figure 1-2 are RPLs, the link between node 3 and node 4 is the RPL of the Ethernet ring ERPS 1 (node 1-2-3-4), and the link between node 5 and node 6 is the RPL of the Ethernet ring ERPS 2 (node 3-5-6).

A node that is adjacent to an RPL and is used to block the RPL to prevent loops when the Ethernet ring is free of faults is called an RPL owner node. As shown in Figure 1-2, node 4 is the RPL owner node of the Ethernet ring ERPS 1 (node 1-2-3-4) and node 6 is the RPL owner node of the ERPS 2 (node 3-5-6).

Any nodes other than the RPL owner node in an Ethernet ring are non-RPL owner nodes. As shown in Figure 1-2, nodes except node 4 and node 6 are non-RPL owner nodes of the rings.



Blocked ports on RPLs are RPL ports, and RPL ports do not forward data packets to prevent loops. RPL ports are on RPL owner nodes, and the RPL owner nodes block the RPL ports. Each Ethernet ring has only one RPL owner node.

Figure 1-2 Typical Topology of Tangent Rings

As shown in Figure 1-2, the link between node 3 and node 4 is the RPL of the Ethernet ring ERPS 1. As the RPL owner node of ERPS 1, node 4 blocks the RPL port. The link between node 5 and node 6 is the RPL of the Ethernet ring ERPS 2. As the RPL owner node of ERPS 2, node 6 blocks the RPL port. ERPS 1 (node 1-2-3-4) and ERPS 2 (node 3-5-6) share node 3, forming a tangent-ring topology. Node 3 is the tangent node.

Figure 1-3 Typical Topology of Intersecting Rings

As shown in Figure 1-3, ERPS 1 (node 1-2-3-4) is a major ring, and ERPS 2 (node 3-4-5) is a subring. ERPS 1 and ERPS 2 share node 3 and node 4, forming an intersecting-ring topology. The links between node 4 and node 5, and between node 3 and node 5 are links of the subring ERPS 2 and are controlled by ERPS 2. The link between node 3 and node 4 belongs to the major ring not the subring, and is not controlled by the subring. However, the protocol packets of the subring are transmitted through the direct link between node 3 and node 4. This direct link is the R-APS virtual channel of the subring ERPS 2. Node 2 only belongs to the major ring ERPS 1, and is called a single-ring node. Node 6 only belongs to the subring ERPS 3, and is also called a single-ring node. Node 3 and node 4 are tangent nodes.

1.1.5 ERPS Packet

ERPS packets (also called R-APS packets) are classified into Signal Fail (SF) packets, No Request (NR) packets, No Requests-RPL Blocked (NR-RB) packets, and Flush packets.

- SF packet: When the link of a node is down, the node sends an SF packet to notify other nodes of its link

failure.

- NR packet: When the failed link is restored, the node sends an NR packet to notify the RPL owner node of its link recovery.
- NR-RB packet: When all nodes in an ERPS ring function properly, the RPL owner node sends NR-RB packets periodically.
- Flush packet: In intersecting rings, when a topology change occurs in a subring, the intersecting nodes send flush packets to notify other devices in the Ethernet ring to which the subring is connected.

1.1.6 ERPS Timer

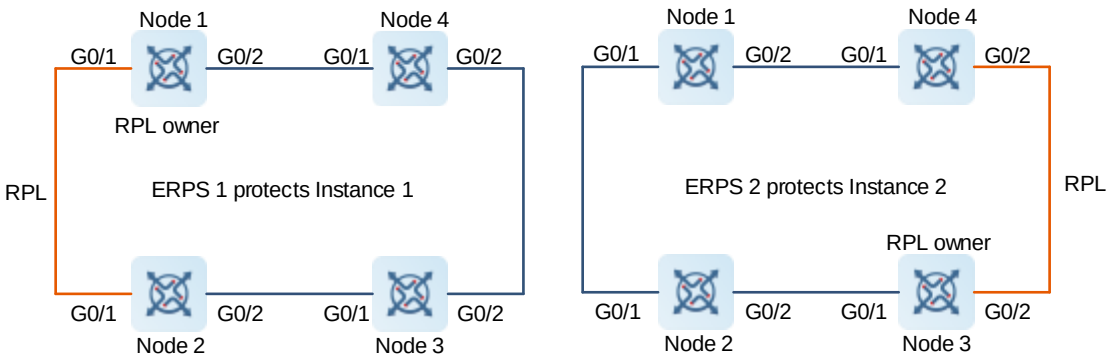
ERPS supports three timers: Holdoff timer, Guard timer, and Wait-To-Restore (WTR) timer.

- Holdoff timer: The timer is used to minimize frequent ERPS topology switching due to intermittent link failures. After you configure the Holdoff timer, ERPS performs topology switching only if the link failure still persists after the timer times out.
- Guard timer: The timer is used to prevent a device from receiving expired R-APS PMDU packets. When a device detects that a link failure is cleared, it sends link recovery packets and starts the Guard timer. Before the timer expires, all packets except Flush packets indicating a subring topology change will be discarded.
- WTR timer: The timer is effective only for RPL owner nodes. It is used to avoid ring status misjudgment by the RPL owner node. When an RPL owner node detects that a failure is cleared, it will not perform topology switching immediately but only if the Ethernet ring is recovered after the WTR timer times out. If a ring failure is detected again before the timer expires, the RPL owner node cancels the timer and does not perform topology switching.

1.1.7 Ring Protection

The ring protection function prevents broadcast storms caused by data loops and can rapidly recover the communication between nodes when a link is disconnected in the Ethernet ring.

- Normal state
  - All nodes in the physical topology are connected in ring mode.
  - ERPS blocks the RPL to prevent loops.
  - ERPS detects failures on each link between adjacent nodes.
- Link fault
  - A node adjacent to a failed node detects the fault.
  - The node adjacent to the failed link blocks the failed link and sends SF packets to notify other nodes in the same ring.
  - An SF packet triggers the RPL owner node to enable the RPL port, and also triggers all nodes to update their MAC address entries and ARP/ND entries and enter the protection state.
- Link recovery
  - When a failed link is restored, an adjacent node still blocks the link and sends NR packets indicating that no local fault exists.
  - When the RPL owner node receives the first NR packet, it starts the WTR timer.
  - When the WTR timer times out, the RPL owner node blocks the RPL and sends an NR-RB packet.



- After receiving this NR-RB packet, other nodes update their MAC address entries and ARP/ND entries, and the node that sends the NR packet stops sending the NR packet and enables the blocked ports.
- The ring network is restored to the normal state.

1.1.8 Load Balancing

One control VLAN identifies one ERPS ring and corresponds to the data VLANs that it needs to protect. By default, an ERPS ring protects all VLANs. You do not need to configure the VLANs to be protected by an Ethernet ring.

If multiple control VLANs are configured in the same physical ring network to form multiple Ethernet rings and they need to protect different data VLANs, load balancing can be achieved. In this case, the traffic from different VLANs is forwarded along their respective paths. When a link in the ring network with load balancing enabled fails, the traffic can be quickly switched to a normal link.

Figure 1-4 Typical Application of Load Balancing

As shown in Figure 1-4, two Ethernet rings (ERPS 1 and ERPS 2) are configured on the physical ring network to protect different VLANs. Node 1 is the RPL owner of ERPS 1, and node 3 is the RPL owner of ERPS 2. With such configurations, data of different VLANs can be transmitted by different links to achieve load balancing.

1.1.9 Protocols and Standards

ITU-T G.8032/Y.1344: Ethernet ring protection switching

1.2 Configuration Task Summary

The configuration includes the following tasks:

(1) Configuring a Control VLAN for an Ethernet Ring

(2) Configuring Member Ports for an Ethernet Ring

(3) (Optional) Configuring an RPL Port

(4) (Optional) Configuring Major Rings to Associate with Subrings

(5) (Optional) Configuring Subring Topology Change Notification

(6) (Optional) Configuring a Protected VLAN for an Ethernet Ring

(7) Enabling ERPS for an Ethernet Ring

(8) (Optional) Configuring ERPS Timers

(9) Enabling ERPS Globally

1.3 Configuring a Control VLAN for an Ethernet Ring

1.3.1 Overview

A control VLAN, also known as an R-APS VLAN, is used to transmit ERPS protocol packets. A group of interconnected devices in the same control VLAN constitute an Ethernet ring (ERPS ring). For an ERPS ring, the same Ethernet ring R-APS VLAN needs to be configured on each node that it passes through. In practice, one or more ERPS rings may pass through a node, and one control VLAN needs to be configured for each ERPS ring on the node.

- As shown in Figure 1-2, ERPS 1 (node 1-2-3-4) is tangent to ERPS 2 (node 3-5-6) on node 3, on which two ERPS control VLANs need to be created.
- As shown in Figure 1-3, the major ring ERPS 1 (node 1-2-3-4) intersects the subring ERPS 2 (node 3-4-5) on node 3, and the major ring ERPS 1 (node 1-2-3-4) also intersects the subring ERPS 3 (node 3-4-6) on node 3, on which three ERPS control VLANs need to be created.
- As shown in Figure 1-3, only the major ring ERPS 1 (node1-2-3-4) passes through node 2, on which only one ERPS control VLAN needs to be created. Only the subring ERPS 2 (node 3-4-5) passes through node 5, on which only one ERPS control VLAN needs to be created.

1.3.2 Restrictions and Guidelines

- An R-APS VLAN must be an unused VLAN on a device. VLAN 1 cannot be configured as an R-APS VLAN.
- The packets of different ERPS rings are distinguished using the control VLANs (R-APS VLANs). Therefore, the control VLANs of different ERPS rings must be different.
- If a device with ERPS disabled needs to transparently transmit ERPS packets, ensure that only the two ports connecting the device to an ERPS ring allow packets from the control VLAN of the ERPS ring to pass through. Otherwise, packets from other VLANs may be transparently transmitted to the R-APS VLAN, causing impact on the ERPS ring.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a control VLAN for an Ethernet ring, and enter the R-APS VLAN configuration mode.

erps raps-vlan *vlan-id*

No R-APS VLAN is configured by default.

1.4 Configuring Member Ports for an Ethernet Ring

1.4.1 Overview

An Ethernet ring has two ring member ports on each node that it passes through: the **west** and **east** ports.

If an ERPS ring is a closed major ring, each node that the ring passes through has two interfaces used as the **west** and **east** ports for adding the node to the ERPS ring. If an ERPS ring is a non-closed subring, a non-intersecting node has two interfaces used as the **west** and **east** ports for adding the node to the ERPS subring. On an intersecting node, only one physical port is added to the ERPS subring as a ring member port, and the other ring member port is a virtual channel (indicated by **virtual channel**).

According to the type of an ERPS ring (major ring or subring), add a physical port or virtual channel of a node to the control VLAN of an ERPS ring so that the port becomes a member port.

1.4.2 Restrictions and Guidelines

- Only Trunk, Uplink or Hybrid ports can join the ERPS ring. Only a Layer 2 Ethernet interface or Layer 2 aggregate interface can be configured as Trunk, Uplink, or Hybrid port and join the ERPS ring.
- If an Ethernet ring (major or subring) passes through two interfaces on a node, run the **ring-port west** *interface-type interface-number-1* **east** *interface-type interface-number-2* command to add the two interfaces to the Ethernet ring.
- If an Ethernet ring (subring only) passes through one physical port on a node, run the **ring-port west** *interface-type interface-number* **east virtual-channel** command to configure the physical port as the west port of the Ethernet ring, or run the **ring-port west virtual-channel east** *interface-type interface-number* command to configure the physical port as the east port of the Ethernet ring.
- The trunk attributes of a port cannot be modified after it is added to an ERPS ring. To modify the trunk attributes, enter the control VLAN configuration mode (that is, R-APS VLAN configuration mode), and run the **no ring-port** command to delete the port from the ERPS ring.
- The ports added to an ERPS ring will not participate in the spanning tree calculation no matter whether the ERPS ring is enabled. When you configure an ERPS ring, ensure that loops do not exist on the member ports of the ring.
- In R-APS VLAN configuration mode, configure the ports that form an ERPS ring as ERPS ring ports.
- ERPS cannot share ports with the Rapid Ethernet Ring Protection (RERP) and Rapid Ethernet Uplink Protection (REUP).
- Do not configure IP address on the ring member ports; otherwise ERPS may be abnormal.
- When an ERPS ring topology changes and a port needs to be modified, to avoid loops during configuration modification, do as follows in sequence: Run the **shutdown** command to shut down one ERPS port in this ring. Enter the control VLAN configuration mode and run the **no state enable** command to disable the ERPS function. Run the **no ring-port** command to delete the ring member port. Finally, add a new member port to the Ethernet ring and run the **state enable** command to enable the ERPS function for the Ethernet ring. Upon completion of configuration, run the **no shutdown** command to enable the port.

1.4.3 Prerequisites

(1) Configure the interface as a Layer 2 interface.

- Configure the mode of the Layer 2 interface as Trunk, Uplink or Hybrid.

1.4.4 Procedure

(1) Configure interfaces as trunk ports.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

(2) Enter the R-APS VLAN configuration mode of an Ethernet ring.

erps raps-vlan *vlan-id*

By default, an Ethernet ring control VLAN does not exist.

(3) Configure the Layer 2 Ethernet interface or Layer 2 aggregate interface as a member port of the Ethernet ring.

ring-port west { *interface-type interface-number* | **virtual-channel** } **east** { *interface-type interface-number* | **virtual-channel** }

No member port exists in an Ethernet ring by default.

1.5 Configuring an RPL Port

1.5.1 Overview

Each ERPS ring has only one RPL and only one RPL owner node. Blocked ports on RPLs are RPL ports, which do not forward data packets to prevent loops.

On an ERPS ring, select a device as the RPL owner, enter the R-APS VLAN configuration mode of the Ethernet ring on this device, and configure the west or east port as an RPL port. For non-RPL owner nodes, no RPL port needs to be configured.

1.5.2 Restrictions and Guidelines

- The **west** parameter indicates that the west port is specified as an RPL port, and the **east** parameter indicates that the east port is specified as an RPL port.
- Two tangent rings have two RPLs and two RPL owner nodes. However, do not configure a tangent node as an RPL owner node.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the R-APS VLAN configuration mode of an Ethernet ring.

erps raps-vlan *vlan-id*

By default, an Ethernet ring control VLAN does not exist.

(4) Configure an RPL port on an RPL owner node.

rpl-port { **west** | **east** } **rpl-owner**

No RPL port exists in an ERPS ring by default.

1.6 Configuring Major Rings to Associate with Subrings

1.6.1 Overview

When there are intersecting rings in an Ethernet ring topology, the major ring needs to be configured to associate with all subrings on all nodes in the major ring (no matter whether the subrings are directly connected to the nodes) so that the ERPS packets of subrings can be transmitted in the major ring. The association of major rings with subrings does not need to be configured on nodes only in subrings.

1.6.2 Restrictions and Guidelines

- On all nodes in a major ring of intersecting rings, including intersecting nodes and non-intersecting nodes, the association of the major ring with all subrings needs to be configured so that the ERPS packets of the subrings can be transmitted in the major ring.
- You can also use the command provided by the VLAN module to configure a control VLAN and its member ports so that ERPS packets of subrings can be transmitted in other Ethernet rings and are not leaked to user networks.
- If the subring topology change notification has been configured in a subring of intersecting rings and the link between intersecting nodes is faulty or blocked in the event of a subring topology change, the intersecting nodes will send packets to instruct the nodes in other Ethernet rings associated with the subring to update the topology.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the R-APS control VLAN configuration mode of a major ring.

erps raps-vlan *major-ring-vlan-id*

(4) Associate the major ring with all subrings.

associate sub-ring raps-vlan *sub-ring-vlan-list*

An ERPS major ring is not associated with any subrings by default.

1.7 Configuring Subring Topology Change Notification

1.7.1 Overview

This function is required only in the subrings on intersecting nodes. When the subring topology changes, the intersecting nodes send a topology change notification.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the R-APS control VLAN configuration mode of a subring.

erps raps-vlan *sub-ring-vlan-id*

(4) Enable the subring topology change notification.

sub-ring tc-propagation enable

1.8 Configuring a Protected VLAN for an Ethernet Ring

1.8.1 Overview

This section describes how to configure the data VLANs to be protected by an ERPS ring. All VLANs are protected by an ERPS ring by default. When load balancing is needed, multiple Ethernet rings can be configured on the same physical ring network, and different Ethernet rings protect different VLANs. In this way, different Ethernet rings send traffic from different VLANs separately, achieving load balancing. When a link in a ring network with load balancing enabled fails, the traffic can be quickly switched to a normal link.

1.8.2 Restrictions and Guidelines

- Before you configure load balancing, configure the mapping between VLANs and instances in MST configuration mode.
- When you configure load balancing, add all data VLANs of the devices to the ERPS protected VLAN list; otherwise, any unprotected VLAN may cause loops.

1.8.3 Procedure

(1) Configure the mapping between instances and VLANs.

a Enter the privileged EXEC mode.

enable

b Enter the global configuration mode.

configure terminal

c Enter the MST configuration mode.

spanning-tree mst configuration

d Add a VLAN group to an MST instance.

instance *instance-id* **vlan** *vlan-range*

e Return to the global configuration mode.

exit

(2) Enter the R-APS control VLAN configuration mode of an Ethernet ring.

erps raps-vlan *vlan-id*

By default, an Ethernet ring control VLAN does not exist.

(3) Configure the Ethernet ring to protect the defined instance so as to protect the specified data VLANs.

protected-instance *instance-id-list*

An Ethernet ring protects all VLANs by default.

1.9 Enabling ERPS for an Ethernet Ring

1.9.1 Overview

This section describes how to enter the R-APS VLAN configuration mode of a specified Ethernet ring, and enable the ERPS function for this Ethernet ring. If more than one Ethernet ring passes through a node, the ERPS function of each Ethernet ring needs to be enabled separately.

1.9.2 Restrictions and Guidelines

ERPS takes effect only after ERPS is enabled both globally and for a specified ring on each node that the Ethernet ring passes through.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the R-APS VLAN configuration mode of an Ethernet ring.

erps raps-vlan *vlan-id*

No Ethernet ring control VLAN is configured by default.

(4) Enable the ERPS function of the Ethernet ring.

state enable

The ERPS function of an Ethernet ring is disabled by default.

1.10 Configuring ERPS Timers

1.10.1 Overview

This section describes how to configure the Holdoff, Guard, and WTR timers.

1.10.2 Restrictions and Guidelines

- Run the **timer holdoff-time** command to configure the Holdoff timer. *interval1* indicates the value of the Holdoff timer, in 100 milliseconds. The value range is from 0 to 100, and the default value is **0**.
- Run the **timer guard-time** command to configure the Guard timer. *interval2* indicates the value of the Guard timer, in 10 milliseconds. The value range is from 1 to 200, and the default value is **50**.
- Run the **timer wtr-time** command to configure the WTR timer. *interval3* indicates the value of the WTR timer, in minutes. The value range is from 1 to 12, and the default value is **2**.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the control VLAN configuration mode.

erps raps-vlan *vlan-id*

(4) Configure a timer.

timer { **holdoff-time** *interval1* | **guard-time** *interval2* | **wtr-time** *interval3* }

1.11 Enabling ERPS Globally

1.11.1 Overview

After completing all configurations of the ERPS function, you need to enable ERPS globally on each node that an Ethernet ring passes through so that ERPS takes effect.

1.11.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the global ERPS function.

erps enable

The global ERPS function is disabled by default.

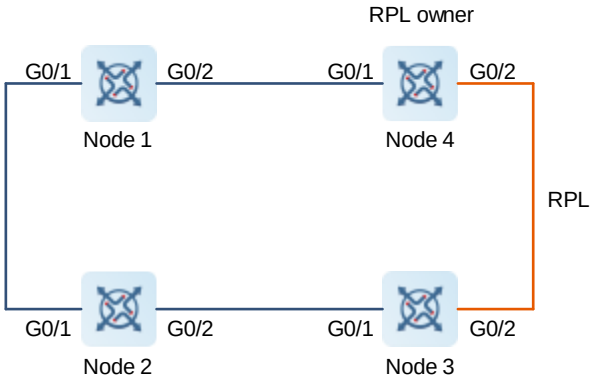
1.12 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Table 1-2 Monitoring

Command	Purpose
show erps [**global** | **raps_vlan** *vlan-id* [*sub_ring*]]	Displays the ERPS configuration and state of a device.

1.13 Configuration Examples



1.13.1 Configuring Single-Ring Protection

1. Requirements

As shown in Figure 1-5, there is only one ring in the network topology. All nodes are connected in a ring in the physical topology. ERPS blocks the RPL to prevent loops, and detects faults on each link between adjacent nodes. There is only one RPL owner node and only one RPL in an Ethernet ring. All nodes must belong to the same R-APS VLAN. All devices in the ring network must support ERPS. Each link between devices must be a direct link without any intermediate device.

2. Topology

Figure 1-5 Topology of Configuring Single-Ring Protection

3. Notes

- Before adding a physical port to an Ethernet ring, configure the link of the member port to work in trunk mode.
- Node 1, node 2, and node 3 are all non-RPL owner nodes, through which only ERPS 1 passes. Notes for configuring these nodes are as follows:
  - Configure R-APS VLAN 100, add interfaces GigabitEthernet 0/1 and 0/2 to the Ethernet ring, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.
- Only ERPS 1 passes through node 4 and node 4 is the RPL owner node of the ERPS ring. Notes for configuring this node are as follows:
  - Configure R-APS VLAN 100, add interfaces GigabitEthernet 0/1 and 0/2 to the Ethernet ring, configure GigabitEthernet 0/2 as an RPL port, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.

4. Procedure

(1) Configure single-ring nodes (node 1, node 2, and node 3) in the same way. The following uses node 1 as an example.

Configure the links of the member ports to work in trunk mode.

```
Node1> enable
Node1# configure terminal
Node1(config)# interface range gigabitethernet 0/1-2
Node1(config-if-rang)# switchport
Node1(config-if-rang)# switchport mode trunk
Node1(config-if-rang)# exit
```

Create an Ethernet ring control VLAN, that is, R-APS VLAN 100.

```
Node1(config)# erps raps-vlan 100
```

Add the two interfaces GigabitEthernet 0/1 and 0/2 to the Ethernet ring.

```
Node1(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
```

Enable the ERPS function for the Ethernet ring.

```
Node1(config-erps 100)# state enable
Node1(config-erps 100)# exit
```

Enable the global ERPS function.

```
Node1(config)# erps enable
```

(2) Configure node 4 that is a single-ring node and an RPL owner node.

Configure the links of the member ports to work in trunk mode.

```
Node4> enable
Node4# configure terminal
Node4(config)# interface range gigabitethernet 0/1-2
Node4(config-if-rang)# switchport
Node4(config-if-range)# switchport mode trunk
Node4(config-if-range)# exit
```

Create an Ethernet ring control VLAN, that is, R-APS VLAN 100.

```
Node4(config)# erps raps-vlan 100
```

Add the two interfaces GigabitEthernet 0/1 and 0/2 to the Ethernet ring.

```
Node4(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
```

Configure GigabitEthernet 0/2 (east) as the RPL port of R-APS VLAN 100.

```
Node4(config-erps 100)# rpl-port east rpl-Owner
```

Enable the ERPS function for the Ethernet ring.

```
Node4(config-erps 100)# state enable
Node4(config-erps 100)# exit
```

Enable the global ERPS function.

```
Node4(config)# erps enable
```

5. Verification

(1) Verify the configurations of non-RPL owner nodes: node 1, node 2, and node 3. These three nodes use the same configurations. The following uses node 1 as an example.

```
Node1# show erps
ERPS Information
Global Status             : Enabled
Link monitored by         : Not Oam
------------------------------------------
R-APS VLAN               : 100
Ring Status              : Enabled
West Port                : Gi0/1       (Forwarding)
East Port                : Gi0/2       (Forwarding)
RPL Port                 : None
Protected VLANs           : ALL
```

```
RPL Owner                : Disabled
Holdoff Time             : 0 milliseconds
Guard Time               : 500 milliseconds
WTR Time                 : 2 minutes
Current Ring State       : idle
Associate R-APS VLAN     :
```

(2) Verify the configurations of node 4, an RPL owner node.

```
Node4# show erps
ERPS Information
Global Status            : Enabled
Link monitored by        : Not Oam
----------------------------------------
R-APS VLAN               : 100
Ring Status              : Enabled
West Port                : Gi0/1       (Forwarding)
East Port                : Gi0/2       (Blocking)
RPL Port                 : East Port
Protected VLANs          : ALL
RPL Owner                : Enabled
Holdoff Time             : 0 milliseconds
Guard Time               : 500 milliseconds
WTR Time                 : 2 minutes
Current Ring State       : idle
Associate R-APS VLAN     :
```

6. Configuration Files

- Configuration files for node 1, node 2, and node 3

```
erps enable
!
erps raps-vlan 100
 ring-port west GigabitEthernet 0/1 east GigabitEthernet 0/2
 state enable
!
interface GigabitEthernet 0/1
switchport mode trunk
!
interface GigabitEthernet 0/2
 switchport mode trunk
```

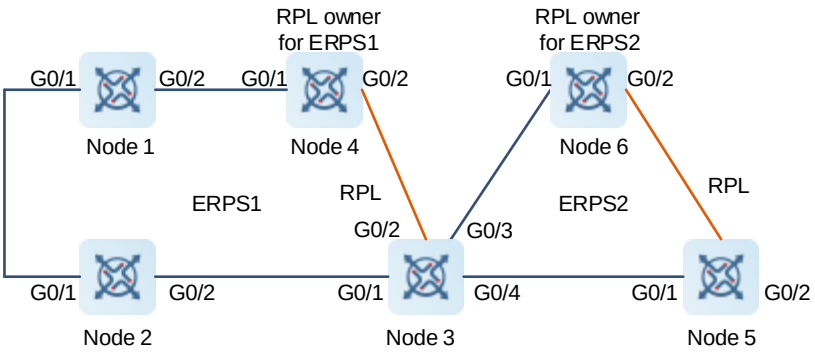
- Configuration file for node 4

```
erps enable
!
erps raps-vlan 100
 ring-port west GigabitEthernet 0/1 east GigabitEthernet 0/2
rpl-port east rpl-Owner
 state enable
```

```
!
interface GigabitEthernet 0/1
switchport mode trunk
!
interface GigabitEthernet 0/2
 switchport mode trunk
```

7. Common Errors

- Different R-APS VLANs are configured for the nodes in one ring.
- The ERPS function is not enabled globally and for an Ethernet ring on all nodes in the Ethernet ring. As a result, the ERPS function does not take effect.
- Multiple RPL owner nodes are configured in one ring.
- If member ports on an RPL owner node in an Ethernet ring are modified, the configuration of the RPL port will be deleted by the system. The RPL owner node may fail to operate properly if the RPL port is not configured again.



1.13.2 Configuring Tangent-Ring Protection

1. Requirements

In the network topology shown in Figure 1-6, two ring networks share the same device to implement ERPS protection. ERPS is used to detect faults on each link between adjacent nodes. All nodes are connected in a ring in a physical topology. ERPS blocks the RPL of each ring to prevent loops. Each ring has only one RPL owner node and only one RPL. Different rings belong to different R-APS VLANs. All devices in the ring network must support ERPS. Each link between devices must be a direct link without any intermediate device.

2. Topology

Figure 1-6 Topology of Configuring Tangent-Ring Protection

3. Notes

- Before adding a physical port to an Ethernet ring, configure the link of the member port to work in trunk mode.
- Node 1 and node 2 are non-RPL owner nodes, through which only ERPS 1 passes. Notes for configuring these nodes are as follows:
  - Configure R-APS VLAN 100, add GigabitEthernet 0/1 and 0/2 to the Ethernet ring, and enable the

ERPS function for the Ethernet ring.

- Enable the global ERPS function.

- Node 3 is the tangent node of ERPS 1 and ERPS 2. Notes for configuring this node are as follows:
  - Configure R-APS VLAN 100, add GigabitEthernet 0/1 and 0/2 to R-APS VLAN 100, and enable the ERPS function for the Ethernet ring.
  - Configure R-APS VLAN 200, add GigabitEthernet 0/3 and 0/4 to R-APS VLAN 200, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.
- Only ERPS 1 passes through node 4 and node 4 is the RPL owner node of ERPS 1. Notes for configuring this node are as follows:
  - Configure R-APS VLAN 100, add GigabitEthernet 0/1 and 0/2 to the Ethernet ring, configure GigabitEthernet 0/2 as an RPL port, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.
- Only ERPS 2 passes through node 5 and node 5 is a non-RPL owner node. Notes for configuring this node are as follows:
  - Configure R-APS VLAN 200, add GigabitEthernet 0/1 and 0/2 to the Ethernet ring, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.
- Only ERPS 2 passes through node 6 and node 6 is the RPL owner node of ERPS 2. Notes for configuring this node are as follows:
  - Configure R-APS VLAN 200, add GigabitEthernet 0/1 and 0/2 to the Ethernet ring, configure GigabitEthernet 0/2 as an RPL port, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.

4. Procedure

(1) Configure single-ring nodes (node 1 and node 2) of ERPS 1 in the same way. The following uses node 1 as an example.

Configure the links of Ethernet ring ports GigabitEthernet 0/1 and 0/2 of ERPS 1 to work in trunk mode. Create the Ethernet ring R-APS VLAN 100, add interfaces to the Ethernet ring, and enable the ERPS function for the Ethernet ring.

```
Node1> enable
Node1# configure terminal
Node1(config)# interface range gigabitethernet 0/1-2
Node1(config-if-range)# switchport
Node1(config-if-range)# switchport mode trunk
Node1(config-if-range)# exit
Node1(config)# erps raps-vlan 100
Node1(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node1(config-erps 100)# state enable
Node1(config-erps 100)# exit
```

Enable the global ERPS function.

```
Node1(config)# erps enable
```

(2) Configure the tangent node: node 3.

Configure the links of Ethernet ring ports GigabitEthernet 0/1 and 0/2 of ERPS 1 to work in trunk mode. Create the Ethernet ring R-APS VLAN 100, add interfaces to the Ethernet ring, and enable the ERPS function for the Ethernet ring.

```
Node3> enable
Node3# configure terminal
Node3(config)# interface range gigabitethernet 0/1-2
Node3(config-if-range)# switchport
Node3(config-if-range)# switchport mode trunk
Node3(config-if-range)# exit
Node3(config)# erps raps-vlan 100
Node3(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node3(config-erps 100)# state enable
Node3(config-erps 100)# exit
```

Configure the links of Ethernet ring ports GigabitEthernet 0/3 and GigabitEthernet 0/4 of ERPS 2 to work in trunk mode. Create the Ethernet ring R-APS VLAN 200, add interfaces to the Ethernet ring, and enable the ERPS function for the Ethernet ring.

```
Node3(config)# interface range gigabitethernet 0/3-4
Node3(config-if-range)# switchport
Node3(config-if-range)# switchport mode trunk
Node3(config-if-range)# exit
Node3(config)# erps raps-vlan 200
Node3(config-erps 200)# ring-port west gigabitethernet 0/3 east gigabitethernet
0/4
Node3(config-erps 200)# state enable
Node3(config-erps 200)# exit
```

Enable the global ERPS function.

```
Node3(config)# erps enable
```

(3) Configure node 4 that is a single-ring node and an RPL owner node of ERPS 1.

Configure the links of Ethernet ring ports GigabitEthernet 0/1 and 0/2 of ERPS 1 to work in trunk mode. Create Ethernet ring R-APS VLAN 100 and add interfaces to the Ethernet ring. Specify the RPL owner port and enable the ERPS function for the Ethernet ring.

```
Node4> enable
Node4# configure terminal
Node4(config)# interface gigabitethernet 0/1
Node4(config-if-GigabitEthernet 0/1)# switchport
Node4(config-if-GigabitEthernet 0/1)# switchport mode trunk
Node4(config-if-GigabitEthernet 0/1)# exit
Node4(config)# interface gigabitethernet 0/2
Node4(config-if-GigabitEthernet 0/2)# switchport
```

```
Node4(config-if-GigabitEthernet 0/2)# switchport mode trunk
Node4(config-if-GigabitEthernet 0/2)# exit
Node4(config)# erps raps-vlan 100
Node4(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node4(config-erps 100)# rpl-port east rpl-owner
Node4(config-erps 100)# state enable
Node4(config-erps 100)# exit
```

Enable the global ERPS function.

```
Node4(config)# erps enable
```

(4) Configure the single-ring node (node 5) of ERPS 2.

Configure the links of Ethernet ring ports GigabitEthernet 0/1 and GigabitEthernet 0/2 of ERPS 2 to work in trunk mode. Create Ethernet ring R-APS VLAN 200, add interfaces to the Ethernet ring, and enable the ERPS function for the Ethernet ring.

```
Node5> enable
Node5# configure terminal
Node5(config)# interface gigabitethernet 0/1
Node5(config-if-GigabitEthernet 0/1)# switchport
Node5(config-if-GigabitEthernet 0/1)# switchport mode trunk
Node5(config-if-GigabitEthernet 0/1)# exit
Node5(config)# interface gigabitethernet 0/2
Node5(config-if-GigabitEthernet 0/2)# switchport
Node5(config-if-GigabitEthernet 0/2)# switchport mode trunk
Node5(config-if-GigabitEthernet 0/2)# exit
Node5(config)# erps raps-vlan 200
Node5(config-erps 200)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node5(config-erps 200)# state enable
Node5(config-erps 200)# exit
```

Enable the global ERPS function.

```
Node5(config)# erps enable
```

(5) Configure node 6 that is a single-ring node and an RPL owner node of ERPS 2.

Configure the links of Ethernet ring ports GigabitEthernet 0/1 and GigabitEthernet 0/2 of ERPS 2 to work in trunk mode. Create Ethernet ring R-APS VLAN 200 and add interfaces to the Ethernet ring. Specify the RPL owner port and enable the ERPS function for the Ethernet ring.

```
Node6> enable
Node6# configure terminal
Node6(config)# interface gigabitethernet 0/1
Node6(config-if-GigabitEthernet 0/1)# switchport mode trunk
Node6(config-if-GigabitEthernet 0/1)# exit
Node6(config)# interface gigabitethernet 0/2
Node6(config-if-GigabitEthernet 0/2)# switchport mode trunk
Node6(config-if-GigabitEthernet 0/2)# exit
```

```
Node6(config)# erps raps-vlan 100
Node6(config-erps 200)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node6(config-erps 200)# rpl-port east rpl-owner
Node6(config-erps 200)# state enable
```

Enable the global ERPS function.

```
Node6(config)# erps enable
```

5. Verification

Run the **show erps** command on each node to verify the configuration. The following uses node 3 as an example.

```
Node3# show erps
ERPS Information
Global Status                : Enabled
Link monitored by            : Not Oam
------------------------------------------
R-APS VLAN                   : 200

Associate R-APS VLAN         :
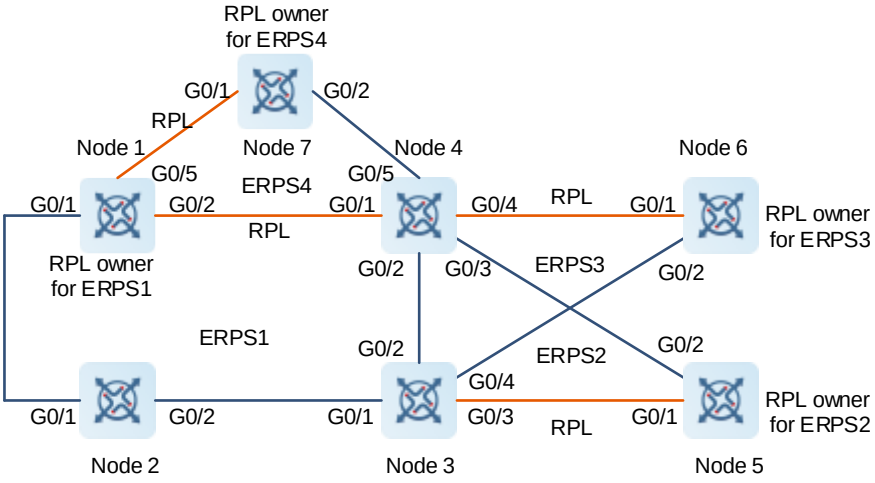
```

6. Common Errors

- The Ethernet ring ERPS function is enabled, but the global ERPS function is not enabled. In this case, the ERPS function does not take effect. An R-APS ring has been enabled but ERPS is not enabled globally, so ERPS does not take effect yet.

- Multiple RPL owner nodes are configured in one ring.
- Different R-APS VLANs are configured for the nodes in one ring.



1.13.3 Configuring Intersecting-Ring Protection

1. Requirements

As shown in Figure 1-7, there are four rings in the network topology. All nodes are connected in a ring in the physical topology. Nodes are connected through direct links. Each ring has only one RPL owner node and only one RPL. Two or more rings share one link. All devices in the ring network support ERPS. Configure ERPS. ERPS blocks the RPL of each ring to prevent loops, and detects faults on each link between adjacent nodes.

2. Topology

Figure 1-7 Topology of Configuring Intersecting-Ring Protection

3. Notes

- Before adding a physical port to an Ethernet ring, configure the link of the member port to work in trunk mode.
- Node 1 is the intersecting node of the major ring ERPS 1 and subring ERPS 4, as well as the RPL owner node of ERPS 1. Notes for configuring this node are as follows:
  - Configure R-APS VLAN 100, add GigabitEthernet 0/1 and GigabitEthernet 0/2 to R-APS VLAN 100, configure GigabitEthernet 0/2 as the RPL port, associate the major ring with subrings R-APS VLANs 200, 300, and 400, and enable the ERPS function for the Ethernet ring.
  - Configure subring R-APS VLAN 400, add GigabitEthernet 0/5 and virtual channel to R-APS VLAN 400, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.
- Only major ring ERPS 1 passes through node 2. Notes for configuring this node are as follows:
  - Configure R-APS VLAN 100, add GigabitEthernet 0/1 and GigabitEthernet 0/2 to R-APS VLAN 100, associate the major ring with subrings R-APS VLANs 200, 300, and 400, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.

- Node 3 is the intersecting node of the major ring ERPS 1 and subrings ERPS 2 and ERPS 3. Notes for configuring this node are as follows:
  - Configure the major ring R-APS VLAN 100, add GigabitEthernet 0/1 and GigabitEthernet 0/2 to R-APS VLAN 100, associate the major ring with subrings R-APS VLANs 200, 300, and 400, and enable the ERPS function for the Ethernet ring.
  - Configure subring R-APS VLAN 200, add GigabitEthernet 0/3 and virtual channel to R-APS VLAN 200, and enable the ERPS function for the Ethernet ring.
  - Configure subring R-APS VLAN 300, add GigabitEthernet 0/4 and virtual channel to R-APS VLAN 300, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.
- Node 4 is the intersecting node of the major ring ERPS 1 and subrings ERPS 2, ERPS 3, and ERPS4. Notes for configuring this node are as follows:
  - Configure the major ring R-APS VLAN 100, add GigabitEthernet 0/1 and GigabitEthernet 0/2 to R-APS VLAN 100, associate the major ring with subrings R-APS VLANs 200, 300, and 400, and enable the ERPS function for the Ethernet ring.
  - Configure subring R-APS VLAN 200, add GigabitEthernet 0/3 and virtual channel to R-APS VLAN 200, and enable the ERPS function for the Ethernet ring.
  - Configure subring R-APS VLAN 300, add GigabitEthernet 0/4 and virtual channel to R-APS VLAN 300, and enable the ERPS function for the Ethernet ring.
  - Configure subring R-APS VLAN 400, add GigabitEthernet 0/5 and virtual channel to R-APS VLAN 400, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.
- Node 5 is the non-intersecting single-ring node of the subring ERPS 2, as well as the RPL owner node of ERPS 2. Notes for configuring this node are as follows:
  - Configure the subring R-APS VLAN 200, add GigabitEthernet 0/1 and GigabitEthernet 0/2 to R-APS VLAN 200, configure GigabitEthernet 0/1 as the RPL port, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.
- Node 6 is the non-intersecting node of the subring ERPS 3, as well as the RPL owner node of ERPS 3. Notes for configuring this node are as follows:
  - Configure the subring R-APS VLAN 300, add GigabitEthernet 0/1 and GigabitEthernet 0/2 to R-APS VLAN 300, configure GigabitEthernet 0/1 as the RPL port, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.
- Node 7 is the non-intersecting single-ring node of the subring ERPS 4, as well as the RPL owner node of ERPS 4. Notes for configuring this node are as follows:
  - Configure the subring R-APS VLAN 400, add GigabitEthernet 0/1 and GigabitEthernet 0/2 to R-APS VLAN 400, configure GigabitEthernet 0/1 as the RPL port, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.

4. Procedure

(1) Configure node 1.

Configure the major ring ERPS 1 of the intersecting rings. Create a control VLAN (R-APS VLAN 100), add interfaces to the Ethernet ring, configure the east port as the RPL owner port, associate the major ring R-APS VLAN 100 with subrings R-APS VLANs 200, 300, and 400, and enable the ERPS function.

```
Node1> enable
Node1# configure terminal
Node1(config)# interface rang gigabitethernet 0/1-2
Node1(config-if-range)# switchport
Node1(config-if-range)# switchport mode trunk
Node1(config-if-range)# exit
Node1(config)# erps raps-vlan 100
Node1(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node1(config-erps 100)# rpl-port east rpl-owner
Node1(config-erps 100)# associate sub-ring raps-vlan 200,300,400
Node1(config-erps 100)# state enable
Node1(config-erps 100)# exit
```

Configure the subring ERPS 4 of the intersecting rings. Create a control VLAN (R-APS VLAN400), add interfaces to the Ethernet ring, and enable the ERPS function.

```
Node1(config)# interface rang gigabitethernet 0/5
Node1(config-if-range)# switchport
Node1(config-if-range)# switchport mode trunk
Node1(config-if-range)# exit
Node1(config)# erps raps-vlan 400
Node1(config-erps 400)# ring-port west gigabitethernet 0/5 east virtual-channel
Node1(config-erps 400)# state enable
Node1(config-erps 400)# exit
```

Enable the global ERPS function.

```
Node1(config)# erps enable
```

(2) Configure node 2.

Configure R-APS VLAN 100, add interfaces to the Ethernet ring, associate the major ring R-APS VLAN 100 with subrings R-APS VLANs 200, 300, and 400, and enable the ERPS function.

```
Node2> enable
Node2# configure terminal
Node2(config)# interface rang gigabitethernet 0/1-2
Node2(config-if-range)# switchport
Node2(config-if-range)# switchport mode trunk
Node2(config-if-range)# exit
Node2(config)# erps raps-vlan 100
Node2(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node2(config-erps 100)# associate sub-ring raps-vlan 200,300,400
```

```
Node2(config-erps 100)# state enable
Node2(config-erps 100)# exit
```

Enable the global ERPS function.

```
Node2(config)# erps enable
```

(3) Configure node 3.

Configure the link mode for Ethernet ring ports, configure the major ring R-APS VLAN 100, add interfaces to the Ethernet ring, associate the major ring R-APS VLAN 100 with subrings R-APS VLANs 200, 300, and 400, and enable the ERPS function.

```
Node3> enable
Node3# configure terminal
Node3(config)# interface range gigabitethernet 0/1-2
Node3(config-if-range)# switchport
Node3(config-if-range)# switchport mode trunk
Node3(config-if-range)# exit
Node3(config)# erps raps-vlan 100
Node3(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node3(config-erps 100)# associate sub-ring raps-vlan 200,300,400
Node3(config-erps 100)# state enable
Node3(config-erps 100)# exit
```

Configure the link mode for ports in ERPS 2, configure an R-APS VLAN for ERPS 2, add interfaces to the subring, and enable the ERPS function.

```
Node3(config)# interface gigabitethernet 0/3
Node3(config-if-GigabitEthernet 0/3)# switchport
Node3(config-if-GigabitEthernet 0/3)# switchport mode trunk
Node3(config-if-GigabitEthernet 0/3)# exit
Node3(config)# erps raps-vlan 200
Node3(config-erps 200)# ring-port west virtual-channel east gigabitethernet 0/3
Node3(config-erps 200)# state enable
Node3(config-erps 200)# exit
```

Configure the link mode for ports in ERPS 3, configure an R-APS VLAN for ERPS 3, add interfaces to the subring, and enable the ERPS function.

```
Node3(config)# interface gigabitethernet 0/4
Node3(config-if-GigabitEthernet 0/4)# switchport
Node3(config-if-GigabitEthernet 0/4)# switchport mode trunk
Node3(config-if-GigabitEthernet 0/4)# exit
Node3(config)# erps raps-vlan 300
Node3(config-erps 300)# ring-port west virtual-channel east gigabitethernet 0/4
Node3(config-erps 300)# state enable
Node3(config-erps 300)# exit
```

Enable the global ERPS function.

```
Node3(config)# erps enable
```

(4) Configure node 4.

Configure the link mode for ports in the major ring, configure R-APS VLAN 100, add interfaces to the Ethernet ring, associate the major ring R-APS VLAN 100 with subrings R-APS VLANs 200, 300, and 400, and enable the ERPS function.

```
Node4> enable
Node4# configure terminal
Node4(config)# interface range gigabitethernet 0/1-2
Node4(config-if-range)# switchport
Node4(config-if-range)# switchport mode trunk
Node4(config-if-range)# exit
Node4(config)# erps raps-vlan 100
Node4(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node4(config-erps 100)# associate sub-ring raps-vlan 200,300,400
Node4(config-erps 100)# state enable
Node4(config-erps 100)# exit
```

Configure the link mode for ports in subring ERPS 2, configure an R-APS VLAN for subring ERPS 2, add interfaces to the subring, and enable the ERPS function.

```
Node4(config)# interface gigabitethernet 0/3
Node4(config-if-GigabitEthernet 0/3)# switchport
Node4(config-if-GigabitEthernet 0/3)# switchport mode trunk
Node4(config-if-GigabitEthernet 0/3)# exit
Node4(config)# erps raps-vlan 200
Node4(config-erps 200)# ring-port west virtual-channel east gigabitethernet 0/3
Node4(config-erps 200)# state enable
Node4(config-erps 200)# exit
```

Configure the link mode for ports in subring ERPS 3, configure an R-APS VLAN for subring ERPS 3, add interfaces to the subring, and enable the ERPS function.

```
Node4(config)# interface gigabitethernet 0/4
Node4(config-if-GigabitEthernet 0/4)# switchport
Node4(config-if-GigabitEthernet 0/4)# switchport mode trunk
Node4(config-if-GigabitEthernet 0/4)# exit
Node4(config)# erps raps-vlan 300
Node4(config-erps 300)# ring-port west virtual-channel east gigabitethernet 0/4
Node4(config-erps 300)# state enable
Node4(config-erps 300)# exit
```

Configure the link mode for ports in subring ERPS 4, configure an R-APS VLAN for subring ERPS 4, add interfaces to the subring, and enable the ERPS function.

```
Node4(config)# interface gigabitethernet 0/5
Node4(config-if-GigabitEthernet 0/5)# switchport
Node4(config-if-GigabitEthernet 0/5)# switchport mode trunk
Node4(config-if-GigabitEthernet 0/5)# exit
Node4(config)# erps raps-vlan 400
Node4(config-erps 400)# ring-port west virtual-channel east gigabitethernet 0/5
Node4(config-erps 400)# state enable
```

```
Node4(config-erps 400)# exit
```

Enable the global ERPS function.

```
Node4(config)# erps enable
```

(5) Configure node 5.

Configure the link mode for Ethernet ring ports, configure an R-APS VLAN, add interfaces to the ring, configure GigabitEthernet 0/1 as the RPL port, and enable the ERPS function.

```
Node5> enable
Node5# configure terminal
Node5(config)# interface range gigabitethernet 0/1-2
Node5(config-if-range)# switchport
Node5(config-if-range)# switchport mode trunk
Node5(config-if-range)# exit
Node5(config)# erps raps-vlan 200
Node5(config-erps 200)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node5(config-erps 200)# rpl-port west rpl-owner
Node5(config-erps 200)# state enable
Node5(config-erps 200)# exit
```

Enable the global ERPS function.

```
Node5(config)# erps enable
```

(6) Configure node 6.

Configure the link mode for Ethernet ring ports, configure an R-APS VLAN, add interfaces to the ring, configure GigabitEthernet 0/1 as the RPL port, and enable the ERPS function.

```
Node6> enable
Node6# configure terminal
Node6(config)# interface range gigabitethernet 0/1-2
Node6(config-if-range)# switchport
Node6(config-if-range)# switchport mode trunk
Node6(config-if-range)# exit
Node6(config)# erps raps-vlan 300
Node6(config-erps 300)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node6(config-erps 300)# rpl-port west rpl-owner
Node6(config-erps 300)# state enable
Node6(config-erps 300)# exit
```

Enable the global ERPS function.

```
Node6(config)# erps enable
```

(7) Configure node 7.

Configure the link mode for Ethernet ring ports, configure an R-APS VLAN, add interfaces to the ring, configure GigabitEthernet 0/1 as the RPL port, and enable the ERPS function.

```
Node7> enable
Node7# configure terminal
```

```
Node7(config)# interface range gigabitethernet 0/1-2
Node7(config-if-range)# switchport
Node7(config-if-range)# switchport mode trunk
Node7(config-if-range)# exit
Node7(config)# erps raps-vlan 400
Node7(config-erps 400)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node7(config-erps 400)# rpl-port west rpl-owner
Node7(config-erps 400)# state enable
Node7(config-erps 400)# exit
```

Enable the global ERPS function.

```
Node7(config)# erps enable
```

5. Verification

Run the **show erps** command on each node to verify the configuration. The following uses node 3 as an example.

```
Node3# show erps
ERPS Information
Global Status                : Enabled
Link monitored by            : Not Oam
-------------------------------------------
R-APS VLAN                   : 200
Ring Status                  : Enabled
West Port                    : Virtual Channel
East Port                    : Gi 0/3 (Forwarding)
RPL Port                     : None
Protected VLANs              : ALL
RPL Owner                    : Disabled
Holdoff Time                 : 0 milliseconds
Guard Time                   : 500 milliseconds
WTR Time                     : 2 minutes
Current Ring State           : Idle
Associate R-APS VLAN         :

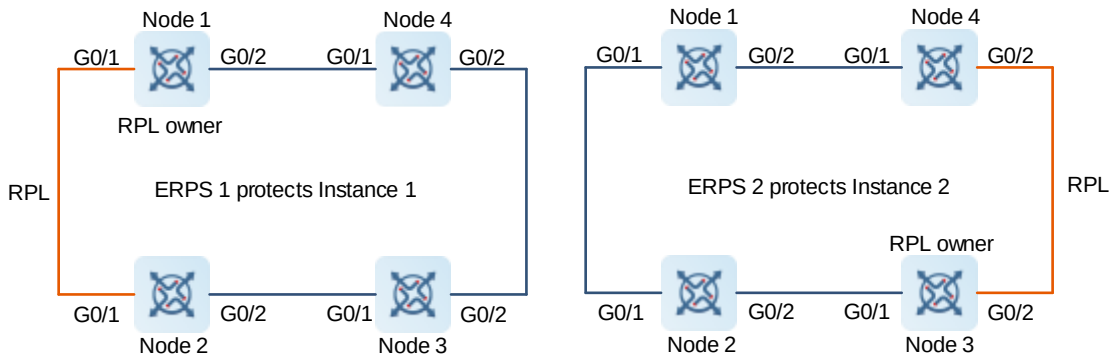
Associate R-APS VLAN          : 200,300,400
```

6. Common Errors

- The Ethernet ring ERPS function is enabled, but the global ERPS function is not enabled. In this case, the ERPS function does not take effect.
- Multiple RPL owner nodes are configured in one ERPS ring.
- Different R-APS VLANs are configured for the nodes in one ERPS ring.
- The nodes in the major ring are not associated with its subring.



1.13.4 Configuring Load Balancing

1. Requirements

As shown in Figure 1-8, two Ethernet rings are configured in the same physical network: ERPS 1 (nodes 1-2-3-4) protects VLANs 1-2000, and ERPS 2 (nodes 3-4-1-2) protects VLANs 2001-4094.

2. Topology

Figure 1-8 Topology of Configuring Load Balancing

3. Notes

- Before adding a physical port to an Ethernet ring, configure the link of the member port to work in trunk mode.
- Before configuring the protected VLANs, create Instances 1 and 2 on nodes 1-4, and map instance 1 to

VLANs 1-2000 and instance 2 to VLANs 2001-4094.

- ERPS 1 and ERPS 2 enabled with load balancing pass through node 1 and node 1 is the RPL owner node of ERPS 1. Notes when configuring this node are as follows:
  - Configure R-APS VLAN 100, add interfaces GigabitEthernet 0/1 and 0/2 to the Ethernet ring, configure GigabitEthernet 0/1 as the RPL port, configure the Ethernet ring to protect VLANs corresponding to instance 1, and enable the ERPS function for the Ethernet ring.
  - Configure R-APS VLAN 200, add interfaces GigabitEthernet 0/1 and GigabitEthernet 0/2 to the Ethernet ring, configure VLANs corresponding to instance 2 protected by the Ethernet ring, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.
- ERPS 1 and ERPS2 with load balancing enabled pass through node 2 and node 4, and node 2 and node 4 are non-RPL owner nodes. Notes for configuring these nodes are as follows:
  - Configure R-APS VLAN 100, add interfaces GigabitEthernet 0/1 and GigabitEthernet 0/2 to the Ethernet ring, configure VLANs corresponding to instance 1 protected by the Ethernet ring, and enable the ERPS function for the Ethernet ring.
  - Configure R-APS VLAN 200, add interfaces GigabitEthernet 0/1 and GigabitEthernet 0/2 to the Ethernet ring, configure VLANs corresponding to instance 2 protected by the Ethernet ring, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.
- ERPS 1 and ERPS 2 enabled with load balancing pass through node 3 and node 3 is the RPL owner node of ERPS 2. Notes for configuring this node are as follows:
  - Configure R-APS VLAN 100, add interfaces GigabitEthernet 0/1 and GigabitEthernet 0/2 to the Ethernet ring, configure VLANs corresponding to instance 1 protected by the Ethernet ring, and enable the ERPS function for the Ethernet ring.
  - Configure R-APS VLAN 200, add interfaces GigabitEthernet 0/1 and GigabitEthernet 0/2 to the Ethernet ring, configure GigabitEthernet 0/2 as the RPL port, configure VLANs corresponding to instance 2 protected by the Ethernet ring, and enable the ERPS function for the Ethernet ring.
  - Enable the global ERPS function.

4. Procedure

(1) Create instance 1 and instance 2, and add protected VLAN groups to the instances. Nodes 1-4 are configured in the same way.

Configure node 1.

```
Node1> enable
Node1# configure terminal
Node1(config)# spanning-tree mst configuration
Node1(config-mst)# instance 1 vlan 1-2000
Node1(config-mst)# instance 2 vlan 2001-4094
Node1(config-mst)# exit
```

Configure node 2.

```
Node2> enable
```

```
Node2# configure terminal
Node2(config)# spanning-tree mst configuration
Node2(config-mst)# instance 1 vlan 1-2000
Node2(config-mst)# instance 2 vlan 2001-4094
Node2(config-mst)# exit
```

Configure node 3.

```
Node3> enable
Node3# configure terminal
Node3(config)# spanning-tree mst configuration
Node3(config-mst)# instance 1 vlan 1-2000
Node3(config-mst)# instance 2 vlan 2001-4094
Node3(config-mst)# exit
```

Configure node 4.

```
Node4> enable
Node4# configure terminal
Node4(config)# spanning-tree mst configuration
Node4(config-mst)# instance 1 vlan 1-2000
Node4(config-mst)# instance 2 vlan 2001-4094
Node4(config-mst)# exit
```

(2) Configure a single-ring node, namely, node 1.

Configure the links of the Ethernet ring ports (GigabitEthernet 0/1 and GigabitEthernet 0/2) to work in trunk mode.

```
Node1(config)# interface range gigabitethernet 0/1-2
Node1(config-if-rang)# switchport
Node1(config-if-rang)# switchport mode trunk
Node1(config-if-rang)# exit
```

Configure VLANs in instance 1 protected by ERPS 1.

```
Node1(config)# erps raps-vlan 100
Node1(config-erps 100)# protected-instance 1
Node1(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node1(config-erps 100)# rpl-port west rpl-owner
Node1(config-erps 100)# state enable
Node1(config-erps 100)# exit
```

Configure VLANs in instance 2 protected by ERPS 2.

```
Node1(config)# erps raps-vlan 200
Node1(config-erps 200)# protected-instance 2
Node1(config-erps 200)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node1(config-erps 200)# state enable
Node1(config-erps 200)# exit
```

Enable the global ERPS function.

```
Node1(config)# erps enable
```

(3) Configure a single-ring node, namely, node 2. The configuration commands are the same as those on node 1, except that no RPL needs to be configured.

Configure the links of the Ethernet ring ports (GigabitEthernet 0/1 and GigabitEthernet 0/2) to work in trunk mode.

```
Node2(config)# interface range gigabitethernet 0/1-2
Node2(config-if-rang)# switchport
Node2(config-if-rang)# switchport mode trunk
Node2(config-if-rang)# exit
```

Configure VLANs in instance 1 protected by ERPS 1, add the ports to the ring, specify the RPL owner port, and enable the ERPS function.

```
Node2(config)# erps raps-vlan 100
Node2(config-erps 100)# protected-instance 1
Node2(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node2(config-erps 100)# state enable
Node2(config-erps 100)# exit
```

Configure VLANs in instance 2 protected by ERPS 2, add the ports to the Ethernet ring, and enable the ERPS function.

```
Node2(config)# erps raps-vlan 200
Node2(config-erps 200)# protected-instance 2
Node2(config-erps 200)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node2(config-erps 200)# state enable
Node2(config-erps 200)# exit
```

Enable the global ERPS function.

```
Node2(config)# erps enable
```

(4) Configure a single-ring node, namely, node 3. The commands are the same as those on node 1, except that the RPL owner port is configured on ERPS 2.

Configure the links of the Ethernet ring ports (GigabitEthernet 0/1 and GigabitEthernet 0/2) to work in trunk mode.

```
Node3(config)# interface range gigabitethernet 0/1-2
Node3(config-if-rang)# switchport
Node3(config-if-rang)# switchport mode trunk
Node3(config-if-rang)# exit
```

Configure VLANs in instance 1 protected by ERPS 1, add the ports to the ring, specify the RPL owner port, and enable the ERPS function.

```
Node3(config)# erps raps-vlan 100
Node3(config-erps 100)# protected-instance 1
Node3(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node3(config-erps 100)# state enable
Node3(config-erps 100)# exit
```

Configure VLANs in instance 2 protected by ERPS 2, add the ports to the Ethernet ring, and enable the ERPS function.

```
Node3(config)# erps raps-vlan 200
Node3(config-erps 200)# protected-instance 2
Node3(config-erps 200)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node3(config-erps 200)# rpl-port east rpl-owner
Node3(config-erps 200)# state enable
Node3(config-erps 200)# exit
```

Enable the global ERPS function.

```
Node3(config)# erps enable
```

(5) Configure a single-ring node, namely, node 4. The configuration is the same as that on node 2.

Configure the links of the Ethernet ring ports (GigabitEthernet 0/1 and GigabitEthernet 0/2) to work in trunk mode.

```
Node4(config)# interface range gigabitethernet 0/1-2
Node4(config-if-rang)# switchport
Node4(config-if-rang)# switchport mode trunk
Node4(config-if-rang)# exit
```

Configure VLANs in instance 1 protected by ERPS 1, add the ports to the ring, specify the RPL owner port, and enable the ERPS function.

```
Node4(config)# erps raps-vlan 100
Node4(config-erps 100)# protected-instance 1
Node4(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node4(config-erps 100)# state enable
Node4(config-erps 100)# exit
```

Configure VLANs in instance 2 protected by ERPS 2, add the ports to the Ethernet ring, and enable the ERPS function.

```
Node4(config)# erps raps-vlan 200
Node4(config-erps 200)# protected-instance 2
Node4(config-erps 200)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/2
Node4(config-erps 200)# state enable
Node4(config-erps 200)# exit
```

Enable the global ERPS function.

```
Node4(config)# erps enable
```

5. Verification

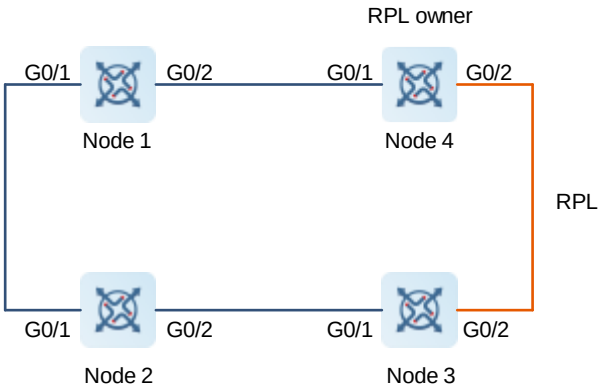
Run the **show erps** command on each node to verify the configuration. The following uses the configuration on node 1 as an example.

```
Node1# show erps
ERPS Information
Global Status                : Enabled
```

```
Link monitored by             : Not Oam
-----------------------------------------
R-APS VLAN                    : 100
Ring Status                   : Enabled
West Port                     : Gi 0/1 (Blocking)
East Port                     : Gi 0/2 (Forwarding)
RPL Port                      : West Port
Protected VLANs               : 1-2000
RPL Owner                     : Enabled
Holdoff Time                  : 0 milliseconds
Guard Time                    : 500 milliseconds
WTR Time                      : 2 minutes
Current Ring State            : Idle
Associate R-APS VLAN          :
-----------------------------------------
R-APS VLAN                    : 200
Ring Status                   : Enabled
West Port                     : Gi 0/1 (Forwarding)
East Port                     : Gi 0/2 (Blocking)
RPL Port                      : West Port
Protected VLANs               : 2001-4094
RPL Owner                     : Enabled
Holdoff Time                  : 0 milliseconds
Guard Time                    : 500 milliseconds
WTR Time                      : 2 minutes
Current Ring State            : Idle
Associate R-APS VLAN          :
```

6. Common Errors

- The Ethernet ring ERPS function is enabled, but the global ERPS function is not enabled. In this case, the ERPS function does not take effect.
- Multiple RPL owner nodes are configured in one ERPS ring.
- Different R-APS VLANs are configured for the nodes in one ERPS ring.



1.13.5 Modifying ERPS Configuration

1. Requirements

ERPS has been configured in an Ethernet ring. An ERPS port needs to be changed because of a physical topology change.

2. Topology

Figure 1-9 Topology of ERPS Configuration Modification

3. Notes

- Shut down a link in the ring and configure the link mode for the new Ethernet ring port.
- Disable ERPS for the ring in R-APS VLAN configuration mode.
- Reconfigure the ports that will participate in ERPS calculation.
- Enable the ERPS function for this ring.
- Modify the ERPS timers.

4. Procedure

(1) Configure node 1.

In Layer 2 Ethernet interface configuration mode, shut down a link in the ring to prevent loops.

```
Node1> enable
Node1# configure terminal
Node1(config)# interface gigabitethernet 0/1
Node1(config-if-GigabitEthernet 0/1)# shutdown
Node1(config-if-GigabitEthernet 0/1)# exit
```

Configure the link mode for the new Ethernet ring port.

```
Node1(config)# interface gigabitethernet 0/3
Node1(config-if-GigabitEthernet 0/3)# switchport
Node1(config-if-GigabitEthernet 0/3)# switchport mode trunk
Node1(config-if-GigabitEthernet 0/3)# exit
```

Enter the R-APS VLAN configuration mode, disable the ERPS function and delete previous ring configurations.

```
Node1(config)# erps raps-vlan 100
Node1(config-erps 100)# no state enable
Node1(config-erps 100)# no ring-port
```

Modify the configuration of Ethernet ring ports, change GigabitEthernet 0/2 to GigabitEthernet 0/3, and enable the ERPS function.

```
Node1(config-erps 100)# ring-port west gigabitethernet 0/1 east gigabitethernet
0/3
```

```
Node1(config-erps 100)# state enable
Node1(config-erps 100)# exit
```

Enable the port that is previously disabled.

```
Node1(config)# interface gigabitethernet 0/1
Node1(config-if-GigabitEthernet 0/1)# no shutdown
```

(2) Configure node 4, enter the ERPS configuration mode, and modify timers.

```
Node4> enable
Node4# configure terminal
Node4(config)# erps raps-vlan 100
Node4(config-erps 100)# timer wtr-time 1
```

5. Verification

Wait for 1 minute. After the ERPS ring is restored to the idle state, run the **show erps** command on node 1 to verify the configuration.

```
Node1# show erps
ERPS Information
Global Status                : Enabled
Link monitored by            : Not Oam
-----------------------------------------
R-APS VLAN                   : 100
Ring Status                  : Enabled
West Port                    : Gi 0/1 (Forwardin)
East Port                    : Gi 0/3 (Forwardin)
RPL Port                     : None
Protected VLANs              : ALL
RPL Owner                    : Enabled
Holdoff Time                 : 0 milliseconds
Guard Time                   : 500 milliseconds
WTR Time                  : 2 minutes
Current Ring State           : Idle
Associate R-APS VLAN         :
```

Wait for 1 minute. After the ERPS ring is restored to the idle state, run the **show erps** command on node 4 to verify the configuration.

```
Node4# show erps
ERPS Information
Global Status                : Enabled
Link monitored by            : Not Oam
-----------------------------------------
R-APS VLAN                   : 100
Ring Status                  : Enabled
West Port                    : Gi 0/1 (Forwardin)
East Port                    : Gi 0/2 (Blocking)
RPL Port                     : East Port
Protected VLANs              : ALL
```

```
RPL Owner                     : Enabled
Holdoff Time                  : 0 milliseconds
Guard Time                    : 500 milliseconds
WTR Time                   : 1 minutes
Current Ring State            : Idle
Associate R-APS VLAN          :
```

6. Common Errors

- The R-APS ring is not enabled after the configuration is modified.
- The ports that are previously disabled are not enabled after the configuration is modified.

1 Configuring LLDP

1.1 Introduction

1.1.1 Overview

The Link Layer Discovery Protocol (LLDP) is a L2 discovery protocol defined in the IEEE 802.1AB standard. It is used to discover a topology and identify topological changes. LLDP encapsulates local information of a device into LLDP data units (LLDPDUs) in the type length value (TLV) format and then sends the LLDPDUs to neighbors. It also stores LLDPDUs from neighbors in the management information base (MIB) to be accessed by the network management system (NMS).

With LLDP, the NMS can learn about topology connections, for example, interfaces of a device connected to other devices, as well as the rates and duplex modes of interfaces at both ends of a link. Administrators can quickly locate and eliminate a fault based on the information. An LLDP-compliant device is capable of discovering neighbors when its peer is either an LLDP-compliant device or a device supporting the Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED).

1.1.2 LLDP Packet

An LLDP-compliant device advertises to neighbors its own information by sending LLDP packets, and obtains the information of neighbors by receiving LLDP packets. LLDP packets can be encapsulated in two formats: Ethernet II and SNAP (Sub Network Access Protocols). Figure 1-1shows the format of an LLDP packet encapsulated in Ethernet frame format.

Figure 1-1 LLDP Packet Encapsulated in Ethernet Frame Format

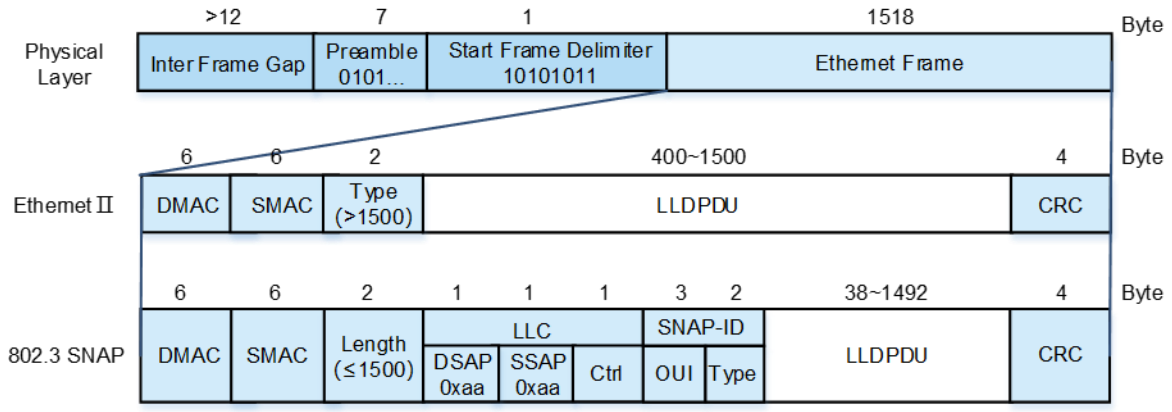

Table 1-1 describes the related fields of an LLDP packet encapsulated in Ethernet II format.

Table 1-1 Description of Fields in an LLDP Packet Encapsulated in Ethernet II Format

Field	Byte	Description
DMAC	6	Destination Address, which is a fixed multicast address 0180.c200.000e.
SMAC	6	Source Address, which is the MAC address of the device's interface.

Field	Byte	Description
Type	2	Ethernet type, which is 0x88CC.
LLDPDU	400-1500	LLDP data unit.
CRC	4	Frame check sequence.

Table 1-2 describes the related fields of an LLDP packet encapsulated in SNAP format.

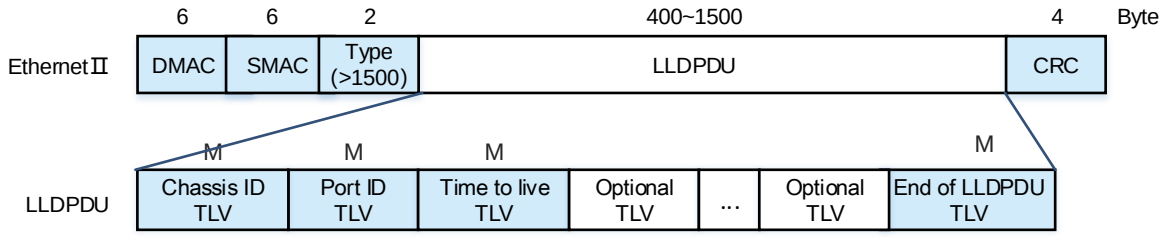

Table 1-2 Description of Fields in an LLDP Packet Encapsulated in SNAP Format

Field	Byte	Description
DMAC	6	Destination Address, which is a fixed multicast address 0180.c200.000e.
SMAC	6	Source Address, which is the MAC address of the device's interface.
DSAP	1	Destination Service Access Point. The value is 0xaa.
SSAP	1	Source Service Access Point. The value is 0xaa.
Control	1	Control information, for storing various control information and identify the type of frame. The value is 0x03.
OUI	3	Organizationally Unique Identifier, for distinguishing between basic management TLVs and TLVs defined by different organizations.
Type	2	Ethernet type, which is 0x88CC.
LLDPDU	38-1492	LLDP data unit.
CRC	4	Frame check sequence.

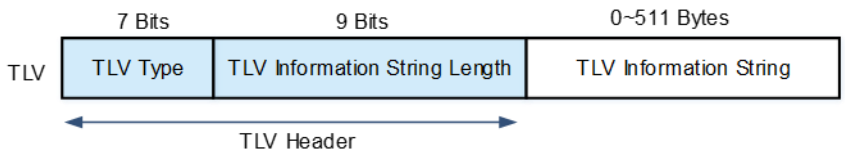
1.1.3 LLDPDU

The data unit in the LLDP packet is called LLDPDU (short for Link Layer Discovery Protocol Data Unit). According to the LLDP, each LLDPDU can contain 28 TLVs, starting from the Mandatory TLV - Chassis ID TLV, Port ID TLV and Time To Live TLV, Optional TLV in the middle, and LLDPDU TLV at the end. **Figure 1-2** shows the format of LLDPDU, where M represents the mandatory TLV.

Figure 1-2 Format of LLDPDU

1.1.4 TLV

The data unit field in the LLDP frame is LLDPDU, which is composed of a series of variable length information elements. Each information element is called a TLV. The device supporting LLDP function records the status information of the device to the TLV to and advertise it to the neighbor, and obtains the status information of the neighbor through the TLV.



TLVs encapsulated in LLDPDUs are classified into basic management TLVs and organizationally specific TLVs.

Organizationally specific TLVs are defined by standard organizations or other institutions, for example, the IEEE 802.1 working group, the IEEE 802.3 working group, Internet Engineering Task Force (IETF), and equipment suppliers define their own TLV collections.

Organizationally specific TLVs are optional and are advertised in an LLDPDU selectively. Currently, there are three types of common organizationally specific TLVs: IEEE 802.1 organizationally specific TLVs, IEEE 802.3 organizationally specific TLVs, and LLDP-MED TLVs.

Figure 1-3 shows the structure of a TLV.

Figure 1-3 Structure of a TLV

- TLV Type: TLV type number. Different organizations advertise private information of devices by defining specific TLV types, and different TLV types are represented by numerical numbers in the TLV packet. Different organizations may define the same TLV Type number, so it is necessary to distinguish TLVs of different organizations based on the OUI (Organizationally Unique Identifier) field in the LLDP packet, and determine the TLV type based on the TLV Type value.
- TLV Information String Length: The length of TLV information. The 9-bit binary number can represent 0-511 bytes, so the length of TLV information is 0-511 bytes.
- TLV Information String: TLV information value.

1. Basic Management TLVs

Basic management TLVs are a collection of basic TLVs used for network management. This collection consists of two types of TLVs: mandatory TLVs and optional TLVs. A mandatory TLV must be contained in an LLDPDU for advertisement and an optional TLV is contained selectively. Table 1-3 describes the types of basic management TLVs.

Table 1-3 Basic Management TLVs

TLV Type	Description	Mandatory/Optional
End Of LLDPDU TLV	End flag of an LLDPDU, occupying two bytes.	Mandatory
Chassis ID TLV	Device ID, represented using a MAC address.	Mandatory
Port ID TLV	Interface sending an LLDPDU.	Mandatory

Time To Live TLV	TTL of local information on a neighbor. When a device receives a TLV with TTL of 0, it deletes the neighbor information.	Mandatory
Port Description TLV	Descriptor of the interface sending an LLDPDU.	Optional
System Name TLV	Device name.	Optional
System Description TLV	Device description, including the hardware version, software version, and operating system.	Optional
System Capabilities TLV	Main functions supported by the device, such as the bridge, routing, and relay functions.	Optional
Management Address TLV	Management address, which contains the interface ID and object identifier (OID).	Optional

Note

This LLDP-compliant device supports advertisement of basic management TLVs.

2. 802.1 TLV

- Table 1-4 describes IEEE 802.1 organizationally specific TLVs. All TLV types are optional.

Table 1-4 IEEE 802.1 Organizationally Specific TLVs

TLV Type	Description
Port VLAN ID TLV	TLV Type is 1. Virtual local area network (VLAN) identifier of an interface.
Port And Protocol VLAN ID TLV	TLV Type is 2. Protocol VLAN identifier of an interface.
VLAN Name TLV	TLV Type is 3. VLAN name of an interface.
Protocol Identity TLV	TLV Type is 4. Protocol type supported by an interface.

Note

This LLDP-compliant device does not send the protocol identity TLV but receives this TLV.

3. 802.3 TLV

- Table 1-5 describes IEEE 802.3 organizationally specific TLVs. All TLV types are optional.

Table 1-5 IEEE 802.3 Organizationally Specific TLVs

TLV Type	Description

TLV Type	Description
MAC/PHY Configuration//Status TLV	TLV Type is 1. Rate and duplex mode of an interface, and whether auto-negotiation is supported and enabled.
Power Via MDI TLV	TLV Type is 2. Power supply capacity of an interface.
Link Aggregation TLV	TLV Type is 3. Link aggregation capacity of an interface and the current aggregation state.
Maximum Frame Size TLV	TLV Type is 4. Maximum size of the frame that can be transmitted by an interface.

Note

This LLDP-compliant device supports advertisement of IEEE 802.3 organizationally specific TLVs.

- **LLDP-MED TLV**

LLDP-MED (Link Layer Discovery Protocol-Media Endpoint Discovery) is an extension to LLDP based on IEEE 802.1AB LLDP. It enables users to conveniently deploy the Voice over IP (VoIP) network and detect faults. It provides applications including the network configuration policies, device discovery, and inventory management, which can meet requirements for low cost, effective management, and easy deployment and help simplify deployment of audio devices. Table 1-6 describes LLDP-MED TLVs. All TLV types are optional.

Table 1-6 LLDP-MED TLV

TLV Type	Description
LLDP-MED Capabilities TLV	Whether the device supports LLDP-MED, the type of the LLDP-MED TLV encapsulated into an LLDPDU, and device type (network connectivity device or endpoint device).
Network Policy TLV	Interface VLAN configuration, supported application type (such as voice or video services), and L2 priority information.
Location Identification TLV	Contains city location (common address and device type) and emergency contact number, which can be used to accurately locate endpoint devices in applications such as network topology collection.
Extended Power-via-MDI TLV	Extended power supply capacity.
Inventory – Hardware Revision TLV	Hardware version of a MED device.
Inventory – Firmware Revision TLV	Firmware version of a MED device.
Inventory – Software Revision TLV	Software version of a MED device.
Inventory – Serial Number TLV	Serial number of a MED device.

TLV Type	Description
Inventory – Manufacturer Name TLV	Name of the manufacturer of a MED device.
Inventory – Model Name TLV	Module name of a MED device.
Inventory – Asset ID TLV	Asset identifier of a MED device, used for inventory management and asset tracking.

Note

This LLDP-compliant device supports advertisement of LLDP-MED TLVs.

1.1.5 LLDP Packet Transmission Mechanism

LLDP-compliant devices can send LLDP packets to peers. LLDP packets are used to inform peers of their neighbors. When the LLDP transmission mode is canceled or the interface is disabled, LLDP packets can inform peers that their neighbors are no longer valid.

LLDP supports three work modes.

- TxRx: Transmits and receives LLDPDUs.
- Rx Only: Only receives LLDPDUs.
- Tx Only: Only transmits LLDPDUs.

LLDP periodically transmits LLDP packets when working in TxRx or Tx Only mode. When information about the local device changes, LLDP immediately transmits LLDP packets. You can configure an LLDP packet transmission delay to avoid frequent transmission of LLDP packets caused by frequent changes of local information. This delay can be manually configured.

LLDP provides two types of packets:

- Standard LLDP packet: It contains management and configuration information of the local device.
- Shutdown packet: When the LLDP work mode is disabled or the interface is shut down, LLDP shutdown packets will be transmitted. A shutdown packet consists of the chassis ID TLV, port ID TLV, TTL TLV, and end of LLDP TLV. TTL in the TTL TLV is 0. When a device receives an LLDP shutdown packet, it considers the neighbor information invalid and immediately deletes it.

When the LLDP work mode is changed from disabled or Rx to TxRx or Tx, or LLDP discovers a new neighbor (that is, a device receives a new LLDP packet and the neighbor information is not stored locally), the fast transmission mechanism is started so that the neighbor quickly learns the device information. The fast transmission mechanism enables a device to transmit a certain number of LLDP packets at an interval of 1 second.

1.1.6 LLDP Packet Receiving Mechanism

LLDP-compliant devices can receive LLDP packets from the peers. A device can discover its neighbors and determine when to age the neighbor information according to received LLDP packets.

A device can receive LLDP packets when working in TxRx or Rx Only mode. After receiving an LLDP packet, a device conducts a validity check. After the packet passes the check, the device checks whether the packet

provides information about a new neighbor or information update of an existing neighbor and stores the neighbor information locally. The device sets the TTL of neighbor information according to the value of TTL TLV in the packet. If the value of TTL TLV is 0, the neighbor information needs to be aged immediately.

1.1.7 Protocols and Standards

- IEEE 802.1AB 2005:IEEE Standard for Local and metropolitan area networks - Station and Media Access Control Connectivity Discovery
- ANSI/TIA-1057: Link Layer Discovery Protocol for Media Endpoint Devices

1.2 Restrictions and Guidelines

- LLDP can only be enabled on a physical interface, including Layer 2 Ethernet interface, Layer 3 Ethernet interface and management interface.
- For the aggregate interface, LLDP can be enabled on the member ports of the aggregate interface. The stack port and VSL (Virtual Switching Link) port also do not support LLDP.

1.3 Configuration Task Summary

The following tasks are optional:

(1) Enabling the LLDP Function

(2) Configuring the LLDP Transmission Mechanism

- Configuring the LLDP Packet Encapsulation Format
- Configuring LLDP Work Mode

(3) Configuring LLDP performance parameters

- Configuring Interface Initialization Delay Time
- Configuring Packet Sending Interval
- Configuring TTL Multiplier
- Configuring LLDP Packet Sending Delay Time
- Configuring LLDP Packets Fast Sending Count

(4) Configuring TLV Published in LLDPDU

- Configuring LLDP Management Address
- Configuring Optional TLVs that an Interface can Publish
- Configuring Interface to Publish City Location
- Configuring Interface to Publish Emergency Contact Number
- Configuring Interface to Publish Network Policy TLV

(5) Configuring the Device to Ignore PVID Detection

(6) Configuring Compatibility with Competitor Device Discovery

(7) Configuring LLDP Alarm Function

(8) Configuring LLDP Error Detection Function

1.4 Enabling the LLDP Function

1.4.1 Overview

This section describes how to enable or disable the LLDP function globally and on an interface. The LLDP function is enabled globally and on an interface by default. The function configuration is optional.

1.4.2 Restrictions and Guidelines

- You can enable the LLDP function on a Layer 2 Ethernet interface, Layer 3 Ethernet interface and management interface.
- To make the LLDP function take effect on an interface, the LLDP function must be enabled globally and on the interface.
- You can run the **lldp enable** command in global configuration mode to enable the LLDP function globally, and run the **lldp enable** command in interface configuration mode to enable LLDP function on an interface.
- LLDP function is enabled by default. You can use the **no lldp enable** command to disable the LLDP function.
- When a neighbor does not support LLDP but it is connected to an LLDP-supported device in downlink direction, an interface may learn information about the device that is not directly connected to the interface because the neighbor may forward LLDP packets.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the LLDP function globally.

lldp enable

The global LLDP function is enabled by default.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 3 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the management interface configuration mode.

  interface mgmt *interface-number*

(5) Enable the LLDP function on the interface.

lldp enable

The LLDP function is enabled on interfaces by default.

1.5 Configuring the LLDP Packet Encapsulation Format

1.5.1 Overview

The same LLDP packet encapsulation format needs to be configured on the local device and its neighbors in interface configuration mode to ensure their normal communication.

You can use the **no lldp encapsulation snap** command to configure the LLDP packet encapsulation format as SNAP, or use the **no lldp encapsulation snap** command to restore the packet encapsulation format to Ethernet II.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 3 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the management interface configuration mode.

  interface mgmt *interface-number*

(4) Set the LLDP packet encapsulation format to SNAP.

lldp encapsulation snap

The default LLDP packet encapsulation format is Ethernet II.

1.6 Configuring LLDP Work Mode

1.6.1 Overview

LLDP supports three work modes. This device has a default configuration, and configuration commands of this function are optional.

- TxRx: Transmits and receives LLDPDUs.
- Rx Only: Only receives LLDPDUs.
- Tx Only: Only transmits LLDPDUs.

When the LLDP work mode of the interface changes, the interface will initialize the protocol state machine. To avoid frequent initialization of the state machine caused by frequent changes in the interface work mode, the delay time of interface initialization can be configured in the global configuration mode.

1.6.2 Restrictions and Guidelines

- By default, the work mode of LLDP is **txrx**, indicating that the interface sends and receives LLDPDU. You can configure the work mode as **tx** or **rx** according to actual needs.

- When the LLDP work mode of the interface is **tx**, the interface can only send packets but not receive packets.
- When the LLDP work mode of the interface is **rx**, the interface can only receive packets but not send packets.

You can use the **no lldp mode** command to disable LLDP work mode of the interface, and the interface will not send or receive LLDP packets.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 3 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the management interface configuration mode.

  interface mgmt *interface-number*

(4) Configure the LLDP work mode.

lldp mode { **rx** | **tx** | **txrx** }

By default, the LLDP work mode is sending and receiving LLDPDU.

1.7 Configuring Interface Initialization Delay Time

1.7.1 Overview

To avoid frequent initialization of the state machine caused by frequent changes in the interface work mode, the delay time of interface initialization can be configured in the global configuration mode.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the interface initialization delaytime.

lldp timer reinit-delay *reinit-delay*

By default, the LLDP interface initialization delaytime is 2 seconds.

1.8 Configuring Packet Sending Interval

1.8.1 Overview

The time interval for sending LLDP packet refers to the period for sending LLDP packet. A short period indicates high LLDP transmission frequency, increasing the system resource consumption. If the period is too long, the peer device may not discover the local device in time. According to the actual needs of the network, the time interval for sending LLDP packets can be configured to change the network topology discovery frequency.

1.8.2 Restrictions and Guidelines

- For standard MIB, the sending interval of LLDP packet is 5-32768 seconds.
- The value range of *tx-interval* is 1-32768, in seconds. The range is larger than that of the standard MIB to meet the requirements of more scenarios.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the sending interval of LLDP packets.

lldp timer tx-interval *tx-interval*

By default, the LLDP packet sending interval is 30 seconds.

1.9 Configuring TTL Multiplier

1.9.1 Overview

In the LLDP packet, TLV indicates the lifetime of the device's information on the neighbor device.

Time To Live TLV = TTL Multiplier x Packet Sending Interval + 1. TLV value can be modified by configuring TTL multiplier and LLDP packet sending interval. For example, if the TTL multiplier is 2, and the packet sending interval is 30 seconds, then the time to live of the LLDP packet of this device on the neighbor device is 2 x 30+1=61 seconds.

1.9.2 Restrictions and Guidelines

- You can use the **lldp hold-multiplier** *ttl-value* command to adjust the TTL multiplier in order to control the time to live of the device information on the neighbor device.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the TTL multiplier.

lldp hold-multiplier *ttl-value*

By default, the TTL multiplier of LLDP packet is 4.

1.10 Configuring LLDP Packet Sending Delay Time

1.10.1 Overview

When the status information of a local device changes, the local device will send a LLDP packet to neighbor devices immediately. To avoid frequently sending LLDP packets caused by frequent changes in local status information, you can configure the LLDP packet sending delay time to restrict the frequent sending of LLDP packets.

1.10.2 Restrictions and Guidelines

- The LLDP packet sending delay time is 2 seconds by default. *tx-delay* is the LLDP packet sending delay time configuration parameter, with a value range of 1-8192 seconds.
- If the value of delay time is too small, LLDP packets will be frequently sent due to the change of local status information. If the value of delay time is too large, the LLDP packet cannot be sent in time after a change occurred in the local status information. You are advised to configure the delay time according to the actual situation.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the LLDP packet sending delay time.

lldp timer tx-delay *tx-delay*

By default, the LLDP packet sending delay time is 2 seconds.

1.11 Configuring LLDP Packets Fast Sending Count

1.11.1 Overview

When a new neighbor is discovered, or the LLDP work mode is changed from Disabled or Rx to TxRx or Tx, the device will start the fast sending mechanism to enable the neighbor device to learn the information of the device as soon as possible. The fast sending mechanism will shorten the sending period of LLDP packet to 1 second, and continuously send a certain number of LLDP packets, and then resume the normal sending interval. You can use this function to configure the number of LLDP packets sent under the fast sending mechanism.

1.11.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the fast sending count of LLDP packets.

lldp fast-count *fast-count-value*

By default, the fast sending count of LLDP packets is 3.

1.12 Configuring LLDP Management Address

1.12.1 Overview

The LLDP management address is used to identify a device on the network and is transmitted in the Management Address TLV field in the basic management TLV.

The Management Address TLV is an optional basic management TLV, as shown in **Table 1-3**However, in this device, the Management Address TLV is included in the LLDPDU by default. You can use this function to configure the content to be included in the Management Address TLV. The Management Address TLV may change if you configure the LLDP packet to publish the management address. If no management address is configured, the default management address will be used in LLDP packet.

1.12.2 Restrictions and Guidelines

- In the global configuration mode or interface configuration mode, the LLDP packet management address can be configured. The management address configured in the global configuration mode has priority over that configured in the interface configuration mode. When there is a global management address, the interface management address cannot be configured.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the management address to be advertised in LLDP packets.

lldp management-address-tlv { *ipv4-address* | *ipv6-address* }

By default, the management address is the IPv4 address of the minimum VLAN supported by an interface. If no IPv4 address is configured for the VLAN, LLDP keeps searching for the next allowed minimum VLAN until a qualified IP address is found. If no IPv4 address is found, LLDP searches for the IPv6 address of the minimum VLAN supported by an interface. If no IPv6 address is found, the local address 127.0.0.1 is used as the management address.

1.13 Configuring Optional TLVs that an Interface can Publish

1.13.1 Overview

You can use this function to configure types of optional TLVs that an interface can publish or not publish, so as to change the LLDPDU content in the LLDP packet sent by the interface.

- **Table 1-3**shows basic management TLVs, where Chassis ID TLV, Port ID TLV, Time To Live TLV and End Of LLDPDU TLV are mandatory and do not need to be configured. For optional TLVs (except Management

Address TLV), you can use this function to configure whether to publish these optional TLVs in the LLDPDU.

- Table 1-4 shows TLVs defined by IEEE 802.1. TLV types are optional. You can use this function to configure whether to publish Port VLAN ID TLV, Port And Protocol VLAN ID TLV and VLAN Name TLV in the LLDPDU. The LLDP protocol of this product does not support sending Protocol Identity TLVs, but supports receiving TLVs of this type.
- Table 1-5 shows TLVs defined by IEEE 802.3. TLV types are optional. You can use this function to configure whether to publish these TLVs in the LLDPDU.
- Table 1-6 shows TLVs defined by LLDP-MED. TLV types are optional. You can use this function to configure whether to publish these TLVs in the LLDPDU.

1.13.2 Restrictions and Guidelines

- Run the **lldp tlv-enable basic-tlv** command to configure optional basic management TLVs that an interface can publish. Run the **no lldp tlv-enable basic-tlv** command to configure the interface not to publish optional basic management TLVs.
  - **all**: Port Description TLV, System Capabilities TLV, System Description TLV and System Name TLV in basic management TLVs.
  - **port-description**: Port Description TLV, indicating that the interface sends the interface description information of LLDPDU.
  - **system-capability**: System Capabilities TLV, which describes the main functions of the device, such as bridging, routing and relay.
  - **system-description**: System Description TLV, which describes the device hardware version, software version and operating system, etc.
  - **system-name**: System Name TLV, which describes the name of the device.
- Run the **lldp tlv-enable dot1-tlv** command to configure the interface to publish 802.1 TLV. Run the **no lldp tlv-enable dot1-tlv** command to configure the interface not to publish 802.1 TLVs.
  - **all**: Port VLAN ID TLV, Port And Protocol VLAN ID TLV and VLAN Name TLV in 802.1 TLVs.
  - **port-vlan-id**: Port VLAN ID TLV, indicating port VLAN identifier.
  - **protocol-vlan-id** [*protocol-vlan-id*]: Port And Protocol VLAN ID TLV, indicating port and VLAN identifiers. *protocol-vlan-id* indicates the protocol VLAN ID of the interface. The value range is 1-4094.
  - **vlan-name** [*vlan-id*]: VLAN Name TLV, indicating VLAN name of the interface. *vlan-id* indicates the protocol VLAN ID of the interface. The value range is 1-4094.
- Run the **lldp tlv-enable dot3-tlv** command to configure the interface to publish 802.3 TLVs. Run the **no lldp tlv-enable dot3-tlv** command to configure the interface not to publish 802.3 TLVs.
  - **all**: All optional TLVs in 802.3 TLVs.
  - **link-aggregation**: Link Aggregation TLV, which describes the link aggregation capability and current aggregation state of the interface.
  - **mac-physic**: MAC/PHY Configuration/Status TLV, which describes the duplex status of the interface, the support of the automatic negotiation function and the disable or enable state of the function.
  - **max-frame-size**: Maximum Frame Size TLV, which describes the maximum size of frames that can be transmitted by the interface.

- **power**: Power Via MDI TLV, which describes the power supply capability of the interface.

- Run the **lldp tlv-enable med-tlv** command to configure the interface to publish LLDP-MED TLVs. Run the **no lldp tlv-enable med-tlv** command to configure the interface not to publish LLDP-MED TLVs.
  - **all**: The **all** parameter in the **lldp tlv-enable med-tlv** command indicates that the interface can publish all LLDP-MED TLVs except the Location Identification TLV. The **all** parameter in the **no lldp tlv-enable med-tlv** indicates that the interface does not publish all LLDP-MED TLVs, including the Location Identification TLV.
  - **capability**: LLDP-MED Capabilities TLV, which describes whether the device supports LLDP-MED, LLDP-MED TLV type encapsulated in LLDPDU, and current device type (network connecting device or client).
  - **inventory**: Describes the media device directory management TLV, including hardware version, firmware version, software version, serial number, vendor name, module name, asset identifier, etc.
  - **power-over-ethernet**: Extended Power-via-MDI TLV, which indicates extended power supply capacity of the interface.
  - **location civic-location identifier** *id*: City location information in Location Identification TLV, including general address and device type. **identifier** *id* is the configured city location policy ID, and the value range is 1-1024. The LLDP city location information must be configured before the TLV can be published. See **Configuring Interface to Publish City Location** for details.
  - **location elin identifier** *id*: Emergency contact number information in Location Identification TLV. **identifier** *id* is the configured emergency contact number policy ID, and the value range is 1-1024. LLDP emergency contact number information must be configured first before the TLV can be published. See **Configuring Interface to Publish Emergency Contact Number** for details.
  - **network-policy profile** [*profile-number*]: Network Policy TLV, which advertises VLAN configuration, supported application types (such as voice or video), Layer 2/Layer 3 priority information of the interface. *profile-number* indicates the network policy ID, with a value range of 1-1024. When the device is connected to an IP phone, if the IP phone supports LLDP-MED, you can configure the Network Policy TLV to issue policies to the IP phone. You must first configure the Network Policy TLV policy, and then configure to allow the interface to publish this TLV. See **Configuring Interface to Publish Network Policy TLV** for details.

  You can run the **show lldp tlv-config** [**interface** *interface-type interface-number*] command to view the TLV publish status on the interface, where the value of the STATUS field indicates the publish status. The value of the DEFAULT field indicates the default publish status.

- Follow the following steps to configure the interface to publish TLVs:
  a Allow the interface to publish LLDP 802.3 MAC/PHY Configuration/Status TLV.
  b Allow the interface to publish LLDP-MED Capabilities TLV.
  c Allow the interface to publish other types of LLDP-MED TLVs except Network Policy TLV.

- Follow the following steps to configure the interface not to publish TLVs:
  a Configure the interface not to publish other TLVs in LLDP-MED except the Network Policy TLV.
  b Configure the interface not to publish LLDP-MED Capabilities TLV.
  c Configure the interface not to publish MAC/PHY Configuration/Status TLV.

1.13.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 3 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the management interface configuration mode.

  interface mgmt *interface-number*

(4) Configure the interface to publish TLVs. Configure at least one of following items.

- Configure the interface to publish optional basic management TLVs except Management Address TLV.

  lldp tlv-enable basic-tlv { **all** | **port-description** | **system-capability** | **system-description** | **system-name** }

  By default, the interface publishes Port Description TLV, System Capabilities TLV, System Description TLV, and System Name TLV.

- Configure the interface to publish 802.1 TLVs except Protocol Identity TLV.

  lldp tlv-enable dot1-tlv { **all** | **port-vlan-id** | **protocol-vlan-id** [*protocol-vlan-id*] | **vlan-name** [*vlan-id*] }

  By default, the interface publishes Port VLAN ID TLV, Port And Protocol VLAN ID TLV, and VLAN Name TLV.

- Configuration the interface to publish 802.3 TLVs.

  lldp tlv-enable dot3-tlv { **all** | **link-aggregation** | **mac-physic** | **max-frame-size** | **power** }

  By default, the interface publishes all 802.3 TLVs.

- Configuration the interface to publish LLDP-MED TLVs.

  lldp tlv-enable med-tlv { **all** | **capability** | **inventory** | **location civic-location identifier** *id* | **location elin identifier** *id* | **network-policy profile** [*profile-number*] | **power-over-ethernet** }

  By default, the interface publishes all LLDP-MED TLVs except Location Identification TLV.

1.14 Configuring Interface to Publish City Location

1.14.1 Overview

As shown in Table 1-6, the Location Identification TLV field in LLDP-MED TLV contains city location information (common address, device type) and emergency contact number, which are used to accurately locate endpoint devices in applications such as network topology collection.

You can use this function to configure the interface to publish city location information (common address, device type). First, create an LLDP Civic Address policy, and enter the LLDP Civic Address configuration mode

to configure the common address and device type. Next, enter the interface configuration mode of a specified interface, and configure the interface to publish the city location information (common address, device type) in the Location Identification TLV.

1.14.2 Restrictions and Guidelines

- Use the **lldp location civic-location identifier** *id* to create an LLDP Civil Address policy, and enter the LLDP Civil Address configuration mode.
- In the LLDP Civic Address configuration mode, use the **civic-location** command to configure the common address information of the device. This parameter has two parts: address type *ca-type* and address information *ca-word*. The **civic-location** keyword is not reflected in the configuration command. The configuration starts with the parameter of the address type *ca-type*. Use the *ca-type ca-word* command to configure the address of the device, and use the **no** *ca-type* command to delete the address information.
- Optional parameters of address type *ca-type* include: **country**; **state**; **county** ; **city**; **division**; **neighborhood**; **street-group**; **leading-street-dir**; **trailing-street-suffix**; **street-suffix**; **number**; **street-number-suffix**; **landmark**; **additional-location-information**; **name**; **postal-code**; **building**; **unit**; **floor**; **room**; **type-of-place**; **postal-community-name**; **post-office-box**; and **additional-code**.
- Use the Address information *ca-word* field to configure specific information. Note that when the address type is **country**, use only two characters to represent the country. For example, **country** CH represents China.
- In the LLDP Civic Address configuration mode, use the **device-type** *device-type* command to to configure the device type. The default value of *device-type* is 1. The value 0 indicates a DHCP Server, 1 indicates a switch, and 2 indicates an LLDP MED client. You can use the **no device-type** command to restore the default configuration.
- In the interface configuration mode, use the **lldp tlv-enable med-tlv location civic-location identifier** *id* command to configure the interface to publish LLDP city location information (common address, device type). **med-tlv** indicates that the published information is encapsulated in LLDP MED TLV (Link Layer Discovery Protocol Media Endpoint Discovery). **location civic-location identifier** *id* indicates that the interface is allowed to publish the city location information in the Location Identification TLV. The policy ID of this information is id, and the value range is 1-1024. The LLDP city location information must be configured before the TLV can be published.
- Multiple city location information policies can be configured. You can use the **lldp tlv-enable med-tlv location civic-location identifier** *id* command on different interfaces to publish different city location information TLVs.
- You can use the **show lldp location civic-location** { **identifier** *id* | **interface** *interface-type interface-number* | **static** } command to view the configuration result.

1.14.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a LLDP city location information, and enter the LLDP Civil Address configuration mode.

lldp location civic-location identifier *id*

By default, no LLDP city location information exists.

(4) Configure the city location information.

a Configure common address information.

{ **country** | **state** | **county** | **city** | **division** | **neighborhood** | **street-group** | **leading-street-dir** | **trailing-street-suffix** | **street-suffix** | **number** | **street-number-suffix** | **landmark** | **additional-location-information** | **name** | **postal-code** | **building** | **unit** | **floor** | **room** | **type-of-place** | **postal-community-name** | **post-office-box** | **additional-code** } *ca-word*

By default, no common address information exists.

b Configure the device type information.

device-type *device-type*

By default, the device type is switch.

c Exit the global configuration mode.

exit

(5) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 3 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the management interface configuration mode.

  interface mgmt *interface-number*

(6) Configure the interface to publish LLDP city location information.

lldp tlv-enable med-tlv location civic-location identifier *id*

By default, the interface does not publish LLDP city location information.

1.15 Configuring Interface to Publish Emergency Contact Number

1.15.1 Overview

As shown in Table 1-6, the Location Identification TLV field in LLDP-MED TLV contains city location information (common address, device type) and emergency contact number, which are used to accurately locate endpoint devices in applications such as network topology collection.

You can use this function to configure the interface to publish emergency contact number. First, configure an LLDP emergency contact number policy, and configure the emergency contact number. Next, enter the interface configuration mode of a specified interface, and configure the interface to publish the emergency contact number in the Location Identification TLV.

1.15.2 Restrictions and Guidelines

- In the global configuration mode, use the **lldp location elin identifier** *id* **elin-location** *telephone-number* command to configure an emergency contact number policy and telephone number.
- In the interface configuration mode, use the **lldp tlv-enable med-tlv location elin identifier** *id* command to configure the interface to publish LLDP emergency contact number. **med-tlv** indicates that the emergency

contact number is encapsulated in LLDP MED TLV (Link Layer Discovery Protocol Media Endpoint Discovery). **location elin identifier** *id* indicates that the interface is allowed to publish the emergency contact number in the Location Identification TLV. The value range of the policy ID is 1-1024. LLDP emergency contact number must be configured first before the TLV can be published.

- Multiple emergency contact numbers can be configured. You can use the **lldp tlv-enable med-tlv location elin identifier** *id* command on different interfaces to allow the interface to publish different emergency contact number TLVs.
- You can use the **show lldp location elin-location** { **identifier** *id* | **interface** *interface-type interface-number* | **static** } command to view the configuration result.

1.15.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the emergency contact number of the device.

lldp location elin identifier *id* **elin-location** *telephone-number*

By default, no emergency contact number exists.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 3 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the management interface configuration mode.

  interface mgmt *interface-number*

(5) Configure the interface to publish LLDP emergency contact number.

lldp tlv-enable med-tlv location elin identifier *id*

By default, the interface does not publish LLDP emergency phone number.

1.16 Configuring Interface to Publish Network Policy TLV

1.16.1 Overview

If the downstream IP phone supports LLDP (Link Layer Discovery Protocol), when it goes online, it will actively send LLDP packets. If the device is configured with LLDP Network Policy TLV, it can capture LLDP packets sent by the IP phone and send Voice VLAN policies to the IP phone. If a policy is configured to allow the IP phone to send tagged frames, and the IP phone supports sending tagged packets, the IP phone will add VLAN tags when sending voice packets according to the policy. If the policy requires the IP phone to send an untagged frame, the IP phone will send untagged packets.

1.16.2 Restrictions and Guidelines

- **network-policy profile** [*profile-number*]: Allow the interface to publish Network Policy TLV and advertise the VLAN configuration of the interface, supported application types (such as voice or video), Layer 2/Layer 3 priority information, etc. *profile-number* indicates the network policy ID, with a value range of 1-1024. When the device is connected to an IP phone, if the IP phone supports LLDP-MED, you can configure the Network Policy TLV to issue policies to the IP phone. You must first configure the Network Policy TLV policy, and then configure the interface to publish this TLV.
- **voice**: Specifies the application type of Voice. **voice-signaling**: Specifies the application type of voice signaling. One LLDP Network Policy can only have one Voice application type and one Voice Signaling application type. Voice and Voice Signaling application types can exist at the same time.
- { *vlan-id* | **dot1p** } [**cos** *cos* | **dscp** *dscp*]: Configures to send tagged frames in Voice VLAN.
  - *vlan-id*: Voice VLAN ID of the voice stream in the VLAN Tag. The value range is 1-4094. The voice packet will be tagged with this ID.
  - **dot1p**: VLAN ID as 0 in the VLAN Tag, that is, the frame contains only the priority information *cos* and *dscp*.
  - **cos** *cos*: CoS (Class of Service) value of Voice VLAN voice traffic priority in the VLAN Tag. The value range is 0-7, and the default value is 5. The higher the value, the higher the priority. Ordinary VLAN packets has a CoS value of 0, with the lowest priority. By default, the CoS value of voice traffic packets entering Voice VLAN is increased to 6, which is higher than the priority of ordinary VLAN packets. The CoS value represents the Layer 2 priority, which is stored in the Layer 2 header of the packet and filled in the PRI field of the 802.1Q VLAN Tag.
  - **dscp** *dscp*: DSCP (Differentiated Services Code Point) value of Voice VLAN voice traffic priority. The value range is 0-63, and the default value is 46. The higher the value, the higher the priority. The DSCP value of ordinary IP packets is 0, with the lowest priority. The default value of Voice VLAN voice traffic packets has a DSCP value of 46, which is higher than that of ordinary IP packets. The DSCP value represents the IP priority (IP PRE) and is stored in the Layer 3 header of the packet. For IPv4 packets, the DSCP value is filled in the first six bits (bit0-bit5) of the ToS domain of the IPv4 packet header.

    For IPv6 packets, the DSCP value is filled in the first 6 bits of Traffic Class field of the IPv6 packet header.
- **untagged**: Configures the VoIP device to send untagged frames. No VLAN ID or CoS values exist in the frame. The DSCP value exists in the IP header and cannot be configured using this command.
- **none**: Indicates that the LLDP network policy is not issued (that is, the default case), and the VoIP device determines the frame to be sent according to its own configuration.

In addition to creating LLDP Network Policy on the device, you also need to:

- Enable the Voice VLAN function, and statically add the interface connecting the IP phone to the Voice VLAN. If the downstream IP phone does not support LLDP-MED, you need to manually configure the MAC address of the IP phone to the Voice VLAN OUI list. See *Configuring Voice VLAN* for details.
- Configure QoS trusted interface priority modification. See *Configuring QoS* in the *ACL and QoS Configuration Guide* for details.
- Configure a secure channel if 802.1x Authentication is also enabled on the interface, in order to allow packets in Voice VLAN to pass through. See *Configuring ACL* in the *ACL and QoS Configuration Guide* for

details.

- You can use the **show lldp tlv-config** [**interface** *interface-type interface-number*] command to view the TLV publish status on the interface. The STATUS field indicates the configured publish status, and the DEFAULT field indicates the default publish status.

1.16.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an LLDP network policy, and enter the LLDP Network Policy configuration mode.

lldp network-policy profile *profile-number*

By default, no LLDP network policy exists.

(4) Configure the Voice VLAN policy. The following configuration tasks are exclusive. Configure one of the following items.

- Configure the Voice VLAN policy to instruct IP phone to send tagged frames.

  { **voice** | **voice-signaling** } **vlan** { *voice-vlan-id* | **dot1p** } [**cos** *cos* | **dscp** *dscp*]

  By default, no Voice VLAN policy exists.

- Configure the Voice VLAN policy to instruct the IP phone to send untagged frames. In this case, the interface can only be manually added to the Voice VLAN.

  { **voice** | **voice-signaling** } **vlan untagged**

  By default, no Voice VLAN policy exists.

- Cancel the Voice VLAN policy, and the IP phone determines the frame to be sent according to its own configuration.

  { **voice** | **voice-signaling** } **vlan none**

  By default, no Voice VLAN policy exists.

(5) Exit the global configuration mode.

exit

(6) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 3 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the management interface configuration mode.

  interface mgmt *interface-number*

(7) Configure the interface to publish the Network Policy TLV policy.

lldp tlv-enable med-tlv network-policy profile *profile-number*

By default, the interface publishes the Network Policy TLV.

1.17 Configuring the Device to Ignore PVID Detection

1.17.1 Overview

You can configure the device to ignore PVID detection on the device.

1.17.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the device to ignore PVID detection.

lldp ignore pvid-error-detect

The device does not ignore PVID detection by default,

1.18 Configuring Compatibility with Competitor Device Discovery

1.18.1 Overview

You can configure the compatibility with competitive device discovery function on the device.

1.18.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the compatibility with competitive device discovery function.

lldp compliance vendor

By default, the compatibility with competitive device discovery function is disabled.

1.19 Configuring LLDP Alarm Function

1.19.1 Overview

LLDP alarm function, namely LLDP Trap. By configuring the LLDP alarm function, you can send the LLDP information of the local device (such as discovering a new neighbor, detecting a communication link failure with a neighbor, and so on) to the network management server. The administrator can monitor the network operation according to this information.

To prevent the LLDP alarm information from being sent too frequently, the interval for sending LLDP alarms can be configured in the global configuration mode. During this interval, if LLDP information changes are detected, an alarm will be sent to the network management server.

1.19.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Configure the interval for sending LLDP alarms.

lldp timer notification-interval *trap*

By default, the interval for sending LLDP alarm is 5 seconds.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 3 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the management interface configuration mode.

  interface mgmt *interface-number*

(5) Enable the LLDP alarm function.

lldp notification remote-change enable

By default, the LLDP alarm function is disabled.

1.20 Configuring LLDP Error Detection Function

1.20.1 Overview

After this function is enabled, when an error is detected by the LLDP, a system log will be printed out and sent to the administrator.

Errors to be detected include VLAN configuration detection, interface status detection, interface aggregation configuration detection, MTU configuration detection and loop detection at both ends of the link.

1.20.2 Restrictions and Guidelines

- The LLDP error detection function depends on the devices at both ends of the link to send and receive specific TLVs in the LLDP packet. For this function to work properly, correct TLVs must be published by the device.

1.20.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the Layer 3 Ethernet interface configuration mode.

  interface { *ethernet-type interface-number* | **range** *ethernet-type interface-range* }

- Enter the management interface configuration mode.

  interface mgmt *interface-number*

(4) Enable the LLDP error detection function.

lldp error-detect

By default, the LLDP error detection function is enabled.

1.21 Configuring the Maximum Number of Neighbors for an LLDP Interface

1.21.1 Overview

The maximum number of neighbors that can be learned by an LLDP interface is the maximum number of neighbors for the interface. If the number of learned neighbors is not limited, a large amount of neighbor information may exhaust the device memory, affecting the normal operation of the device.

1.21.2 Restrictions and Guidelines

- If the configured maximum number of neighbors on an interface is smaller than the actual number of neighbors on the interface, the excess neighbors are deleted. The neighbor with a smaller TTL value is preferentially deleted. If the TTL values of the neighbors are the same, the neighbor with a smaller index value is preferentially deleted.

1.21.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the maximum number of neighbors for an LLDP interface.
lldp neighbor-maxmium *neighbor-maxmium*

By default, the maximum number of neighbors for an LLDP interface is 5.

1.22 Monitoring

Run the **show** commands to check configuration.

Run the **debug** commands to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **clear** commands to clear information.

Caution

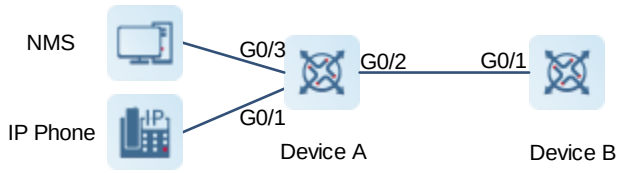
During device operation, running the **clear** command may cause service interruption due to key information loss.

Table 1-7 Monitoring

Command	Purpose
clear lldp active-ip-change-log	Clears the address change records of the management port enabled with LLDP.
clear lldp statistics [**interface** *interface-type interface-number*]	Clears LLDP statistics.
clear lldp table [**interface** *interface-type interface-number*]	Clears LLDP neighbor information.
show lldp active-ip	Displays address information of the management port enabled with LLDP on the local device.
show lldp active-ip change-log	Displays the address change records of the management port enabled with LLDP on the local device.
show lldp local-information [**global** | **interface** interface-type interface-number]	Displays LLDP information on the local device, which will be organized as TLVs and sent to neighbors.
show lldp location { **civic-location | elin-location** } { **identifier** *id* **| interface** *interface-type interface-number* **| static** }	Displays the LLDP civic address or emergency contact number of the local device.
show lldp neighbors [interface *interface-type interface-number*] [**detail** | **enhance**]	Displays the LLDP information of a neighbor.
show lldp network-policy { **profile** [*profile-num*] | **interface** *interface-type interface-number* }	Displays the LLDP network policy configuration of the local device.
show lldp statistics [**global | interface** *interface-type interface-number*]	Displays LLDP statistics.
show lldp status [**interface** *interface-type interface-number*]	Displays the LLDP status information.
show lldp tlv-config [**interface** *interface-type interface-number*]	Displays the configuration of TLVs to be advertised by an interface.
debug lldp error	Debugs LLDP error processing.

Command	Purpose
debug lldp event	Debugs LLDP event processing.
debug lldp ha	Debugs LLDP hot backup processing.
debug lldp packet	Debugs the LLDP packet receiving.
debug lldp stm	Debugs the LLDP state machine.

1.23 Configuration Examples



1.23.1 Checking the Neighbors Connected to the Device by Using the LLDP Function

1. Requirements

As shown in Figure 1-4, GigabitEthernet 0/1 of Device A is connected to the neighbor IP phone (MED device), and GigabitEthernet 0/2 is connected to the neighbor Device B. One NMS is connected to GigabitEthernet 0/3 of Device A. Check neighbor information on Device A by using the LLDP function.

2. Topology

Figure 1-4 Topology of Checking the Neighbors Connected to the Device by Using the LLDP Function

3. Notes

- The LLDP function is enabled by default and no configuration is required.
- The default LLDP work mode of an interface is TxRx and no configuration is required.
- The default LLDP packet transmission interval is 30 seconds, the default LLDP packet transmission delay is 2 seconds, and no configuration is required.

4. Verification

Check information about the neighbor connected to port GigabitEthernet 0/2 of Device A. It can be seen that GigabitEthernet 0/2 of Device A is connected to GigabitEthernet 0/1 of Device B, and the neighbor supports the bridging (B) and routing (R) functions.

```
DeviceA# show lldp neighbors interface gigabitethernet 0/2
Capability codes:
    (R) Router, (B) Bridge, (T) Telephone, (C) DOCSIS Cable Device
    (W) WLAN Access Point, (P) Repeater, (S) Station, (O) Other
System Name      Local Intf         Port ID         Capability      Aging-time
DeviceB          Gi0/2              Gi0/1           B, R            1minutes
49seconds
```

```
Total entries displayed: 1
```

Check details about the neighbor connected to GigabitEthernet 0/2 of Device A.

```
DeviceA# show lldp neighbors interface gigabitethernet 0/2 detail

1.23.2 Configuring the LLDP Error Detection Function

1. Requirements

As shown in **Figure 1-5**, Device A and Device B are connected through Gigabit Ethernet (GE) interfaces. When an administrator configures the VLAN, port rate, duplex mode, aggregate interface, and port MTU, an error will be prompted if the configurations do not match those on the connected neighbor.

2. Topology

Figure 1-5 Topology of the LLDP Error Detection Function

3. Notes

- The LLDP function is enabled by default and no configuration is required.
- The default LLDP work mode of an interface is TxRx and no configuration is required.
- The LLDP error detection function is enabled by default and no configuration is required.
- The default LLDP packet transmission interval is 30 seconds, the default LLDP packet transmission delay is 2 seconds, and no configuration is required.

4. Verification

Forcibly set the rate of GigabitEthernet 0/2 of Device A to 100 Mbps. When the system prompts a mismatch with the rate and duplex mode of the connected port on the neighbor, the LLDP error detection function takes effect.

```
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# speed 100
%Warning: the speed/duplex of port GigabitEthernet 0/2 may not match with it's neighbor.
```

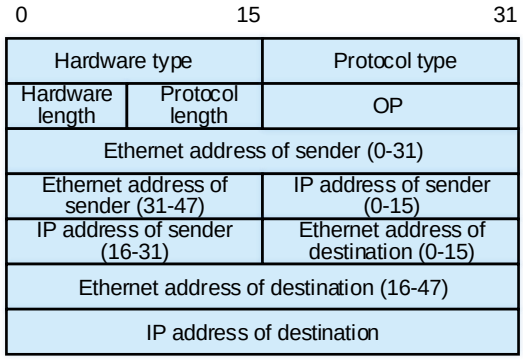
1 Configuring ARP

1.1 Introduction

1.1.1 Overview

If two IP-enabled hosts need to communicate, a sender must learn the IP address and media access control (MAC) address of the receiver. With the MAC address, the sending host encapsulates IP datagrams into the data link layer (DLL) frames and transmits them over the physical network. The process of converting an IP address to a MAC address is called address resolution. There are two types of address resolution: Address Resolution Protocol (ARP) and proxy ARP.



ARP maps an IP address into a MAC address. The mappings of IP and MAC addresses are stored in the ARP cache of the network device.

1.1.2 Basic Concepts

1. ARP Messages

An ARP message can be an ARP request or ARP reply. The format of an ARP message is as follows:

Figure 1-1 ARP Message Format

The description of fields in the ARP message is as follows:

- Hardware type: Indicates the type of a hardware address. For an Ethernet network, this value is **1**.
- Protocol type: Indicates the type of the protocol address to be mapped. For the IP protocol, this value is **0x0800**.
- Hardware length: Indicates the length of a hardware address, in bytes. For an Ethernet network, this value is **6**.
- Protocol length: Indicates the length of a protocol address, in bytes. For ARP requests or replies, this value is **4**.
- OP: Indicates the operation type. **1** indicates ARP requests, and **2** indicates ARP replies.
- Ethernet address of sender: Indicates a source MAC address, that is, the hardware address of a sender device.

- IP address of sender: Indicates a source IP address, that is, the IP address of a sender device.
- Ethernet address of destination: Indicates a destination MAC address, that is, the hardware address of a destination device. The value of this field is 0x00-00-00-00-00-00 for ARP requests.
- IP address of destination: Indicates a destination IP address, that is, the IP address of a destination device.

2. ARP Table

Each host maintains an ARP table that contains the mappings between IP addresses and MAC addresses. The mappings are called ARP entries.

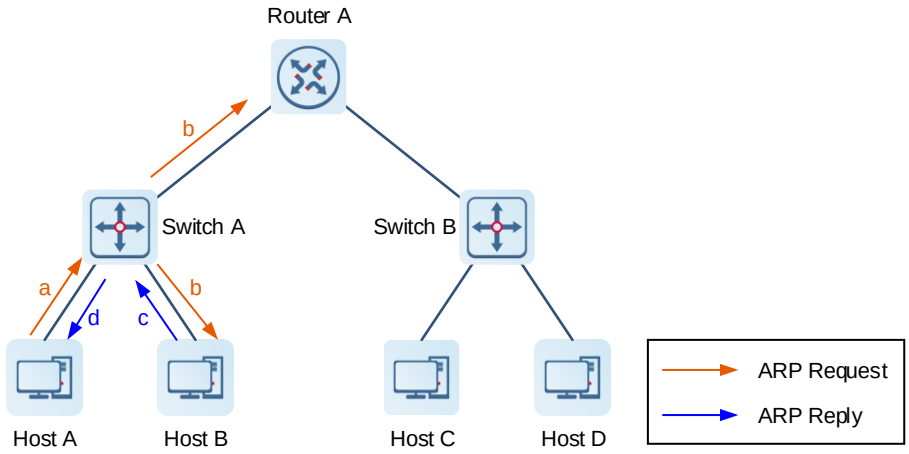
Before sending an IP packet, a host first searches the ARP table for the MAC address corresponding to the destination IP address. If there is a corresponding MAC address in the ARP table, the host sends the IP packet directly to the MAC address instead of sending an ARP request message. If there is no corresponding MAC address in the ARP table, the host broadcasts an ARP request message to request the MAC address of the destination host. ARP entries can help greatly reduce the network traffic.

ARP entries can be classified as dynamic ARP entries or static ARP entries. The difference between them is as follows:

- Dynamic ARP entries are automatically generated and updated by the ARP protocol that exchanges ARP messages among devices, and will be aged and overwritten by new dynamic ARP entries.
- Static ARP entries are manually configured and maintained by the network administrator, and will not be aged or overwritten by dynamic ARP entries.

1.1.3 Principles

1. Static ARP Entries



Static ARP entries are fixed mappings of IP and MAC addresses and they are created manually by the network administrator. The device cannot update the ARP entries. Static ARP entries can be deployed when communication security is a priority and network resources are sufficient.

2. Dynamic ARP Entries

Dynamic ARP allows devices to dynamically learn and update the mappings between IP and MAC addresses by exchanging ARP messages. Dynamic ARP entries can be deployed when real-time communication is priority or network resources are insufficient.

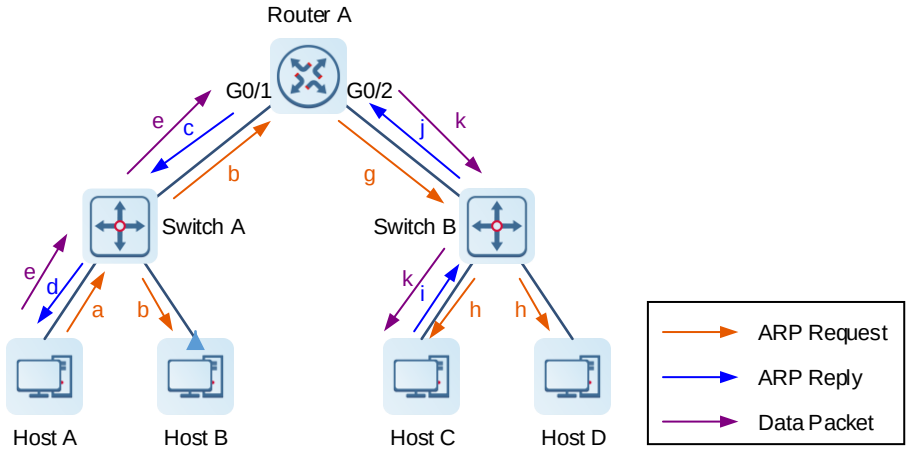
- **ARP implementation in the same network segment**

Figure 1-2 ARP Implementation in the Same Network Segment

As illustrated in Figure 1-2, host A has learned the IP address of host B and wants to send IP packets to host B. The address resolution process is as follows:

a Host A looks up in its ARP table and does not find the mapping between the IP and MAC addresses of host B. Host A then broadcasts an ARP request to request the MAC address of host B.

b After switch A receives the ARP request, switch A broadcasts the ARP request on the local network segment.



c After host B receives the ARP request, host B adds the MAC address of host A to its ARP table, and sends an ARP reply to host A. Since the destination IP address of the ARP request is not the IP address of router A, router A directly discards the ARP request after receiving it.

d Switch A forwards the ARP reply to the destination host A after receiving it.

e After host A receives the ARP reply, host A adds the MAC address of host B to its ARP table and sends the IP packets to host B.

- **ARP implementation in different network segments**

Figure 1-3 ARP Implementation in Different Network Segments

As illustrated in Figure 1-3, host A has learned the IP address of host C. For example, when host A sends an IP packet to host C, the address resolution process is as follows:

a Host A looks up in its ARP table and does not find the mapping between IP and MAC addresses of port GigabitEthernet 0/1 on the default gateway router A that is reachable to host C. Host A then sends an ARP broadcast request to request the MAC address of port GigabitEthernet 0/1 of router A.

f After receiving the ARP request, switch A broadcasts the packet on the local network segment.

g After receiving the ARP request, router A adds the MAC address of host A into its ARP table, and sends an ARP reply to host A. Since the destination IP address of the ARP request is not the IP address of host B, host B directly discards the ARP request after receiving it.

h Switch A forwards the ARP reply to the destination host A after receiving it.

i After receiving the ARP reply, host A adds the MAC address of port GigabitEthernet 0/1 of router A into its ARP table and sends the IP packet to router A.

j Router A looks up in the routing table and sends the IP packet from port GigabitEthernet 0/1 to port GigabitEthernet 0/2.

k Router A looks up in its ARP table and finds that there is no MAC address of host C. Router A then sends an ARP broadcast request to request the MAC address of host C.

l After switch B receives the ARP request, switch B broadcasts the packet on the local network segment.

m After host C receives the ARP request, host C adds the MAC address of port GigabitEthernet 0/2 of router A into its ARP table, and sends an ARP reply to router A. Since the destination IP address of the ARP request is not the IP address of host D, host D directly discards the ARP request after receiving it.

n Switch B forwards the ARP reply to the destination router A after receiving it.

o After router A receives the ARP reply, router A adds the MAC address of host C into its ARP table and sends the IP packet to host C.

3. Trusted ARP

When a user goes online on a GPRS support node (GSN) client, the authentication server obtains the user's real the mapping between IP and MAC addresses through the access device, and adds trusted ARP entries on the user's gateway device. This process is transparent to network administrators and does not require their extra work.

Trusted ARP entries have characteristics of both static and dynamic ARP entries, with a priority higher than that of dynamic ARP entries and lower than that of static ARP entries. Trusted ARP entries have an aging mechanism similar to that of dynamic ARP entries. When an ARP entry ages, the device actively sends an ARP request to detect whether the peer host exists. If the host sends a reply, the device regards the host active and updates the aging time of the ARP entry. Otherwise, the device deletes the ARP entry. Trusted ARP entries have characteristics of static ARP entries. The device cannot dynamically update information about the MAC addresses and interfaces in the trusted ARP entries by learning ARP messages.

Since trusted ARP entries come from authentic sources and will not be updated, they can efficiently prevent ARP spoofing targeting the gateway.

4. Gratuitous ARP

A gratuitous ARP message is a special ARP message. In a gratuitous ARP message, both the source and the destination IP addresses carried are the IP address of the local device.

Gratuitous ARP packets have the following purposes:

- Detecting IP address conflict If the device receives a gratuitous ARP packet and finds that the IP address in the packet is the same as its own IP address, it sends an ARP reply to notify the peer of the IP address conflict.
- Sending a gratuitous ARP packet to notify other devices to update ARP entries when the interface MAC address of a device changes. For example, in dual-node hot standby mode, when services are switched from the master device to the slave device, the MAC address of the previously slave device in the ARP entries on the connected device needs to be updated as that of the current master device. Generally, when services are switched from the master device to the slave device, the new master device after switchover sends a gratuitous ARP request to the network to notify other devices to update their ARP entries.
- Updating ARP entries based on gratuitous packets After receiving a gratuitous ARP message, the device checks whether a dynamic ARP entry corresponding to the source IP address in the gratuitous ARP packet exists. If yes, the device updates the ARP entry based on the information carried in the gratuitous ARP packet.

5. Proxy ARP

Proxy ARP allows devices on different subnets to resolve IP addresses into MAC addresses. If a device receives an ARP request whose source IP address is on a different network segment from the destination IP address and knows the route to the destination IP address, the device sends an ARP reply containing its own MAC address.

6. Local Proxy ARP

Local proxy ARP means that a device acts as a proxy ARP in the same virtual local area network (VLAN) that can be a common VLAN or sub VLAN.

After local proxy ARP is enabled on a device, the device can help hosts obtain the MAC addresses of other hosts in the VLAN. When port protection is enabled on the device, hosts connected to different ports are isolated at Layer 2. After receiving an ARP request, the device with local proxy ARP enabled serves as a proxy to send an ARP reply with its own Ethernet MAC address. In this case, hosts communicate with each other through Layer 3 routes.

7. Any IP ARP

Any IP ARP allows a device to access the network with any IP address. For example, a user is using a laptop in a hotel and wants to access the Internet without changing the configured IP address and gateway. After the gateway receives an ARP request and finds that the source IP address of the sender is in a different subnet and the destination address may not be its own address, the gateway still sends an ARP reply, with the MAC address of the gateway's Ethernet MAC address, and creates a direct route for the host.

1.1.4 Protocols and Standards

- RFC 826: An Ethernet Address Resolution Protocol
- RFC 1027: Using ARP to implement transparent subnet gateways

1.2 Configuration Task Summary

All the configuration tasks below are optional. Perform the configuration tasks as required.

- Configuring a Static ARP Entry
- Configuring Dynamic ARP Learning Attributes
- Configuring ARP Entry Management
- Enabling Trusted ARP
- Enabling Gratuitous ARP
- Enabling Proxy ARP
- Configuring Local Proxy ARP
- Configuring Any IP ARP
- Configuring other advanced ARP functions
  - Enabling ARP Trust Detection
  - Enabling ARP-based IP Guard
  - Configuring ARP Packet Filtering
  - Restraining the Device from Sending ARP Requests to Authenticated VLANs
  - Configuring Host Existence Judgment Prior to Proxy ARP Service
  - Configuring ARP Entry Update During Active/Standby Switchover
  - Sending ARP Requests to a Specific Sub VLAN
  - Configuring ARP Learning for a Specific Network Segment
  - Enabling Fast ARP Entry Deletion When a Layer 2 Interface Is Down

1.3 Configuring a Static ARP Entry

1.3.1 Overview

Users can manually configure static ARP entries to prevent the device from learning incorrect ARP entries, thus affecting the network connectivity.

1.3.2 Restrictions and Guidelines

After a static ARP entry is configured on a Layer 3 switch, the Layer 3 switch performs routing only after learning the physical port corresponding to MAC address carried in the static ARP entry.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a static ARP entry.

arp [**vrf** *vrf-name* | **oob** [**mgmt** *port-number*]] *ipv4-address mac-address arp-type*

No static ARP entry is configured by default.

1.4 Configuring Dynamic ARP Learning Attributes

1.4.1 Overview

The dynamic ARP learning function is enabled by default. You can configure ARP learning attributes as needed, for example, specify ARP entry timeout time, the number of times and interval that an ARP request can be transmitted consecutively, strict dynamic ARP learning function, ARP scanning, and scheduled automatic ARP scanning.

1.4.2 Configuration Tasks

All the configuration tasks below are optional. Perform the configuration tasks as required.

- Configuring the ARP Timeout Time
- Configuring ARP Request Retransmission
- Configuring Dynamic ARP Learning
- Configuring Strict Dynamic ARP Learning
- Configuring ARP Scanning
- Configuring Scheduled Automatic ARP Scanning

1.4.3 Configuring the ARP Timeout Time

1. Overview

Before an ARP entry times out, the device sends a unicast ARP request to detect whether the peer is online. If the device receives an ARP reply from the peer, it means that the peer is still online and the ARP entry is reserved. Otherwise, this ARP entry will be deleted. The ARP timeout time can be set as required.

2. Restrictions and Guidelines

The ARP timeout configuration only applies to dynamic mappings between IP and MAC addresses. When the ARP timeout time is set to a smaller value, the mapping table stored in the ARP cache is more accurate but ARP consumes more network bandwidth. In general, the ARP timeout time does not need to be set.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

(4) Configure the ARP timeout time.

arp timeout *time*

The default timeout time of dynamic ARP entries in the ARP cache is **3600** seconds.

1.4.4 Configuring ARP Request Retransmission

1. Overview

The device sends a certain number of ARP requests at a certain time interval during address resolution until the device receives an ARP reply. This function is used to configure the interval and number of times that an ARP request can be transmitted consecutively.

2. Restrictions and Guidelines

The shorter the retransmission interval is, the faster the resolution is. The more times the ARP request can be transmitted consecutively, the more likely the resolution will succeed and the more bandwidth ARP will be consumed.

If the network resources are insufficient, you are advised to set the ARP request retransmission interval to a larger value and the number of retransmission times to a smaller value, to reduce bandwidth consumption.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Configure the ARP request retransmission interval.

arp retry interval *interval*

The default ARP request retransmission interval is 1 second.

(5) Configure the number of times that an ARP request can be transmitted consecutively.

arp retry times *times*

The default number of times that an ARP request can be transmitted consecutively is 5. That is, if no ARP reply packet is received for the first ARP request, the ARP request packet will be retransmitted for four consecutive times.

1.4.5 Configuring Dynamic ARP Learning

1. Overview

The dynamic ARP learning function can be disabled on an interface. Then, the interface will not perform dynamic ARP learning.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Configure dynamic ARP learning.

- Configure dynamic ARP to learn only IPv4 addresses in the specified range.

  arp-learning *start-ipv4-address* [*end-ipv4-address*]

- Disable dynamic ARP learning.

  no arp-learning enable

The ARP learning function is enabled by default.

1.4.6 Configuring Strict Dynamic ARP Learning

1. Overview

After this function is enabled on a device, only the ARP replies in response to the ARP requests actively sent by the device can trigger the device to learn ARP entries.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Enable strict dynamic ARP learning.

arp strict-learning enable

Strict dynamic ARP learning is disabled by default.

1.4.7 Configuring ARP Scanning

1. Overview

This function is usually used together with the Web-based dynamic-to-static ARP entry conversion function. After ARP scanning is enabled on an interface, the device scans neighbors in the specified range and learns the ARP entries of these neighbors.

2. Restrictions and Guidelines

The device can scan the neighbors in the network segments, to which the primary IP address and secondary IP addresses belong, on an interface or scans only the neighbors in the specified address range. ARP scanning takes effect once after it is configured, and can be executed when the Layer 3 interface is up (that is, the link is up and an IP address is configured for the interface). However, ARP scanning configuration cannot be saved and will lose effect the next time.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Enable ARP scanning.

arp scan [*start-ipv4-address end-ipv4-address*]

ARP scanning is disabled by default.

1.4.8 Configuring Scheduled Automatic ARP Scanning

1. Overview

After scheduled automatic ARP scanning is enabled on an interface, the device scans neighbors in the specified range and learns the ARP entries of these neighbors. If ARP entries are not learned from neighbors, after the current scanning ends, the device waits for the scanning interval (5 minutes by default) and then starts next scanning until the entries are learned.

2. Restrictions and Guidelines

- Since this function adds a strict confirmation procedure in the ARP learning process, it affects the efficiency of ARP learning.
- The scanning interval ranges from 1 to 30, in minutes.
- The scanning rate ranges from 1 to 100, in IP addresses per second.
- Up to 30 instances can be configured.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Enable scheduled automatic ARP scanning.

arp scan auto [*start-ipv4-address end-ipv4-address*]

The scheduled automatic ARP scanning function is disabled by default.

(5) (Optional) Configure the scheduled automatic ARP scanning interval.

arp scan interval *time*

The default interval of scheduled automatic ARP scanning is 5 minutes.

(6) (Optional) Configure the scheduled automatic ARP scanning rate.

arp scan rate *rate-value*

The default scheduled automatic ARP scanning rate is **20** IP addresses per second.

1.5 Configuring ARP Entry Management

1.5.1 Overview

Entries in the ARP cache can be managed as required, such as limiting the capacity of ARP entries and configuring fast aging of ARP entries.

1.5.2 Configuration Tasks

All the configuration tasks below are optional. Perform the configuration tasks as required.

- Configuring a Limit on the Number of Unresolved ARP Entries
- Configuring an ARP Learning Limit for a Card
- Configuring an ARP Learning Limit for an Interface
- Configuring ARP Link Tracking
- Configuring Fast ARP Entry Aging for an Interface
- Configuring ARP Packet Rate Statistics Collection
- Configuring the ARP Alarm Rate Limit

1.5.3 Configuring a Limit on the Number of Unresolved ARP Entries

1. Overview

In a local area network (LAN), ARP attacks and scanning may cause a large number of unresolved ARP entries generated on the gateway. As a result, the gateway fails to learn the MAC addresses of the hosts. To prevent this situation, if a large number of unresolved entries exist in the ARP cache and remain in the table after a while, you are advised to use this command to limit the number of unresolved ARP entries.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure a limit on the number of unresolved ARP entries.

arp unresolve *unresolved-number*

The maximum number of unresolved ARP entries that can be held in an ARP cache is the total capacity of ARP entries by default.

1.5.4 Configuring an ARP Learning Limit for a Card

1. Overview

This section describes how to configure the maximum number of ARP entries that can be learned by a line card in a specified slot, to limit the ARP learning ability of line cards in different slots. When the ARP capacity reaches the limit, the line card no longer learns ARP entries. ARP entries can be flexibly assigned by slot or on demand.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the ARP capacity limit for a line card.

arp dynamic-entry-limit slot *slot_string limit*

The function of limiting the ARP capacity of a line card is disabled by default.

1.5.5 Configuring an ARP Learning Limit for an Interface

1. Overview

Limiting the number of ARP entries that can be learned by an interface can flexibly control the on-demand assignment of ARP entry resources, to prevent resource waste. In addition, this can prevent malicious ARP attacks. When the device is attacked maliciously and the ARP entry learning number is not limited, the device will generate a large number of ARP entries, which occupy excessive entry resources.

2. Restrictions and Guidelines

The configured value must be equal to or greater than the number of the ARP entries learned by the interface. Otherwise, the configuration does not take effect. The configuration is subject to the ARP entry capacity supported by the device.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Configure an ARP learning limit for the interface.

arp cache interface-limit *limit*

The number of ARP entries that can be learned by an interface is not limited by default.

1.5.6 Configuring ARP Link Tracking

1. Overview

ARP link tracking is used to delete the ARP entry corresponding to the IP address of a tracked object on the device when the tracked object becomes unreachable. If the device needs to send a packet destined to this IP address later, it performs ARP learning again. After active/standby switchover of downlink devices, if the master device does not actively send gratuitous ARP packets, the uplink device fails to update its MAC address table timely and discards the packets destined to the IP address of the master device. When this function is configured, the device deletes the corresponding ARP entry if the destination IP address becomes unreachable. Then, the downlink master device is triggered to send an ARP reply through ARP learning, so as to help the uplink device update the MAC address table about the downlink master device.

2. Restrictions and Guidelines

- This function can be configured only on switch virtual interfaces (SVIs).
- In gateway authentication mode, the ARP entry of a tracked object in an authenticated VLAN cannot be deleted when the tracked object is unreachable.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable ARP link tracking.

arp [**vrf** *vrf-name*] *ipv4-address* **track** *object-number*

arp *ipv4-address* **track** *object-number*

ARP link tracking is disabled by default.

1.5.7 Configuring Fast ARP Entry Aging for an Interface

1. Overview

If a host goes offline or encounters an abnormal condition, the device fails to learn the ARP entry. When the MAC address corresponding to the ARP entry ages, the dynamic ARP entry starts aging one hour after the aging time by default. If this feature is enabled on an interface, after the MAC address ages, the dynamic ARP entry ages rapidly to realize fast route convergence of the host.

2. Restrictions and Guidelines

- This function can be configured only on SVIs interfaces.
- When the conversion of ARP entries into host routes is enabled on the device, you are advised to also enable this function to help achieve fast route convergence.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Enable fast ARP entry aging.

arp fast-aging enable

The fast ARP entry aging function is disabled by default.

1.5.8 Configuring ARP Packet Rate Statistics Collection

1. Overview

After this function is enabled, the device collects statistics on ARP messages received by each interface in a fixed period of time by replies, requests, and unknown packets.

2. Restrictions and Guidelines

The default statistics collection interval is 5 seconds. If there are many interfaces and the rate is not as expected, appropriately adjust the statistics collection interval. The minimum statistics collection interval can be set to 1 second.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable ARP packet rate statistics collection.

arp rate-statistic enable

The ARP packet rate statistics collection is disabled by default.

(4) (Optional) Configure the interval for ARP packet rate statistics collection.

arp rate-statistic compute interval *interval*

The default interval for collecting ARP packet rate statistics is 5 seconds.

1.5.9 Configuring the ARP Alarm Rate Limit

1. Overview

You can configure the ARP alarm rate limit to adjust the printing rate of ARP syslog alarms.

2. Restrictions and Guidelines

The actual ARP alarm rate may be lower than the configured rate, depending on system performance.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the ARP alarm rate limit.

arp warning-limit interval *interval* **times** *time*

The default ARP alarm rate limit interval is 50 seconds and the default upper limit of alarms allowed within this interval is 10.

1.6 Enabling Trusted ARP

1.6.1 Overview

Since trusted ARP entries come from authentic sources and will not be updated, they can efficiently prevent ARP spoofing targeting the gateway.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable trusted ARP.

service trustedarp

Trusted ARP is disabled by default.

(4) (Optional) Enable VLAN translation when a trusted ARP entry is added.

arp trusted user-vlan *vlan-id* **translated-vlan** *vlan-id*

The VLAN translation is disabled when a trusted ARP entry is added by default.

Configure this command only when the VLAN delivered by the server differs from the valid VLAN in the trusted ARP entry.

(5) (Optional) Enable trusted ARP aging.

arp trusted aging

Trusted ARP entries are not aged by default.

After you configure this command, trusted ARP entries begin to age, and the aging time is the same as that of dynamic ARP entries. You can run the **arp timeout** command in interface configuration mode to set the aging time.

(6) (Optional) Adjust the capacity of trusted ARP entries.

arp trusted *number*

The maximum number of trusted ARP entries is half of the capacity of the ARP table by default.

Trusted ARP entries and other entries share the memory. If trusted ARP entries occupy much space, dynamic ARP entries may not have sufficient space. Set the capacity based on the actual requirement. Do not set it to an excessively large value.

1.7 Enabling Gratuitous ARP

1.7.1 Overview

Gratuitous ARP packets are special ARP messages. In a gratuitous ARP message, the source and destination IP addresses are the IP address of the local device. This function enables an interface to periodically send gratuitous ARP packets.

1.7.2 Restrictions and Guidelines

Generally, you need to enable this function on an interface that serves as the gateway of downlink devices so that the MAC address of the gateway of the downlink devices are updated periodically to prevent others from faking the gateway.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of learning gratuitous ARPs.

(4) The function of learning gratuitous ARPs is enabled by default. Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(5) Enable the function of sending gratuitous ARP requests.

arp gratuitous-send enable

The function of sending gratuitous ARP requests is enabled by default.

(6) Configure the interval for sending gratuitous ARP requests.

arp gratuitous-send interval *interval* [*number*]

The function of sending gratuitous ARP requests at intervals is disabled by default.

1.8 Enabling Proxy ARP

1.8.1 Overview

The device acts as a proxy to reply to ARP requests from other hosts. If a device receiving an ARP request finds the source IP address in a different network from the destination IP address and knows the route to the destination address, the device sends an ARP reply containing its own Ethernet MAC address.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Enables proxy ARP.

ip proxy-arp

Whether this command is supported depends on the actual product version.

1.9 Configuring Local Proxy ARP

1.9.1 Overview

After local proxy ARP is enabled, the device can help hosts obtain the MAC addresses of other hosts in the same subnet.

1.9.2 Restrictions and Guidelines

This function can be configured only on SVIs interfaces.

1.9.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the SVI configuration mode.

interface vlan *interface-number*

(4) Enables local proxy ARP.

local-proxy-arp

Local proxy ARP is disabled by default.

1.10 Configuring Any IP ARP

1.10.1 Overview

Users can access the network with any IP address. This applies when a user uses a laptop in a hotel and wants to access the Internet without changing the configured IP address and gateway.

1.10.2 Restrictions and Guidelines

This function is not applicable in the following two scenarios, in which a user must modify the configuration before accessing the Internet.

- The user's IP address is in the same network segment as the interface directly connected to the device. However, the configured gateway IP address is not the IP address configured for the interface directly connected to the device.
- The user's IP address is not in the same network segment as the interface directly connected to the device, but in the network segment of another interface. That means an IP address conflict occurs.

  As the user's IP address is not in the same network segment as the interface directly connected to the device, the dynamic ARP entry and direct route are generated only when the user initiates an ARP request. Therefore, in some scenarios (including but not limited to the following ones), the user will not be able to access the Internet unless the ARP entry is cleared and the gateway address is relearned on the user host.

  - The device acts as a proxy to respond to ARP requests. After the user host learns the MAC address of the device, the administrator deletes the dynamic ARP entry on the device. As a result, the user's

dynamic ARP entry and direct route are removed and the user cannot receive the reply.

- The device acts as a proxy to respond to ARP requests. After the user host learns the MAC address of the device, if any IP ARP is disabled and then enabled again on the interface, the user cannot receive the reply. The cause is that the user's dynamic ARP entry and direct route are immediately deleted when the any IP ARP function is disabled on the interface.

Caution

If static ARP entries or the ARP entries involving the Virtual Router Redundancy Protocol (VRRP) IP addresses exist, dynamic ARP entries generated by any IP ARP will be overwritten or fail to be added, and any IP ARP does not take effect.

1.10.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Enable any IP ARP.

arp any-ip [**dip-route**]

The any IP ARP function is disabled by default.

1.11 Enabling ARP Trust Detection

1.11.1 Overview

ARP trust detection is used to prevent excessive useless ARP entries generated due to ARP spoofing from occupying device resources. After ARP trust detection is enabled on an Layer 3 interface and the device receives an ARP request from this interface:

(1) If the corresponding entry does not exist, the device creates a dynamic ARP entry and performs neighbor unreachability detection (NUD) after 1 to 5 seconds. That is, the device ages the newly learned ARP entry

and sends a unicast ARP request. If the device receives an ARP update packet from the peer within the aging time, it stores the entry. Otherwise, it deletes the entry.

(2) If the corresponding ARP entry exists, the device does not perform NUD.

(3) If the MAC address in the existing dynamic ARP entry is updated, the device performs NUD.

1.11.2 Restrictions and Guidelines

- Since this function adds a strict confirmation procedure in the ARP learning process, it affects the efficiency of ARP learning.
- After this function is disabled, the device no longer performs NUD for learning or updating ARP entries.

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

(4) Enable ARP trust detection.

arp trust-monitor enable

ARP trust detection is disabled by default.

1.12 Enabling ARP-based IP Guard

1.12.1 Overview

When receiving unresolved IP packets, the device cannot forward them through the hardware but sends them to the CPU for address resolution, that is, ARP learning. If a large number of such packets are sent to the CPU, the CPU will be congested, affecting other services on the device.

After ARP-based IP guard is enabled, the device will count the number of received ARP packets based on the destination IP address. When the number of packets with the same destination IP address exceeds a certain threshold, the device deems it as a CPU attack and will send a drop entry to the hardware so that the hardware will not send subsequent ARP packets with this destination IP address to the CPU. After the address resolution

is complete, the device updates the entry to the forwarding state and continues to forward the packets with this destination IP address.

1.12.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable ARP-based IP guard.

arp anti-ip-attack *attack-num*

The default number of IP packets for triggering the discarding of ARP entries is 3.

1.13 Configuring ARP Packet Filtering

1.13.1 Overview

- ARP packet filtering supports the following functions:
  Filters out received gratuitous APR packets.
- Filters out ARP packets that hit ACL rules.
- Filters out ARP packets whose source MAC addresses is not consistent with the Ethernet source MAC address.
- Filters out ARP packets whose destination MAC addresses is not consistent with the Ethernet destination MAC address.

1.13.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure ARP packet filtering. Perform at least one of the following configuration steps:

- Enable gratuitous ARP filtering.

  arp filter gratuitous

  Gratuitous ARP filtering is disabled by default.

- Enable ARP-based ACL filtering.

  arp filter acl *acl-number*

  ARP-based ACL filtering is disabled by default.

- Enables the function of checking the source MAC addresses of ARP packets.

  arp filter smac-illegal

  The function of checking the source MAC addresses of ARP packets is disabled by default.

- Enable the function of checking the destination MAC addresses of ARP packets.

arp filter dmac-illegal

The function of checking the destination MAC addresses of ARP packets is disabled by default.

1.14 Restraining the Device from Sending ARP Requests to Authenticated VLANs

1.14.1 Overview

In gateway authentication mode, all sub VLANs in a super VLAN are authenticated VLANs by default. Users in an authenticated VLAN have to pass authentication to access the network. After authentication, a static ARP entry is generated on the device. Therefore, when accessing an authenticated user, the device does not need to send ARP requests to the authenticated VLAN. If the device attempts to access users in an authentication-exempt VLAN, it only needs to send ARP requests to the authentication-exempt VLAN.

1.14.2 Restrictions and Guidelines

- This function can be configured only on SVIs.
- In gateway authentication mode, the device does not send ARP requests to the authenticated VLANs by default. If the device needs to access authentication-exempt users in an authenticated VLAN, disable this function.

1.14.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the SVI configuration mode.

interface vlan *interface-number*

(4) Configure the device not to send ARP requests to authenticated VLANs.

arp suppress-auth-vlan-req

ARP requests are not sent to authenticated VLANs by default.

1.15 Configuring Host Existence Judgment Prior to Proxy ARP Service

1.15.1 Overview

When two devices form a VRRP network and local proxy ARP is enabled on them, if the slave VRRP device sends an ARP request to a terminal, the master VRRP device will act as a proxy of the terminal and send an ARP reply to the slave VRRP device regardless of whether the terminal exists. As a result, the slave VRRP device learns a large number of proxy ARP entries.

After the host existence judgment prior to proxy ARP service is enabled, the master VRRP device, upon receiving an ARP request, first judges whether the ARP entry corresponding to the destination IP address exists. If yes, the master VRRP device acts as a proxy ARP. If no, the master VRRP device does not act as a proxy

ARP. In addition, the gateway automatically broadcasts an ARP request for the ARP entry corresponding to the destination IP address. This prevents the case that the gateway fails to act as a proxy to respond to an ARP request of the destination ARP address if it does not have an ARP entry corresponding to the destination IP address.

After the host existence judgment prior to proxy ARP service is disabled, if the proxy conditions are met, the master ARP device directly acts as a proxy upon receiving an ARP request, without judging whether the ARP entry corresponding to the destination IP address has been resolved.

1.15.2 Restrictions and Guidelines

The **arp proxy-resolved** command is enabled on devices by default. That is, the master VRRP device responds to an ARP request as a proxy only after the destination IP address has been resolved.

1.15.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the master VRRP device to forcibly respond to ARP requests as a proxy.

no arp proxy-resolved

By default, the master VRRP device judges the existence of the ARP entry corresponding to a destination IP address before the device responds to an ARP request as a proxy ARP.

1.16 Configuring ARP Entry Update During Active/Standby Switchover

1.16.1 Overview

This function can be enabled to quickly update ARP entries of a downlink device after VSU active/standby switchover, especially when the downlink device is similar to a server with dual network interface cards. When the slave device becomes the master, it will actively send ARP requests to SVIs (that are not in a super VLAN) of up to 1000 downlink terminals. After the terminals reply to these ARP requests, the device can update the ARP and MAC tables.

1.16.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of actively sending ARP requests to SVIs of downlink terminals during active/standby switchover.

arp switch-over resolve

ARP requests are not actively sent to downlink terminals during VSU active/standby switchover by default.

This command is supported only when the device is in VSU mode.

1.17 Sending ARP Requests to a Specific Sub VLAN

1.17.1 Overview

In a super VLAN scenario, the device actively broadcasts ARP resolution requests to the entire super VLAN by default. If there are many sub VLANs in the super VLAN, the ARP messages will be replicated in large quantities, which will affect device performance.

Most terminals (such as PCs and servers) request ARP information of the gateway before accessing the network. Therefore, there is no need to actively broadcast ARP resolution requests to the sub VLANs where these terminals reside. For dumb terminals (that do not actively send gratuitous ARP packets), this command can be deployed in a specified *vlan-list* to enable the device to actively send ARP resolution requests to these VLANs.

1.17.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable ARP to broadcast resolution requests to a specific sub VLAN in a super VLAN.

arp resolve vlan { *vlan-list* | **none** }

ARP broadcasts resolution requests to all sub VLANs in a super VLAN by default.

1.18 Configuring ARP Learning for a Specific Network Segment

1.18.1 Overview

When you manage a specific network segment of a Layer 3 interface, run the **arp disable-learning** command to disable ARP learning of the specific network segment. After configuration, the interface does not learn any dynamic ARP of the network segment. Note that after disabling ARP learning of the specific network segment, the device does not automatically delete the existing dynamic ARP on the network segment. After the user goes offline, the device deletes aging ARPs. To delete it immediately, run the **clear arp-cache ipv4-address mask** command to clear the dynamic ARPs on the network segment.

1.18.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) (Optional) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

(4) Disable dynamic ARP learning of a specific network segment.

arp disable-learning *network-address mask*

The function is not configured on an interface by default.

1.19 Configuring ARP Probing Upon MAC Address Flapping

1.19.1 Overview

When MAC address flapping occurs (that is, when the Layer 2 interface in a MAC address entry changes to another one different from the Layer 2 interface in the mapping ARP entry), a device immediately updates the Layer 2 interface in the mapping ARP entry by default. To prevent a device from updating the Layer 2 interface in the mapping ARP entry to an incorrect one when attacked, you can enable ARP probing upon MAC address flapping. After the function is enabled, the device will send unicast ARP probe packets to the new interface and the old one, respectively. If an ARP response is received, the Layer 2 interface in the ARP entry will be updated to the one that sends the response. If no ARP response is received, the Layer 2 interface in the ARP entry will be updated to the new one after ARP probing.

1.19.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable ARP probing upon MAC address flapping.

arp mac-flapping resolve enable

ARP probing upon MAC address flapping is disabled by default.

(4) Configure an interval for ARP probing upon MAC address flapping.

arp mac-flapping resolve interval *seconds*

ARP probing is performed upon MAC address flapping at an interval of two seconds by default.

(5) Configure the number of times for ARP probing upon MAC address flapping.

arp mac-flapping resolve times *number*

ARP probing is performed upon MAC address flapping five times by default.

1.20 Enabling Fast ARP Entry Deletion When a Layer 2 Interface Is Down

1.20.1 Overview

ARP entries are deleted when the aging time expires by default. To accelerate routing convergence, enable fast ARP entry deletion when a Layer 2 interface is Down. When this function is enabled on an SVI and a Layer 2 interface of the SVI goes Down, the device deletes ARP entries immediately.

1.20.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the SVI configuration mode.

interface vlan *interface-number*

(4) Enable fast ARP entry deletion when a Layer 2 interface is Down.

arp l2port-down fast-delete

ARP entries are not deleted immediately when a Layer 2 interface is Down by default.

1.21 Configuring ARP Snooping

1.21.1 Overview

In some network O&M scenarios, the NMS needs to obtain IP addresses and MAC addresses of the devices obtain a topology for convenient O&M. After ARP snooping is enabled, the device delivers corresponding CPP and NFPP rules to ensure that ARP packets from the underlying layer can be forwarded to the CPU. The CPU parses the ARP packets forwarded by the CPU to obtain the IP address and MAC address of a network device in the topology and establish ARP snooping entries.

ARP snooping entries are created based on the source IP address and VLAN ID of ARP packets. If the source IP address or VLAN ID of the received ARP packet is different from that in the existing ARP snooping entry, a new ARP snooping entry is created. If the source IP address and VLAN ID of the received ARP packet are the same as those in the existing ARP snooping entry, the MAC address and interface information in the existing entry are updated, and the aging time is reset.

When the aging time of an ARP snooping entry expires, an ARP snooping probe request is sent. If a response is received, the aging time is reset; otherwise, the entry is deleted. The default source IP address of aging probe packets is 0.0.0.0, and the source MAC address is the MAC address of the interface that sends the packets on the device. The default padding format of aging probe packets is the same as that of ARP probe packets sent when a terminal goes online, and ARP probe packets are used to detect address conflicts. Therefore, the peer device may determine that an address conflict exists on the network when receiving the aging probe packet. To address this issue, you can change the source IP address and MAC address of the probe packet based on the specified VLAN, or configure the device not to age the snooping entry corresponding to the specified IP address.

1.21.2 Configuration Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable ARP snooping.

arp snooping enable

(4) Configure the maximum number of ARP snooping entries.

arp snooping limit *number*

The maximum number of ARP snooping entries is 65536 by default.

(5) Configure the timeout interval of ARP snooping entries.

arp snooping timeout *time*

The default timeout interval of ARP snooping entries is 900s.

(6) Configure the source address used for aging probe of ARP snooping entries in a specified VLAN.

arp snooping detect vlan *vlan-id* ***default-ip*** *default-ip-address* ***default-mac*** *default-mac-address*

By default, the source IP address of ARP aging probe packets is 0.0.0.0, and the source MAC address is the MAC address of the interface that sends the packets.

(7) Configure the device not to age ARP snooping entries corresponding to a specified IP address..

arp snooping detect ignored-ip { ***ignored-ip-****address* **| all** }

By default, the device sends aging probe packets when the ARP snooping entries of all IP addresses expire.

1.22 Monitoring

Run the **show** command to check the configuration.

Run the **debug** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **clear** command to clear information.

Caution

Inappropriate use of the **clear** command may lose vital information and thus interrupt services.

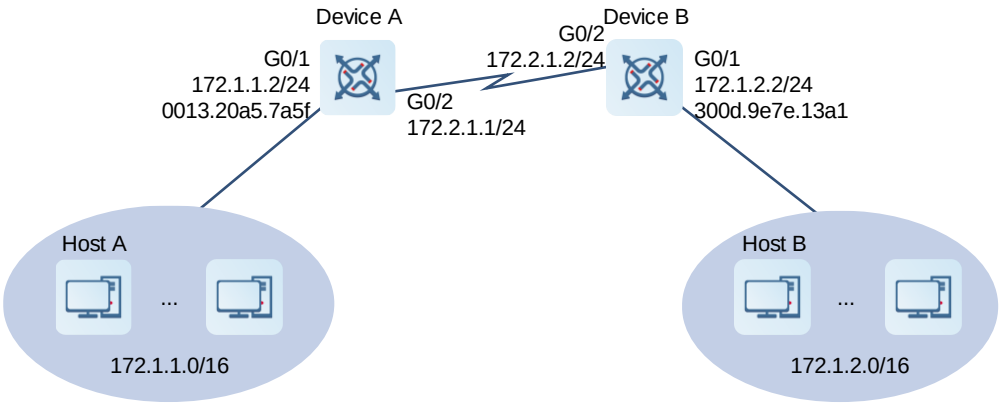
Table 1-1 Monitoring

Command	Purpose
show arp trusted [*ipv4-address* [*mask*]]	Displays trusted ARP entries.
clear arp snooping { **all** | **interface** *interface-type interface-number* | **ip-address** *ipv4-address* | **mac-address** *mac-address* | **vlan** *vlan-id* }	Clears ARP snooping entries.
clear arp flapping record	Clears ARP flapping records.
clear arp anti-attack statistics	Clears statistics on invalid ARP packets.
clear arp-cache [**vrf** *vrf-name* | **oob**] **trusted** [*ipv4-address* [*mask*]]	Clears trusted ARP entries.
clear arp-cache [[**vrf** *vrf-name* | **oob**] [*ipv4-address* [*mask*]] | **interface** *interface-type interface-number*]	Clears dynamic ARP entries.
clear arp-cache packet statistics [*interface-type interface-number*]	Clears ARP packet statistics.
show arp [[**vrf** *vrf-name*] [*ipv4-address* [*mask*] | *interface-type interface-number* | *mac-address* | **complete** | **incomplete** | **static** | **trusted** [*ipv4-address* [*mask*]]]] **show arp** [[*ipv4-address* [*mask*] | *interface-type interface-number* | *mac-address* | **complete** | **incomplete** | **static** | **trusted** [*ipv4-address* [*mask*]]]]	Displays the ARP table.

show arp detail [[**vrf** *vrf-name*] [*ipv4-address* [*mask*] | *interface-type interface-number* | *mac-address* | **complete** | **incomplete** | **static** | **trusted** [*ipv4-address* [*mask*]]] | **subvlan** { **min-max** *min-value max-value* | *subvlan-number* }] **show arp detail** [[**vrf** *vrf-name*] [*ipv4-address* [*mask*] | *interface-type interface-number* | *mac-address* | **complete** | **incomplete** | **static** | **trusted** [*ipv4-address* [*mask*]]] **show arp detail** [*ipv4-address* [*mask*] | *interface-type interface-number* | *mac-address* | **complete** | **incomplete** | **static** | **trusted** [*ipv4-address* [*mask*]] | **subvlan** { **min-max** *min-value max-value* | *subvlan-number* }] **show arp detail** [*ipv4-address* [*mask*] | *interface-type interface-number* | *mac-address* | **complete** | **incomplete** | **static** | **trusted** [*ipv4-address* [*mask*]]	Displays the detailed ARP table.
show arp oob [*ipv4-address* [*mask*] | **static** | **complete** | **incomplete** | *mac-address*]	Displays the ARP table on the management interface.
show ip arp [**vrf** *vrf-name*] **show ip arp**	Displays the ARP table.
show arp [**detail**] **trusted** [*ipv4-address* [mask]]	Displays the trusted ARP table.
show arp counter	Displays the count of ARP entries.
show arp timeout	Displays the aging time of dynamic ARP entries.
show arp packet statistics [*interface-type interface-number*]	Displays ARP packet statistics.
show arp rate-statistic [**interface** *interface-type interface-number*]	Displays ARP packet rate statistics.
show arp flapping record [*ipv4-address*]	Displays ARP flapping records.

show arp snooping { **all** | **interface** *interface-type interface-number* | **ip-address** *ipv4-address* | **mac-address** *mac-address* | **vlan** *vlan-id* }	Displays ARP snooping entries.
show arp suppress table [**ip** *ipv4-address*]	Displays the ARP suppression table.
show arp anti-attack statistics	Displays the statistics on illegal ARP packets.
show arp dynamic-entry-limit	Displays the statistics on the ARP capacity limit of a line card.
debug arp	Displays the statistics on ARP packets sent and received.
debug arp event	Displays the creation and deletion status of ARP entries.

1.23 Configuration Examples



1.23.1 Configuring Proxy ARP

1. Requirements

As shown in Figure 1-4, the IP addresses of host A and host B are on the same network segment, but are isolated in two LANs by routers. Neither of the two hosts is configured with a default gateway, and the two routers are connected over a serial link. Enable proxy ARP on the routers to achieve direct communication between hosts in different LANs.

2. Topology

Figure 1-4 Topology of Proxy ARP

3. Notes

- Enable proxy ARP on interfaces of device A and device B that are connected to hosts.
- Configure default routes on device A and device B.

4. Procedure

(1) Configure device A.

Configure an IP address for a Layer 3 Ethernet port GigabitEthernet 0/1.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# ip address 172.1.1.2 24
```

Enable proxy ARP on a Layer 3 Ethernet port GigabitEthernet 0/1.

```
DeviceA(config-if-GigabitEthernet 0/1)# ip proxy-arp
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Configure an IP address for a Layer 3 Ethernet port GigabitEthernet 0/2.

```
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# ip address 172.2.1.1 24
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

Configure the static route to 172.1.2.0/16.

```
DeviceA(config)# ip route 172.1.2.0 255.255.0.0 gigabitethernet 0/2
```

(2) Configure device B.

Configure an IP address for a Layer 3 Ethernet port GigabitEthernet 0/1.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# ip address 172.1.2.2 24
```

Enable proxy ARP on a Layer 3 Ethernet port GigabitEthernet 0/1.

```
DeviceB(config-if-GigabitEthernet 0/1)# ip proxy-arp
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Configure an IP address for a Layer 3 Ethernet port GigabitEthernet 0/2.

```
DeviceB(config)# interface gigabitethernet 0/2
DeviceB(config-if-GigabitEthernet 0/2)# ip address 172.2.1.2 24
DeviceB(config-if-GigabitEthernet 0/2)# exit
```

Configure the static route to 172.1.1.0/16.

```
DeviceB(config)# ip route 172.1.1.0 255.255.0.0 gigabitethernet 0/2
```

(3) Configure hosts.

Set the IP address of host A to 172.1.1.1/24.

Set the IP address of host B to 172.1.2.1/24.

5. Verification

Host A can ping host B successfully.

You can check the ARP table of host A and find that the MAC address corresponding to host B is the MAC address of a Layer 3 Ethernet port GigabitEthernet 0/1 on device A.

6. Configuration Files

- Device A configuration file

```
!
hostname DeviceA
ip route 172.1.0.0 255.255.0.0 gigabitethernet 0/2
!
 interface gigabitethernet 0/1
 ip address 172.1.1.2 24
 ip proxy-arp
!
 interface gigabitethernet 0/2
 ip address 172.2.1.1 24
!
```

- Device B configuration file

```
!
hostname DeviceB
ip route 172.1.0.0 255.255.0.0 gigabitethernet 0/2
!
 interface gigabitethernet 0/1
 ip address 172.1.2.2 24
 ip proxy-arp
!
 interface gigabitethernet 0/2
 ip address 172.2.1.2 24
!
```

1 Configuring IPv4 Basics

1.1 Introduction

1.1.1 Overview

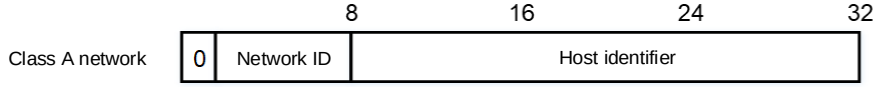
Internet Protocol (IP) is one of the most core protocols in the Transmission Control Protocol (TCP)/IP protocol suite and works at the network layer. Each IP device in the network needs a logical virtual address, which is used by the IP protocol to realize communication between devices. This address is usually called IP address.

The Internet Protocol version 4 (IPv4) is the fourth revision of the Internet Protocol, and is also the first version that has been widely used. The Internet Protocol version 6 (IPv6), the successor of IPv4, is still in its early stage of deployment in 2011 when IPv4 addresses were about to be used up. IPv4 uses the 32-bit address format, so there are only 4,294,967,296 addresses in the address space, some of which are reserved for special purposes.

Note

The following description is for IPv4 only, and IP addresses mentioned in this document refer to IPv4 addresses.

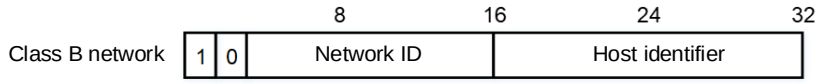
1.1.2 Basic Concepts



1. Classification of IP Addresses

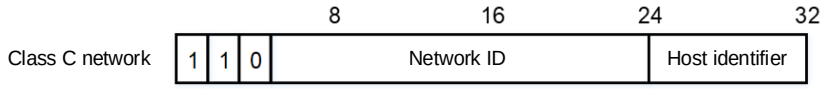
IP addresses are used for interconnection at the IP layer. An IP address consists of 32-bit binary digits. To facilitate writing and description, an IP address is generally expressed in decimal notation. When expressed in decimal notation, an IP address is divided into four groups, with eight bits in each group. The value range of each group is from 0 to 255, and groups are separated by dots (.), which are called dotted decimal notation. For example, "192.168.1.1" is an IP address expressed in decimal notation.

A 32-bit IP address consists of two parts: network ID and local address. A network ID indicates a network identifier, and a local address identifies a host. Based on the values of the first several bits in the network part, IP addresses in use can be classified into four classes.



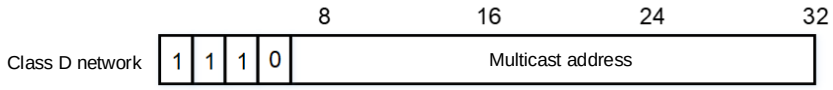
- For a class A address, the most significant bit is "0", the following 7 bits indicate a network ID, and the last 24 bits indicate a local address (host identifier). There are 2^7 = 128 class A networks in total.

Figure 1-1 Class A Network



- For a class B address, the two most significant bits are "10", the following 14 bits indicate a network ID (network identifier), and the last 16 bits indicate a local address (host identifier). There are 2^{14}=16,384 class B networks in total.

Figure 1-2 Class B Network



- For a class C address, the three most significant bits are "110", and the following 21 bits indicate a network ID, and the last 8 bits indicate a local address. There are 2^{21}=2,097,152 class C networks in total.

Figure 1-3 Class C Network

- For a class D address, the four most significant bits are "1110" and other bits are designated for multicast addresses.

Figure 1-4 Class D Network

Note

The addresses with the four most significant bits of "1111" cannot be assigned. These addresses are called class E addresses and are reserved for experimental use.

IP addresses must be assigned according to the nature of the network during IP address planning in the process of network construction. If the network needs to be connected to the Internet, users need to apply to relevant organizations for IP addresses. IP addresses can be applied from China Internet Network Information Center (CNNIC) in China, and the Internet Corporation for Assigned Names and Numbers (ICANN) is responsible for the final IP address assignment. If the network is built to be an internal private network, users do not need to apply for IP addresses and can be assigned dedicated private network addresses.

Table 1-1 Reserved and Available Addresses

Class	Address Range	Status
Class Anetwork	0.0.0.0~0.255.255.255	Reserved
	1.0.0.0~126.255.255.255	Available
	127.0.0.0~127.255.255.255	Reserved
Class B network	128.0.0.0~191.254.255.255	Available
	191.255.0.0~191.255.255.255	Reserved

Class	Address Range	Status
Class C network	192.0.0.0~192.0.0.255	Reserved
	192.0.1.0~223.255.254.255	Available
	223.255.255.0~223.255.255.255	Reserved
Class D network	224.0.0.0~239.255.255.255	Multicast addresses
Class E network	240.0.0.0~255.255.255.254	Reserved
	255.255.255.255	Broadcast addresses

2. Private Network IP Addresses

Private network IP addresses are not used in the Internet. If the devices to which private addresses are assigned need to be connected to the Internet, these IP addresses need to be converted into valid Internet addresses. Table 1-2 lists private network address ranges. Private network addresses are defined in RFC 1918 and include three address blocks.

Table 1-2 Private Network Addresses

Class	Address Range	Status
Class Anetwork	10.0.0.0–10.255.255.255	One class Anetwork
Class B network	172.16.0.0–172.31.255.255	16 class B networks
Class C network	192.168.0.0–192.168.255.255	256 class C networks

For assignment of IP addresses, TCP/User Datagram Protocol (UDP) ports, and other codes, refer to RFC 1166.

3. Special IP Addresses

The IP addresses listed below are used for special purposes and cannot be used as host IP addresses.

- Addresses with the network ID of all zeros: Indicates the host in the network. For example, 0.0.0.16 indicates the host numbered 16 in the network.
- Addresses with the host ID of all zeros: Indicates a network address, used for identifying a network, for example, 192.168.1.0.
- Addresses with the host ID of all ones: Indicates a broadcast address of the network. For example, the packets with the destination address of 192.168.1.255 will be forwarded to all hosts in the 192.168.1.0 network.

4. Network Mask

A network mask is also a 32-bit value and identifies the bits occupied by the network part of an IP address. In a network mask, the IP address bits corresponding to the bits whose values are ones are the network part, and the IP address bits corresponding to the bits whose values are zeros are the host address. For example, for class A networks, the network mask is 255.0.0.0. Network masks can be used to divide a network into several

subnets. Some bits of the host address are used as the network ID to decrease the host capacity and increase the number of networks. In this case, network masks are called subnet masks.

5. MTU

Maximum transmission unit (MTU) is the maximum size, in bytes, of the data transmitted by the data link layer to its upper layer, such as IP. The MTU is protocol-specific, for example:

- The MTU for IEEE802.3/802.2 is 1,492 bytes.
- The MTU range of an Ethernet port is 64 to 1,518 bytes. Ethernet frames beyond this range may be dropped.

The IP protocol decides whether to fragment data based on the Layer 2 MTU value. When two hosts communicate through multiple networks, MTUs of different sizes may exist in every link. The smallest MTU determines the transmission rate.

6. TTL

Time to live (TTL) refers to the number of network segments, through which packets are allowed to pass before the packets are discarded. The TTL value is used to judge whether packets stay on the network for a long time and should be discarded.

When two hosts communicate through multiple networks, a TTL value is set at the source end and decreases by 1 each time the IP packet passes through a router. When the TTL value drops to zero, the router deems the destination unreachable and discards the packet. TTL prevents infinite transmission of useless packets and bandwidth waste.

1.1.3 Principles

1. Obtaining IP Addresses

A device must have an IP address before sending and receiving IP datagrams. Only the interface configured with an IP address can run the IP protocol.

An interface can obtain IP addresses in the following four ways. These ways are mutually exclusive. If you configure a new way to obtain an IP address, the old IP address will be overwritten.

(1) Manually configuring IP addresses

(2) Obtaining IP addresses through the Dynamic Host Configuration Protocol (DHCP): For details about the DHCP protocol, see *Configuring DHCP*.

2. Configuring Multiple IP Addresses for an Interface

An interface on a device can be configured with multiple IP addresses, of which one is the primary IP address and the others are secondary IP addresses. Theoretically, the number of secondary IP addresses is not limited. However, secondary IP addresses must belong to different networks and secondary IP addresses must be in different networks from primary IP addresses. In network construction, secondary IP addresses are often used in the following circumstances:

- A network does not have enough host addresses. For example, when the number of hosts exceeds 254 in a local area network (LAN), one class C network is not enough and another class C network is needed. In this case, two networks need to be connected. Therefore, more IP addresses are needed.
- Many old networks are based on Layer 2 bridged networks without subnetting. You can use secondary IP addresses to upgrade the network to a routing network based on IP layer. For each subnet, one device is

configured with one IP address.

- When two subnets of one network are isolated by another network, in consideration that one subnet cannot be configured on two or more interfaces of a device, you can connect the isolated subnets by creating a subnet on the isolated network and configuring a secondary address.

3. Broadcast Packet Processing

Broadcast packets refer to the packets destined for all hosts on a physical network. The device supports two types of broadcast packets. One type is limited broadcast packets, with the 32-bit destination address of all ones, that is, 255.255.255.255. The other type is directed broadcast packets, with the destination address of all hosts in a specified network, that is, host ID bits of all ones, for example, 192.168.1.255/24. Limited broadcast packets are blocked by the router, whereas directed broadcast packets can be forwarded.

If IP network devices forward limited broadcast packets, the network may be overloaded, which severely affects network performance. This circumstance is called a broadcast storm. Devices provide multiple approaches to confine broadcast storms within the local network and prevent continuous spread of broadcast storms. Layer 2 network devices such as bridges and switches still forward and spread broadcast storms.

The best way to avoid broadcast storms is to assign a broadcast address to each network, which is directed broadcast. This requires the IP protocol to use directed broadcast packets rather than limited broadcast packets to spread data. When receiving IP directed broadcast packets, the devices that is not directly connected to the destination subnet will forward them in the same way as that for unicast packets. After directed broadcast packets reach the device that is directly connected to the destination subnet, the device converts the directed broadcast mode into limited broadcast mode and broadcasts the packets to all hosts on the destination subnet at the link layer.

For details about broadcast, see RFC 919 and RFC 922.

4. ICMP Packet

Internet Control Message Protocol (ICMP) is a sub protocol of the TCP/IP protocol suite and is used to transfer control messages between IP hosts and network devices to notify certain devices of packet transmission exceptions. The following describes common ICMP packets.

- Echo request and echo reply

  Common ping operations use echo requests and echo replies. A device sends an echo request to another node. If there is no exception on the way, the destination host returns an echo reply, indicating that the host is reachable.

- Protocol unreachable message

  When a device receives a non-broadcast packet destined for itself and the packet uses the IP protocol that cannot be processed by the device, the device sends an ICMP protocol unreachable message to the source host.

- Host unreachable message

  When a device receives a non-broadcast packet destined for itself but the device does not know a route to forward the packet, it sends an ICMP host unreachable message to the source address.

- Redirection message

  Sometimes a network device sends packets from the interface that receives the packets, indicating that a route may be less than optimal. If this condition occurs, the device will send an ICMP redirection message

to the data source, informing the source that the gateway reachable to the destination address is another device on the same subnet. In this way, the data source sends subsequent packets according to the optimal path.

- Mask reply message

  Sometimes, a network device sends an ICMP mask request message to obtain the mask of a subnet. The network device that receives the ICMP mask request message sends a mask reply message.

- TTL timeout error message

  When a device forwards an IP packet, if the TTL expires, the device responds to the source end with a TTL timeout error message.

  To prevent attacks from other devices after the device is located through traceroute, you can disable the function of sending TTL timeout errors on the device. After this function is disabled, the device will no longer make a response when receiving a TTL timeout message.

- Timestamp query

  RFC 792 requires the system to return its current time after receiving an ICMP timestamp query request.

  To prevent attackers from obtaining the system time through this protocol and attacking other time-based protocols, you can disable the timestamp query function. Then, the device directly discards received ICMP timestamp query requests.

5. Limiting Transmission Rate of ICMP Error Packets

This function limits the transmission rate of ICMP error packets by using the token bucket algorithm to prevent denial of service (DoS) attacks.

If an IP packet needs to be fragmented but the Don't Fragment (DF) bit in the header is set to 1, the device returns an ICMP destination unreachable message to the source host. This ICMP error message is used to discover the path MTU. When there are too many other ICMP error messages, the ICMP destination unreachable message may not be sent. As a result, the path MTU discovery function fails. To avoid this problem, you should limit the transmission rate of ICMP destination unreachable messages and other ICMP error messages respectively.

6. IP MTU

The IP protocol at the network layer checks the size of each packet from the upper layer protocol and determines whether it should be "fragmented" based on the MTU size of the local device.

If an IP packet exceeds the IP MTU size, the device fragments the packet. For all devices on the same physical network segment, the IP MTU of interconnected interfaces must be the same. After the link MTU of interfaces is changed, the IP MTU of interfaces will be changed accordingly. The IP MTU of interfaces automatically keeps consistent with the link MTU of interfaces. However, if the IP MTU of interfaces is adjusted, the link MTU of interfaces will not be changed.

7. IP Source Routing

When a device receives an IP packet, it checks the options such as the strict source route, loose source route, and record route in the IP packet header. These options are detailed in RFC 791. If the device detects that the packet enables one option, it performs an action accordingly. If the device detects an invalid option, it returns an ICMP parameter error message to the source and then discards the packet.

After the function of processing IP source routing information is enabled on a device, the source route option is added to an IP packet to test the throughput of a specific network or help the packet bypass the failed network. However, this may cause network attacks such as source address spoofing and IP spoofing.

1.1.4 Protocols and Standards

- RFC 1918: Address Allocation for Private Internet
- RFC 1166: Internet Numbers
- RFC 919: Broadcasting Internet Datagrams
- RFC 922: Broadcasting Internet Datagrams Subnets
- RFC 791: Internet Protocol
- RFC 792: Internet Control Message Protocol

1.2 Configuration Task Summary

All the configuration tasks below are optional. Perform the configuration tasks as required.

- Configuring an IP Address for an Interface
- Configuring the Default Gateway for a Management Interface
- Configuring Directed Broadcast Packets
- Configuring ICMP Messages
- Configuring the Transmission Rate of ICMP Error Messages
- Setting the IP MTU Value
- Configuring the IP Fragment Reassembly
- Setting the IP TTL Value
- Configuring IP Routed Port Protection
- Configuring the IP Source Route Option

1.3 Configuring an IP Address for an Interface

1.3.1 Overview

This section describes how to configure an IP address for an interface for communication over the IP network. IP addresses can be manually configured or obtained through DHCP. In general, an interface only needs to be configured with one IP address to achieve communication with other hosts.

1.3.2 Configuration Tasks

(1) Configure an IP address for an interface. The configuration steps below are mutually exclusive. Please configure only one task.

- Configuring a Static IP Address for an Interface
- Configuring an IP Address Combination for an Interface

(2) (Optional) Configuring an IP Broadcast Address

1.3.3 Configuring a Static IP Address for an Interface

1. Restrictions and Guidelines

Manual configuration of IP addresses and dynamic acquisition of IP addresses are mutually exclusive. If you configure a new approach to obtain an IP address, the old IP address will be overwritten.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

- Enter the management interface configuration mode.

  interface mgmt *interface-number*

- Enter the tunnel interface configuration mode.

  interface tunnel *interface-number*

- Enter the loopback interface configuration mode.

  interface loopback *interface-number*

(4) Configure an IP address for an interface.

ip address *ipv4-address* { *mask* | *mask-length* } [**secondary**]

No IP address is configured for an interface by default.

1.3.4 Configuring an IP Address Combination for an Interface

1. Restrictions and Guidelines

The IP address combination configuration command can be configured only on switch virtual interfaces (SVIs) and management (MGMT) interfaces.

The IP address combination configuration command and the static IP address configuration command as well as DHCP are mutually exclusive, but the IP address combination configuration command can be used to configure both static IP addresses and DHCP.

- When the IP address combination configuration command is used to configure a static IP address, if an IP address on the same network segment is already configured, the configuration fails.
- When the IP address combination configuration command is used to configure both a static IP address and a dynamic IP address, if the IP address obtained through DHCP does not conflict with the network segment of the static IP address, the IP address obtained through DHCP is the primary IP address and the static IP address is a secondary IP address. If the IP address obtained through DHCP conflicts with the network segment of the static IP address, an IP address will be obtained again, during which the static IP address is a primary IP address.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

- Enter the management interface configuration mode.

  interface mgmt *interface-number*

(4) Configure an IP address combination for the interface.

ip address mix { *ipv4-address* { *mask* | *mask-length* } | **dhcp** }

No IP address combination is configured for an interface by default.

1.3.5 Configuring an IP Broadcast Address

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

(4) Configure an IP broadcast address.

ip broadcast-address *ipv4-address*

The default IP broadcast address of an interface is 255.255.255.255.

1.4 Configuring the Default Gateway for a Management Interface

1.4.1 Overview

This section describes how to configure the default gateway for a management interface. After configuration, a default route is generated, with the outbound interface of the management interface and the next hop of the configured gateway.

1.4.2 Restrictions and Guidelines

This command can be configured on a management interface only.

1.4.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the management interface configuration mode.

interface mgmt *interface-number*

(4) Configure the default gateway for the management interface.

gateway *ipv4-address*

No default gateway is configured for a management interface by default.

1.5 Configuring Directed Broadcast Packets

1.5.1 Overview

You can configure a specified interface to forward directed broadcast packets. Then, the interface can forward directed broadcast packets destined for the directly connected network.

1.5.2 Restrictions and Guidelines

- This function applies to the transmission of directed broadcast packets within the destination s ubnet and will not affect the forwarding of other directed broadcast packets.
- On an interface, you can define an access control list (ACL) to control the forwarding of certain directed broadcast packets. After an ACL is defined, only directed broadcast packets that match the ACL are forwarded.

1.5.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

(4) Configure the interface to allow forwarding directed broadcast packets.

ip directed-broadcast [*acl-number*]

The function of translating the IP directed broadcast mode to the physical broadcast mode is disabled by default.

1.6 Configuring ICMP Messages

1.6.1 Overview

The ICMP protocol is used to transfer control messages between IP hosts and network devices to notify network exceptions. You can enable the functions of sending TTL timeout messages, ICMP destination unreachable messages, ICMP redirection messages, and ICMP mask reply messages, and timestamp query function.

1.6.2 Configuration Tasks

All the configuration tasks below are optional. Perform the configuration tasks as required.

- Enabling the Function of Sending TTL Timeout Messages
- Enabling the Timestamp Query
- Enabling the Function of Sending ICMP Destination Unreachable Messages
- Enabling the Function of Sending ICMP Redirection Messages
- Enabling the Function of Sending ICMP Mask Reply Messages

1.6.3 Enabling the Function of Sending TTL Timeout Messages

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of sending TTL timeout messages.

ip ttl-expires enable

The function of sending TTL timeout messages is enabled by default.

1.6.4 Enabling the Timestamp Query

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the timestamp query function.

ip icmp timestamp

The timestamp query function is disabled by default.

1.6.5 Enabling the Function of Sending ICMP Destination Unreachable Messages

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

(4) Enable the function of sending ICMP destination unreachable messages.

ip unreachables

The function of sending ICMP destination unreachable messages is enabled by default.

1.6.6 Enabling the Function of Sending ICMP Redirection Messages

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

(4) Enable the function of sending ICMP redirection messages.

ip redirects

The function of sending ICMP redirection messages is enabled by default.

1.6.7 Enabling the Function of Sending ICMP Mask Reply Messages

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

(4) Enable the function of sending ICMP mask reply messages.

ip mask-reply

The function of sending ICMP mask reply messages is disabled by default.

1.7 Configuring the Transmission Rate of ICMP Error Messages

1.7.1 Overview

This function limits the transmission rate of ICMP error packets by using the token bucket algorithm to prevent denial of service (DoS) attacks.

If an IP packet needs to be fragmented but the Don't Fragment (DF) bit in the header is set to 1, the device sends an ICMP destination unreachable message to the source host. This ICMP error message is used to discover the path MTU. If there are too many other ICMP error messages, the ICMP destination unreachable packet may not be sent. As a result, the path MTU discovery function fails. To avoid this problem, you should limit the transmission rate of ICMP destination unreachable messages and other ICMP error messages respectively.

1.7.2 Restrictions and Guidelines

Since the precision of the timer is 10 milliseconds, you are advised to set the refresh cycle of a token bucket to an integer multiple of 10 milliseconds. If the refresh cycle is set to a value greater than 0 and smaller than 10 milliseconds, the refresh cycle that actually takes effect is 10 milliseconds. For example, if the transmission rate is set to 1 packet per 5 milliseconds, two ICMP error packets are actually sent per 10 milliseconds. If the refresh cycle is not an integral multiple of 10 milliseconds, the refresh cycle that actually takes effect is automatically converted into an integral multiple of 10 milliseconds. For example, if the transmission rate is set to 3 packets per 15 milliseconds, two ICMP error packets are actually sent per 10 milliseconds.

1.7.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the transmission rate of ICMP error packets.

ip icmp error-interval [**df**] *interval* [*bucket-size*]

Ten ICMP error packets are transmitted within 100 milliseconds by default.

1.8 Setting the IP MTU Value

1.8.1 Overview

This section describes how to set the MTU of an IP packet. If the size of an IP packet exceeds the IP MTU size, the packet will be fragmented.

1.8.2 Restrictions and Guidelines

For all devices on the same physical network segment, the IP MTU of interconnected interfaces must be the same. The IP MTU of interfaces automatically keeps consistent with the link MTU of interfaces. If the link MTU of interfaces is changed, the IP MTU of interfaces will be changed accordingly. However, if the IP MTU of interfaces is adjusted, the link MTU of interfaces will not be changed.

1.8.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the Layer 3 Ethernet subinterface configuration mode.

  interface *ethernet-type interface-number.subnumber*

- Enter the SVI configuration mode.

  interface vlan *interface-number*

- Enter the Layer 3 aggregated subinterface configuration mode.

  interface aggregateport *interface-number.subnumber*

(4) Set the IP MTU.

ip mtu *mtu*

The default MTU of an IP packet is 1500 bytes.

1.9 Configuring the IP Fragment Reassembly

1.9.1 Overview

By default, a device reassembles IP packets sent to the CPU, and then determines whether to forward them or process them locally. If you do not want to reassemble the IP packets sent to the CPU, you can disable the IP fragment reassembly.

1.9.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable the IP fragment reassembly function.

ip reassemble disable

The IP fragment reassembly function is enabled by default.

1.10 Setting the IP TTL Value

1.10.1 Overview

When an IP packet is transmitted from the source address to the destination address through routers, a TTL value is set at the source end and decreases by 1 every time that the IP packet passes through a router. When the TTL value drops to zero, the router discards the packet. TTL prevents infinite transmission of useless packets and waste of bandwidth.

1.10.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Set the IP TTL.

ip ttl

The default TTL value of unicast packets sent by the device is 64.

1.11 Configuring IP Routed Port Protection

1.11.1 Overview

This section describes how to enable routed port protection to prevent packets from being transmitted through the same interface that receives the packets.

1.11.2 Restrictions and Guidelines

This command can only be used for Layer 3 routed ports.

1.11.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

interface *interface-type interface-number*

(4) Configure the IP routed port protection.

ip redirect-drop

The IP routed port protection function is disabled by default.

1.12 Configuring the IP Source Route Option

1.12.1 Overview

The IP source route option is used to test the throughput of a specific network and help the packet bypass a failed network.

1.12.2 Restrictions and Guidelines

Enabling the IP source route option may cause network attacks such as source address spoofing and IP spoofing.

1.12.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the IP source route option.

ip source-route

The IP source route option is enabled by default.

1.13 Configuring the Packet Priority

1.1.1 Overview

You can specify the IEEE 802.1p or DSCP value for protocol packets sent by the local device.

1.1.2 Restrictions and Guidelines

You can run the **set priority** command to configure the packet priority, which takes effect only for protocol packets sent by the device's own protocol stack, but not for packets forwarded by the local device. In addition, the **set priority ip dscp** command takes effect only for IPv4 packets sent by the device's own protocol stack, but does not take effect for IPv6 packets.

1.1.3 Procedure

(1) Enter the privileged EXEC mode.
enable

(2) Enter the global configuration mode.
configure terminal

(3) Configure the IEEE 802.1p value for protocol packets sent by the device's own protocol stack.
set priority 802.1p *802.1p-value*

No IEEE 802.1p value is configured for protocol packets sent by the device's own protocol stack. In this case, the IEEE 802.1p value is 0.

(4) Configure the DSCP value for IP packets sent by the device's own protocol stack.
set priority ip dscp *dscp-value*

By default, the DSCP value is not configured for IP packets sent by the device's own protocol stack. In this case, the DSCP value is 0.

1.14 Monitoring

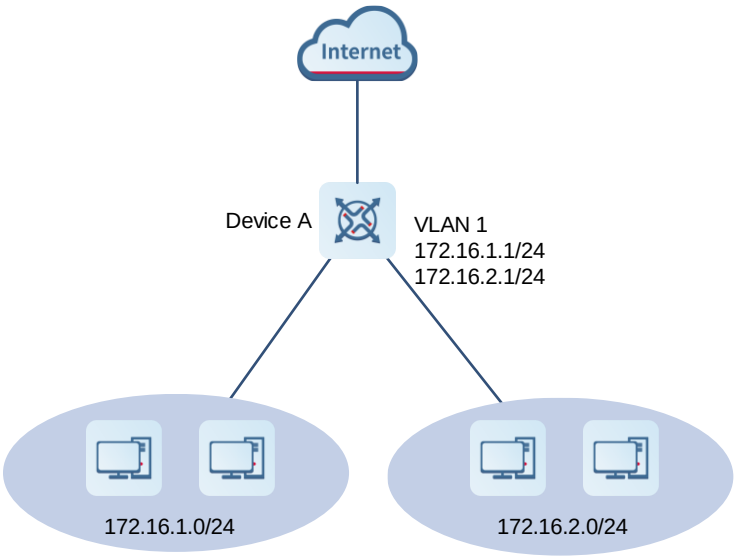
This section describes the **show** commands used for checking the running status of a configured function to verify the configuration effect.

Table 1-3 Monitoring

Command	Purpose
show ip interface [*interface-type interface-number* | **brief**]	Displays the IP address of an interface.
show ip packet statistics [*interface-type interface-number* | **total**]	Displays IP packet statistics.
show ip packet queue	Displays the statistics on sent and received IP packets in the protocol stack.
show ip raw-socket [*protocol-number*]	Displays all IPv4 raw sockets.
show ip sockets	Displays all IPv4 sockets.

Command	Purpose
show ip udp [**local-port** *port-number* | **peer-port** *port-number*]	Displays all IPv4 UDP sockets.
show ip udp statistics	Displays the statistics on all IPv4 UDP sockets.

1.15 Configuration Examples



1.15.1 Configuring IPv4 Addresses for Network Communication

1. Requirements

As shown in Figure 1-5, device A is connected to a LAN (belonging to VLAN 1), which involves two network segments: 172.16.1.0/24 and 172.16.2.0/24. Computers on the two network segments are required to access the Internet through device A and hosts on the two network segments can also communicate with each other.

2. Topology

Figure 1-5 Topology of Configuring IPv4 Addresses for Network Communication

3. Notes

- Configure two IP addresses on the interface VLAN 1, of which one is a primary IP address and the other is a secondary IP address.
- Configure the device as the gateway on the hosts on these two network segments.

4. Procedure

(1) Configure device A.

Configure a primary IP address and a secondary IP address for the interface VLAN 1.

```
DeviceA> enable
```

```
DeviceA# configure terminal
DeviceA(config)# interface vlan 1
DeviceA(config-if-VLAN 1)# ip address 172.16.1.1 255.255.255.0
DeviceA(config-if-VLAN 1)# ip address 172.16.2.1 255.255.255.0 secondary
```

(2) Configure the hosts on the 172.16.1.0/24 network segment.

Set the gateway to 172.16.1.1/24 for the hosts.

(3) Configure the hosts on the 172.16.2.0/24 network segment.

Set the gateway to 172.16.2.1/24 on the hosts.

5. Verification

Run the **ping** command on device A to check the connectivity with the hosts in the 172.16.1.0/24 network segment.

```
DeviceA# ping 172.16.1.2
Sending 5, 100-byte ICMP Echoes to 172.16.1.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Run the **ping** command on device A to check the connectivity with the hosts in the 172.16.2.0/24 network segment.

```
DeviceA# ping 172.16.2.2
Sending 5, 100-byte ICMP Echoes to 172.16.2.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 38/45/55 ms.
```

Run the **ping** command to check the connectivity between the hosts in the 172.16.1.0/24 network segment and the hosts in the 172.16.2.0/24 network segments.

6. Configuration Files

Device A

```
hostname DeviceA
!
interface vlan 1
 ip address 172.16.1.1 255.255.255.0
 ip address 172.16.2.1 255.255.255.0 secondary
!
```

1 Configuring DHCP

1.1 Introduction

1.1.1 Overview

Dynamic Host Configuration Protocol (DHCP) is a local area network (LAN) protocol that dynamically assigns reusable network addresses and additional configurations to hosts. DHCP uses User Datagram Protocol (UDP) as its transport protocol to send and receive DHCP messages through port 67.

DHCP works in client/server mode. A DHCP client sends a request message to a DHCP server for an IP address and other configurations. When a DHCP client and a DHCP server are not on the same network segment, they need a DHCP relay agent to forward DHCP request and reply messages.

1.1.2 Origin and Development

DHCP originates from the Bootstrap Protocol (BOOTP), which is used by diskless hosts to obtain their own IP addresses, server IP address, boot image file name, gateway IP address, and other information from a server. BOOTP is designed for static environments. It requires the hardware address of a host be manually added to the BOOTP table and mappings between hardware addresses and IP addresses be static. In other words, BOOTP is less dynamic. In an environment with limited IP addresses, one-to-one mapping of BOOTP wastes IP addresses.

As the network scale expands and network complexity increases, BOOTP designed for static hosts can no longer meet requirements in wireless network scenarios and scenarios in which the number of computers exceeds the number of available IP addresses.

Therefore, the Internet Engineering Task Force (IETF) proposes a new protocol, that is, DHCP. DHCP is an enhanced version of BOOTP and consists of a server and a client. A DHCP server centrally manages all IP network settings and processes DHCP requests from DHCP clients. DHCP clients use the IP environment data assigned by the DHCP server. Compared with BOOTP, DHCP employs the lease concept to allocate clients' TCP/IP settings effectively and dynamically. As an enhancement version of BOOTP, DHCP also meets compatibility requirements of BOOTP clients.

1.1.3 Benefits

During network construction, a DHCP server can bring the following benefits:

- Low network access cost: Generally, the static address assignment mode considers the real locations of hosts and the labor cost is high. A DHCP application mode only needs to be uniformly configured on a server, thereby reducing a network access cost.
- Simplified configuration and low network construction cost: Dynamic address assignment significantly simplifies device configuration and reduces the deployment cost if no professional technical personnel are available to deploy devices.
- Centralized management: You can modify configurations for multiple subnets by simply modifying the DHCP server configuration.

1.2 Principles

1.2.1 Basic Concepts

- DHCP server

  A DHCP server is implemented based on RFC 2131. It assigns IP addresses to hosts and manages these IP addresses.

- DHCP client

  A DHCP client enables a device to automatically obtain an IP address and other configurations from a DHCP server.

- DHCP relay agent

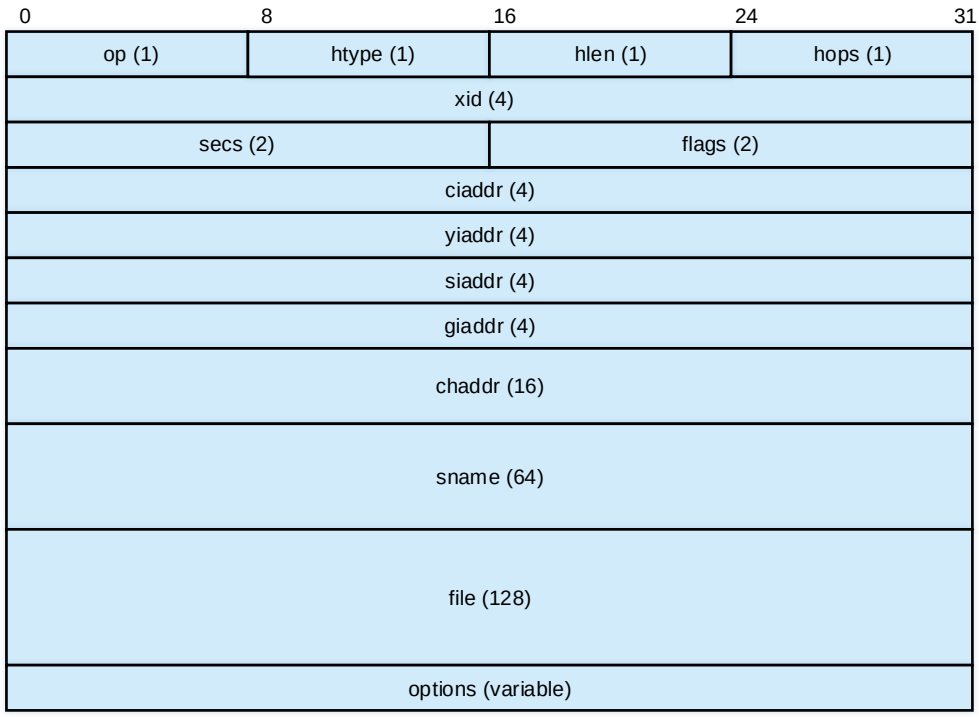
  When a DHCP client and a DHCP server are not in the same subnet, they need a DHCP relay agent to forward DHCP request and reply messages.

- Lease time

  Lease time is a period of time specified by a DHCP server for a client to use an assigned IP address. An IP address can be leased to a client when a lease time is active. Before a lease expires, a client needs to renew the lease through a server. When a lease expires or is deleted from a server, the lease time becomes inactive.

- Address pool

  An address pool is a collection of IP addresses that a DHCP server can assign to clients.



- Option type

  An option type is a parameter specified by a DHCP server when it provides the lease service to a DHCP client. For example, common options include the IP addresses of the default gateway, Windows Internet Name Service (WINS) server, and Domain Name System (DNS) server. A DHCP server also allows configuration of other options. Most options are predefined in RFC 2132. You can add user-defined options.

1.2.2 Message Format

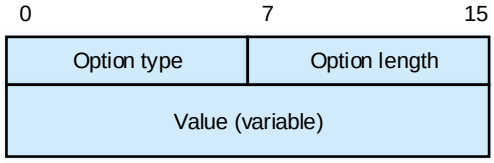
1. DHCP Packet

Figure 1-1 DHCP Packet

The following describes fields contained in a DHCP packet:

- **op**: Packet type, including request packets and reply packets. A packet with **op** set to **1** is a request, and a packet with **op** set to **2** is a reply. The specific packet type is identified by the **options** field.
- **htype** (hardware type): Hardware address type of a DHCP client. For Ethernet clients, the field value is **1**.
- **hlen** (hardware length): Length of the hardware address of a DHCP client. For Ethernet clients, the field value is **6**.
- **hops**: Number of DHCP relay agents that a DHCP packet passes through. The field value increments by 1 each time a DHCP request packet passes through one DHCP relay agent.
- **xid**: Random number selected by a DHCP client when it sends a request. It is used to identify an address requesting process.
- **secs**: Time (in seconds) elapsed since a DHCP client starts a DHCP request.
- **flags**: The first bit is the broadcast reply flag bit and is used to identify whether a DHCP server sends a reply packet in unicast or broadcast mode. **0** indicates unicast, and **1** indicates broadcast. The other 15 bits are set to **0**.
- **ciaddr** (client IP address): IP address of a DHCP client. If a client has a valid and available IP address, add it to this field. During initialization, the client does not have an IP address, and this field is set to **0.0.0.0**. This field is not used to apply for a specific IP address by the client.
- **yiaddr** (your client IP address): IP address assigned by a DHCP server to a DHCP client.

- **siaddr** (server IP address): IP address of the server from which a DHCP client obtains boot configurations.
- **giaddr** (gateway IP address): IP address of the first DHCP relay agent that a request packet of a DHCP client passes through.
- **chaddr** (client hardware address): Hardware address of a DHCP client.
- **sname** (server name): Name of the server from which a DHCP client obtains boot configurations.
- **file**: Boot configuration file name and path specified by a DHCP server for a DHCP client.
- **options**: Optional fields with variable length, including the packet type, valid lease time, IP address of the DNS server, and IP address of the WINS server.



2. Message Types

- DHCP DISCOVER: first message broadcast by a DHCP client for DHCP interaction when it accesses a network for the first time.
- DHCP OFFER: message sent by a DHCP server in response to the DHCP DISCOVER message. The message carries various configuration parameters.
- DHCP REQUEST: This message has the following functions:
  - After a client is initialized, it broadcasts a DHCP REQUEST message to respond to the DHCP OFFER message of a DHCP server.
  - After a client is restarted and initialized, it broadcasts a DHCP REQUEST message to confirm the previously assigned IP address and other configurations.
  - After a client is bound to an IP address, it sends a DHCP REQUEST message to update the IP address lease.
- DHCP ACK: acknowledgment message of a DHCP server in response to a DHCP client's DHCP REQUEST message. A client obtains an IP address and related configuration parameters only after receiving this message.
- DHCP NAK: After a DHCP server receives a DHCP REQUEST message, the server cannot find the lease record or assign an IP address to the client due to some reasons. The server sends a DHCP NAK packet to inform the DHCP client that no proper IP address can be assigned.
- DHCP DECLINE: After a DHCP client receives an ACK message, the client finds that the IP address assigned by a server has been used through address conflict detection. Or the assigned IP address is unavailable due to other reasons. The client sends a DHCP DECLINE packet to inform the DHCP server that the assigned IP address is unavailable and request for a new IP address.
- DHCP REALEASE: When a DHCP client no longer uses the assigned IP address, it sends a DHCP RELEASE packet to inform the DHCP server of the assigned IP address not be used any longer and request the DHCP server to release the assigned IP address.

3. Option Format

A DHCP server uses the Options field to transfer control information and network configuration parameters to dynamically assign IP addresses and provide rich network configurations to clients. The Options field consist of the type, length, and value parts. Figure 1-2 shows the format.

Figure 1-2 Option Format

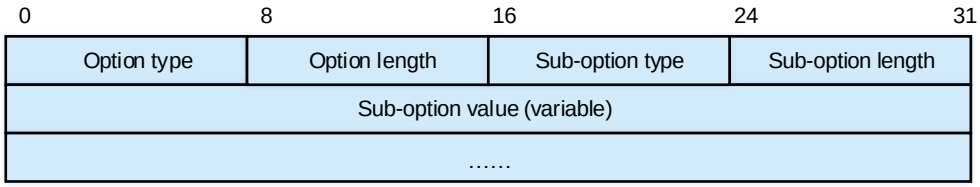
- **Option type**: option number.
- **Option length**: length of the information content.
- **Value**: information content.

4. Common DHCP Options

The type value of the **Options** field ranges from 1 to 255. Common DHCP options include:

- Option 1: subnet mask.
- Option 3: gateway address.
- Option 6: DNS address.
- Option 15: domain name.
- Option 33: static route. This option contains a group of classified static routes (that is, the mask of the destination network address is a natural mask and cannot be used for subnet division). After a client receives this option, it adds these static routes to the routing table. If Option 33 and Option 121 coexist, Option 33 is ignored.
- Option 51: IP address lease time.
- Option 53: DHCP message type.
- Option 55: parameter request list. A client uses this option to specify the network configurations that need to be obtained from a server. The option content is the values of parameters requested by a client.
- Option 121: classless static route. This option contains a group of classless static routes (that is, the mask of the destination network address is any value and subnets can be divided by mask). After a client receives this option, it adds these static routes to the routing table. If Option 33 and Option 121 coexist, Option 33 is ignored.

For details about more DHCP options, see RFC 2132 and RFC 3442.



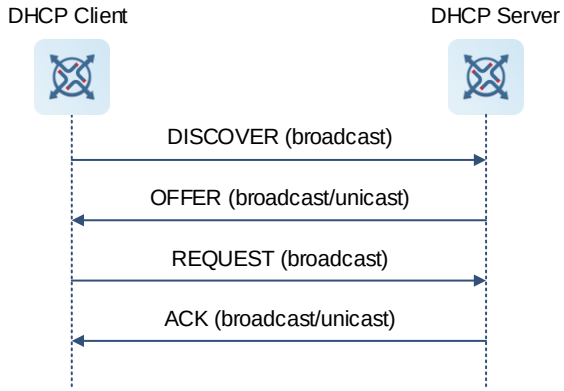
5. User-Defined DHCP Options

- Option 43: specific vendor information

  A DHCP server uses Option 43 to assign specific vendor information to a client. Option 43 uses several sub-options to assign different network configurations to users. The sub-option fields are as follows:

  - **Sub-option type**: type of a sub-option. The value can be **0x01** (ACS parameter), **0x02** (service provider identifier), or **0x80** (PXE boot server address).
  - **Sub-option length**: length of a sub-option.
  - **Sub-option value**: value of a sub-option.

Figure 1-3 Option 43



- Option 82: relay agent information

  Option 82 records the location information of a DHCP client. When a DHCP relay agent receives a request packet destined for a DHCP server from a DHCP client, the DHCP relay agent adds Option 82 to the packet and forwards the packet to the DHCP server. An administrator obtains the DHCP client location information from Option 82 to locate the DHCP client, assign an address in a specific range to the client, and control the client security and accounting.

1.2.3 DHCP Lease Process

Figure 1-4 DHCP Lease Process

A DHCP client requests an IP address as follows:

(1) The DHCP client broadcasts a DHCP DISCOVER packet to find a DHCP server in the network.

(2) The DHCP server sends a DHCP OFFER packet to the client in unicast/broadcast mode based on the broadcast bit in the **flags** field of the DISCOVER packet, with the packet containing an IP address, a Media Access Control (MAC) address, a domain name, and a lease time.

(3) The DHCP client broadcasts a DHCP REQUEST packet to formally request an IP address from the DHCP server.

(4) The DHCP server searches for the corresponding lease record based on the MAC address carried in the DHCP REQUEST packet.

   - If the lease record exists, the DHCP server sends a DHCP ACK packet to the DHCP client. After receiving the DHCP ACK packet, the DHCP client sends a free Address Resolution Protocol (ARP) packet to check whether another host uses the IP address assigned by the DHCP server. If the DHCP client does not receive a response within the specified time, the DHCP client uses the assigned IP address. If the DHCP client finds IP address conflict, it sends a DHCP DECLINE message to notify the

server and requests another IP address from the server after 10s.

- If the lease record does not exist or the DHCP server cannot assign an IP address to the client due to some reasons, the DHCP server sends a DHCP NAK packet to inform the DHCP client that no proper IP address can be assigned. The DHCP client needs to send another DHCP DISCOVER packet to apply for a new IP address.

Note

- The DHCP client may receive DHCP OFFER packets from multiple DHCP servers, but usually it accepts only the first DHCP OFFER packet.
- In addition, the address specified in the DHCP OFFER packet is not necessarily assigned to the client. Generally, the DHCP server reserves this address until the client sends a DHCP REQUEST packet.
- A client broadcasts a DHCP REQUEST packet to inform all DHCP servers that respond with DHCP OFFER packets. The servers not selected by the DHCP REQUEST message will release the previously assigned IP address.

1.2.4 DHCP Server

1. Address Pool

After a DHCP server receives a client's request, it chooses a valid address pool, determines an available IP address from the pool by using the ping mechanism, and delivers the pool configurations and IP address to the client. In addition, the server saves the lease information locally for validity check upon lease renewal.

Address pool configurations include the IP address range, gateway address, DNS address, and lease time.

2. Address Assignment Policy

A DHCP server selects an IP address for a client based on the following sequence:

(1) The DHCP server selects an IP address statically bound to the MAC address of the client from its own database.

(2) The DHCP server selects an IP address previously used by the client, that is, the address specified in the IP address option of the DHCP DISCOVER packet sent by the client.

(3) The DHCP server selects an available IP address first found from the DHCP address pool.

(4) If no available IP address is found from the DHCP address pool, the DHCP server checks whether an expired or conflicted IP address exists. If yes, it assigns an available IP address to the client. If not, it reports an error.

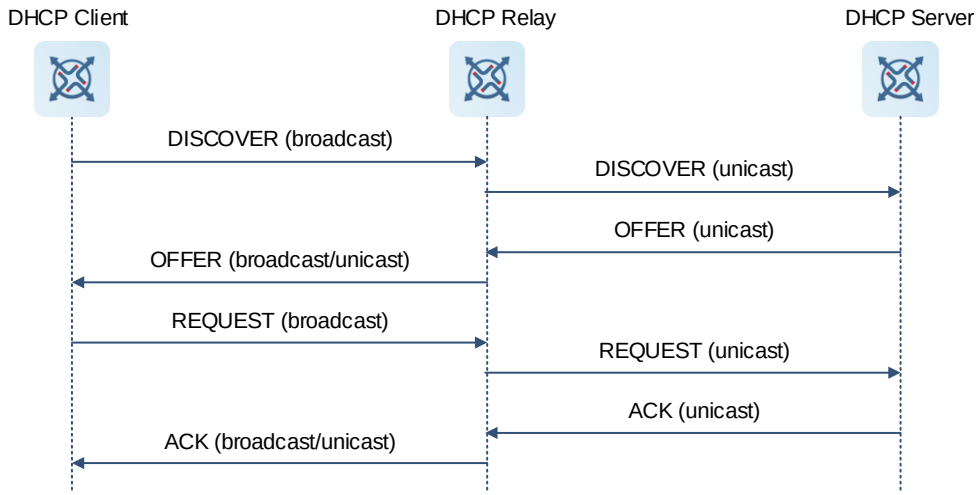
3. ARP Entry Check

The ARP entry check function can be used together with the ping mechanism to detect IP address conflicts. If a firewall is enabled on hosts in an actual environment, the ping operation for address conflict detection of a DHCP server becomes invalid. DHCP clients that dynamically apply for IP addresses may be assigned with the same IP address. Address conflict may occur. If the ARP entry check function is enabled, the DHCP server queries the ARP entries after detecting an IP address conflict by using the ping operation. If an ARP entry exists for the IP address to be assigned and is inconsistent with the MAC address of the client to which the IP address is assigned, the DHCP server regards that the IP address is occupied by another user.

You are not advised to enable the ARP entry check function in an environment with ARP attacks. Otherwise, the IP address assignment is affected, resulting in slow or failed IP address assignment.

4. Compulsory NAK Reply

In wireless applications, DHCP clients usually move from one network to another. When receiving a REQUEST packet from a client for lease renewal, a DHCP server replies with a NAK packet for the client if the server finds that the network segment of the client is changed or the lease expires. Such practice avoids the DHCP client from repeatedly sending REQUEST packets and avoids the DHCP client from obtaining an IP address only after the REQUEST packet times out.



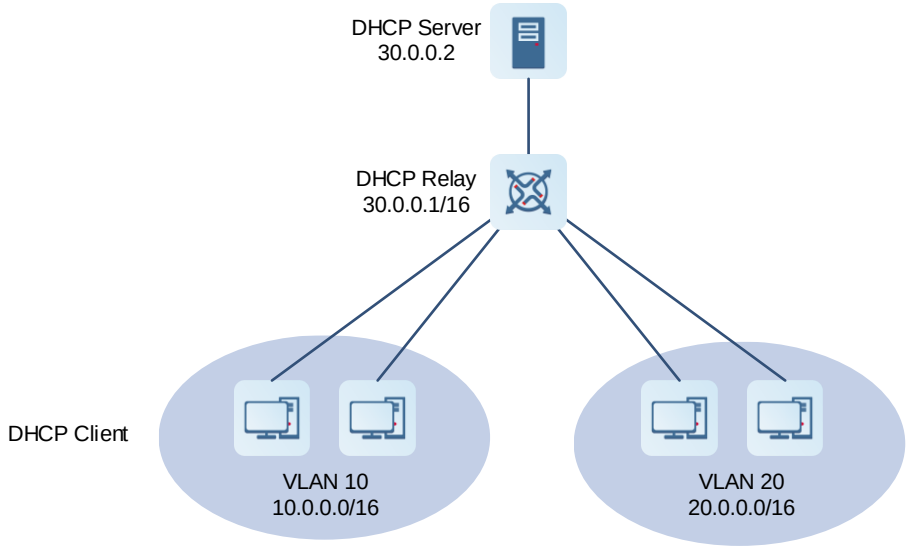
However, the DHCP server can send NAK packets only to its managed DHCP clients because it has lease records of its managed clients only. When a DHCP client moves from another network to the local network, if the DHCP server cannot find the corresponding lease record locally, the DHCP server does not reply with a NAK packet. In this case, the DHCP client needs to send REQUEST packets repeatedly. The client can obtain an IP address again only when the request times out. The time for obtaining an IP address is lengthened. This case also occurs when a client requires lease renewal but the DHCP server loses the lease record of the client due to a restart. In this case, you can configure compulsory NAK reply for the DHCP server if no lease record is found, so as to ensure that the client can obtain an IP address quickly.

1.2.5 DHCP Relay Agent

1. Principles

A DHCP relay agent helps to implement dynamic IP address assignment across network segments. The DHCP relay agent transparently forwards DHCP packets in unicast mode between a DHCP server and DHCP clients that reside on diverse network segments. It serves as a repeater. The Client-Relay-Server mode achieves dynamic management of IP addresses across multiple network segments with only one DHCP server.

Figure 1-5 Working Process



(1) After a DHCP relay agent receives a DHCP DISCOVER or DHCP REQUEST packet broadcast by a DHCP client, the DHCP relay agent adds its own IP address to the **giaddr** field of the packet and forwards the packet to a specified DHCP server in unicast mode.

(2) Based on the **giaddr** field, the DHCP server assigns an IP address and other configurations to the client, so that the DHCP relay agent forwards the configurations to the client, ensuring dynamic client configuration.

2. Typical Applications

Figure 1-6 DHCP Relay Application Scenario

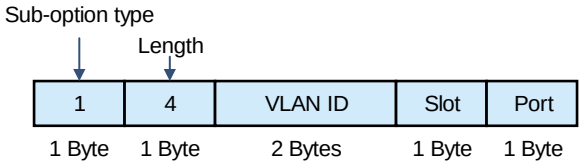
VLAN 10 and VLAN 20 are on the network segments 10.0.0.1/16 and 20.0.0.1/16, respectively. A DHCP server with the IP address 30.0.0.2 is in network segment 30.0.0.1/16. To achieve dynamic management of IP addresses in VLAN 10 and VLAN 20 by the DHCP server, you only need to enable the DHCP relay function on a gateway and configure the IP address 30.0.0.2 for the DHCP server.

3. Option 82

As defined in RFC 3046, a DHCP relay agent can add the DHCP relay agent information option to indicate a DHCP client's network information, so that a DHCP server can assign IP addresses of various privileges based on more accurate information. The option is called Option 82.

Based on the physical port that receives DHCP request packets and the MAC address of the device, the DHCP relay agent constructs Option 82. Option 82 can contain a maximum of 255 sub-options. If Option 82 is defined, it should contain at least one sub-option. Currently, the device supports sub-option 1 (**Circuit ID**) and sub-option 2 (**Remote ID**). Figure 1-7 and Figure 1-8 show the formats of the two sub-options.

Figure 1-7 Option 82 Circuit ID



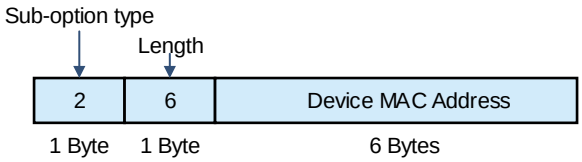


Figure 1-8 Option 82 Remote ID

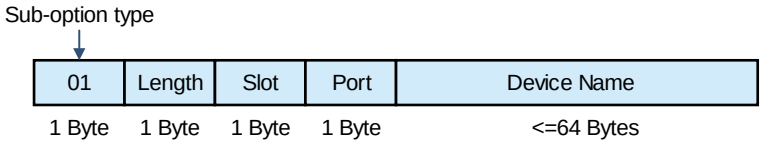
4. Custom Option 82

Option 82 can be customized. A DHCP relay agent can form an Option 82 based on the physical port that receives DHCP request packets and the MAC address and the name of the device. Figure 1-9 and Figure 1-10 show the formats of the sub-options.

Figure 1-9 Custom Option 82 Circuit ID



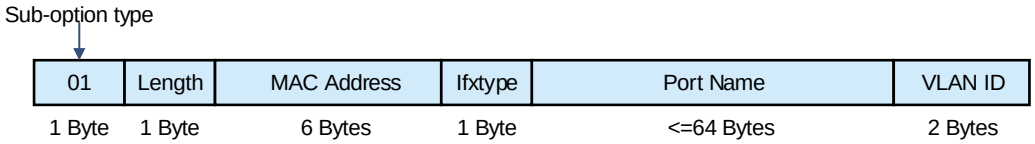


Figure 1-10 Custom Option 82 Remote ID

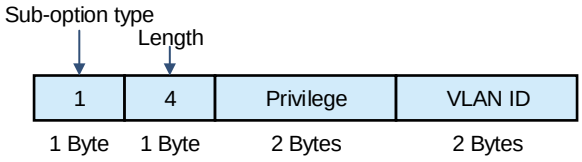


5. Option Dot1x

Option Dot1x should be used in combination with 802.1X authentication and SAM authentication and accounting management system.

A DHCP relay agent constructs the **Circuit ID** sub-option based on the IP privilege delivered during 802.1X authentication and the VLAN ID of a DHCP client. Figure 1-11 shows the option format.

Figure 1-11 Option Dot1x Circuit ID Sub-option

1.2.6 DHCP Associated with VRRP Monitoring

In a Virtual Router Redundancy Protocol (VRRP) scenario, DHCP provides a command to monitor the VRRP status of the current interface. For interfaces configured with a VRRP address and VRRP monitoring, a DHCP

server processes DHCP clients' request packets from an interface on a master device but discards the request packets from an interface on a backup device. If no VRRP address is configured on an interface, the DHCP server does not monitor the VRRP status and processes all DHCP request packets from this interface. VRRP monitoring is configured only on Layer 3 interfaces. It is disabled by default, namely, only the master device provides the DHCP service.

1.2.7 Protocols and Standards

- RFC 2131: Dynamic Host Configuration Protocol
- RFC 2132: DHCP Options and BOOTP Vendor Extensions
- RFC 3046: DHCP Relay Agent Information Option
- RFC 3442: Classless Static Route Option for DHCPv4

1.3 Configuring DHCP Server

1.3.1 Overview

Configure the device as a DHCP server to assign IP addresses to DHCP clients and manage these IP addresses and other configurations. You can also configure other custom functions for the DHCP server as required to customize DHCP services.

1.3.2 Configuration Task Summary

(1) Enabling DHCP Server

(2) (Optional) Configuring Static IP Address Assignment

(3) Configuring Dynamic Assignment of IP Addresses and Network Parameters

(4) (Optional) Configuring DHCP Address Pool Management Function

(5) Enabling the Device to Retain IP Addresses with the Expired DHCP Server Lease

(6) (Optional) Enabling Logging for the Special Status of Clients That Go Online or Offline on the DHCP Server

(7) (Optional) Providing the Boot Image File Name

(8) (Optional) Assigning IP Addresses Based on Class Rules

(9) (Optional) Assigning IP Addresses Based on AM Rules

(10) Configuring security functions of a DHCP server: All the configuration tasks below are optional. Perform the configuration tasks as required.

- Refreshing Trusted ARP Entries
- Configuring Rogue DHCP Server Detection

(11) Configuring other custom functions of the DHCP server: All the configuration tasks below are optional. Perform the configuration tasks as required.

- Configuring IP Address Exclusion
- Configuring IP Address Conflict Detection
- Configuring Compulsory NAK Reply
- Configuring Preferential Assignment of External DNS Server Addresses
- Configuring VRRP Monitoring

- Configuring ARP-based Go-Offline Detection
- Saving Historical Leases
- Configuring the DHCP Server to Use the Destination IP Address in Packets Forwarded by the DHCP Relay as Server ID

1.3.3 Enabling DHCP Server

1. Overview

For the device to function as a DHCP server and assign IP addresses and other network parameters to DHCP clients, enable the DHCP Server function on the device.

2. Restrictions and Guidelines

The **service dhcp** command enables both the DHCP server and DHCP relay functions. When the device is configured with a valid address pool, it acts as a server and directly processes packets. Otherwise, it serves as a relay and forwards the packets.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the DHCP server function.

service dhcp

The DHCP server function is disabled by default.

1.3.4 Configuring Static IP Address Assignment

1. Overview

Static IP address assignment is used to assign specific IP addresses and other configuration information to certain DHCP clients (such as servers and printers). This function allows you to configure multiple static IP address bindings in an address pool, greatly increasing the number of static IP address bindings. Each address pool can be configured with a maximum of 2,000 static IP address bindings. Each IP address can be bound to only one static user using either a MAC address or a client ID.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an address pool and enter the DHCP address pool configuration mode.

ip dhcp pool *dhcp-pool*

(4) Configure binding of static user addresses.

static-bind ip-address *ipv4-address* { *mask-address* | *mask-length* } { **hardware-address** *hardware-address* | **client-identifier** *unique-identifier* }

Static user address binding is not configured by default.

1.3.5 Configuring Dynamic Assignment of IP Addresses and Network Parameters

1. Overview

Configure address pool attributes, such as the address lease time, DNS address, and custom options. A DHCP server can use options to send the information to clients, so as to ensure dynamic network parameter assignment.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an address pool and enter the DHCP address pool configuration mode.

ip dhcp pool *dhcp-pool*

(4) Configure the primary network segment for dynamic assignment in a DHCP address pool.

network *network-number mask* [*low-ipv4-address high-ipv4-address*]

No primary network segment for dynamic assignment in a DHCP address pool is configured by default.

(5) (Optional) Configure the default gateway for a client.

default-router *ipv4-address*&<1-8>

No default gateway is configured for a DHCP client by default.

The gateway address that a DHCP server specifies for a DHCP client must be in the same network segment as the address assigned to the client.

(6) (Optional) Configure the domain name for a client.

domain-name *domain-name*

No domain name is configured for a DHCP client by default.

After a DHCP client obtains a specified domain name, it can directly use its host name to access a host whose name contains the same domain name.

(7) (Optional) Configure the DNS server to be assigned to a DHCP client.

dns-server *ipv4-address*&<1-8>

No DNS server is configured for a DHCP client by default.

When multiple DNS servers are defined, the first defined DNS server has the highest priority. A DHCP client selects the next DNS server only when it fails to communicate with the first defined DNS server.

(8) (Optional) Configure the NetBIOS WINS server for a DHCP client.

netbios-name-server { *ipv4-address*&<1-8> }

No NetBIOS WINS server is configured for a DHCP client by default.

When multiple NetBIOS WINS servers are defined, the first defined NetBIOS WINS server has the highest priority. A DHCP client selects the next NetBIOS WINS server only when it fails to communicate with the first defined NetBIOS WINS server.

(9) (Optional) Configure the type of a NetBIOS node to be assigned to a DHCP client.

netbios-node-type *type*

The default node type of a DHCP client running a Microsoft operating system is broadcast or hybrid. If no WINS server is configured, the client is a broadcast node. Otherwise, it is a hybrid node.

(10) (Optional) Define DHCP server options.

option *code* { **ascii** *string* | **hex** *string* | **ip** *ipv4-address* }

No DHCP server option is defined by default.

1.3.6 Configuring DHCP Address Pool Management Function

1. Configuration Tasks

All the configuration tasks below are optional. Perform the configuration tasks as required.

- Configuring an Address Lease Time
- Adding Trusted ARP Entries During Address Assignment
- Forcibly Disabling Gateway Assignment
- Enabling or Disabling an Address Pool
- Configuring an Alarm Threshold for an Address Pool

2. Configuring an Address Lease Time

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an address pool and enter the DHCP address pool configuration mode.

ip dhcp pool *dhcp-pool*

(4) Configure an address lease time.

lease { *days* [*hours*] [*minutes*] | **infinite** }

The default lease time of a static address pool is permanent by default. The default lease time of other address pools is 1 day.

For address pools other than static address pools, you are not advised to set the lease time to permanent.

3. Adding Trusted ARP Entries During Address Assignment

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an address pool and enter the DHCP address pool configuration mode.

ip dhcp pool *dhcp-pool*

(4) Add trusted ARP entries.

update arp

No trusted ARP entry is added during DHCP address assignment by default.

4. Forcibly Disabling Gateway Assignment

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an address pool and enter the DHCP address pool configuration mode.

ip dhcp pool *dhcp-pool*

(4) Forcibly disable gateway assignment.

force-no-router

A DHCP server assigns a gateway to a DHCP client by default.

5. Enabling or Disabling an Address Pool

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an address pool and enter the DHCP address pool configuration mode.

ip dhcp pool *dhcp-pool*

(4) Enable or disable the address pool.

pool-status { **disable** | **enable** }

A created address pool is enabled by default.

6. Configuring an Alarm Threshold for an Address Pool

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create an address pool and enter the DHCP address pool configuration mode.

ip dhcp pool *dhcp-pool*

(4) Configure an alarm threshold for the address pool.

lease-threshold *threshold-percentage*

The default alarm threshold is 90% for the address pool.

1.3.7 Enabling the Device to Retain IP Addresses with the Expired DHCP Server Lease

1. Overview

By default, the device is enabled to reclaim expired addresses. That is, when there is no other address that can be allocated in the address pool, the expired address is reclaimed and allocated to a new user. However, in scenarios where the IP address stability is required, the reclaim mechanism may cause the instability of the IP address obtained by a user. To ensure IP address stability, you can configure the device to retain IP addresses with the expired lease and sets the retention period for the addresses.

When the DHCP server is configured to retain IP addresses with the expired lease and the retention period is not reached, the IP address can be allocated only to the original user. Expired IP addresses that are not in the retention period will be reclaimed and allocated to new users after idle addresses are exhausted.

2. Restrictions and Guidelines

- You can run the **ip dhcp server expired-reserve-time** command to configure the retention period of expired IP addresses. If the retention period is 0, retention of expired IP addresses is disabled. This function is disabled by default.
- The adjusted retention period takes effect immediately in global configuration mode, that is, the retention period of all IP addresses whose leases have expired is the latest configured retention period. If the configured retention period is shortened, expired addresses that have exceeded the retention period will be reclaimed immediately.
- You can run the **clear ip dhcp expired-reserved** command to forcibly reclaim expired IP addresses that are still within the protection period. These addresses will be allocated to other new users. You are advised to run this command to reclaim expired addresses in retention state when no address is available in the address pool. Note that if the address is reclaimed using this command, the original user of the address cannot apply for the reclaimed address again.
- You can run the **show ip dhcp binding pool** command to check whether the IP address is in retention state.

3. Configuring the Retention Period of Expired Addresses

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the retention period of IP addresses whose leases have expired.

ip dhcp server expired-reserve-time *time*

The default value is 0, indicating that retention of expired IP addresses is disabled.

4. Manually Reclaiming Expired Addresses in the Retention Period

(1) Enter the privileged EXEC mode.

enable

(2) Manually reclaim IP addresses whose leases have expired during the retention period.

clear ip dhcp expired-reserved *ipv4-address*

(3) (Optional) Reclaim all IP addresses whose leases have expired during the retention period.

clear ip dhcp expired-reserved*

1.3.8 Enabling Logging for the Special Status of Clients That Go Online or Offline on the DHCP Server

1. Overview

DHCP clients may be in special states during login and logout, such as lease renewal failure and allocation IP address conflict. This function allows the device to notify users through logs in such cases. This command can be configured in global configuration mode and Layer 3 Ethernet interface configuration mode. When this function is enabled in Layer 3 Ethernet interface configuration mode, only logs of DHCP packets exchanged on the interface are displayed. When this function is enabled in global configuration mode, logs of all DCHP packets exchanged on the Layer 3 Ethernet interface are displayed.

2. Enabling Logging for the Special Status of Clients That Go Online or Offline on the DHCP Server in Global Configuration Mode

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable logging for the special status of clients that go online or offline on the DHCP server.

ip dhcp server logging [**allocation-fail** | **allocation-success** | **detect-conflict** | **recycle-conflict** | **release** | **renew-fail** | **renew-success**]

Logging for the special status of clients that go online or offline is disabled on a DHCP server by default.

(4) (Optional) Configure the rate limit for generating syslogs on the DHCP server.

ip dhcp server syslog limit-rate *number*

Ten syslogs are generated per second on the DHCP server by default.

3. Enabling Logging for the Special Status of Clients That Go Online or Offline on the DHCP Server in Interface Mode

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet sub-interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 aggregate interface configuration mode.

  interface aggregateport *interface-number*

(4) Enable logging for the special status of clients that go online or offline on the DHCP server.

ip dhcp server logging [**allocation-fail** | **allocation-success** | **detect-conflict** | **recycle-conflict** | **release** | **renew-fail** | **renew-success**]

Logging for the special status of clients that go online or offline is disabled on a DHCP server by default..

1.3.9 Providing the Boot Image File Name

1. Overview

Some DHCP clients need to download the operating system or configuration file in the boot process. A DHCP server must provide the required image file name during boot for a DHCP client to download the file from the corresponding server.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the DHCP address pool configuration mode.

ip dhcp pool *dhcp-pool*

(4) Configure the list of boot servers that a DHCP client needs to access during boot.

next-server { *ipv4-address*&<1-8> }

No list of boot servers that a DHCP client needs to access during boot is configured by default.

When multiple boot servers are defined, the first defined boot server has the highest priority. A DHCP client selects the next boot server only when it fails to communicate with the first defined boot server.

(5) (Optional) Configure the boot file name for a DHCP client.

bootfile *file-name*

No boot file name is configured for a DHCP client by default.

1.3.10 Assigning IP Addresses Based on Class Rules

1. Overview

In DHCP relay scenarios, addresses in a DHCP address pool can be assigned based on Option 82. When clients apply for IP addresses through different access points (APs), Option 82 carried in packets of the clients may be different. After class rules are configured on a DHCP server, the DHCP server can assign IP addresses in different network segments to clients based on Option 82 carried in the packets of the clients.

During address assignment, a DHCP server first determines an available address pool based on the network segment of a client. Then, it determines the class of the client based on Option 82, and assigns an IP address from the network segment corresponding to the class. When a request packet matches multiple classes in the address pool, the DHCP server assigns an IP address from the network segments corresponding to the classes based on the class configuration sequence. If the number of assigned IP addresses of a class reaches the limit, the DHCP server assigns an IP address based on the next matching class.

2. Restrictions and Guidelines

A DHCP address pool can be associated with multiple classes.

Each class corresponds to one network segment. Network segments are assigned in ascending order, and the network segments of multiple classes can overlap. If a class is associated with an address pool but no network

segment is configured for the class, the default network segment of the class is the same as the network segment of the address pool.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Create a class rule and enter the class configuration mode.

ip dhcp class *class-name*

No class rule is configured by default.

(4) (Optional) Configure identification information for a class.

remark *class-remark*

No identification information is configured for a class by default.

(5) Enter the Option 82 information configuration mode.

relay agent information

(6) Configure an Option 82 information matching rule for a class.

relay-information hex *hex-string*

No Option 82 matching rule is configured by default.

(7) Return to the global configuration mode.

exit

(8) Enter the DHCP address pool configuration mode.

ip dhcp pool *dhcp-pool*

(9) Associate an address pool with a class.

class *class-name*

No class is associated with a DHCP address pool by default.

(10) (Optional) Configure the IP address range corresponding to a class rule.

address range *low-ipv4-address high-ipv4-address*

The IP address range corresponding to a class rule is the network segment of the associated address pool by default.

(11) Return to the global configuration mode.

exit

(12) Enable address assignment based on class rules.

ip dhcp use class

Address assignment based on class rules is not configured by default.

1.3.11 Assigning IP Addresses Based on AM Rules

1. Overview

Address management (AM) rules can be used to efficiently assign IP addresses to DHCP clients in different scenarios. In super VLAN scenarios, the AM rules can be used to plan the IP range for DHCP clients from different VLANs or ports. After an AM rule is configured, all DHCP clients from the specified VLANs ports can obtain IP addresses. If a DHCP client is from a VLAN, port that is not specified, there are two cases: If a default AM rule is configured, the client obtains an IP address from the default IP address range; if no default AM rule is configured, the client cannot obtain an IP address.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the AM rule configuration mode.

address-manage

(4) Configure an AM rule. Select at least one of the following configuration steps.

- Configure the default IP address range matched with an AM rule.

  match ip default *ipv4-address* { *mask* | *mask-length* }

- Configure dynamic address assignment based on the VLAN and port.

  match ip *ipv4-address* { *mask* | *mask-length* } [*interface-type interface-number*] [**add | remove**] **vlan** *vlan-id*

- Configure dynamic address assignment based on the VLAN.

  match ip *ipv4-address* { *mask* | *mask-length* } [**add** | **remove**] **vlan** *vlan-id*

No AM matching rule is configured by default.

(5) (Optional) Configure the loose mode for an AM rule.

match ip loose

The loose mode of AM rules is disabled by default.

If the loose mode is configured, clients that match no AM rule can obtain IP addresses in the way same as the case with no AM rule configured.

(6) (Optional) Clear the matching rules in AM rules.

clear match ip [interface-type interface-number | **loose**]

1.3.12 Refreshing Trusted ARP Entries

1. Overview

Trusted ARP entries protect a gateway from ARP spoofing. Ruijie devices with DHCP enabled provide a configuration command to determine whether trusted ARP entries are delivered during address assignment. After the function of adding trusted ARP entries is configured, a DHCP server adds trusted ARP entries during

address assignment to prevent ARP spoofing. A trusted ARP entry has a higher priority than a dynamic ARP entry and is not overridden by the dynamic ARP entry.

2. Restrictions and Guidelines

After the function of refreshing trusted ARP entries is configured, a DHCP server refreshes trusted ARP entries only for clients assigned with addresses from an address pool that is configured with the **update arp** command.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Refresh trusted ARP entries.

ip dhcp refresh arp

1.3.13 Configuring Rogue DHCP Server Detection

1. Overview

If a DHCP server is deployed illegally, when clients request IP addresses from this server, clients are assigned with wrong addresses. This server is a rogue server. Ruijie devices with DHCP enabled provide a command to enable rogue server detection. After rogue server detection is enabled, DHCP packets are checked for Option 54 (**Server Identifier**). If Option 54 is carried and its value is different from the actual DHCP server identifier, the IP address of the rogue server and the port receiving the packets are recorded. Rogue server detection is only a post-event detection function for security and cannot prevent an illegal DHCP server from assigning IP addresses to clients.

After rogue server detection is configured, rogue servers in a network are recorded into logs.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure rogue server detection.

ip dhcp server detect

Rogue server detection is disabled by default.

1.3.14 Configuring IP Address Exclusion

1. Overview

An excluded address is an IP address or address segment excluded from the address pool of a DHCP server, so that the DHCP server does not assign this IP address or address segment to a client. Excluding IP addresses can improve the address assignment efficiency.

2. Configuring Excluded IP Addresses

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure excluded IP addresses.

ip dhcp excluded-address *low-ipv4-address* [*high-ipv4-address*]

By default, a DHCP server assigns all addresses from an IP address pool to DHCP clients.

1.3.15 Configuring IP Address Conflict Detection

1. Overview

When the DHCP server attempts to assign an IP address from the address pool, it uses the ping operation to check whether the IP address is occupied by another host. If yes, the DHCP server records the IP address. If not, the DHCP server assigns the IP address to a DHCP client.

The ARP entry check function can be used with the ping operation to detect IP address conflicts. If a client is configured with a static IP address and Layer 2 isolation is configured in an environment and the ping operation for IP address conflict detection becomes invalid (for example, a firewall is enabled on the client), this IP address may be assigned to another client that dynamically requests an address, resulting in an IP address conflict.

2. Configuration Tasks

All the configuration tasks below are optional. Perform the configuration tasks as required.

- Configuring the Number of Ping Operations Executed for Address Conflict Detection
- Configuring the Timeout Time of a Ping Operation Executed for Address Conflict Detection
- Configuring ARP Entry Check

3. Configuring the Number of Ping Operations Executed for Address Conflict Detection

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the number of ping operations executed by a DHCP server when it detects IP address conflicts.

ip dhcp ping packets *ping-times*

A DHCP server pings a conflicted IP address two times by default.

4. Configuring the Timeout Time of a Ping Operation Executed for Address Conflict Detection

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the timeout time of a ping operation executed when a DHCP server detects address conflicts.

ip dhcp ping timeout *time*

The default timeout time of a ping operation for detecting address conflicts is 500 ms.

5. Configuring ARP Entry Check

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the ARP entry check.

ip dhcp arp-probe

The ARP entry check is disabled by default.

1.3.16 Configuring Compulsory NAK Reply

1. Overview

When a DHCP client moves from another network to the local network, the DHCP server does not reply with a NAK packet because it cannot find the corresponding lease record locally. In this case, the DHCP client needs to send REQUEST packets repeatedly. The client can obtain an IP address again only when the request times out, and the time for obtaining an IP address is lengthened. This case also occurs when a client requires lease renewal but the DHCP server loses the lease record of the client due to a restart. In this case, you can configure compulsory NAK reply for the DHCP server if no lease record is found, so as to ensure that the client can obtain an IP address quickly.

2. Restrictions and Guidelines

When compulsory NAK reply is enabled, enable only one DHCP server in a broadcast domain. Configuring compulsory NAK reply may cause exceptions to other servers.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure compulsory NAK reply for a DHCP server.

ip dhcp force-send-nak

Compulsory NAK reply is enabled by default.

1.3.17 Configuring Preferential Assignment of External DNS Server Addresses

1. Overview

When a device works in the Point-to-Point Protocol over Ethernet (PPPoE) or DHCP client mode, it can obtain DNS server addresses automatically from an external DHCP server. Configure the DNS server addresses on the DHCP server of the local device, so that users do not need to perform DNS configuration. When a device

serves as a DHCP server, it preferentially assigns clients with a DNS server address obtained from an external DHCP server.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure preferential assignment of external DNS server addresses to clients when the device works in the DHCP client or PPPoE mode.

ip dhcp dns dynamic

By default, run the **dns-server** command to assign DNS server addresses to clients.

1.3.18 Configuring VRRP Monitoring

1. Overview

After VRRP monitoring is enabled in VRRP application scenarios, only the master server processes DHCP packets.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

(4) Enable VRRP monitoring.

ip dhcp monitor-vrrp-state

VRRP monitoring is disabled for an interface by default.

1.3.19 Configuring ARP-based Go-Offline Detection

1. Overview

Ruijie devices with DHCP enabled provide a command to enable ARP-based go-offline detection. After this function is enabled, a DHCP server receives an ARP entry aging notification when a client goes offline, and reclaims the client's IP address. If the client does not go online within a period of time (5 minutes by default), the

DHCP server reclaims the IP address and assigns it to another client. If the client goes online again within the specified period, it can still use the original IP address.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure ARP-based go-offline detection.

ip dhcp server arp-detect

ARP-based go-offline detection is not configured for a DHCP server by default.

1.3.20 Saving Historical Leases

1. Overview

Enable a DHCP server to save historical leases, the DHCP server saves the IP address lease of a client to the database after an IP address is assigned to a client and the client goes offline. When the client goes online again, the DHCP server assigns this address to the client again. Historical leases are saved when a DHCP process restarts or the device performs a hot backup switchover.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of saving historical leases.

ip dhcp save-history-enable

The function of saving historical leases is disabled by default.

1.3.21 Disabling a DHCP Server from Adding Dynamic ARP Entries to Packets

1. Overview

You can disable a DHCP server from adding dynamic ARP entries when sending packets to improve network stability and security.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable the function of adding dynamic ARP entries to packets sent by a DHCP server.

ip dhcp server unicast-update-arp disable

By default, a DHCP server adds dynamic ARP entries into packets to be sent.

1.3.22 Enabling a DHCP Server to Synchronize DHCP Information to an SDN Controller

1. Overview

In a software-defined networking (SDN) environment, DHCP information synchronization is important to help network administrators better manage and control network resources.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable the function of synchronizing DHCP information from a DHCP server to an SDN controller.

ip dhcp server notification batch disable

By default, a DHCP server synchronizes DHCP information to an SDN controller.

1.3.23 Configuring the DHCP Server to Use the Destination IP Address in Packets Forwarded by the DHCP Relay as Server ID

1. Overview

This command is configured on a DHCP server. In most cases, this command is used in a scenario with a DHCP relay agent. The DHCP client is on a VPN, the inbound interface on the DHCP server is a public network interface, and the server IP address specified on the DHCP relay agent is usually the IP address of a non-public network interface on the DHCP server. When applying for lease renewal, the DHCP client sets the server ID as the destination address in the renewal request packet. If this command is not configured, the server ID advertised to the DHCP client is the IP address of a public network interface on the DHCP server by default. As a result, the DHCP client fails to extend the lease. After this command is configured, the server ID advertised to the client is the destination IP address in the request packet forwarded by the DHCP relay agent, so as to ensure that the client can normally renew the lease.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the DHCP server to use the destination IP address in the packets forwarded by the DHCP relay agent as the server ID.

ip dhcp server identifier destination-ip

By default, a DHCP server uses the IP address of an inbound interface (public network interface) as the server ID.

1.4 Configuring DHCP Relay

1.4.1 Overview

When a DHCP client and a DHCP server are in different network segments, a DHCP relay agent is required for dynamic IP address management.

1.4.2 Configuration Task Summary

(1) Configuring Basic DHCP Relay Functions

(2) Configuring extended DHCP relay functions: All the configuration tasks below are optional. Perform the configuration tasks as required.

- Configuring Option 82
- Configuring Server-ID Check
- Enabling DHCP Relay Suppression
- Configuring Multiple Gateway IP Addresses
- Forcing a DHCP Relay to Send a Reply Packet
- Configuring the Source IP Address of DHCP Relay Packets

1.4.3 Configuring Basic DHCP Relay Functions

1. Overview

Generally, the DHCP relay function is implemented by an interface on a device. The IP address of the server should be specified on the DHCP relay agent. In this case, DHCP broadcast packets received over this interface are sent to the specified server.

2. Restrictions and Guidelines

To enable DHCP relay, configure IPv4 unicast routing in a network.

- The **service dhcp** command is used to enable both the DHCP server and DHCP relay functions. However, a device cannot function as a DHCP server and relay at the same time. When a device is configured with a valid address pool, it acts as a server. Otherwise, it serves as a relay.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the DHCP relay function.

service dhcp

The DHCP relay function is disabled by default.

(4) Configure the IP address of the DHCP server.

ip helper-address { **cycle-mode** | [**vrf** *vrf-name*] *ipv4-address* }

The IP address of the DHCP server is not configured for the DHCP relay agent by default.

The DHCP server address can be globally configured or configured on an Layer 3 interface. A maximum of 20 DHCP server addresses can be globally configured or configured on each Layer 3 interface. When an interface receives a DHCP request packet, the DHCP server list on the interface prevails over that configured globally. If the interface is not configured with the DHCP server list, the global DHCP server list takes effect.

1.4.4 Configuring Option 82

1. Overview

A DHCP relay agent can use Option 82 to identify network information of DHCP clients, so that a DHCP server can assign IP addresses of different privileges to the clients more accurately based on this option.

2. Restrictions and Guidelines

- Configure basic DHCP relay functions.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable DHCP Option 82.

ip dhcp relay information option82

DHCP Option 82 is disabled by default.

(4) Configure sub-options of DHCP Option 82. All the configuration steps below are optional. Select configuration steps as required.

- Customize information in **Circuit ID**.

  ip dhcp relay information option82 user-defined circuit-id *circuit-id-text*

  No custom information is configured for **Circuit ID** of DHCP Option 82 by default.

- Customize information in **Remote ID**.

  ip dhcp relay information option82 user-defined remote-id *remote-id-text*

  No custom information is configured for **Remote ID** of DHCP Option 82 by default.

(5) (Optional) Customize the MAC address format.

ip dhcp relay information option82 user-defined mac-format *mac-format-type*

The default MAC address format is H.H.H.

(6) Set the **Circuit ID** sub-option in DHCP Option 82 to a user-defined hexadecimal or ASCII string.

ip dhcp relay information circuit-id format { **hex | ascii** } *string*

The **Circuit ID** sub-option in DHCP Option 82 is not set to a user-defined hexadecimal or ASCII string by default.

(7) (Optional) Set the **Circuit ID** sub-option in DHCP Option 82 to a user-defined device name.

ip dhcp relay information circuit-id string *devicename*

The **Circuit ID** sub-option in DHCP Option 82 is not set to a user-defined device name by default.

(8) (Optional) Set the **Remote ID** sub-option in DHCP Option 82 to a user-defined hexadecimal or ASCII string globally.

ip dhcp relay information remote-id format { **hex | ascii** } *string*

The **Remote ID** sub-option in DHCP Option 82 is not set to a user-defined hexadecimal or ASCII string by default.

(9) (Optional) Set the **Remote ID** sub-option in DHCP Option 82 to a user-defined interface name globally.

ip dhcp relay information remote-id string *portname*

The **Remote ID** sub-option in DHCP Option 82 is not set to a user-defined interface name by default.

(10) (Optional) Enable the function of filling DHCP Option 82 with content in Verbose format.

ip dhcp relay information verbose-opt82

The function of filling DHCP Option 82 with content in Verbose format is disabled by default.

(11) Enter interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

(12) (Optional) Set the **Remote ID** sub-option in DHCP Option 82 to a user-defined hexadecimal or ASCII string for the interface.

ip dhcp relay information remote-id format { **hex | ascii** } *string*

The **Remote ID** sub-option in DHCP Option 82 is not set to a user-defined hexadecimal or ASCII string by default.

(13) (Optional) Set the **Remote ID** sub-option in DHCP Option 82 to a user-defined interface name for the interface.

ip dhcp relay information remote-id string *portname*

The **Remote ID** sub-option in DHCP Option 82 is not set to a user-defined interface name by default.

1.4.5 Configuring Server-ID Check

1. Overview

In a DHCP relay application environment, multiple DHCP servers are configured in each network to provide server backup, thereby helping ensure uninterrupted network operation. When a DHCP client has selected a DHCP server to send a DHCP REQUEST packet, a **Server-ID** option is carried in the packet. To reduce server load in specific environments, enable the **Server-ID** check function on the DHCP relay agent, so as to send the DHCP REQUEST packet only to the DHCP server specified in this option.

In this case, the DHCP relay agent sends DHCP request packets only to the specified server. If this function is not configured, the DHCP relay agent sends DHCP request packets to all configured DHCP servers.

2. Restrictions and Guidelines

Configure basic DHCP relay functions.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable a DHCP relay agent to check **Server-ID**.

ip dhcp relay check server-id

By default, a DHCP relay agent forwards a DHCP Request message to all DHCP servers.

1.4.6 Enabling DHCP Relay Suppression

1. Overview

After you enable DHCP relay suppression on an interface, DHCP request packets received over the interface are filtered out, but the other DHCP requests are forwarded.

2. Restrictions and Guidelines

Configure basic DHCP Relay functions.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Enable the DHCP relay suppression function.

ip dhcp relay suppression

The DHCP relay suppression function is disabled on all interfaces by default.

1.4.7 Configuring Multiple Gateway IP Addresses

1. Overview

After the function of configuring multiple gateway IP addresses is enabled, a DHCP relay agent can use multiple interface IP addresses to send address requests to a DHCP server. Generally, the primary IP address is used as the gateway IP address, and the DHCP server assigns a network segment based on the gateway IP address. When a client fails to apply for an IP address through the gateway by using the primary IP address, it applies for an IP address through the gateway by using a secondary IP address.

After the automatic gateway switchover function is enabled, the DHCP relay agent adds another address to the **giaddr** field if it does not receive a reply for three consecutive DISCOVER packets.

2. Restrictions and Guidelines

Configure basic DHCP Relay functions.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of configuring multiple gateway IP addresses on a DHCP relay agent.

ip dhcp relay multiple-giaddr

The function of configuring multiple gateway IP addresses on a DHCP relay agent is disabled by default.

(4) (Optional) Enable the automatic gateway switchover function.

ip dhcp smart-relay

The automatic gateway switchover function is disabled by default.

1.4.8 Forcing a DHCP Relay to Send a Reply Packet

1. Overview

After the function of forcing a DHCP relay agent to send a reply packet is enabled, a DHCP relay agent forcibly specifies a gateway interface to send a reply if it fails to find a MAC address egress. When the function is disabled, the DHCP relay agent discards packets if it fails to find a MAC address egress.

2. Restrictions and Guidelines

You must enable basic DHCP Relay functions.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the function of forcing a DHCP relay agent to send a reply packet.

ip dhcp relay force-send-reply-pack

The function of forcing a DHCP relay agent to send a reply packet is disabled by default.

1.4.9 Configuring the Source IP Address of DHCP Relay Packets

1. Overview

You can run the **ip dhcp relay source** command on an interface to configure the source IP address of DHCP relay packets.

2. Restrictions and Guidelines

- Configure basic DHCP Relay functions.

- Only one source IP address can be specified for DHCP relay packets on each interface.
- This function must be used with Option 82.

3. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

(4) Configure the source IP address for DHCP relay packets.

ip dhcp relay source *ipv4-address*

No source address is configured for DHCP relay packets by default.

1.4.10 Configuring the DHCP Relay to Specify the Link Selection Sub-option

1. Overview

You can enable the function of specifying the Option 82 (sub-option 5) field by a DHCP relay agent.

2. Restrictions and Guidelines

- Basic functions of the DHCP relay must be configured.
- Only one source IP address can be specified for DHCP relay packets on an interface.
- This function must be used together with Option 82 and a specified source address. The command takes effect only when both functions are enabled.

2. Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  interface aggregateport *interface-number*
- Enter the SVI configuration mode.
  interface vlan *interface-number*
- Enter the tunnel interface configuration mode.

interface tunnel *interface-number*

- Enter the loopback interface configuration mode.
  interface loopback *interface-number*

(4) Enable a DHCP relay agent to specify the address in the link-selection sub-option.
ip dhcp relay link-selection *ipv4-address*

By default, this function is enabled, and the primary IPv4 address of the interface is specified.

1.5 Monitoring

Run the **show** command to check the configuration.

Run the **debug** command to output debugging information.

Caution

The output of debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **clear** command to clear information.

Caution

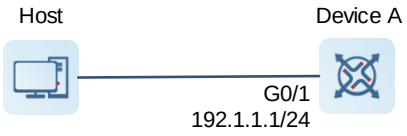
Running the **clear** commands may lose vital information and thus interrupt services.

Table 1-1 Monitoring

Command	Purpose
clear ip dhcp binding { *ipv4-address* | ***** }	Clears DHCP address binding records.
clear ip dhcp conflict { *ipv4-address* | ***** }	Clears DHCP address conflict records.
clear ip dhcp expired-reserved { ***** | *ipv4-address* }	Forcibly reclaims IP addresses whose leases have expired during the retention period.
clear ip dhcp history { *mac-address* | ***** }	Clears DHCP historical lease records.
clear ip dhcp server detect { *ipv4-address* | ***** }	Clears rogue DHCP server detection records.
clear ip dhcp server rate	Clears DHCP server performance statistics.
clear ip dhcp server statistics	Clears DHCP server statistics.
clear ip dhcp relay statistics	Clears DHCP relay statistics.
show dhcpserver exclude	Displays the excluded address range of a DHCP server.
show dhcpserver manual-bind	Displays statically bound IP addresses of a DHCP server.
show dhcpserver pool	Displays configurations of the specified IP address pool on a DHCP server.

show dhcpserver support	Displays functions supported by a DHCP server.
show ip dhcp binding	Displays DHCP address bindings.
show ip dhcp binding pool *pool-name*	Displays detailed information about a DHCP address pool.
show ip dhcp conflict	Displays address conflict records of a DHCP server.
show ip dhcp database	Displays the running status of the database backup function of a DHCP server.
show ip dhcp dns dynamic	Displays DNS server addresses obtained from an external DHCP server when the device works in the PPPoE or DHCP client mode.
show ip dhcp history	Displays DHCP historical lease records.
show ip dhcp identifier	Displays the address pool ID and address usage of a DHCP server.
show ip dhcp pool [*pool-name*]	Displays the address pool status and utilization of a DHCP server.
show ip dhcp server relay-binding [**detail**]	Displays binding information about a DHCP relay agent.
show ip dhcp server relay-ifx	Displays all interface data of a DHCP relay agent.
show ip dhcp relay-statistic	Displays DHCP relay statistics.
show ip dhcp server detect	Displays rogue DHCP server detection information.
show ip dhcp server statistic	Displays DHCP server statistics.
show ip dhcp socket	Displays DHCP socket indexes.
show ip dhcp server status	Displays status of a DHCP server.
debug ip dhcp server agent	Debugs a DHCP server.
debug ip dhcp server ha	Debugs DHCP hot backup.
debug ip dhcp server pool	Debugs DHCP address pools.
debug ip dhcp server vrrp	Debugs association between a DHCP server and a VRRP group.
debug ip dhcp server all	Debugs all DHCP servers.
debug ip dhcp relay	Debugs a DHCP relay.

1.6 Configuration Examples



1.6.1 Configuring Static Address Binding

1. Requirements

As shown in Figure 1-12, a host that serves as a DHCP client obtains a statically bound IP address from Device A that serves as a DHCP server. The MAC address of the host is 0050.56b0.2f50.

2. Topology

Figure 1-12 Static Address Binding

3. Notes

Configure Device A:

- Configure the IP address of the interface.
- Enable the DHCP server service and configure address pool parameters.

4. Procedure

(1) Configure Device A.

Configure the IP address of the interface.

```
DeviceA> enable
DeviceA # configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no switchport
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.1.1.1 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
```

Enable the DHCP server service.

```
DeviceA(config)# service dhcp
```

Create an address pool named **pool1**.

```
DeviceA(config)# ip dhcp pool pool1
```

Assign a statically bound IP address to the host.

```
DeviceA(dhcp-config)# static-bind ip-address 192.1.1.99 255.255.255.0
hardware-address 0050.56b0.2f50
```

(2) Configure the host.

Enable DHCP on the host to obtain an IP address. (Omitted)

5. Verification

Check that the host has obtained the IP address 192.1.1.99/24.

6. Configuration Files

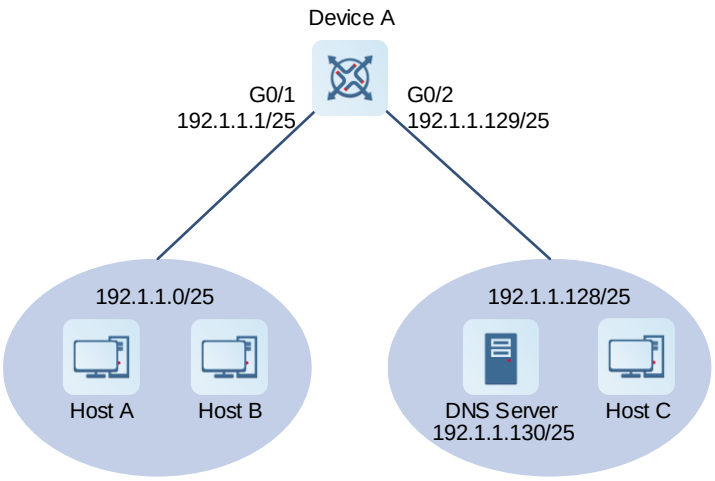
Device A configuration file

```
hostname DeviceA
!
service dhcp
!
ip dhcp pool pool1
 hardware-address 0050.56b0.2f50
 host 192.1.1.99 255.255.255.0
!
interface GigabitEthernet 0/1
 no switchport
 ip address 192.1.1.1 255.255.255.0
!
```

7. Common Errors

- No address pool is configured.
- The DHCP Server service is not enabled.

1.6.2 Dynamically Assigning IP Addresses



1. Requirements

As shown in Figure 1-13, Device A serving as a DHCP server dynamically assigns IP addresses to clients in the same network segment. The address pool is divided into two network segments: 192.1.1.0/25 and 192.1.1.128/25.

The lease time of IP addresses in network segment 192.1.1.0/25 is 5 days, the domain name suffix is **test.com**, the DNS address is 192.1.1.130, and the gateway address is 192.1.1.1. The lease time of IP addresses in network segment 10.1.1.128/25 is 3 days, the domain name suffix is **test.com**, the DNS address is 192.1.1.130, and the gateway address is 192.1.1.129.

2. Topology

Figure 1-13 Dynamically Assigning IP Addresses

3. Notes

Configure Device A:

- Configure the IP address of the interface for connecting to the host.
- Enable the DHCP Server service and configure parameters of two address pools.

4. Procedure

(1) Configure Device A:

Configure the IP address of the interface for connecting to the host.

```
DeviceA> enable
DeviceA # configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no switchport
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.1.1.1 255.255.255.128
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# no switchport
DeviceA(config-if-GigabitEthernet 0/2)# ip address 192.1.1.129 255.255.255.128
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

Enable the DHCP Server service.

```
DeviceA(config)# service dhcp
```

Configure network parameters of pool 1.

```
DeviceA(config)# ip dhcp pool pool1
DeviceA(dhcp-config)# network 192.1.1.0 255.255.255.128
DeviceA(dhcp-config)# default-router 192.1.1.1
DeviceA(dhcp-config)# dns-server 192.1.1.130
DeviceA(dhcp-config)# domain-name test.com
DeviceA(dhcp-config)# lease 5
DeviceA(dhcp-config)# exit
```

Configure network parameters of pool 2.

```
DeviceA(config)# ip dhcp pool pool2
DeviceA(dhcp-config)# network 192.1.1.128 255.255.255.128
DeviceA(dhcp-config)# default-router 192.1.1.129
DeviceA(dhcp-config)# dns-server 192.1.1.130
DeviceA(dhcp-config)# domain-name test.com
DeviceA(dhcp-config)# lease 3
```

(2) Configure the DNS server:

Set the DNS server IP address to 192.1.1.130/25. (Omitted)

(3) Configure the host:

Enable DHCP on Host A, Host B, and Host C to obtain IP addresses. (Omitted)

5. Verification

Check that Host A and Host B have obtained addresses in network segment 192.1.1.0/25.

Check that Host C has obtained an address in network segment 192.1.1.128/25.

Run the **show ip dhcp pool** command on Device A to display address pool configurations and usage.

```
DeviceA(config)# show ip dhcp pool
Pool  name    Dynamic total  Dynamic distributed  Dynamic remained  Static-bind total
Static-bind distributed     Static-bind remained  Disable/conflict  Percentage
------------  -------------  -------------------  ----------------
-----------------
-----------------------     --------------------  ----------------  ----------
pool1         125           2                     123               0
0                           0                     0                 0.98400
pool2         125           1                     124               0
0                           0                     0                 0.80000
```

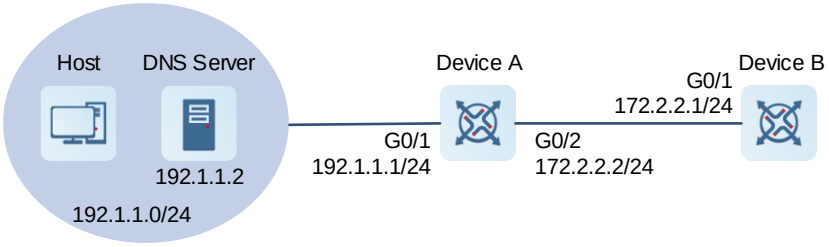
6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
 interface gigabitethernet 0/1
 no switchport
 ip address 192.1.1.1 255.255.255.128
!
 interface gigabitethernet 0/2
 no switchport
 ip address 192.1.1.129 255.255.255.128
!
 service dhcp
!
 ip dhcp pool pool1
 network 192.1.1.0 255.255.255.128
 default-router 192.1.1.1
 dns-server 192.1.1.130
 domain-name test.com
 lease 5
!
 ip dhcp pool pool2
 network 192.1.1.128 255.255.255.128
 default-router 192.1.1.129
 dns-server 192.1.1.130
 domain-name test.com
 lease 3
!
```

7. Common Errors

- No address pool is configured.
- The DHCP Server service is not enabled.



1.6.3 Configuring DHCP Relay

1. Requirements

As shown in Figure 1-14, a host serving as a DHCP client is located in network segment 192.1.1.0/24, Device A is the gateway, and Device B is a DHCP server. To apply for an IP address and other configurations from the DHCP server, the DHCP client needs to use the gateway as a DHCP relay agent, so that the DHCP relay agent forwards DHCP packets to the DHCP server.

2. Topology

Figure 1-14 Configuring DHCP Relay

3. Notes

- Configure Device A:
  - Configure the IP address of the interface.
  - Enable the DHCP relay function.
- Configure Device B:
  - Configure the IP address of the interface.
  - Configure a route from Device B to GigabitEthernet 0/1 on Device A.
  - Enable the DHCP server service and configure address pool parameters.

4. Procedure

(1) Configure Device A:

Configure the IP address of the interface.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no switchport
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.1.1.1 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# no switchport
```

```
DeviceA(config-if-GigabitEthernet 0/2)# ip address 172.2.2.2 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

Enable the DHCP relay function.

```
DeviceA(config)# service dhcp
```

Add the DHCP server address to the DHCP relay agent.

```
DeviceA(config)# ip helper-address 172.2.2.1
```

(2) Configure Device B:

Configure the IP address of the interface.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# no switchport
DeviceB(config-if-GigabitEthernet 0/1)# ip address 172.2.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Configure a static route to network segment 192.1.1.0/24.

```
DeviceB(config)# ip route 192.1.1.0 255.255.255.0 gigabitethernet 0/1 172.2.2.2
```

Enable the DHCP server function.

```
DeviceB(config)# service dhcp
```

Configure network parameters of pool 1.

```
DeviceB(config)# ip dhcp pool pool1
DeviceB(dhcp-config)# network 192.1.1.0 255.255.255.0
DeviceB(dhcp-config)# default-router 192.1.1.1
DeviceB(dhcp-config)# dns-server 192.1.1.2
DeviceB(dhcp-config)# exit
```

(3) Enable DHCP on the host to obtain an IP address. (Omitted)

5. Verification

Check that the host has obtained an address in network segment 192.1.1.0/24.

Run the **show ip dhcp pool** command on Device B to display the address pool configurations and usage.

```
DeviceB(config)# show ip dhcp pool
Pool  name    Dynamic total  Dynamic distributed  Dynamic remained  Static-bind total
Static-bind distributed     Static-bind remained  Disable/conflict  Percentage
------------  -------------  -------------------  ----------------
-----------------
----------------------     --------------------  ----------------  ----------
pool1         253           1                  252             0
0                        0                 0               0.99604
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
```

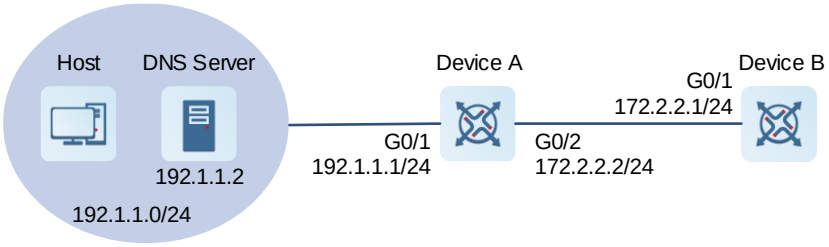
```
 interface gigabitethernet 0/1
 no switchport
 ip address 192.1.1.1 255.255.255.0
!
 interface gigabitethernet 0/2
!
 service dhcp
 ip helper-address 172.2.2.1
!
```

- Device B configuration file

```
hostname DeviceB
!
 interface gigabitethernet 0/1
 no switchport
 ip address 172.2.2.1 255.255.255.0
!
 ip route 192.1.1.0 255.255.255.0 gigabitethernet 0/1 172.2.2.2
 service dhcp
!
 ip dhcp pool pool1
 network 192.1.1.0 255.255.255.0
 default-router 192.1.1.1
 dns-server 192.1.1.2
!
```

7. Common Errors

- The DHCP relay function is disabled on the DHCP relay agent.
- No route is configured between the DHCP relay agent and DHCP server.
- The IP address of the DHCP server is configured on the DHCP relay agent.



1.6.4 Assigning IP Addresses Based on Class Rules

1. Requirements

As shown in Figure 1-15, Device A serves as a DHCP relay agent to forward DHCP packets between the clients and server, and Device B serves as a DHCP server to assign IP addresses and other network configurations to the clients. It is required that Device A assign an IP address in the range of 192.1.1.200 to 192.1.1.254 if a DHCP request packet carries Option 82 and assigns an IP address in the range of 192.1.1.1 to 192.1.1.199 if a DHCP request packet does not carry Option 82.

2. Topology

Figure 1-15 Assigning IP Addresses Based on Class Rules

3. Notes

- Configure Device A:
  - Configure the IP address of the interface.
  - Enable the DHCP relay function.
  - Enable the Option 82 function.
- Configure Device B:
  - Configure the IP address of the interface.
  - Configure a route from Device B to GigabitEthernet 0/1 on Device A.
  - Enable the DHCP server service and configure address pool parameters.
  - Add a specific class rule.

4. Procedure

(1) Configure Device A:

Configure the IP address of the interface.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no switchport
DeviceA(config-if-GigabitEthernet 0/1)# ip address 192.1.1.1 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/1)# exit
DeviceA(config)# interface gigabitethernet 0/2
DeviceA(config-if-GigabitEthernet 0/2)# no switchport
DeviceA(config-if-GigabitEthernet 0/2)# ip address 172.2.2.2 255.255.255.0
DeviceA(config-if-GigabitEthernet 0/2)# exit
```

Enable the DHCP relay function.

```
DeviceA(config)# service dhcp
```

Add the DHCP server address.

```
DeviceA(config)# ip helper-address 172.2.2.1
```

Enable Option 82.

```
DeviceA(config)# ip dhcp relay information option82
```

(2) Configure Device B:

Configure the IP address of the interface.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# no switchport
DeviceB(config-if-GigabitEthernet 0/1)# ip address 172.2.2.1 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Configure a static route to network segment 192.1.1.0/24.

```
DeviceB(config)# ip route 192.1.1.0 255.255.255.0 gigabitethernet 0/1 172.2.2.2
```

Enable the DHCP Server function.

```
DeviceB(config)# service dhcp
```

Configure a class rule.

```
DeviceB(config)# ip dhcp class myclass
DeviceB(config-dhcp-class)# relay agent information
DeviceB(config-dhcp-class-relayinfo)# relay-information hex 060223*
```

Create an address pool and configure related network parameters.

```
DeviceB(config)# ip dhcp pool pool1
DeviceB(dhcp-config)# network 192.1.1.0 255.255.255.0
DeviceB(dhcp-config)# default-router 192.1.1.1
DeviceB(dhcp-config)# dns-server 192.1.1.2
```

Configure the network segment for assigning an IP address when a class is matched.

```
DeviceB(dhcp-config)# class myclass
DeviceB(config-dhcp-pool-class)# address range 192.1.1.200 192.1.1.254
DeviceB(config-dhcp-pool-class)# exit
```

(3) Enable DHCP on the host to obtain an IP address. (Omitted)

5. Verification

Capture packets on Device B and check that the clients that match class rules obtain IP addresses in the range of 192.1.1.200 to 192.1.1.254 and other clients obtain IP addresses in the range of 192.1.1.1 to 192.1.1.199.

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
 service dhcp
 ip helper-address 172.2.2.1
 ip dhcp relay information option82
!
 interface gigabitethernet 0/1
 no switchport
 ip address 192.1.1.1 255.255.255.0
 exit
```

```
 interface gigabitethernet 0/2
 no switchport
 ip address 172.2.2.2 255.255.255.0
!
```

- Device B configuration file

```
hostname DeviceB
!
 ip route 192.1.1.0 255.255.255.0 gigabitethernet 0/1 172.2.2.2
 service dhcp
!
 interface gigabitethernet 0/1
 no switchport
 ip address 172.2.2.1 255.255.255.0
!
 ip dhcp class myclass
 relay agent information
 relay-information hex 060223*
!
 ip dhcp pool pool1
 network 192.1.1.0 255.255.255.0
 default-router 192.1.1.1
 dns-server 192.1.1.2
 class myclass
   address range 192.1.1.200 192.1.1.254
!
```

7. Common Errors

- The DHCP Relay function is disabled.
- No route is configured between the DHCP relay agent and DHCP server.
- No DHCP server IP address is configured.

1 Configuring DHCP Client

1.1 Introduction

1.1.1 Overview

Dynamic Host Configuration Protocol (DHCP) is a local area network (LAN) protocol based on the User Datagram Protocol (UDP) for dynamically assigning reusable network resources over port 68, for example, IP addresses.

The DHCP works in client/server mode. A DHCP client sends a request message to a DHCP server to obtain an IP address and other configurations. When a DHCP client and a DHCP server are not in the same subnet, they need a DHCP relay agent to forward DHCP request and reply messages.

1.1.2 Principles

1. DHCP client

A DHCP client enables a device to automatically obtain an IP address and other configurations from a DHCP server.

For details about interaction between the DHCP client and server, see *Configuring DHCP*.

2. Lease renewal

Generally, a dynamic IP address assigned from a DHCP server to a DHCP client has a lease period (one day by default). After the lease period expires, the DHCP server will reclaim this IP address. If the DHCP client wants to continue to use this IP address, it automatically sends a DHCP REQUEST packet to the DHCP server at half of the lease period to renew the lease. If this IP address is valid, the DHCP server returns a DHCP ACK packet to inform the DHCP client that it has obtained a new IP address lease.

If the lease renewal operation performed at half of the lease period fails (for example, the DHCP server does not make a response), the DHCP client broadcasts another DHCP REQUEST packet at 7/8 of the lease period to renew the lease. The DHCP server renews the lease in the same way.

3. Network reconnection

When a DHCP client reconnects to the network after it goes offline, it does not need to send a DHCP DISCOVER packet but only broadcasts a DHCP REQUEST packet that carries the previously assigned IP address.

After receiving the DHCP REQUEST packet, the DHCP server returns a DHCP ACK packet to inform the DHCP client that it can continue to use the original IP address if this IP address is not assigned. If the original IP address has been assigned to another client, the DHCP server returns a DHCP NAK packet. Upon receiving the DHCP NAK packet, the DHCP client needs to re-send a DHCP DISCOVER packet to apply for a new IP address.

4. Lease release

When a DHCP client no longer needs to use the assigned IP address, it can send a DHCP RELEASE packet to inform the DHCP server, for the DHCP server to release the DHCP lease and reclaim the IP address. The

DHCP server saves the configuration information of the DHCP client temporarily for reuse in next IP address application by the DHCP client.

1.1.3 Protocols and Standards

- RFC 2131: Dynamic Host Configuration Protocol
- RFC 2132: DHCP Options and BOOTP Vendor Extensions
- RFC 3046: DHCP Relay Agent Information Option
- RFC 1542: Clarifications and Extensions for the Bootstrap Protocol

1.2 Configuration Task Summary

DHCP client configuration includes the following tasks:

(1) Enabling DHCP Client Function

(2) (Optional) Configuring Characteristics of DHCP Reply Packets

1.3 Enabling DHCP Client Function

1.3.1 Overview

After the DHCP Client function is enabled on a device, the device can dynamically obtain IP addresses and other configurations, such as the default gateway and Domain Name System (DNS) server.

1.3.2 Restrictions and Guidelines

The device supports DHCP client configurations on Ethernet, Frame Relay (FR), Point-to-Point Protocol (PPP), and High-Level Data Link Control (HDLC) interfaces.

1.3.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 3 link aggregation configuration mode.

  interface aggregateport *interface-number*

- Enter the switch virtual interface (SVI) configuration mode.

  interface vlan *interface-number*

(4) Enable the DHCP Client function on an interface.

ip address dhcp

No interface can obtain an IP address through DHCP by default.

1.4 Configuring Characteristics of DHCP Reply Packets

1.4.1 Overview

When a DHCP client requests an IP address, no detection mechanism is deployed between the client and server. Therefore, when multiple DHCP servers exist on a network, the DHCP client selects the first server that sends an Offer message to request an IP address. When multiple DHCP servers exist, DHCP clients can apply for IP addresses randomly and can be easily interfered by unauthorized DHCP servers. You can configure characteristics of DHCP Reply packets. In this case, only the server that meets the characteristics can allocate IP addresses to clients.

1.4.2 Configuration Procedure

(1) Enter the privileged EXEC mode.
enable

(2) Enter the global configuration mode.
configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 3 Ethernet interface configuration mode.
  interface *ethernet-type interface-number*
- Enter the Layer 3 aggregate interface configuration mode.
  interface aggregateport *interface-number*
- Entry the SVI configuration mode.
  interface vlan *interface-number*

(4) Configure characteristics of DHCP Reply packets.
ip dhcp client specify-server { **ip** *ip-address* | **option** *id* **include** { **ascii** *ascii-data* | **hex** *hex-data* | **ip** *ip-address* } }

By default, characteristics of DHCP Reply packets are not configured.

1.5 Monitoring

Run the **show** commands to check the running status of a configured function to verify the configuration effect.

Run the **debug** commands to output debugging information.

Caution

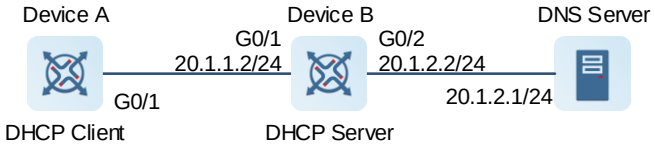
The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
clear ip dhcp client statistics	Clears statistics of a DHCP client.
show ip dhcp client statistics	Displays packet statistics of a DHCP client

show dhcp lease	Displays lease information of a DHCP client.
debug ip dhcp client	Debugs DHCP packets.

1.6 Configuration Examples



1.6.1 Enabling DHCP Client Function

1. Requirements

As shown in Figure 1-1, GigabitEthernet 0/1 on Device A uses DHCP to obtain an IP address and DNS server address 20.1.1.1/24 from Device B (DHCP server).

2. Topology

Figure 1-1 DHCP Client Function

3. Notes

- Enable the DHCP Client function on GigabitEthernet 0/1 of Device A.
- Enable the DHCP Server function on Device B and configure address pool parameters as required.

4. Procedure

(1) Configure Device A:

Enable the DHCP Client service on GigabitEthernet 0/1.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)# no switchport
DeviceA(config-if-GigabitEthernet 0/1)# ip address dhcp
```

(2) Configure Device B:

Enable the DHCP Server service.

```
DeviceB> enable
DeviceB# configure terminal
DeviceB(config)# service dhcp
```

Configure the interface IP address used to connect to the DHCP client.

```
DeviceB(config)# interface gigabitethernet 0/1
DeviceB(config-if-GigabitEthernet 0/1)# no switchport
DeviceB(config-if-GigabitEthernet 0/1)# ip address 20.1.1.2 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/1)# exit
```

Configure the interface IP address used to connect to the DNS server.

```
DeviceB(config)# interface gigabitethernet 0/2
DeviceB(config-if-GigabitEthernet 0/2)# no switchport
DeviceB(config-if-GigabitEthernet 0/2)# ip address 20.1.2.2 255.255.255.0
DeviceB(config-if-GigabitEthernet 0/2)# exit
```

Configure a dynamic address pool.

```
DeviceB(config)# ip dhcp pool User
DeviceB(dhcp-config)# network 20.1.1.0 255.255.255.0
DeviceB(dhcp-config)# dns-server 20.1.2.1
DeviceB(dhcp-config)# exit
```

Configure excluded IP addresses.

```
DeviceB(config)# ip dhcp excluded-address 20.1.1.2
```

(3) Configure the DNS server:

Set the DNS server IP address to 20.1.2.1/24. (Omitted)

5. Verification

Run the **show dhcp lease** command on Device B to display the IP address information obtained from an interface.

```
DeviceB# show dhcp lease
Temp IP addr: 20.1.1.1  for peer on Interface: GigabitEthernet 0/1
Temp  sub net mask: 255.255.255.0
   DHCP Lease server: 20.1.1.2, state: 7 Bound
   DHCP transaction id: ca811331
   Lease: 14400 secs,  Renewal: 7200 secs,  Rebind: 12600 secs
   Next timer fires after: 4916 secs
   Retry count: 0   Client-ID: 0158696cc59347
```

Run the **show hosts** command on Device A to display DNS server information obtained from an interface.

```
DeviceA# show hosts
Name servers are:
20.1.2.1 dynamic from DHCP
Host                                type    Address              TTL(sec)
dev.registryg.com                     dynamic phasing
---
```

6. Configuration Files

- Device A configuration file

```
hostname DeviceA
!
 interface gigabitethernet 0/1
 no switchport
 ip address dhcp
!
```

- Device B configuration file

```
hostname DeviceB
```

```
!
 service dhcp
 ip dhcp excluded-address 20.1.1.2
!
 interface gigabitethernet 0/1
 no switchport
 ip address 20.1.1.2 255.255.255.0
!
 interface gigabitethernet 0/2
 no switchport
 ip address 20.1.2.2 255.255.255.0
!
 ip dhcp pool User
 network 20.1.1.0 255.255.255.0
 dns-server 20.1.2.1
!
```

1 Configuring DHCP Snooping

1.1 Introduction

1.1.1 Overview

The Dynamic Host Configuration Protocol (DHCP) snooping function allows a device to snoop DHCP packets exchanged between clients and a server to record and monitor the IP address usage and filter out invalid DHCP packets, including request packets from the clients and response packets from the server. User data entries generated from DHCP snooping records may serve security applications such as IP Source Guard.

1.1.2 Principles

1. Basic Concepts

- DHCP request packets

  Request packets are sent from a DHCP client to a DHCP server, including DHCP DISCOVER, DHCP REQUEST, DHCP DECLINE, DHCP RELEASE, and DHCP INFORM packets.

- DHCP response packets

  Response packets are sent from a DHCP server to a DHCP client, including DHCP OFFER, DHCP ACK, and DHCP NAK packets.

- VLAN-based DHCP snooping

  DHCP snooping is enabled on a per-VLAN basis. When DHCP snooping is enabled on a device, it is effective to all VLANs of the device by default. You can flexibly configure the VLANs on which DHCP snooping is enabled.

- DHCP snooping trusted ports

  Packet for obtaining IP addresses through DHCP are exchanged via broadcast. Rough DHCP services affect clients' normal acquisition of IP addresses and lead to user information spoofing and stealing. DHCP snooping ports are classified into trusted ports and untrusted ports to prevent rough DHCP services.

  The device only transmits DHCP response packets received on trusted ports and discards those received from untrusted ports. In this way, the ports connected to legitimate DHCP servers are configured as trusted ports and the other ports are configured as untrusted ports to shield rough DHCP servers.

  On switches, all switching ports or L2 aggregation ports (APs) are defaulted as untrusted, and trusted ports can be specified.

- DHCP snooping binding database

  In a DHCP network, clients may set static IP addresses randomly. This increases not only the difficulty of network maintenance but also the possibility that authorized clients with IP addresses assigned by a DHCP server may fail to use the network due to address conflicts. By snooping packets between the clients and server, DHCP snooping summarizes user entries, including IP addresses, media access control (MAC) addresses, VLAN IDs (VIDs), ports, and lease time to build the DHCP snooping binding database. Combined with Address Resolution Protocol (ARP) detection or ARP check, DHCP snooping controls the reliable assignment of IP addresses to legitimate clients.

- DHCP snooping packet suppression

  To shield all the DHCP packets on a specific client, enable DHCP snooping packet suppression on its untrusted ports.

- DHCP snooping rate limit

  DHCP snooping rate limit can be configured using the rate limit command of Network Foundation Protection Policy (NFPP). For NFPP configuration, see *Configuring NFPP*.

  When an interface is configured as a DHCP snooping trusted interface, the DHCP guard function of NFPP does not take effect to prevent DHCP traffic from being mistakenly blocked on the trusted interface.

- DHCP Option 82

  DHCP Option 82, also called the DHCP relay agent information option, is an option in DHCP packets. Option 82 is used to enhance the DHCP server security and optimize the IP address assignment policy. This option is usually configured on the DHCP relay service component, such as DHCP Relay and DHCP snooping of a network access device. This option is transparent to clients and added or removed by the DHCP relay component.

- Invalid DHCP packets

  The device with DHCP snooping enabled checks validity of received DHCP packets, discards invalid DHCP packets, and records information about legitimate users to form the DHCP snooping binding database for query by other applications (for example, ARP detection). The following types of packets are considered as invalid DHCP packets:

  - DHCP response packets received on untrusted ports, including DHCP ACK, DHCP NAK, and DHCP OFFER packets
  - DHCP request packets carrying the **giaddr** field (gateway information) received on untrusted ports
  - Packets with the source MAC addresses different from the value of the **chaddr** field in DHCP packets in a case with MAC address verification enabled
  - DHCP RELEASE packets corresponding to entries in the DHCP snooping binding database, with the untrusted port on which the packets are received being inconsistent with the untrusted port in the binding table
  - DHCP packets in incorrect formats or incomplete DHCP packets

2. Filtering Invalid DHCP Packets

The device with DHCP snooping enabled checks validity of DHCP packets from untrusted ports to control the transmission scope of the packets and prevent spoofing.

During snooping, it checks the receiving ports and fields of packets to filter packets, and modifies the destination ports of the packets to control the packet transmission scope.

- Checking ports

  When receiving a DHCP packet, the device first checks whether the port receiving the packet is a DHCP trusted port. If yes, the device directly forwards the packet without checking the validity or generating a binding record. If not, the device checks its validity.

- Checking packet encapsulation and length

  The device checks whether received packets are UDP packets, whether the destination port is port 67 or 68, and whether the packet length matches the length field defined in protocols.

- Checking packet fields and types

  According to the invalid DHCP packet types introduced in the "Basic Concepts" section, the device first checks the **giaddr** and **chaddr** fields in packets and then checks whether the restrictive conditions for this packet type are met.

3. Building a DHCP Snooping Binding Database

The device with DHCP snooping enabled detects packets exchanged between the DHCP clients and the DHCP server and generates entries in the DHCP snooping binding database based on information about valid DHCP packets. All these entries are used as the information table of legitimate users, and provided to other security modules of the device as the basis for filtering network packets.

The binding database is updated during snooping based on the types of DHCP packets.

- Generating binding entries

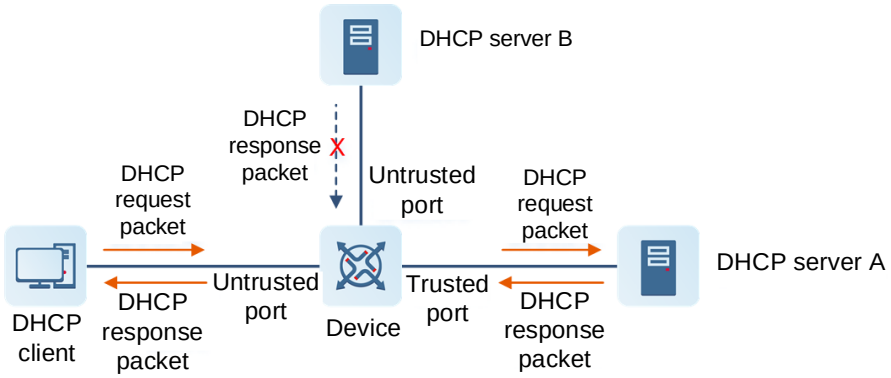
  When a DHCP ACK packet is snooped on a trusted port, the device with DHCP snooping enabled extracts the client's IP address, MAC address, and lease time from the packet and generates a binding entry based on the recorded port ID (interface index) and VLAN ID of the client.

- Deleting binding entries

  A binding entry is deleted in the following scenarios:

  - The recorded lease time expires.
  - A valid DHCP RELEASE or DHCP DECLINE packet sent from the client is snooped.
  - A NAK packet is received from a trusted port.
  - A user runs the **clear** command to delete a binding entry.

1.1.3 Applications



1. Guarding Against DHCP Spoofing

Multiple DHCP servers may exist in a network. It is essential to ensure that PCs can obtain network configurations only from the DHCP servers within a controlled area.

As shown in the following figure, the DHCP client can communicate with a trusted DHCP server only.

- Request packets from the DHCP client are transmitted only to the trusted DHCP server.
- Only response packets from the trusted DHCP server can be transmitted to the DHCP client.

Figure 1-1 Guarding Against DHCP Spoofing

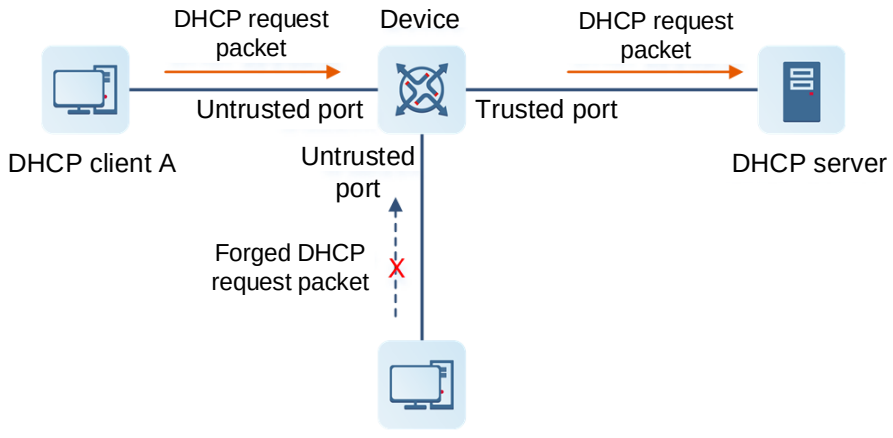
Device is an access device, DHCP Server A is in the controlled area, and DHCP Server B is beyond the controlled area.

- DHCP snooping is enabled on Device to monitor DHCP packets.
- The port on Device for connecting to DHCP Server A is configured as a DHCP trusted port to forward response packets.
- The rest of ports on Device are configured as DHCP untrusted ports to filter response packets.

2. Guarding Against DHCP Packet Flooding

Malicious DHCP clients in a network may send DHCP packets at a high rate. As a result, legitimate users cannot obtain IP addresses, and access devices are heavily loaded or even break down.

- To ensure network stability, the DHCP snooping rate limit function needs to be enabled for DHCP packets. The request packets from DHCP clients are sent at a rate below the limit. Packets sent at rates beyond the limit are discarded. DHCP snooping is correlated with the ARP module to delete entries of non-existing users.



3. Guarding Against Forged DHCP Packets

Malicious DHCP clients in a network may forge DHCP request packets, which consumes applicable IP addresses from the servers and probably preempts legitimate users' IP addresses. Therefore, it is necessary to filter out invalid DHCP packets.

As shown in the following figure, the DHCP request packets sent from DHCP clients are checked.

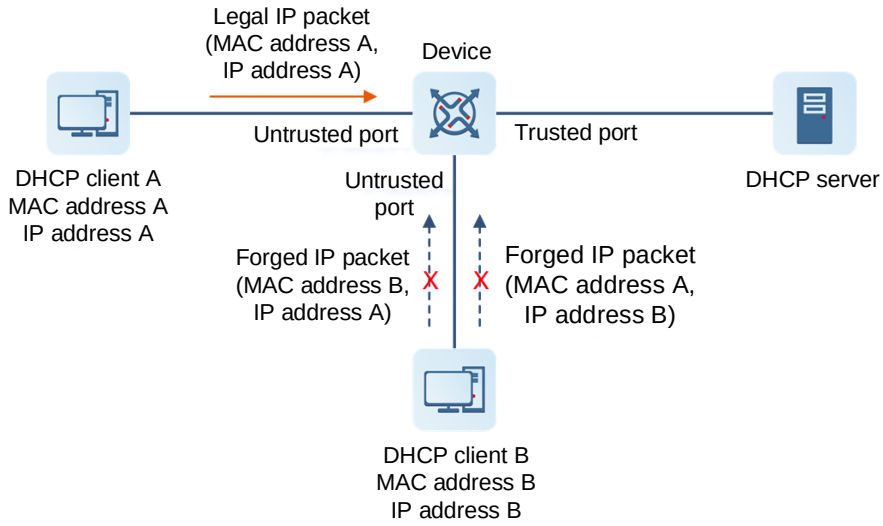
- The source MAC address field in request packets from DHCP clients must match the client hardware address field of the DHCP packets.
- The RELEASE and DECLINE packets from clients must match the entries in the DHCPv6 Snooping binding database.

Figure 1-2 Guarding Against Forged DHCP Packets

Device is an access device, and DHCP Server is in the controlled area.

- DHCP snooping is enabled on Device to monitor DHCP packets.

- The port on Device for connecting to DHCP Server is configured as a DHCP trusted port to forward response packets.
- The rest of ports on Device are configured as DHCP untrusted ports to filter response packets.
- DHCP source MAC addresses need to be verified on untrusted ports of Device to filter out invalid DHCP packets.



4. Guarding Against IP/MAC Address Spoofing

You can check IP packets from untrusted ports based the IP address field or IP address and MAC address fields to filter out forged IP packets.

As shown in the following figure, IP packets sent from DHCP clients are checked.

- The source address field in IP packets must match the IP address assigned by the DHCP server.
- The source MAC address field in L2 packets must match the client hardware address field in DHCP request packets from clients.

Figure 1-3 Guarding Against IP/MAC Address Spoofing

Device is an access device, and DHCP Server is in the controlled area.

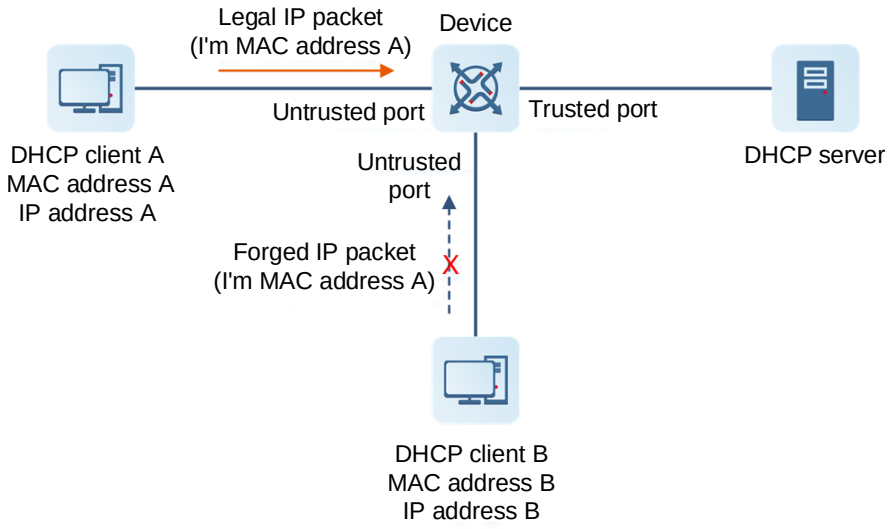
- DHCP snooping is enabled on Device to monitor DHCP packets.
- The port on Device for connecting to DHCP Server is configured as a DHCP trusted port.
- All downlink ports on Device are configured as DHCP untrusted ports.
- IP Source Guard is enabled on Device to filter IP packets.
- The IP Source Guard matching mode is set to IP+MAC on Device to check the MAC address and IP address fields in IP packets.

5. Preventing Private IP Addresses

The device with DHCP snooping enabled checks whether the source addresses in IP packets from untrusted ports are consistent with the IP addresses assigned by the DHCP server.

If the source addresses, connected ports, and L2 source MAC addresses in IP packets do not match the assignments of the DHCP server, such packets are discarded.

The working process of the device in this scenario is the same as that in "Guarding Against IP/MAC Address Spoofing".



6. Detecting ARP Attacks

The device with DHCP snooping enabled checks the ARP packets from untrusted ports and filter out the ARP packets unmatched with the assignments of the DHCP server.

As shown in the following figure, ARP packets sent from DHCP clients are checked.

The ports receiving ARP packets, the L2 MAC addresses, and the hardware addresses of ARP packet senders must be consistent with the snooped DHCP packet records.

Figure 1-4 Detecting ARP Attacks

Device is an access device, and DHCP Server is in the controlled area.

- DHCP snooping is enabled on Device to monitor DHCP packets.
- The port on Device for connecting to DHCP Server is configured as a DHCP trusted port.
- All downlink ports on Device are configured as DHCP untrusted ports.
- IP Source Guard and ARP check are enabled on all untrusted ports on Device to filter ARP packets.

1.1.4 Protocols and Standards

- RFC 2131: Dynamic Host Configuration Protocol
- RFC 2132: DHCP Options and BOOTP Vendor Extensions

1.2 Restrictions and Guidelines

- All security control functions are effective only to DHCP untrusted ports.
- The ports on the device for connecting to trusted DHCP servers must be configured as DHCP trusted ports.

- DHCP snooping takes effect to switching ports, L2 APs, and L2 encapsulation sub-interfaces.
- DHCP snooping and DHCP Relay are mutually exclusive in virtual routing and forwarding (VRF) scenarios.
- A device uses the following rules to process the received DHCP packets:
  - If all interfaces on the device are in the UNTRUST state, the device will discard all the DHCP request and response packets received by the interfaces.
  - If any interface on the device is configured as a trusted interface, the device will use the trusted interface to forward the DHCP request packets received by UNTRUST interfaces, and will discard the DHCP response packets received by UNTRUST interfaces.

1.3 Configuration Task Summary

DHCP snooping configuration includes the following tasks:

The following configuration tasks are mutually exclusive. Please configure only one task.

- Configuring DHCP Snooping
  - a Configuring Basic DHCP Snooping Functions
  - b (Optional) Disabling DHCP Snooping on a VLAN
  - c (Optional) Enabling Source MAC Address Verification
  - d (Optional) Writing Dynamic User Information in the DHCP Snooping Binding Database to the Flash Memory in Real Time
  - e (Optional) Writing Dynamic User Information in the DHCP Snooping Binding Database to a Flash Memory at a Scheduled Time
  - f (Optional) Enabling DHCP Snooping to Support BOOTP Binding
  - g (Optional) Enabling DHCP Snooping to Support Relay Request Packet Processing
  - h (Optional) Enabling DHCP Snooping to Support Binding Entry Migration
  - i (Optional) Enabling DHCP Snooping to Fast Age Client Migration Entries
  - j (Optional) **Enabling the Loose Forward Function for DHCP Snooping**
  - k (Optional) Configuring an Interface in the Suppression State
  - l (Optional) Configuring the Maximum Number of Users Bound to a VLAN
  - m (Optional) Configuring Option 82
- Enabling DHCP Snooping Monitoring

1.4 Configuring Basic DHCP Snooping Functions

1.4.1 Overview

This section describes how to enable basic DHCP snooping functions to copy DHCP packets, generate binding entries based on interaction, check packet validity to filter out unauthorized DHCP packets and control the transmission scope of DHCP packets.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable DHCP snooping globally.

ip dhcp snooping

DHCP snooping is disabled globally by default.

(4) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(5) Configure an interface as a DHCP snooping trusted port.

ip dhcp snooping trust

All interfaces are DHCP snooping untrusted ports by default.

Run this command to configure the interface connected to an authorized DHCP server as a trusted port. DHCP Response packets received on trusted ports are forwarded normally, while those received on untrusted ports are discarded.

The command is only configured and takes effect on Layer 2 Ethernet interfaces, Layer 2 link aggregation interfaces.

1.5 Disabling DHCP Snooping on a VLAN

1.5.1 Overview

DHCP snooping is enabled on a per-VLAN basis. You can flexibly configure the VLANs on which DHCP snooping is enabled.

1.5.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Disable DHCP snooping on a VLAN.

no ip dhcp snooping vlan { *vlan-range* | *vlan-min* [*vlan-max*] }

After DHCP snooping is enabled globally, it takes effect to all VLANs by default.

1.6 Enabling Source MAC Address Verification

1.6.1 Overview

After source MAC address verification is enabled, the MAC addresses in link layer headers and the **CLIENT MAC** fields in DHCP request packets from untrusted ports are checked for consistence. If the verification fails, packets are discarded.

1.6.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable source MAC address verification.

ip dhcp snooping verify mac-address

Source MAC address verification is disabled by default.

1.7 Writing Dynamic User Information in the DHCP Snooping Binding Database to the Flash Memory in Real Time

1.7.1 Overview

You can write dynamic user information in the DHCP snooping binding database to the flash memory in real time.

1.7.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Write dynamic user information in the DHCP snooping binding database to a flash memory in real time.

ip dhcp snooping database write-to-flash

1.8 Writing Dynamic User Information in the DHCP Snooping Binding Database to a Flash Memory at a Scheduled Time

1.8.1 Overview

You can write dynamic user information in the DHCP snooping binding database to the flash memory at a scheduled time.

1.8.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Write dynamic user information in the DHCP snooping binding database to a flash memory at a scheduled time.

ip dhcp snooping database write-delay *time*

The function of writing all dynamic user information in the DHCP snooping binding database to a flash memory at a scheduled time is not configured by default.

1.9 Enabling DHCP Snooping to Support BOOTP Binding

1.9.1 Overview

By default, the DHCP snooping feature only forwards BOOTP packets. After this feature is enabled, the DHCP snooping feature snoops BOOTP packets. After a BOOTP client successfully applies for an IP address, the DHCP snooping feature adds the BOOTP client to the static binding database.

1.9.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable DHCP snooping to support Bootstrap Protocol (BOOTP) binding.

ip dhcp snooping bootp-bind

DHCP snooping does not support BOOTP binding by default.

1.10 Enabling DHCP Snooping to Support Relay Request Packet Processing

1.10.1 Overview

You can enable DHCP snooping to support relay request packet processing.

1.10.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable DHCP snooping to support relay request packet processing.

ip dhcp snooping check-giaddr

DHCP snooping does not support relay request packet processing by default.

After this function is enabled, services (IP Source Guard and Dot1x authentication) using DHCP snooping binding entries generated based on relay requests cannot be deployed. Otherwise, users fail to access the Internet.

After this function is enabled, the **ip dhcp snooping verify mac-address** command cannot be configured. Otherwise, DHCP request packets of the relay are discarded, and users fail to obtain addresses.

1.11 Enabling DHCP Snooping to Support Binding Entry Migration

1.11.1 Overview

You can enable DHCP snooping to support binding entry migration.

1.11.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable DHCP snooping to support binding entry migration.

ip dhcp snooping station-move permit

DHCP snooping does not support binding entry migration by default.

1.12 Enabling DHCP Snooping to Fast Age Client Migration Entries

1.12.1 Overview

You can enable DHCP snooping to fast age client migration entries.

1.12.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable DHCP snooping to fast age client migration entries.

ip dhcp snooping station-move aging

Fast aging of client migration entries is enabled for DHCP snooping by default.

1.13 Enabling the Loose Forward Function for DHCP Snooping

1.13.1 Overview

After this function is enabled, when the DHCP snooping binding table is full, new users' DHCP packets can still be forwarded to obtain address information, but DHCP snooping will not add binding entries for those users.

1.13.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the loose forward function for DHCP snooping.

ip dhcp snooping loose-forward

The loose forward function for DHCP snooping is disabled by default.

1.14 Configuring an Interface in the Suppression State

1.14.1 Overview

You can configure an interface in the suppression state to discard all DHCP packets sent to the interface.

1.14.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure an interface in the suppression state so as to discard all DHCP packets sent to the interface.

ip dhcp snooping suppression

No interface is configured in the suppression state by default.

1.15 Configuring the Maximum Number of Users Bound to a VLAN

1.15.1 Overview

You can configure the maximum number of users bound to a VLAN.

1.15.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(4) Configure the maximum number of users bound to a VLAN.

ip dhcp snooping vlan *vlan-range* **max-user** *user-number*

The maximum number of users bound to a VLAN is not configured by default.

1.16 Configuring Option 82

1.16.1 Overview

Option 82 includes **Circuit ID** (sub-option 1) and **Remote ID** (sub-option 2). **Circuit ID** identifies the VLAN ID and interface information of a client. **Remote ID** identifies the access device of a client, which is the MAC address of the device generally.

A DHCP server assigns IP addresses based on Option 82 carried in DHCP request packets. Option 82 is transparent to clients.

1.16.2 Restrictions and Guidelines

Option 82 and DHCP Relay are mutually exclusive.

1.16.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Add Option 82 to DHCP request packets.

ip dhcp snooping information option [**standard-format** | **user-defined**]

Option 82 is not added to DHCP request packets by default.

(4) (Optional) Configure a strategy for processing Option 82.

ip dhcp snooping information option strategy { **drop** | **keep** | **replace** }

The default strategy for processing Option 82 is **replace**; that is, Option 82 in the received DHCP request packets is replaced and then forwarded.

(5) (Optional) Set **Remote ID** to a user-defined string or the host name.

ip dhcp snooping information option format remote-id { **hostname | string** *ascii-string* }

Remote ID in Option 82 is not set to a user-defined string or host name by default.

(6) (Optional) Customize **Remote ID** in Option 82.

ip dhcp snooping information option user-defined remote-id *text*

Customization of **Remote ID** in DHCP Option 82 is disabled by default.

(7) (Optional) Customize **Circuit ID** in Option 82.

ip dhcp snooping information option user-defined circuit-id *text*

Customization of **Circuit ID** in DHCP Option 82 is disabled by default.

(8) (Optional) Configure the format of the MAC address string in the sub-option of DHCP Option 82.

ip dhcp snooping information option user-defined mac-str-format *type*

The user-defined MAC address string is in **H.H.H** format by default.

(9) Enter the interface configuration mode.

- Enter the Layer 2 Ethernet interface configuration mode.

  interface *ethernet-type interface-number*

- Enter the Layer 2 link aggregation configuration mode.

  interface aggregateport *interface-number*

(10) (Optional) Configure the VLAN in **Circuit ID** as the specified VLAN.

ip dhcp snooping vlan *vlan-id* **information option change-vlan-to vlan** *vlan-id*

When Option 82 is in extended mode, the VLAN in **Circuit ID** is not configured as the specified VLAN by default.

(11) (Optional) Set **the Circuit ID** to user-defined content.

ip dhcp snooping vlan *vlan-id* **information option format-type circuit-id string** *ascii-string*

When Option 82 is in extended mode, **Circuit ID** is not set to user-defined content for forwarding by default.

1.17 Enabling DHCP Snooping Monitoring

1.17.1 Overview

After the DHCP snooping monitoring function is enabled, DHCP snooping only copies DHCP packets and generates binding entries based on the interaction status, but does not check the validity of the packets.

1.17.2 Restrictions and Guidelines

The DHCP snooping monitoring and DHCP snooping functions are mutually exclusive.

1.17.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable DHCP snooping monitoring globally.

ip dhcp snooping monitor

DHCP snooping monitoring is disabled globally by default.

1.18 Monitoring

This section describes the **show** commands used for checking the running status of a configured function to verify the configuration effect, the **clear** commands used for clearing information, and the **debug** commands used for outputting debugging information.

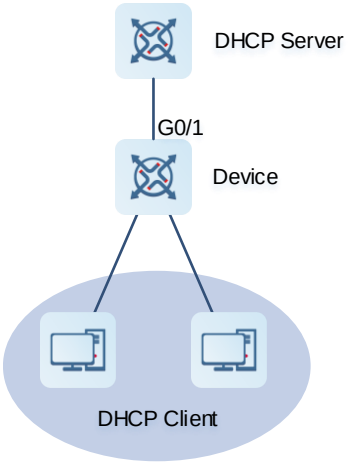
Caution

- Running the **clear** commands may lose vital information and thus interrupt services.
- The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Table 1-1 Monitoring

Command	Purpose
show ip dhcp snooping	Displays DHCP snooping configurations.
show ip dhcp snooping binding	Displays user information in the DHCP snooping database.
show ip dhcp snooping capability	Displays whether DHCP snooping and its features are supported.
show ip dhcp snooping packet [**detail** [*mac-address*]]	Displays packet statistics of DHCP snooping.
show ip dhcp snooping scc-record	Displays security control center (SCC) delivery records.
clear ip dhcp snooping binding [*ipv4-address*] [*mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*]	Clears all dynamic users in the DHCP snooping database.

1.19 Configuration Examples



1.19.1 Configuring DHCP Snooping

1. Requirements

DHCP clients can obtain IP addresses from legitimate DHCP servers dynamically.

2. Topology

Figure 1-5 DHCP Snooping Basic Functions

3. Notes

- Enable DHCP snooping on Device (an access device).
- Configure the uplink interface GigabitEthernet 0/1 as a trusted port.

4. Procedure

Configure Device (an access device).

```
Device> enable
Device# configure terminal
Device(config)# ip dhcp snooping
Device(config)# interface gigabitethernet 0/1
Device(config-if-GigabitEthernet 0/1)# ip dhcp snooping trust
```

5. Verification

Display DHCP snooping configurations on Device and check whether the trusted port is correct.

```
Device# show ip dhcp snooping
Switch DHCP snooping status                 :   ENABLE
DHCP snooping verify hardware address status   :   DISABLE
DHCP snooping database write-delay time       :   0 seconds
DHCP snooping option 82 status              :   DISABLE
DHCP snooping Support bootp bind status       :   DISABLE
Interface                  Trusted      Rate limit (pps)
------------------------      -------      ----------------
GigabitEthernet 0/1          YES          unlimited
Default                       No           unlimited
```

Display entries generated by Device.

```
Device# show ip dhcp snooping binding
Total number of bindings: 1
```

```
NO.   MACADDRESS        IPADDRESS      LEASE(SEC)   TYPE          VLAN  INTERFACE
1     0013.2049.9014    172.16.1.2      86207       DHCP-Snooping 1
GigabitEthernet 0/2
```

6. Configuration Files

Device configuration file

```
hostname Device
!
ip dhcp snooping
!
interface GigabitEthernet 0/1
 ip dhcp snooping trust
!
end
```

1.20 Common Misconfigurations

- The uplink interface is not configured as a DHCP snooping trusted port.
- Another access security option is configured for the uplink interface. As a result, the uplink interface fails to be configured as a DHCP snooping trusted port.

1 Configuring DNS

1.1 Overview

Domain Name System (DNS) is important and commonly used in a Transmission Control Protocol/Internet Protocol (TCP/IP) network environment. The main function of DNS is to convert a domain name that is easy to remember into an IP address that is hard to remember. The process of obtaining an IP address mapped to a domain name or host name is called domain name resolution or host name resolution.

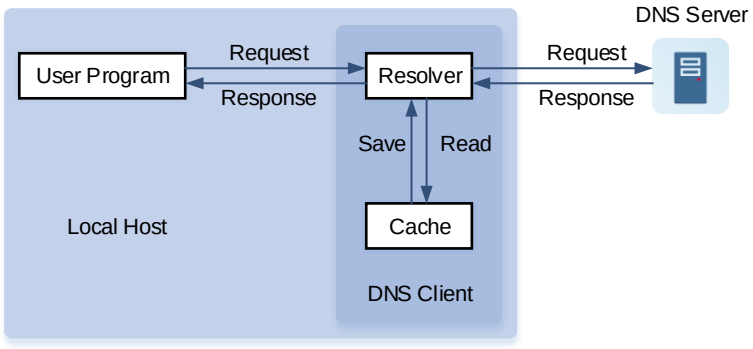
A domain name can be resolved firstly through static domain name resolution. If this fails, dynamic domain name resolution can be used instead. You can put the commonly used domain names into the static domain name resolution table, which improves the efficiency of domain name resolution.

Both the TCP and User Datagram Protocol (UDP) port IDs of DNS are 53, and generally a UDP port is used.

1.2 Principles

1.2.1 Static Domain Name Resolution

Static domain name resolution means that a user presets the mappings between domain names and IP addresses on a device. When you perform domain name operations by using application programs (such as ping and telnet), the system can find the required IP address with no need to connect to the DNS server on the network.



When the application programs access a small number of relatively fixed hosts, the domain name-IP mappings can be configured in advance in the form of static domain name entries. Then, no search request needs to be sent to the DNS server, improving the resolution efficiency.

1.2.2 Dynamic Domain Name Resolution

1. System Structure

Dynamic domain name resolution means that when a user performs domain name operations by using some application programs, the DNS resolver of the system queries an external DNS server for the IP addresses mapped to the domain names.

Figure 1-1 Structure of Dynamic Domain Name Resolution

As shown in Figure 1-1, a resolver is integrated with a cache to form a DNS client, which accepts DNS requests from user programs and makes responses accordingly. In general, user programs (such as ping and traceroute), a cache, and a resolver are on the same host, but a DNS server is on a different host.

2. Resolution Process

The process of dynamic domain name resolution is as follows:

(1) A user application program requests the IP address mapped to a domain name from the DNS resolver of the system.

(2) The DNS resolver queries the dynamic cache at first. If the domain name in the dynamic cache does not expire, the DNS resolver returns the domain name to the application program.

(3) If all domain names expire, the DNS resolver initiates a request for domain name-IP address conversion to the external DNS server.

(4) After receiving a response from the DNS server, the DNS resolver caches and transfers the response to the application program.

3. Cache Function

The dynamic domain name resolution supports the cache function. The cache stores the domain name-IP mappings successfully and dynamically resolved each time. When the same domain name is queried next time, the mapping can be read from the cache, with no need to send a request to the DNS server every time, thereby improving the resolution efficiency.

1.2.3 DNS Proxy

DNS proxy is generally deployed on the front-end egress gateway between a DNS server and a PC, and acts as a proxy of the DNS server to process users' DNS domain name resolution requests. When processing a request packet from the DNS client, the DNS proxy searches for the domain name-IP mapping locally first. If the required domain name-IP mapping is found, the DNS proxy directly returns it to the client. If the required domain name-IP mapping is not found, the DNS resolver searches an external DNS server for the IP address mapped to the domain name and returns a reply packet to the client.

1.2.4 Protocols and Standards

- RFC1034: DOMAIN NAMES - CONCEPTS AND FACILITIES
- RFC1035: DOMAIN NAMES - IMPLEMENTATION AND SPECIFICATION

1.3 Configuration Task Summary

All the following configuration tasks are optional and may be selected as needed.

- Configuring Static Domain Name Resolution
- Configuring Dynamic Domain Name Resolution
- Configuring DNS Proxy

1.4 Configuring Static Domain Name Resolution

1.4.1 Overview

Static domain name resolution allows a user to preset the mappings between domain names and IP addresses on a device. The system can find the IP address mapped to a domain name from the device without obtaining the required IP address from a DNS server on the network.

1.4.2 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Configure the IP address mapped to a domain name.

(IPv4 network)

ip host oob *host-name* [*telnet-port*] *ipv4-address* [**via mgmt** *interface-number*]

ip host [**vrf** *vrf-name*] *host-name* [telnet-port] *ipv4-address*

Static mapping between domain names and IPv4 addresses is not configured by default.

(IPv6 network)

ipv6 host oob *host-name* [*telnet-port*] *ipv6-address* [**via mgmt** *interface-number*]

ipv6 host [**vrf** *vrf-name*] *host-name* [telnet-port] *ipv6-address*

Static mapping between domain names and IPv6 addresses is not configured by default.

1.5 Configuring Dynamic Domain Name Resolution

1.5.1 Overview

Dynamic domain name resolution allows the system DNS resolver to query an external DNS server for the IP addresses mapped to domain names when a user performs domain name operations through applications.

If a source interface is specified in the command, when an IPv4 DNS query packet is sent, the primary IPv4 address of the source interface is used as the source address of the DNS query packet. When an IPv6 DNS query packet is sent, the first effective IPv6 address of the source interface is used as the source address of the DNS query packet.

1.5.2 Restrictions and Guidelines

If no address is configured for a source interface, a DNS query packet fails to be sent. If an IPv4 source address is specified in the command, when an IPv4 DNS query packet is sent, the configured IPv4 address serves as the source address of the IPv4 DNS query packet, and an IPv6 DNS query packet will fail to be sent. If an IPv6 source address is specified in the command, when an IPv6 DNS query packet is sent, the configured IPv6 address serves as the source address of the IPv6 DNS query packet, and an IPv4 DNS query packet will fail to be sent.

Caution

An effective IPv6 address is a unicast address, but it cannot be a local link address or a loopback address.

1.5.3 Prerequisites

The IP address of a DNS server has been obtained.

1.5.4 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable DNS domain name resolution.

ip domain-lookup [**oob** [**via mgmt** *interface-number*] | **vrf** *vrf-name*]

DNS domain name resolution is enabled by default.

(4) Configure a DNS server.

(IPv4 network)

ip name-server oob *ipv4-address*&<1-6> [**via mgmt** *interface-number*]

ip name-server [**vrf** *vrf-name*] *ipv4-address*&<1-6>

No IPv4 address is configured for a DNS server by default.

(IPv6 network)

ip name-server [**oob**] { *ipv6-address*&*<1-6>* } [**via** *mgmt-name*]

ip name-server [**vrf** *vrf-name*] *ipv6-address*&<1-6>

No IPv6 address is configured for a DNS server by default.

(5) Configure the domain name resolution using a specified source interface or address. The configuration steps below are mutually exclusive. Please configure only one task.

- Configure the domain name resolution using a specified source interface.

  ip domain-lookup [**vrf** *vrf-name*] **source** *interface-type interface-number*

- Configure the domain name resolution using a specified source IP address.

  (IPv4 network)

  ip domain-lookup [**vrf** *vrf-name*] **source ip** *ipv4-address*

  (IPv6 network)

  ip domain-lookup [**vrf** *vrf-name*] **source ipv6** *ipv6-address*

By default, no source interface is specified, and the source IP address of a DNS query packet is decided through the routing process.

1.6 Configuring DNS Proxy

1.6.1 Overview

DNS proxy is deployed between a DNS server and a PC, and acts as a proxy of a DNS server to process users' DNS domain name resolution requests.

1.6.2 Prerequisites

The IP address of a DNS server has been obtained.

1.6.3 Procedure

(1) Enter the privileged EXEC mode.

enable

(2) Enter the global configuration mode.

configure terminal

(3) Enable the DNS proxy function.

ip dns proxy enable

DNS proxy is disabled by default.

(4) (Optional) Configure the IP address mapped to a domain name.

(IPv4 network)

ip dns proxy host *host-name ipv4-address*

No static mapping between a domain name and an IPv4 address is configured for the DNS proxy by default.

(IPv6 network)

ip dns proxy host *host-name ipv6-address*

No static mapping between a domain name and an IPv6 address is configured for the DNS proxy by default.

(5) Configure a DNS server.

(IPv4 network)

ip dns proxy nameserver *ipv4-address*

No IPv4 address is configured for a DNS server by default.

Each time this command is run, the device will add one DNS server. The system supports up to six servers. When a domain name cannot be obtained from the first server, the device tries to send a DNS request to subsequent servers until it receives a correct reply.

(IPv6 network)

ip dns proxy nameserver *ipv6-address*

No IPv6 address is configured for a DNS server by default.

Each time this command is run, the device will add one DNS server. The system supports up to six servers. When a domain name cannot be obtained from the first server, the device tries to send a DNS request to subsequent servers until it receives a correct reply.

(6) (Optional) Enable the function of caching dynamic entries on the DNS proxy.

ip dns proxy cache

The function of caching dynamic entries is enabled on the DNS proxy by default.

(7) (Optional) Configure the time to live (TTL) of a reply packet.

ip dns proxy ttl *ttl*

The default TTL of the reply packet in response to a static entry is 3,600 seconds.

(8) (Optional) Configure the range of a source port used for query in upper-level DNS servers.

ip dns proxy port-range *port-min port-max*

The default source port range is from 55,000 to 58,000.

If the port range is too narrow, the concurrent processing performance of the device is affected. If the port range is too wide, excessive flow table entry resources will be occupied and the egress device needs to adjust the flow table restriction synchronously.

1.7 Monitoring

Run the **show** command to check the running status of a configured function to verify the configuration effect.

Run the **debug** command to output debugging information.

Caution

The output debugging information occupies system resources. Therefore, disable the debugging function immediately after use.

Run the **clear** command to clear information.

Caution

Running the **clear** command may lose vital information and thus interrupt services.

Table 1-1 DNS Monitoring

Command	Purpose
clear host [*host-name* | *****]	Clears the dynamic domain name cache table.
show hosts [*host-name*]	Displays DNS parameters.
debug ip dns	Debugs the DNS function.
clear dns proxy host [*host-name*] | *****]	Clears the dynamic domain name cache table on the DNS proxy.
show dns proxy hosts	Displays DNS parameters on the DNS proxy.
show dns proxy statistics	Display packet statistics on the DNS proxy.
debug dns-proxy	Debugs the DNS proxy.

1.8 Configuration Examples

1.8.1 Configuring Static Domain Name Resolution

1. Requirements

As shown in Figure 1-2, device A needs to access the server through the domain name www.test.com. In this case, static domain name resolution can be used to implement the access to the server whose IP address is 192.168.10.2 through the domain name "www.test.com".

2. Topology

Figure 1-2 Topology of Static Domain Name Resolution

3. Notes

Manually create the mapping between www.test.com and IP address 192.168.10.2 in the static resolution table of device A.

4. Procedure

(1) Configure device A.

Configure an IP address for the Layer 3 Ethernet interface GigabitEthernet 0/1.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-GigabitEthernet 0/1)# no switchport
DeviceA(config-GigabitEthernet 0/1)# ip address 192.168.10.1 24
DeviceA(config)# exit
```

Configure the mapping between www.test.com and IP address 192.168.10.2.

```
DeviceA(config)# ip host www.test.com 192.168.10.2
```

(2) Configure the server.

Set the IP address of the server to 192.168.10.2.

5. Verification

Run the **show hosts** command to check whether the static domain name entry is configured.

```
DeviceA# show hosts
Name servers are:

Host                type    Address         TTL(sec)
www.test.com         static   192.168.10.2       ---
```

Run the **ping** www.test.com command on device A. The IP address mapped to www.test.com is resolved as 192.168.10.2.

```
DeviceA# ping www.test.com

Translating "www.test.com"...[OK]
Sending 5, 100-byte ICMP Echoes to 192.168.10.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
 interface gigabitethernet 0/1
 no switchport
 ip address 192.168.10.1 24
!
 ip host www.test.com 192.168.10.2
!
```

1.8.2 Configuring Dynamic Domain Name Resolution

1. Requirements

As shown in Figure 1-3, device A is a DNS client, which can resolve domain names through the DNS server on the network.

2. Topology

Figure 1-3 Topology of Dynamic Domain Name Resolution

3. Notes

On device A, set the IP address of a DNS server to 192.168.10.2.

4. Procedure

(1) Configure device A.

Configure an IP address for port GigabitEthernet 0/1.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitEthernet 0/1
```

```
DeviceA(config-GigabitEthernet 0/1)# no switchport
DeviceA(config-GigabitEthernet 0/1)# ip address 192.168.10.1 24
DeviceA(config)# exit
```

Configure the IP address of the DNS server.

```
DeviceA(config)# ip name-server 192.168.10.2
DeviceA(config)# exit
```

(2) Configure the DNS server.

The way to configure a DNS server varies with the operating system. For details, see the configuration instructions from system vendors.

5. Verification

Run the **show hosts** command to display the configured DNS server.

```
DeviceA(config)# show hosts
Name servers are:
192.168.10.2 static

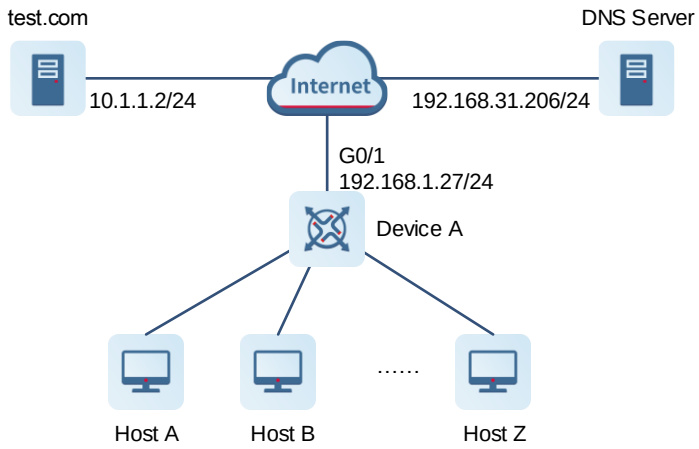
Host                    type        Address         TTL(sec)
www.dnstest.com         dynamic     192.168.10.2     126
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
 interface gigabitEthernet 0/1
 no switchport
 ip address 192.168.10.1 24
!
 ip name-server 192.168.10.2
!
```

1.8.3 Configuring DNS Proxy



1. Requirements

As shown in Figure 1-4, a DNS server is deployed on the network to provide the domain name service for external devices. test.com is deployed on the network to provide services for external devices over test.com.

There are several hosts A-Z in the local area network (LAN). If the IP address of the DNS server is specified on each host, the network administrator needs to change the configuration of all the hosts one by one when the IP address of the DNS server changes. The workload is very heavy. Device A in the LAN needs to be configured as a DNS proxy, the IP address of the DNS server specified on the DNS proxy is the real address of the DNS server. In this way, when the IP address of the DNS server changes, only the configuration on the DNS proxy needs to be changed, which can greatly reduce the workload.

2. Topology

Figure 1-4 Topology of DNS Proxy

3. Notes

- On device A, enable the DNS proxy function.
- On device A, set the IP address mapped to test.com to 10.1.1.2/24.
- On device A, set the IP address of the DNS server to 192.168.31.206/24.

4. Procedure

(1) Configure device A.

Configure an IP address for port GigabitEthernet 0/1.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# interface gigabitethernet 0/1
DeviceA(config-GigabitEthernet 0/1)# no switchport
DeviceA(config-GigabitEthernet 0/1)# ip address 192.168.1.27 24
DeviceA(config-GigabitEthernet 0/1)# exit
```

Configure the DNS proxy function.

```
DeviceA(config)# ip dns proxy enable
DeviceA(config)# ip dns proxy host test.com 10.1.1.2
DeviceA(config)# ip dns proxy nameserver 192.168.31.206
DeviceA(config)# exit
```

(2) Configure the DNS server.

The way to configure a DNS server varies with the operating system. For details, see the configuration instructions from system vendors.

5. Verification

Run the **show dns proxy hosts** command to check whether the DNS proxy is configured.

```
DeviceA(config)# show dns proxy hosts
proxy state: enable
```

```
Name servers are:
192.168.31.206

static host    max: 1024
static host   count: 1
cache domain    max: 5120
cache domain  count: 0
Host                    type          TTL(sec)       Address
host.com                 static         ---           192.168.31.206
```

6. Configuration Files

Device A configuration file

```
hostname DeviceA
!
interface gigabitethernet 0/1
 no switchport
ip address 192.168.1.27 24
!
ip dns proxy enable
ip dns proxy host test.com 10.1.1.2
ip dns proxy nameserver 192.168.31.206
!
#endif /* include(dns_client) */
```

1 Configuring IPv6 Basics

1.1 Overview

As the Internet develops rapidly and IPv4 address space is becoming exhausted, IPv4 limitations become more and more obvious. At present, many researches and practices on Internet Protocol Next Generation (IPng) have been conducted. The IPng working group of the Internet Engineering Task Force (IETF) has formulated an IPng protocol named IP Version 6 (IPv6).

1.2 Advantages

- Larger address space

  Compared with 32-bit IPv4 addresses, the length of an IPv6 address is extended to 128 bits. Therefore, the address space has approximately 2^{128} addresses. IPv6 supports a hierarchical address allocation mode from the Internet core network to intranet subnet.

- Simplified packet header format

  Since the design principle of the IPv6 packet header is to minimize the cost of the packet header, multiple non-key fields and optional fields are removed from the packet header to the extended packet header. Therefore, although the length of an IPv6 address is four times that of an IPv4 address, the IPv6 packet header is only twice the IPv4 packet header in length. Without the checksum field in the IPv6 packet header, IPv6 devices do not need to process fragments during forwarding. Therefore, the packet can be more efficiently forwarded.

- Efficient hierarchical addressing and routing structure

  IPv6 uses a convergence mechanism and defines a flexible hierarchical addressing and routing structure. Multiple networks at the same layer are represented with a uniform network prefix on the upstream device, greatly reducing routing entries maintained by the device and routing and storage costs of the device.

- Easy management: plug and play (PnP)

  IPv6 provides automatic discovery and auto-configuration functions to simplify management and maintenance of network nodes. For example, neighbor discovery (ND), maximum transmission unit (MTU) discovery, router advertisement (RA), router solicitation (RS), and auto-configuration technologies provide related services for PnP.

  IPv6 supports stateful and stateless address configuration modes. In IPv4, Dynamic Host Configuration Protocol (DHCP) realizes auto-configuration of the host IP addresses and related parameters. IPv6 inherits this auto-configuration service from IPv4, which is called stateful auto-configuration. For details, see *Configuring DHCPv6*. Besides, IPv6 also offers the stateless auto-configuration service. During stateless auto-configuration, a host automatically obtains the link-local address, address prefix of the local device, and other parameter configurations.

- Security

  Internet Protocol Security (IPSec) is an optional extension protocol of IPv4 but a part of IPv6 to ensure security of IPv6. At present, IPv6 provides two mechanisms: authentication header (AH) and encapsulated security payload (ESP). AH ensures data integrity and authenticates IP packet sources to ensure that the

packets are from the nodes identified by the source addresses. ESP provides data encryption to realize end-to-end encryption.

- Better QoS support

  A new field in the IPv6 packet header defines how to identify and process data streams. The **Flow Label** field in the IPv6 packet header is used to authenticate a data stream, and users can propose requirements on the communication quality by using this field. A device can identify all packets belonging to a specific data stream based on this field and process these packets according to user requirements.

- New protocol for neighboring node interaction

  IPv6 Neighbor Discovery Protocol (NDP) uses a series of Internet Control Message Protocol Version 6 (ICMPv6) packets to implement interactive management of adjacent nodes (nodes on the same link). IPv6 uses NDP packets and efficient multicast/unicast ND packets to replace the broadcast-based Address Resolution Protocol (ARP) and Internet Control Message Protocol Version 4 (ICMPv4) router discovery packets.

- Extensibility

  IPv6 features strong extensibility, allowing users to add new features to the extension packet headers following the IPv6 packet header. The IPv4 packet header supports at most 40 bytes of options. By contrast, the length of an IPv6 extension packet header is subject to only the maximum number of bytes in the packet.

1.3 Principles

1.3.1 IPv6 Basics

1. IPv6 Address Format

An IPv6 address is represented in the X:X:X:X:X:X:X:X format. A 128-bit IPv6 address is separated into eight groups by colons (:), and the 16 bits in each group are represented by four hexadecimal characters (0-9, A-F). Each "X" represents a group of four hexadecimal values. The following are three valid IPv6 addresses:

2001:ABCD:1234:5678:AAAA:BBBB:1200:2100

800:0:0:0:0:0:0:1

1080:0:0:0:8:800:200C:417A

To simplify the writing of IPv6 addresses, the number "0" in an IPv6 address can be abbreviated as follows:

- Each integer in the address must be represented, except the leading zeros in each integer. For example, 2001:00CD:0034:0078:000A:000B:1200:2100 can be abbreviated as 2001:CD:34:78:A:B:1200:2100.
- If an IPv6 address contains a string of zeros, double colons (::) can be used to represent these zeros. For example, 800:0:0:0:0:0:0:1 can be represented as 800::1. The double colons indicate that this address can be extended to a complete 128-bit address. In this approach, only when the 16-bit integers are all zeros, can they be replaced with double colons. Double colons can exist only once in an IPv6 address.

In an IPv4/IPv6 hybrid environment, in an IPv6 address, the least significant 32 bits can be used to represent an IPv4 address. This IPv6 address can be represented in a hybrid manner, that is, X:X:X:X:X:X:d.d.d.d, "X" is a hexadecimal integer and "d" is an 8-bit decimal integer. For example, 0:0:0:0:0:0:192.168.20.1 is a valid IPv6 address. It can be abbreviated to ::192.168.20.1. One typical application of this hybrid representation is to map

an IPv4 address to an IPv6 address, for example, IPv4 address 1.1.1.1 is mapped to an IPv6 address ::FFFF:1.1.1.1.

2. IPv6 Address Structure

An IP address consists of two parts:

- Network prefix: n bits, similar to the network ID in an IPv4 address.
- Interface ID: (128 – n) bits, similar to the host ID in an IPv4 address.

Therefore, the length of the network prefix can be expressed using an additional value according to the classless inter-domain routing (CIDR), and this value is separated from an IPv6 address by a slash (/), for example, 12AB::CD30:0:0:0:0/60, the prefix length used for routing in the address is 60 bits.

3. IPv6 Address Type

RFC 4291 defines three types of IPv6 addresses:

- Unicast address: ID of a single interface. Packets destined to a unicast address are sent to the interface identified by this address.
- Multicast address: ID of an interface group (the interfaces generally belong to different nodes). Packets destined to a multicast address are sent to all interfaces included in this address.
- Anycast address: ID of an interface group. Packets destined to an anycast address are sent to one of the interfaces included in this address (the nearest interface according to the routing protocol).

Note

IPv6 does not define broadcast addresses.

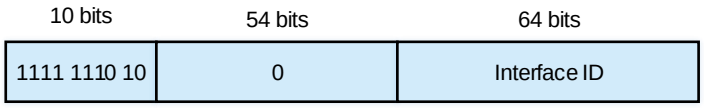
4. Unicast Addresses

Unicast addresses are classified into five types: unspecified address, loopback address, link-local addresses, site-local addresses, and global unicast addresses. Currently site-local addresses have been abolished.

- Unspecified address

  The unspecified address is 0:0:0:0:0:0:0:0, which is usually abbreviated to ::. It has two general purposes:

  - If a host has no unicast address when started, it uses the unspecified address as the source address to send an RS packet to obtain prefix information from the gateway and thereby generate a unicast address.
  - When an IPv6 address is configured for a host, the device detects whether the address conflicts with addresses of other hosts in the same network segment and uses the unspecified address as the source address to send a neighbor solicitation (NS) packet (similar to a gratuitous ARP packet).



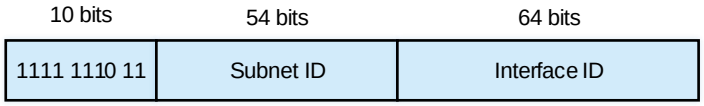
- Loopback address

  The loopback address is 0:0:0:0:0:0:0:1, which is usually abbreviated to ::1. Similar to IPv4 address 127.0.0.1, the loopback address is generally used by a node to send packets to itself.

- Link-local address

  The format of a link-local address is as follows:

Figure 1-1 Link-Local Address



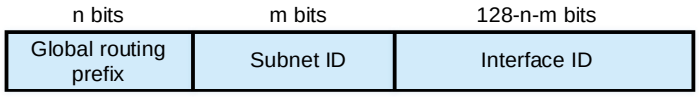
A link-local address is used to number hosts on a single network link. The address identified by the first 10 bits in the prefix is the link-local address. A device will not forward packets in which the source or destination address contains the link-local address. The middle 54 bits of this address is 0, and the last 64 bits represent the interface ID. The address part in the middle allows a single network to connect up to 2^{64} – 1 hosts.

IPv6 link-local addresses can be generated automatically by a device or specified manually.

- Site-local address

  The format of a site-local address is as follows:

Figure 1-2 Site-Local Address



A site-local address can be used to transmit data within a site. A device never forwards packets in which the source or destination address contains a site-local address to the Internet. A site can be assumed as an enterprise's local area network (LAN). Such addresses are similar to IPv4 private addresses such as 192.168.0.0/16. RFC 3879 has abolished site-local addresses. New addresses do not support this prefix and are all regarded as global unicast addresses. Existing addresses can continue to use this prefix.

- Global unicast address

  Except unspecified, loopback, and link-local addresses, all other unicast addresses are global unicast addresses. The format of a global unicast address is as follows:

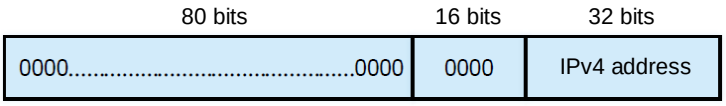


Figure 1-3 Global Unicast Address

Among global unicast addresses, there is a type of IPv4-embedded IPv6 addresses, including IPv4-compatible IPv6 addresses and IPv4-mapped IPv6 addresses. They are used for interconnection between IPv4 nodes and IPv6 nodes.

  - The format of an IPv4-compatible IPv6 address is as follows:

Figure 1-4 Format of an IPv4-compatible IPv6 Address

- The format of an IPv4-mapped IPv6 address is as follows:

Figure 1-5 Format of an IPv4-mapped IPv6 Address

IPv4-compatible IPv6 addresses are mainly used on automatic tunnels. Nodes on automatic tunnels support both IPv4 and IPv6. Using these addresses, IPv4 devices transmit IPv6 packets over tunnels. At present, IPv4-compatible IPv6 addresses have been abolished. IPv4-mapped IPv6 addresses are used by IPv6 nodes to access IPv4-only nodes. For example, if an IPv6 application on an IPv4/IPv6 host requests to resolve the name of an IPv4-only host, the name server dynamically generates an IPv4-mapped IPv6 address and returns it to the IPv6 application.

5. Multicast Addresses

One IPv6 multicast address usually identifies interfaces on a series of different nodes. After a packet is sent to a multicast address, the packet is then forwarded to the interfaces on each node identified by this multicast address.

A multicast address is prefixed with FF00::/8. The format of an IPv6 multicast address is as follows:

Figure 1-6 Multicast Address

- Flag field

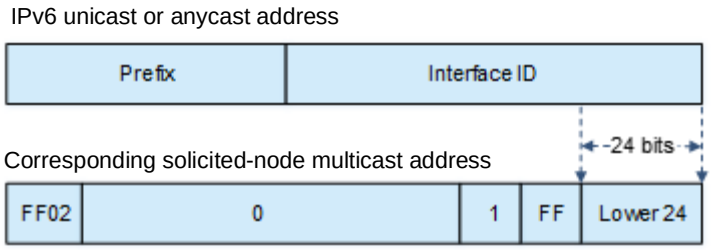
  The flag field consists of four bits. Currently only the fourth bit is specified. If this flag bit is 0, the address is a permanent known multicast address assigned by the Internet Assigned Numbers Authority (IANA). If this flag bit is 1, the address is a temporary multicast address used in a certain scenario. The remaining three flag bits are reserved for future use and set to 0.

- Scope field:

  The scope field consists of four bits to indicate the scope type of a multicast address. The following table lists common multicast address scope types and their corresponding values. Unlisted values indicate reserved or unspecified.

Table 1-1 Common Multicast Address Scope Types

Binary Value	Hexadecimal Value	Scope Type
0001	1	Local interface scope
0010	2	Local link scope
0011	3	Local subnet scope
0100	4	Local management scope
0101	5	Local site scope
1000	8	Organization scope
1110	E	Global scope



- Multicast group ID field:

  The multicast group ID field consists of 112 bits to identify a multicast group. A multicast group ID can represent different groups based on the flag and scope fields.

Multicast addresses for special purposes:

- FF01::1 represents the multicast address of all nodes in the node-local scope.
- FF02::1 represents the multicast address of all nodes in the link-local scope.
- FF01::2 represents the multicast address of all devices in the node-local scope.
- FF02::2 represents the multicast address of all devices in the link-local scope.
- Solicited-node multicast address. The address is mainly used to obtain the link layer address of a neighbor node on the same link and perform the duplicate address detection. Each unicast or anycast IPv6 address has a corresponding solicited-node address. The address is in the format of FF02:0:0:0:0:1:FFXX:XXXX, FF02:0:0:0:0:1:FF is the fixed 104 bits, and XX:XXXX is the last 24 bits of a unicast or anycast IPv6 address. Solicited-node multicast addresses are usually used in NS packets. The address format is as follows:

Figure 1-7 Format of a Solicited-Node Multicast Address

6. Anycast Addresses

Similar to a multicast address, an anycast address can also be shared by multiple nodes. The difference is that only one node using the anycast address receives data packets while all nodes using the multicast address receive data packets. Since anycast addresses are allocated from the normal IPv6 unicast address space, they

use the same format as unicast addresses. Therefore, each member of an anycast address group must be configured explicitly for easier recognition.

Caution

Anycast addresses can be allocated only to devices not hosts and cannot be used as source addresses of packets.

RFC 2373 defines an anycast address called subnet-router anycast address. The following figure shows the format of a subnet-router anycast address. Such an address consists of the subnet prefix and a series of zeros (interface ID).

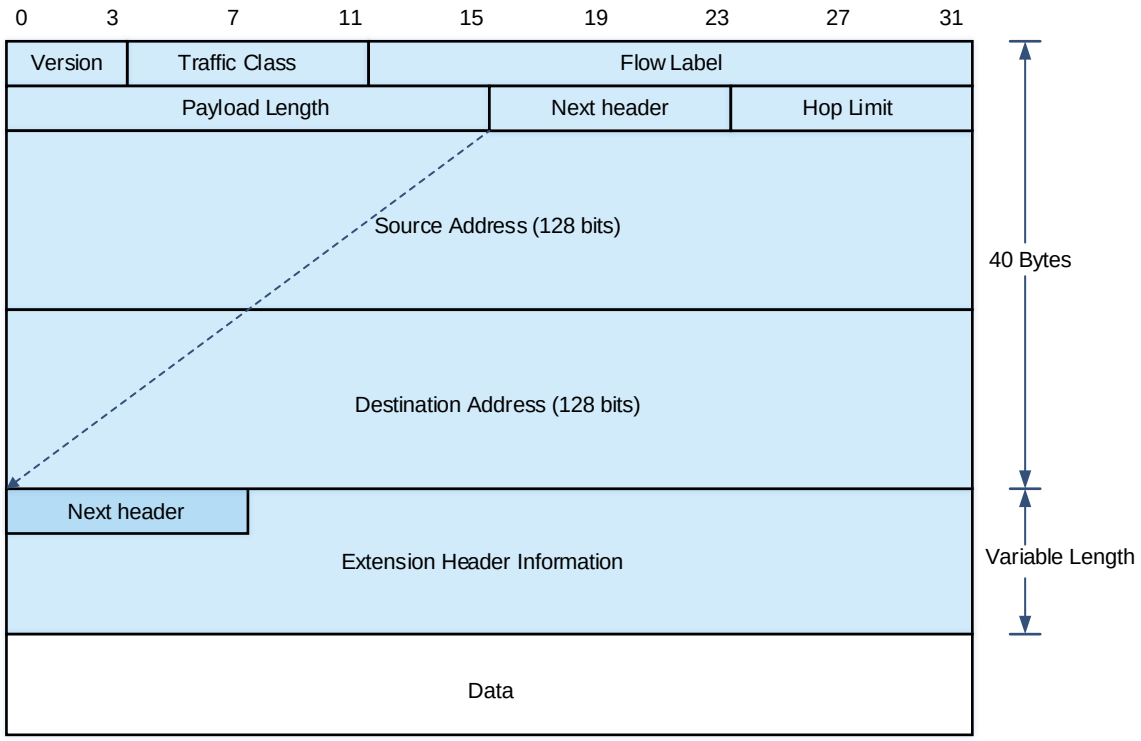
The subnet prefix identifies a specified link (subnet). Packets destined to the subnet-router anycast address will be forwarded to a device on this subnet. A subnet-router anycast address is usually used by the application on a node to communicate with a device on a remote subnet.

Figure 1-8 Format of a Subnet Router Anycast Address

Note

The format of an anycast address is shown in Figure 1-8, that is, n bits of subnet prefix plus (128 – n) bits of all zeros. For example, in the anycast address 1000:1::100/120, the length of the subnet prefix is 120 bits, and the host address is 8-bit all zeros. An anycast address cannot be used as the interface address of a switch.

7. IEEE EUI-64 Interface ID



The 64-bit interface ID in an IPv6 address is used to identify a unique interface on the link. This address is a variation of a link-layer address (such as an MAC address) of an interface. This address is generated by inserting a hexadecimal number FFFE after the 24th bit of an MAC address. To make the scope of an interface ID the same as the original MAC address, the U/L bit (the 7th bit starting from the most significant bit) is negated. The resulting set of numbers is used as the interface ID in EUI-64 format.

For the loopback, VBDIF, and tunnel interfaces, the EUI-64 addresses are generated from the MAC addresses of these interfaces, with the last two bytes of the interface index filled in the middle.

8. Format of an IPv6 Packet Header

The format of an IPv6 packet header is shown in the following figure.

Figure 1-9 Format of an IPv6 Packet Header

The IPv6 packet header consists of 40 bytes, in unit of eight bytes. An IPv6 packet header has the following fields:

- Version

  This field consists of 4 bits. In an IPv6 address, this field must be 6.

- Traffic Class

  This field consists of 8 bits. This field indicates the service provided for this packet, and is similar to the type of service (ToS) field in an IPv4 address.

- Flow Label

  This field consists of 20 bits to identify packets belonging to the same service flow. One node can act as the transmission source of multiple service flows. The flow label and source node address uniquely identify one service flow.

- Payload Length

  This field consists of 16 bits, including the packet payload length and the length of IPv6 extended options (if available). That is, it includes the IPv6 packet length except the IPv6 packet header.

- Next Header

  This field indicates the protocol type in the header field following the IPv6 packet header. Similar to the protocol field in the IPv4 address header, the **Next Header** field is used to indicate whether the upper layer uses Transmission Control Protocol (TCP) or User Datagram Protocol (UDP). It can also be used to indicate existence of an IPv6 extension header.

- Hop Limit

This field contains eight bits. Every time a device forwards a packet, the hop value is reduced by 1. If the hop value reaches 0, this packet will be discarded. It is similar to the lifetime field in the IPv4 packet header.

- Source Address

  This field consists of 128 bits and indicates the sender address in an IPv6 packet.

- Destination Address

  This field consists of 128 bits and indicates the receiver address in an IPv6 packet.

At present, IPv6 defines the following extension headers.

- Hop-By-Hop Options

  This extension header must follow the IPv6 packet header. It consists of option data to be checked on each node along the path.

- Routing Options

  This extension header indicates the nodes that a packet passes through from the source address to the destination address. It consists of the address list of the passerby nodes. The initial destination address in an IPv6 packet header is the first address among the addresses in the routing header, but not the final destination address of the packet. After the node corresponding to the destination address in an IPv6 packet header receives the packet, it processes the IPv6 packet header and routing header, and sends the packet to the second address, the third address, and so on in the list in the routing header till the packet reaches the final destination address.

- Fragment

  The source node uses this extension header to fragment the packets, of which the length exceeds the path MTU (PMTU).

- Destination Options

  This extension header replaces the option fields of IPv4. At present, the **Destination Options** field can only be filled with integral multiples of 64 bits (eight bytes) if required. This extension header can be used to carry information to be checked by the destination node.

- Upper-layer Header

  This extension header indicates the protocol used by the upper layer for data transmission, such as TCP (6) and UDP (17).

Another two extension headers **Authentication** (AH) and **Encapsulating Security Payload** (ESP) will be described in "Configuring IPSec" in "VPN Configuration Guide".

9. IPv6 Source Routing

Similar to the IPv4 loose source routing and loose record routing options, the IPv6 routing header is used to specify the intermediate nodes that a packet passes through. It uses the following format:

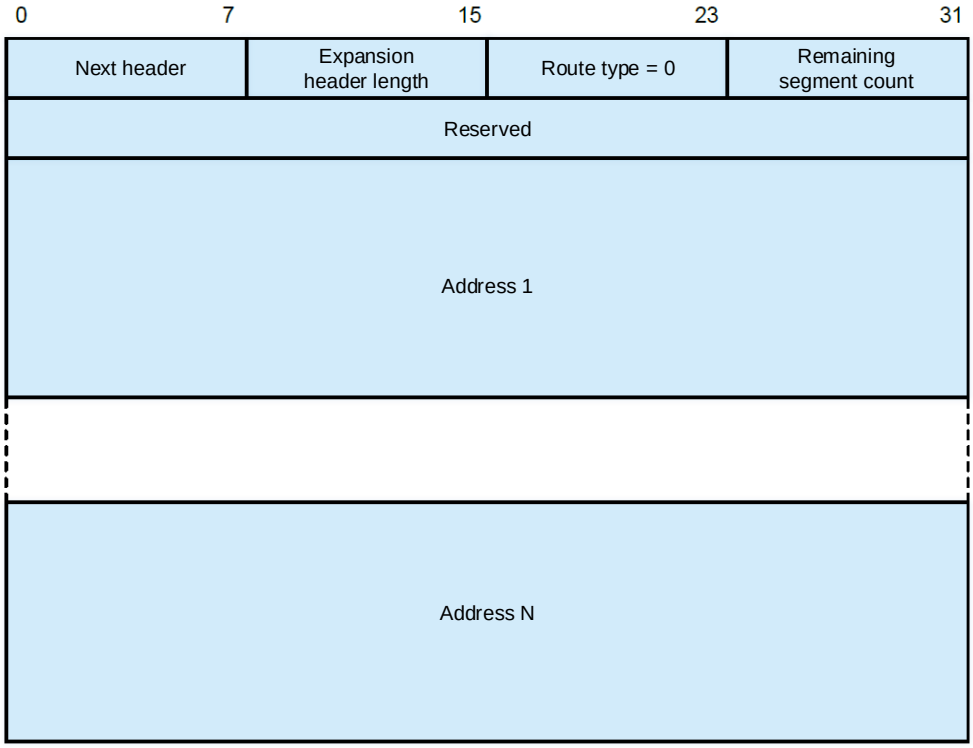


Figure 1-10 IPv6 Routing Header

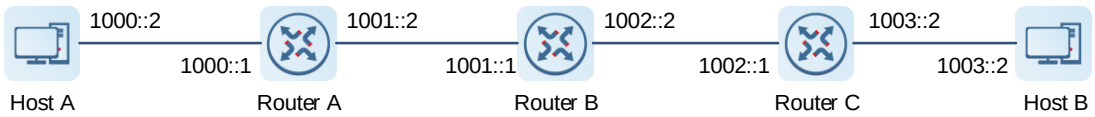
The **Segments Left** field is used to indicate the number of intermediate nodes specified in the routing header that a packet passes through from the current node to the final destination address.



Currently, two routing types are defined: 0 and 2. The Type 2 routing header is used for mobile communication. Type 0 routing header is similar to the loose source routing option of IPv4. The format of the Type 0 routing header is as follows:

Figure 1-11 Type 0 Routing Header

The example describes the application of the Type 0 routing header.

Figure 1-12 Applications of the Type 0 Routing Header

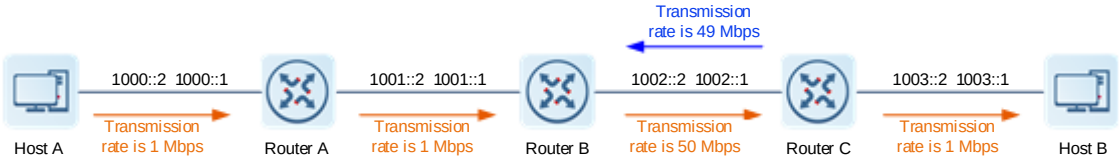
Host A sends host B a packet, which specifies the intermediate nodes router B and router C. The following table lists the changes of fields related to the IPv6 header and routing header during the forwarding process.

Table 1-2 Changes of Fields

Transmission Node	Fields in the IPv6 Header	Fields Related to the Type 0 Routing Header
Host A	Source address = 1000::2 Destination address = 1001::1 (address of router 2)	Segments Left = 2 Address 1 = 1002::1 (address of router 3) Address 2 = 1003::2 (address of host 2)
Router A	No change	
Router B	Source address = 1000::2 Destination address = 1002::1 (address of router 3)	Segments Left = 1 Address 1 = 1001::1 (address of router 2) Address 2 = 1003::2 (address of host 2)
Router C	Source address = 1000::2 Destination address = 1003::2 (address of host 2)	Segments Left = 0 Address 1 = 1001::1 (address of router 2) Address 1 = 1002::2 (address of router 3)
Host B	No change	

The forwarding process is described as follows:

(1) Host A sends a packet in which the destination address is router B's address 1001::1, the Type 0 routing header is filled with router C's address 1002::1 and host B's address 1003::2, and the value of the **Segments Left** field is **2**.



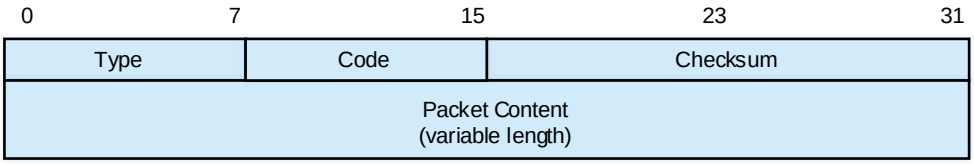
(2) Router A forwards the packet to router B.

(3) Router B interchanges the destination address in the IPv6 header with address 1 in the routing header. That is, the destination address becomes router C's address 1002::1, address 1 in the routing header becomes router B's address 1001::1, and the value of the **Segments Left** field becomes **1**. After modification, router B forwards the packet to router C.

(4) Router C interchanges the destination address in the IPv6 header with address 2 in the routing header. That is, the destination address becomes host B's address 1003::2, address 2 in the routing header becomes router C's address 1002::1, and the value of the **Segments Left** field becomes **0**. After modification, router C forwards the packet to host B.

The Type 0 routing header may be used to initiate denial of service (DoS) attacks. As shown in the following figure, host 1 sends a packet to host 2 at a rate of 1 Mbps and forges a routing header with the **Segments Left** field of 100 to cause multiple round-trips of the packet between router 2 and router 3 (50 times from router 2 to router 3 and 49 times from router 3 to router 2). At the time, the routing header generates the traffic amplification effect: 50 Mbps from router 2 to router 3 and 49 Mbps from router 3 to router 2. Due to this security problem, RFC 5095 abolished the Type 0 routing header.

Figure 1-13 Type 0 Routing Header Used to Initiate DoS Attacks



10. IPv6 Hop-limit

An IPv6 data packet passes through routers from the source address to the destination address. If a hop limit is configured, it decreases by one every time the packet passes through a router. When the hop limit decreases to 0, the router discards the packet to prevent this useless packet from being unlimitedly transmitted on the network and wasting network bandwidth. The hop limit is similar to the time to live (TTL) of IPv4.

1.3.2 ICMPv6 Protocol

1. Packet Format

Figure 1-14 ICMPv6 Packet Format

Field descriptions are as follows:

- The **Type** field indicates the type of a packet, 0 to 127 indicates error messages, and 128 to 255 indicates informational messages.
- The **Code** field indicates the subdivision type of this message type.
- The **Checksum** field indicates the checksum of ICMPv6 packets.

2. ICMPv6 Error Messages

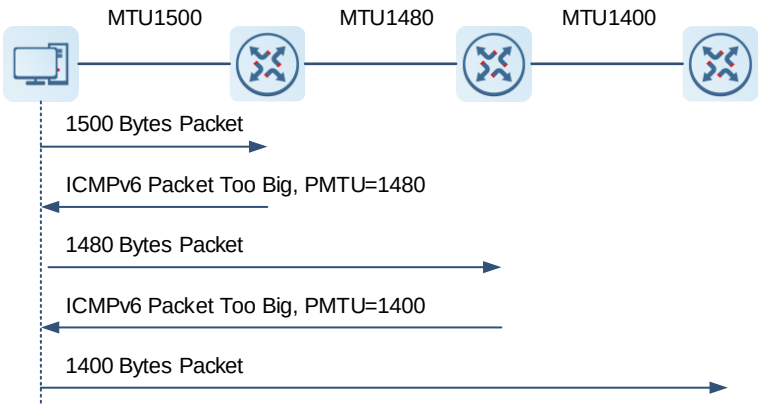
ICMPv6 error messages are sent by a destination node or intermediate router to report the errors incurred during IPv6 data packet forwarding and transmission. There are mainly four types of error messages:

- Destination Unreachable (Type=1), indicating that packets cannot be forwarded to the destination node or the upper-layer protocol.
  - Code=0, indicating that there is no route reachable to the destination.
  - Code=1, indicating that the communication with the destination is prohibited according to the administration policy.
  - Code=2, unspecified.
  - Code=3, address unreachable.
  - Code=4, port unreachable.
  - Code=5, strategy failed.

- Code=6, routing denied.

- Packet Too Big (Type = 2, Code = 0), indicating that the size of a packet exceeds the link MTU of an interface.
- Time Exceeded (Type=3)
  - Code=0, indicating that the hop limit is exceeded during transmission.
  - Code=1, fragmentation timeout.
- Parameter Problem (Type=4), indicating that an error occurs in the IPv6 header or extension header.
  - Code=0, indicating an incorrect header field.
  - Code=1, indicating that the next header cannot be identified.
  - Code=2, indicating that the IPv6 option cannot be identified.

3. ICMPv6 Informational Messages



The following describes common informational messages:

- Type=128, echo request, which is sent to the destination node to trigger the destination node to immediately send back an echo reply packet.
- Type=129, echo reply, which is sent in response to an echo request.
- Type=133, router solicitation (RS) packet. After a node is started, it initiates a solicitation to the router via an RS packet to request the prefix and other configurations.
- Type=134, router advertisement (RA) packet, which is sent in response to an RS packet and advertises prefix options and certain flag bits.
- Type=135, neighbor solicitation (NS) packet, which is similar to an ARP request and used to obtain the link layer address of a neighbor, check whether the neighbor is reachable, and perform duplicate address detection.
- Type=136, neighbor advertisement (NA) packet, which is similar to an ARP reply packet.
- Type=137, Redirect packet. By sending a Redirect packet to the source host, the default gateway triggers the host to re-select a better next-hop address for delivering subsequent packets.

1.3.3 IPv6 PMTUD

Similar to IPv4 path MTU discovery (PMTUD), IPv6 PMTUD allows a host to dynamically discover the MTU size in the data path. If the length of a data packet to be sent by a host is greater than the PMTU, the host performs packet fragmentation.

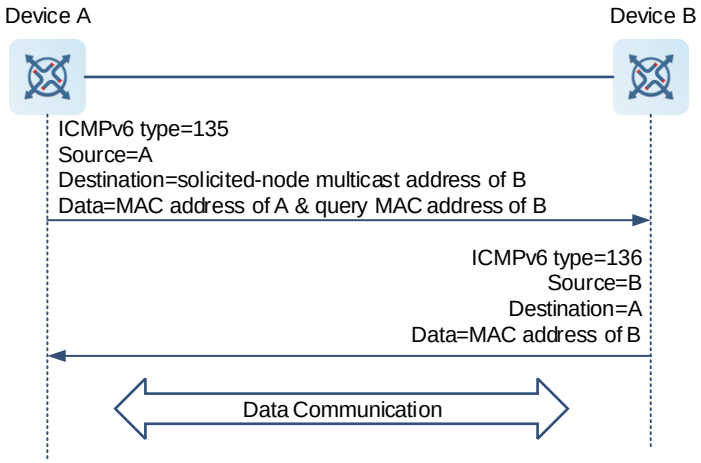
Figure 1-15 IPv6 PMTUD

As shown in the preceding figure, if the length of a packet to be sent by a host is greater than the PMTU, the router discards this packet and sends an ICMPv6 Packet Too Big message containing its PMTU to the host. The host fragments the packet based on the new PMTU. In this manner, the router does not need to perform fragmentation, saving router resources and improving the IPv6 network efficiency.

1.3.4 IPv6 Neighbor Discovery Protocol

Neighbor Discovery Protocol (NDP) is a basic part of IPv6. Its main functions include router discovery, prefix discovery, parameter discovery, address auto-configuration, address resolution (like ARP), next-hop determination, neighbor unreachability detection (NUD), duplicate address detection (DAD), and redirection.

NDP defines five types of ICMP packets: RS, RA, NS, NA, and Redirect.



All the above ICMP packets carry one or more options. These options are optional in some cases but are significant in other cases. NDP mainly defines five options: **Source Link-Layer Address** option, Type = 1; **Target Link-Layer Address** option, Type = 2; **Prefix Information** option, Type = 3; **Redirect Header** option, Type = 4; **MTU** option, Type = 5.

Different NDP mechanisms use different ICMPv6 messages.

1. Address Resolution

When a node attempts to communicate with another, the node has to obtain the link-layer address of the peer by sending an NS packet to the peer. In this packet, the destination address is the solicited-node multicast address corresponding to the IPv6 address of the destination node. This packet also contains the link-layer address of the source node. After receiving this NS packet, the destination node replies with an NA packet, in which the destination address is the source address of the NS packet and the content is the link-layer address of the solicited node. After receiving this NA packet, the source node can communicate with the destination node.

Figure 1-16 Address Resolution

The process of address resolution is as follows:

(1) Device A sends an NS packet in multicast mode. The source address of the NS packet is the IPv6 address of the interface of device A, and the destination address is the solicited-node multicast address of device B. The packet contains the link layer address of device A, and solicits the link layer address of device B.

(2) After receiving the NS packet, device B judges whether the destination address of the packet is its own IPv6 address. If yes, device B can learn the link layer address of device A and returns an NA packet containing its link layer address in unicast mode.

(3) Device A can get the link layer address of device B from the received NA packet. The two devices can then begin to communicate with each other.

2. NUD

If the amount of time that a neighbor is considered reachable has elapsed but an IPv6 unicast packet needs to be sent to the neighbor, the device performs NUD. The NS and NA packets can be used to detect whether the neighbor node is reachable.

(1) The node sends an NS packet, in which the destination address is the IPv6 address of the neighbor node.

(2) If the acknowledgment packet is received from the neighbor node, the neighbor is considered reachable. Otherwise, the neighbor is considered unreachable.

While NUD is underway, the device can continue to forward IPv6 packets to the neighbor.

3. DAD

When obtaining an IPv6 address, a node needs to perform DAD to determine whether the IPv6 address is unique on the link. This feature is similar to the gratuitous ARP in IPv4.

The process of DAD is as follows:

(1) A node sends an NS packet. The source IPv6 address of the NS packet is the unspecified address, and the destination address is the solicited-node multicast address corresponding to the IPv6 address to be detected. The packet content is the IPv6 address to be detected.

(2) After receiving the NS packet, other neighbor nodes check whether the IPv6 address exists in their local IPv6 address collections. If yes, the neighbor node that has the IPv6 address responds with an NA packet that carries the IPv6 address to the source node.

(3) When receiving the NA packet from the neighbor, the source node considers the IPv6 address in use. On the contrary, if the source node receives no NA packet in response to the NS packet, the IPv6 address is available.

If a device detects an address conflict, this address is set in the duplicate state and the device cannot receive IPv6 packets destined to this address. Meanwhile, the device also starts a timer for this duplicate address to periodically perform DAD. If no address conflict is detected, this address can be properly used.

4. RA Packets

An RA packet usually contains the following content:

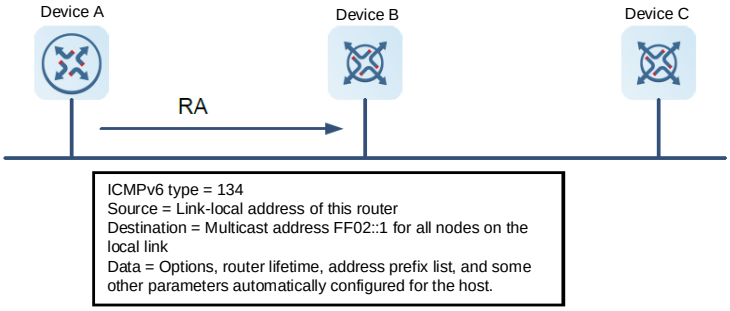
- One or more IPv6 address prefixes (used for on-link determination or stateless address auto-configuration);
- Validity period of the IPv6 address prefix;
- Host auto-configuration method (stateful or stateless);
- Default device information (whether the device acts as the default device; if yes, the duration for acting as the default device is also included);
- Other information provided for host configuration, such as hop limit, MTU and NS retransmission interval.

RA packets can also be used as replies to the RS packets sent by a host. Using RS packets, a host can obtain the auto-configured information immediately after startup rather than wait for the RA packets sent by the device. If no unicast address is configured for a newly started host, the host uses the unspecified address (0:0:0:0:0:0:0:0) as the source address of the RS packet. Otherwise, the host uses the configured unicast address as the source address and the multicast address of all devices in the local link (FF02::2) as the destination address in the RS packet. As a reply to the RS packet, the RA packet uses the source address of the RS packet as the destination address. If the source address is the unspecified address, it uses the multicast address of all nodes in the local link (FF02::1).

In an RA packet, the following parameters can be configured in the IPv6 interface attributes:

- Ra-interval: Indicates the interval for sending the RA packets.
- Ra-lifetime: Indicates the lifetime of a router, that is, whether the device acts as the default router on the local link and the duration for acting as the default router.
- Prefix: Indicates the prefix of an IPv6 address of the local link. It is used for on-link determination or stateless address auto-configuration, including other parameter configurations related to the prefix.
- Ns-interval: Indicates the NS packet retransmission interval.
- Reachable-time: Indicates the period in which the device regards a neighbor reachable after detecting the neighbor reachability event.
- Ra-hoplimit: Indicates the hop count in an RA packet, which is used to set the hop limit for a host to send a unicast packet.
- Ra-mtu: Indicates the value of the MTU field in an RA packet.
- Managed-config-flag: Determines whether a host receiving this RA packet obtains the address through stateful auto-configuration.
- Other-config-flag: Determines whether a host receiving this RA packet uses DHCPv6 to obtain other information except the IPv6 address for auto-configuration.
- RDNSS and DNSSL options: Provide IPv6 terminals with the address of the DNS recursive query server and a search list of DNS domain names.

- Routing options: Provide IPv6 terminals with specific routing information.



5. Router Discovery

RA packets are sent by the device to all link-local nodes on a regular basis. From the RA packets received, the nodes obtain neighbor router information and other configuration parameters. This is called router discovery.

The nodes automatically configure the IPv6 address based on the information obtained from router discovery which is called stateless auto-configuration.

The RA packet sending process during router discovery is shown in the following figure:

Figure 1-17 Router Discovery

6. Redirection

If a router receiving an IPv6 packet finds a better next hop, it sends an ICMP Redirect packet to inform the host of the better next hop. The host will directly send the IPv6 packet to the better next hop next time. This function is the same as ICMP Redirect packets of IPv4.

1.3.5 Protocols and Standards

- RFC4291: IPv6 Addressing Architecture.
